RESOURCE PAPER 4
UPDATED MAXIMUM-RESPONSE SCALE FACTORS

RP4-1 UPDATED MAXIMUM-RESPONSE SCALE FACTORS

The proposed changes below update the "maximum-response scale factors" specified in the site-specific ground motion procedures (Chapter 21) of ASCE/SEI 7-10. These factors increase spectral response accelerations that represent the geometric mean (or a similar metric) of two horizontal ground motion components, such that they represent the maximum response in the horizontal plane. Recall that ASCE/SEI 7-10, via both Chapter 21 and the MCE_R ground motion maps, specifies maximum-response spectral response accelerations. Typical ground motion attenuation relations, including those applied by the USGS in preparing the MCE_R ground motion maps, provide geometric-mean spectral response accelerations.

The values of the updated maximum-response scaling factors proposed herein are illustrated in Figure 1, where they are compared with those in ASCE/SEI 7-10. Also illustrated in the figure are the ratios of the updated factors to the ASCE/SEI 7-10 factors. Note, in particular, that the updated factors at 0.2 and 1.0 s (i.e., 1.2 and 1.25, respectively) are approximately 10% larger and 5% smaller than the respective factors in ASCE/SEI 7-10 (i.e., 1.1 and 1.3).

This resource paper was originally a Provisions Part 1 proposal for change, prepared by the BSSC 2015 Issue Team (IT) 11 on Seismic Design Mapping. That proposal received enough affirmative votes from the 2015 Provisions Update Committee (PUC) to pass, but via responses to the PUC comments on the proposal, IT 11 recommended (and the PUC approved) interim placement of the proposed changes in Part 3 of the Provisions, for the reason that follows. In the course of developing a separate proposal to add longer (than 1 s) period points to the design response spectrum of Section 11.4.5, IT 11 found that, for Site Classes D and E, the longer-period part of the ASCE/SEI 7-10 spectrum is generally un-conservative at high-hazard locations, in some cases by a factor of two. The IT also found that adding longer periods to the response spectrum instigates other issues (e.g., a need to also add shorter periods) that require more research before additional (to 0.2 and 1.0 s) periods can confidently be proposed. In the interim, IT 11 recommended against changing to the updated maximum-response scale factors presented below, which would **decrease** spectral response accelerations at longer periods relative to ASCE/SEI 7-10 (e.g., by approximately 15% at 5 seconds). By placing the updated factors in Part 3 of the Provisions, they can be enacted concurrently (e.g. for the MCE_R ground motion maps) with a future change to the aforementioned un-conservative longer-period part of the ASCE/SEI 7-10 design response spectrum.

The impetus for updating the maximum-response scale factors is the recent research of the Pacific Earthquake Engineering Research Center (PEER) NGA-West2 Directionality Working Group, the results of which are published in (Shahi and Baker, 2013 and 2014). The factors in these twin publications, which are illustrated in Figure 1, include the improvements listed below relative to the factors in ASCE/SEI 7-10, as discussed by IT 11 via email and numerous web conferences. One of the web conferences was joined by both Jack Baker (the chair of the PEER NGA-West2 Directionality Working Group) and Andrew Whittaker, who was the task leader for the development of the maximum-response scale factors in ASCE/SEI 7-10.

1. The updated factors are consistent with the new spectral response acceleration parameter ("RotD50") provided by the NGA-West2 attenuation relations, the relations that have been applied for shallow crustal earthquakes in preparing updated MCE_R ground motion maps for the 2015 Provisions. At long periods (greater than 1 s), RotD50 is approximately 5% larger than the spectral response acceleration parameter that is implicit in the MCE_R ground motion maps of ASCE/SEI 7-10 ("GMRotI50" from NGA-West1). This is part of the reason why, at long periods, the updated factors are smaller than those of ASCE/SEI 7-10.

2. The updated factors are based on approximately 40% more near-fault strong ground motion data (with source-to-site distances of 15km or less and earthquake magnitudes of 6.5 and greater) compared to the factors in ASCE/SEI 7-10. The additional data, from the NGA-West2 database, include ground motions from recent earthquakes in New Zealand, Japan, and China.
3. The updated factors are insensitive to the inclusion or exclusion of the overwhelmingly-large number of ground motion data from the 1999 Chi-Chi earthquake, which generated short-period spectral response accelerations that, on average, are relatively small compared to other similar earthquakes. In contrast, the Huang et al. (2008) factors upon which those in ASCE/SEI 7-10 are based were reported to substantially increase at short periods (less than 1 s), and slightly decrease at long periods, with the exclusion of the Chi-Chi data. This is much of the reason why, at short periods, the updated factors are larger than those of ASCE/SEI 7-10. It is also part of the reason why, at long periods, the updated factors are smaller than those of ASCE/SEI 7-10.
4. The updated factors are based on ratios of maximum-response data to geometric-mean data ("data-to-data" ratios), rather than the ratios of maximum-response data to geometric-mean attenuation relation predictions ("data-to-predictions" ratios) that the ASCE/SEI 7-10 factors are based on. This is likely the reason that, as described in the preceding bullet, the updated factors are insensitive to the Chi-Chi data. Note that in addition to data-to-prediction ratios, Huang et al. (2008) also present data-to-data ratios that are similar to the updated factors proposed herein.
5. The updated factors have been shown by Shahi and Baker (2013) to be practically independent of earthquake magnitude, source-to-site distance, and near-fault directivity parameters. Hence, the maximum-response ground motions resulting from the updated factors (e.g., on the MCE_R ground motions maps) can be thought as those that would result from attenuation relations for maximum response. In fact, this is why the PEER NGA-West2 Directionality Working Group developed maximum-response scaling factors rather than directly developing attenuation relations for maximum response.

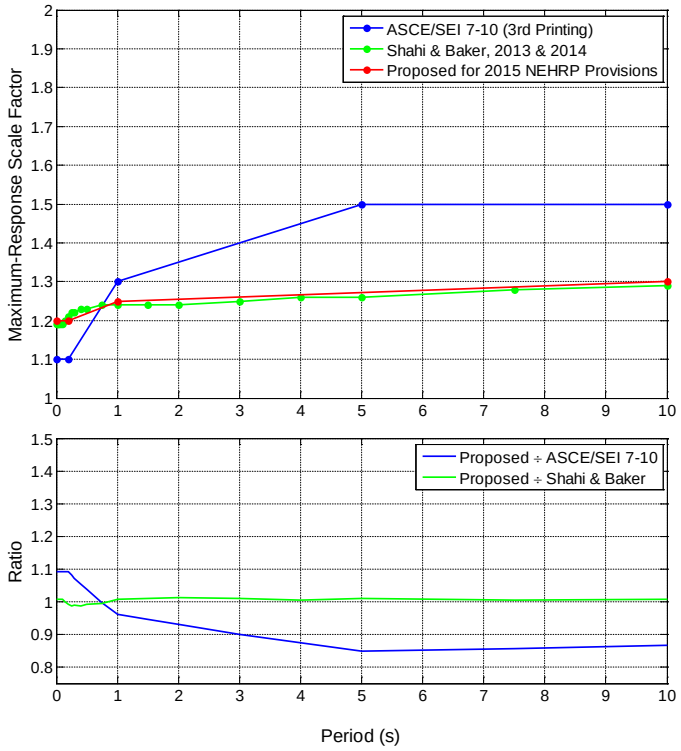

FIGURE 1 A Comparison of the Updated Maximum-Response Scale Factors Proposed herein with those in ASCE/SEI 7-10 (Chapter 21), and those Published in (Shahi and Baker, 2013 and 2014)

RP4-2 PROPOSED CHANGES:

RP4-2.1 Replace ASCE/SEI 7-10 Section 21.2 with the following:

21.2 Risk-Targeted Maximum Considered Earthquake (MCE_R) Ground Motion Hazard Analysis. The requirements of Section 21.2 shall be satisfied where a ground motion hazard analysis is performed or required by Section 11.4.7. The ground motion hazard analysis shall account for the regional tectonic setting, geology, and seismicity, the expected recurrence rates and maximum magnitudes of earthquakes on known faults and source zones, the characteristics of ground motion attenuation, near source effects, if any, on ground motions, and the effects of subsurface site conditions on ground motions. The characteristics of subsurface site conditions shall be considered either using attenuation relations that represent regional and local geology or in accordance with Section 21.1. The analysis shall incorporate current seismic interpretations, including uncertainties for models and parameter values for seismic sources and ground motions. If the spectral response accelerations predicted by the attenuation relations do not represent the maximum response in the horizontal plane, then the response spectral accelerations computed from the hazard analysis shall be scaled by factors to increase the motions to the maximum response. If the attenuation relations predict the geometric mean or similar metric of the two horizontal components, then the scale factors shall be: 1.2 for periods less than or equal to 0.2 sec; 1.25 for a period of 1.0 sec., and, 1.3 for periods greater than or equal to 10.0 sec., unless it can be shown that other scale factors more closely represent the maximum response, in the horizontal plane, to the geometric mean of the horizontal components. Scale factors between these periods shall be obtained by linear interpolation. The analysis shall be documented in a report.

RP4-2.2 Replace ASCE/SEI 7-10 Section C21.2 with the following:

C21.2 Risk-Targeted Maximum Considered Earthquake (MCE_R) Ground Motion Hazard Analysis. Site-specific risk-targeted maximum considered earthquake (MCE_R) ground motions are based on separate calculations of site-specific probabilistic and site-specific deterministic ground motions.

Both the probabilistic and deterministic ground motions are defined in terms of 5 percent damped spectral response in the maximum direction of horizontal response. The maximum direction in the horizontal plane is considered the appropriate ground motion intensity parameter for seismic design using the equivalent lateral force (ELF) procedure of Section 12.8 with the primary intent of avoiding collapse of the structural system.

Most ground motion relations are defined in terms of average (geometric mean) horizontal response. Maximum response in the horizontal plane is greater than average response by an amount that varies with period. Maximum response may be reasonably estimated by factoring average response by period-dependent factors, such as 1.2 at short-periods and 1.25 at a period of 1.0 seconds. These and the other period-dependent factors specified in Section 21.2 are updates of the factors in ASCE/SEI 7-10 and the 2009 *Provisions*. The updated factors are based on (Shahi and Baker, 2013 and 2014), whereas the previous factors were based on (Huang et al., 2008). The improvements included in the updated factors are i) consistency with the new spectral response acceleration parameter of updated ground motion relations for shallow crustal earthquakes (e.g., Boore et al. 2013); ii) additional strong ground motion data from recent earthquakes in New Zealand, Japan, and China (Ancheta et al, 2013); iii) insensitivity to the inclusion or exclusion of the overwhelmingly-large number of strong ground motion data from the 1999 Chi-Chi earthquake, which generated short-period spectral response accelerations that, on average, are relatively small compared to other similar earthquakes; iv) basis in ratios of maximum-response data to average-response data, as opposed to maximum-response data to average-response predictions from ground motion relations; and v) demonstrated independence with respect to earthquake magnitude, source-to-site distance, and near-fault directivity parameters. The maximum direction was adopted as the ground motion intensity parameter for use in seismic design in lieu of explicit consideration of directional effects.

RP4-2.3 Replace ASCE/SEI 7-10 References of Chapter 21 with the following:

RESOURCE PAPER 5
ONE-STORY, FLEXIBLE DIAPHRAGM BUILDINGS WITH STIFF VERTICAL ELEMENTS

RP5-1 INTRODUCTION

The seismic-force-resisting systems (SFRS) of many one-story buildings are constructed with non-filled steel deck or structural wood panel roof diaphragms that transmit inertial seismic force to stiff vertical elements, such as walls or braced frames. Occupancies for these buildings vary widely; common uses include retail, warehouse, athletics, institutional, and industrial. Many of these buildings are large in plan with long horizontal diaphragm spans between the vertical elements of the SFRS. The roof-heights of these buildings typically are 20 to 40 ft above the floor slab to create a large volume of enclosed space. Occasionally, these buildings may have even higher roofs for uses such as airplane hangars or athletic facilities.

In the United States (U.S.), the SFRS of these buildings are designed to meet the provisions of the *Minimum Design Loads for Buildings and Other Structures* (ASCE/SEI 7-10) [ASCE, 2010]. Other than how to treat the diaphragm stiffness for the purposes of distributing loads to vertical elements and the out-of-plane wall anchorage design, ASCE/SEI 7-10 considers the design for earthquake resistance of these buildings similar to that of all other buildings, including multi-story buildings with rigid floor diaphragms. The focus of ASCE/SEI 7-10 is on the design of the vertical elements of the SFRS, which are the elements that are expected to yield and dissipate energy when the building is subjected to severe earthquake ground shaking. The buildings being considered for this white paper have stiff vertical SFRS elements that are commonly constructed of reinforced concrete or masonry walls or steel-braced frames. Reinforced-concrete walls are usually precast but can also be cast in place. The precast walls can be cast on site and tilted up into place or cast in a plant, shipped to the site and lifted into place. The precast concrete walls are usually individual panels that range in width from about 12 ft to 30 ft.

The wood structural panel and metal deck diaphragms for these buildings are idealized as flexible in accordance with ASCE/SEI 7-10. The wood structural panels and the steel deck roofs resist in-plane diaphragm shears. Chords that resist tension and compression from flexural demands are provided at the perimeter of the diaphragm.

For wood diaphragms, the wood structural panels are attached to either wood framing or wood nailers that are fastened to open web steel joists. The flexibility of these wood diaphragms is primarily a function of the deformations at the nailed connections, shear deformation of the panel, and flexural deformation due to elongation and shortening of the diaphragm chords [AF&PA, 2009].

For metal deck diaphragms, the steel deck panels are attached to the steel roof framing, commonly composed of open web steel joists, with puddle welds, powder-actuated fasteners, or self-drilling screws. The steel deck sheets normally are 2 to 3 ft in width and are supplied in lengths that are easily shipped and handled. The sides of adjacent deck sheets are interconnected with button punches, top seam welds, self-drilling screws, or a variety of proprietary connectors and punches. These inter-panel connections are referred to as sidelaps. The flexibility of steel deck diaphragms is dependent on the shear and warping stiffness of the deck between connectors, the movement or slip of framing connections, the movement or slip at sidelap connectors, and the flexural deformations due to elongation and shortening of the diaphragm chords [SDI, 2004].

One-story buildings with stiff vertical elements and flexible roof diaphragms respond differently to earthquake ground shaking than typical multi-story buildings envisioned by codes respond. The response of these buildings is often dominated by diaphragm deformation and yielding rather than deformation and yielding of the vertical elements of the SFRS (Lawson, et al. 2014). The main objective of this study was to develop simplified seismic design procedures for one-story Rigid Wall-Flexible Diaphragm (RWFD)

buildings that better reflect this type of response. For the purposes of this white paper, the RWFD buildings considered are one story with exterior walls of reinforced concrete or masonry construction though it also could include steel braced frames used for interior lines of resistance for large footprint buildings. The proposed design approach presented in Section 5 is only applicable to buildings with wood diaphragms, though it has the potential to be used for steel deck diaphragms as well. The adequacy of current design requirements for this type of building with wood or steel deck diaphragms was also explored. The proposed design approach is not intended to apply to standing seam metal roofs or similar metal roofs that are attached to framing members with clips that allow for relative movement between the metal roofing and the framing. It is also not intended to apply to steel deck attached to wood framing.

RP5-2 BEHAVIOR OF FLEXIBLE DIAPHRAGM BUILDINGS SUBJECTED TO EARTHQUAKE GROUND SHAKING

Performance of one-story RWFD buildings has often been poor when subjected to earthquake ground motion (SEAOC 2008). This poor performance has been primarily due to lack of wall anchorage or failure of inadequate wall anchorage to the diaphragm and partial collapse of the roof, and particularly collapse of perimeter bays of framing that were supported by exterior walls. Damage at re-entrant corners, at pilasters, and in the interior of diaphragms without continuity ties was also observed. In response to this poor performance, U.S. building code detailing requirements have become more restrictive and design forces for support of the top of walls for out-of-plane seismic loads have been increased in multiple editions of model building codes.

In the U.S. the reported failures of this style building due to earthquake ground shaking have been primarily of buildings with wood diaphragms (SEAONC (2001), EERI (1996), SSC (1995), APA (1994), SEAOSC/COLA (1994), EERI (1988), NOAA (1973), and USDOC (1967)). An example of a steel deck diaphragm with a partial roof collapse is the K-Mart building in Yucca Valley, California (Shipp (2010) and Brandow, 2010). There are fewer reports of damage to steel deck diaphragm RWFD buildings compared to wood diaphragm RWFD buildings; however, wood diaphragm RWFD buildings were substantially more numerous in locations where major earthquakes have occurred in the U.S., i.e., Northern and Southern California. In the last 20 years, steel deck diaphragms for this style building have become more common in these locations.

An argument could be made that the steel deck diaphragms have been tested in earthquakes because the roof level diaphragm of multi-story, steel-framed buildings is often an untopped steel deck. However, most multi-story buildings have shorter diaphragm spans, have roof diaphragms that are conservatively designed, do not have heavy exterior walls attached to the diaphragm, have gravity load columns and walls that cantilever above the more rigid top floor level to the roof which reduces the shear forces and deformation demands in the roof diaphragms, and may have been protected by yielding and energy dissipation of the vertical elements of the SFRS. Additionally, several proprietary connectors have been introduced in the last 20 years that have yet to be tested by strong earthquake ground motion. Also, the good performance of steel deck diaphragms of light metal buildings with steel siding should not be extrapolated to the one-story RWFD buildings with heavy walls because the relatively heavy walls create larger diaphragm shears and forces on diaphragm connectors that do not occur in the light metal buildings. Also, the strength of the light metal buildings is often based on wind loads resulting in inherent overstrength for earthquake design.

Responses of low-rise buildings with flexible roof diaphragms instrumented to record the accelerations and displacements during earthquakes have been obtained. Celebi et al. (1989) report the response of a gymnasium building in Saratoga, California with plan dimensions of 144 ft (north-south) by 112 ft (east-west) and a roof diaphragm of 3/8 in. plywood over tongue-and-groove straight sheathing. The response of this building to the 1984 Morgan Hill earthquake is reported. Peak accelerations of the ground-level slab were 0.10g in the north-south (longitudinal) direction and 0.04g in the east-west (transverse) direction. Accelerations at the center of the roof diaphragm, 0.42g and 0.20g in the

longitudinal and transverse directions respectively, were about three times the accelerations at the edges of the roof diaphragm in each direction, 0.13g and 0.15g for the longitudinal direction and 0.06g and 0.07g for the transverse direction. Celebi, et al. report fundamental frequencies of 3.8 Hz and 3.9 Hz in the longitudinal and transverse directions respectively, for a fundamental period in each direction of about 0.26 sec. Damping is estimated to be about 5% to 6% of critical damping.

Bouwkamp, et al. (1994), report the response of three buildings to multiple California earthquakes. The buildings are the gymnasium in Saratoga that Celebi, et al. (1989) studied, a warehouse in Hollister, and a two-story building in Milpitas.

During the Loma Prieta earthquake, the gymnasium in Saratoga experienced peak accelerations at the ground-level slab of 0.35g and 0.24g in the transverse and longitudinal directions, respectively. From the ground-level slab to the diaphragm edge, accelerations were amplified by a factor of 1.27 and 1.46 for the transverse and longitudinal directions respectively. Accelerations were amplified from the diaphragm edge to the diaphragm center by factors of 1.95 and 2.07 for the transverse and longitudinal directions. Comparisons of analyses to measured responses indicated that the damping was approximately equal to 5% of critical damping in each direction.

The Hollister warehouse has plan dimensions of 300 ft by 100 ft and a plywood roof diaphragm. Accelerations are reported only in the transverse direction. The warehouse experienced peak accelerations of the ground-level slab of about 0.08g, 0.11g, and 0.25g during 1984 Morgan Hill, 1986 Hollister, and 1989 Loma Prieta earthquakes, respectively. Response of the warehouse indicates that very little amplification occurs between the ground-level slab and the edge of the roof diaphragm, 0.08g amplified to 0.09g, 0.11g amplified to 0.13g, and 0.25g amplified to 0.25g for the three earthquakes. This small amount of amplification indicates that walls act as rigid bodies for in-plane accelerations. From the edge of the diaphragm to the center of the diaphragm, accelerations are amplified from 0.09g to 0.25g, 0.13g to 0.29g, and 0.25g to 0.79g for the three earthquakes. The acceleration amplifications indicate that the response of this building was dominated by the dynamic properties of the roof diaphragm. The effective fundamental period for this building in the transverse direction was 0.56 sec in the 1984 Morgan Hill earthquake, 0.58 sec in the 1986 Hollister earthquake, and 0.81 sec in the Loma Prieta earthquake. The longer period during the Loma Prieta earthquake is consistent with the higher accelerations and increased levels of yielding relative to those that occurred during the other two earthquakes. Analyses indicated that the damping was 2% of critical damping.

The building in Milpitas is 120 ft by 168 ft in plan and the roof diaphragm is plywood nailed to wood framing. Accelerations were measured during the 1988 Alum Rock earthquake and the 1989 Loma Prieta Earthquake. During the Loma Prieta earthquake, the two-story Milpitas building experienced peak accelerations at the ground level of 0.138g and 0.090g in the longitudinal and transverse directions, respectively. In the longitudinal direction, the acceleration at the ground level is amplified by a factor of 4.2 to an acceleration of 0.58g at the center of roof diaphragm. Acceleration at the edge of roof diaphragm is not provided for the longitudinal direction. In the transverse direction, accelerations were amplified by a factor of 1.26 to 0.11g between the ground-level slab and the edge of the roof diaphragm and amplified by a factor of 2.75 to 0.31g between the edge of the roof diaphragm and the center of the diaphragm. The larger acceleration amplification factor between the ground-level slab and the center of the diaphragm for the longitudinal versus transverse direction, 4.2 versus 3.46 (1.26x2.75) is consistent with the greater diaphragm overstrength leading to higher accelerations in the longitudinal versus transverse direction. Damping was found to be less than 5% of critical damping.

The damping is close to 5% of critical damping for two buildings and about 2% for one of the buildings. The large variation may be due in part to different roofing systems. The roofs with higher damping may have consisted of composition roofing, which would lead to higher damping than for a roof with a single-ply membrane. For new buildings with single-ply roofing membranes and minimal architectural finishes, damping is likely to be closer to 2% of critical.

Hamburger, et al. (1997) studied the response of three tilt up buildings (A, B, and C) that experienced the 1994 Northridge earthquake. The three buildings were located near one another in Chatsworth, California. They were of similar size but had different out-of-plane wall connection details. Building A was constructed in 1969 and retrofitted in 1993 with improved out-of-plane wall support. Building B was constructed in 1970 and Building C was constructed in 1977. Buildings A and B have plan dimensions of 180 ft north-south and 207 ft east-west. Building C has plan dimensions of 185 ft north-south and 200 ft east-west. In the Northridge Earthquake, Building A performed well, Buildings B and C each had roof/wall separation in the north-south loading direction and collapse in the east-west direction.

A non-linear model of each diaphragm was developed and response history analyses were performed. The fundamental period varied between 0.36 and 0.56 sec. The analysis results indicate that the out-of-plane wall anchorage forces are limited by yielding of the diaphragm and that the ground accelerations were amplified on the order of 2.5 times at the center of the roof diaphragm. This was less than 3.0 to 3.5 times amplification for the linear-elastic model. The investigators conclude that for conservatively designed diaphragms or for long, narrow diaphragms loaded in the longitudinal direction, the out-of-plane wall anchorage force may easily exceed forces generated from accelerations equal to more than three times the ground acceleration. The investigators recommended that ductile wall anchorage be provided because no analysis, not even a non-linear response-history analysis can accurately predict these forces to guarantee that they will not be exceeded.

RP5-3 CURRENT SEISMIC DESIGN APPROACH

The current seismic design approach for one-story buildings with flexible roof diaphragms is to base the building's seismic force level, including that of the diaphragm, on parameters defined by the vertical elements of the seismic-force-resisting system (SFRS) (Table 12.2-1, ASCE/SEI 7-10). The wall's out-of-plane force level and anchorage force level are separately derived and account for amplified ground accelerations as identified by Bouwkamp, et al. (1994) and Celebi, et al. (1989), observed failures, and consideration of whether yielding should be allowed. While some out-of-plane yielding of the wall is considered acceptable, top of wall anchorage forces are expected to be resisted by connections and members that behave elastically.

RP5-3.1 Seismic Systems and Response Modification Factors

For commonly used systems in these buildings, the applicable response modification coefficients, R, are listed in Table 1 as given in ASCE/SEI 7-10. In buildings designed for high and moderate levels of earthquake shaking, intermediate precast shear walls with an R of 4 are commonly used for buildings constructed with site-cast tilt-up walls and plant-cast precast walls. Buildings with masonry walls designed for high levels of earthquake shaking utilize special reinforced masonry shear walls, and those designed for moderate levels of earthquake shaking utilize intermediate or ordinary reinforced masonry shear walls. The lateral strengths required for vertical elements of buildings designed for low levels of earthquake shaking are often governed by wind forces. Regardless of whether the buildings are designed for high, moderate, or low seismic force levels, the diaphragm is designed for the same force level as the vertical elements regardless of whether the expected yielding is in the vertical elements or the horizontal diaphragm.

Table 1 Commonly used R values for One-story Flexible Diaphragm Buildings

Seismic-Force-Resisting System	Response Modification Coefficient, R	Limitations
Special reinforced concrete shear walls	5	160 ft roof height for SDCs D to F
Intermediate precast shear wall	4	40 ft or 45 ft roof height for one-story warehouse structures in SDCs D to F
Ordinary precast shear walls	3	Not permitted in SDCs C to F
Special reinforced masonry shear walls	5	160 ft roof height limit for SDCs D to F
Intermediate reinforced masonry shear walls	3-1/2	Not permitted in SDCs D to F
Ordinary reinforced masonry shear walls	2	160 ft roof height limit for SDC C; not permitted for SDCs D to F
Steel buckling-restrained braced frames	8	160 ft limit for SDCs D and E and 100 ft limit for SDC F
Steel special concentrically braced frames	6	160 ft limit for SDCs D and E and 100 ft limit for SDC F
Steel ordinary concentrically braced frames	3-1/4	60 ft roof structure height limit for one-story buildings with a roof dead load is less than 20 psf in SDCs D and E; not permitted in SDC F
Braced frames designed as steel system not specifically detailed for seismic resistance	3	Not permitted in SDCs D to F

RP5-3.2 Seismic Design Forces for the Diaphragm and Diaphragm Strength

In determining the seismic design forces for these buildings the approximate period, T_a, computed with Eq. 3-1, is used to estimate the fundamental period of the building.

$$T_a = C_t h_n^x \quad \text{(Eq.3-1)}$$

Where h_n is the structural height in feet,

C_t is a coefficient equal to 0.02 for these buildings, and

x is a coefficient equal to 0.75 for these buildings.

For most practical cases, the period computed with Eq. 3-1 is in the constant acceleration portion of the design spectrum. In common practice the diaphragm flexibility is not accounted for to obtain a longer period and lower design forces for new building design and there is no specific allowance to do so in code design; however, for evaluation and strengthening of existing buildings, ASCE/SEI 41-06 (ASCE, 2006) has a special provision to allow consideration of diaphragm flexibility that is sometimes used. The force level is equal to the seismic response coefficient, C_s, times the effective seismic weight, W, where C_s is computed in accordance with Eq. 3-2.

$$C_s = \frac{S_{DS}}{\left(\frac{R}{I_e}\right)} \quad \text{(Eq. 3-2)}$$

Where S_{DS} is the design spectral acceleration parameter in the short period range,

R is the response modification factor based on the vertical elements, and

I_e is the importance factor.

Structural wood panel and steel deck diaphragms are designed for the in-plane shear forces, and the chords around the perimeter of the diaphragm are designed for the in-plane flexure. The same force level C_sW, which is based on the vertical SFRS element's period, ductility, and overstrength, is used to determine these in-plane shear and flexural forces acting on the horizontal diaphragm. The effective seismic weight includes a portion of the weight of the walls oriented perpendicular to the direction of the seismic force, the weight of the roof, vertical parapet, and equipment on the roof, and if applicable, a portion of the snow load. Chord forces are almost always determined by dividing the flexural moments by the distance between chords, i.e., the diaphragm depth. Collector elements, if present, are designed for

an amplified force equal to the design force times the system over-strength factor, Ω_o, if designing for moderate or high levels of earthquake shaking, i.e., Seismic Design Categories (SDCs) C to F.

The diaphragm shear strengths are determined in accordance with industry documents. Structural wood panel diaphragms are designed in accordance with tables in AF&*PA Special Design Provisions for Wind and Seismic, 2008 Edition* (AF&PA SDPWS) [AF&PA, 2009]. Tables for combinations of panels, framing, and nailing are provided to determine the diaphragm shear strength based on monotonic test data. Steel deck diaphragms are designed in accordance with the Steel Deck Institute's *Diaphragm Design Manual* (SDI-DDM) [SDI, 2004] or more commonly they are based on evaluation services testing reports such as those produced by the International Code Council's Evaluation Services (ICC-ES). These reports are usually based on monotonic test data of diaphragms tested in accordance with ICC-ES AC43 [ICC-ES, 2010].

Seismic demands for each direction are computed and compared to the diaphragm shear strength provided. Although diaphragms resist shear in both directions with the same panels and connectors, ASCE/SEI 7-10 does not require the shear demands of the two orthogonal directions to be combined in the design of diaphragms.

RP5-3.3 Out-of-Plane Wall and Wall Anchorage Forces

During an earthquake, the ground shakes and moves the base of walls in-plane and out-of-plane, which generates inertial forces in the wall. The wall movement causes the diaphragm to move, which generates inertial forces in the diaphragm. The diaphragm movement causes movement of the tops of the walls, which also leads to inertial forces generated in the walls. These out-of-plane wall anchorage forces can be much larger as determined by the percentage of effective mass than the overall forces for the SFRS.

ASCE/SEI 7-10 requires that walls be designed for an out-of-plane force, F_p, in accordance with the following formula.

$$F_p = 0.4 S_{DS} I_e W_p \geq 0.1 W_p \qquad \text{(Eq. 3-3)}$$

Where W_p is the weight of the wall.

ASCE/SEI 7-10 requires that the anchorage of walls and transfer of forces into the diaphragm be designed for an out-of-plane wall force in accordance with the following formulas.

$$F_p = 0.4 S_{DS} k_a I_e W_p \geq 0.2 k_a I_e W_p \qquad \text{(Eq. 3-4)}$$

$$k_a = 1.0 + \frac{L_f}{100} \leq 2.0 \qquad \text{(Eq. 3-5)}$$

Where k_a is an amplification factor for diaphragm flexibility, and

L_f is the span, in feet, of a flexible diaphragm between resisting walls or rigid frames.

In Eqs. 3.4 and 3.5, K_a and L_f account for diaphragm flexibility. If a diaphragm is rigid, L_f equals 0 but if it is flexible, L_f equals the span length. For many buildings with rigid walls and flexible roof diaphragms, the diaphragm span between supporting walls or frames will be longer than 100 ft so k_a will often be equal to 2.0. For diaphragms in which K_a equals 2.0, the acceleration parameter used to compute the out-of-plane wall anchorage force is $0.8S_{DS}$, which is 80% of the maximum design spectral acceleration parameter. The intent is that the wall anchorage force is resisted elastically for a force level computed using the maximum design spectral acceleration. The 0.8 factor is included to recognize that some connection and member overstrength may be relied upon to resist the top of wall anchorage force.

Eq. 3-4 allows for top of wall anchorage forces less than those computed using the maximum design response spectrum parameter for cases in which the diaphragm span is less than 100 ft. This reduction is inconsistent with the common condition in which a short span diaphragm often has significant overstrength that can result in greater forces developing at the top of wall support.

RP5-3.4 Stiffness of Wall Anchorage Connections

The stiffness of wall-to-diaphragm connections is also considered in design. In previous earthquakes flexible wall-to-diaphragm connections have led to premature failures and loss of wall support. Strap anchors have buckled and fractured prematurely. Also, as the straps elongate the ledger was then loaded in cross grain bending. A similar issue occurs with hold downs that have oversized bolt holes. The slip that occurs as the hold down moves to engage the bolt can also allow the diaphragm shear connectors to load the ledger board in cross grain bending. The cross grain bending and the impact of the loose connections are more likely to lead to loss of wall support. Designs should include wall-to-diaphragm connections that have adequate stiffness to avoid cross grain bending of ledger boards, buckling and subsequent fracture of straps, and other detrimental effects of connections that are too flexible.

Current practice for connecting diaphragms to walls avoids some of the potential problems. For example, steel angles have largely replaced wood ledgers. This eliminates the possibility of cross grain bending. Hybrid roof systems have significantly reduced the number of diaphragms with wood framing, thus eliminating the use of hold downs. For steel deck diaphragms, the welded connections are stiff. Although other issues may exist with the newer connections, such issues may not become evident until the next major earthquake occurs.

RP5-3.5 Transfer of Wall Anchorage Forces to Continuous Diaphragm Ties

Although the interaction of the diaphragm and walls is dynamic in nature, following the flow of forces as if only static forces were involved makes it easier to understand how the connections and roof elements should be designed for support of the walls out-of-plane. For wood diaphragms, the static simplification of the load path for support of out-of-plane wall forces has wall anchorage forces being transferred to sub-diaphragms in the end regions of the diaphragm that transfer anchorage forces into continuity ties that distribute forces into the main diaphragm. Current practice is for the sub-diaphragm to be designed for the top of wall anchorage forces but the shears generated within the sub-diaphragm are not combined with the shears from the main diaphragm even-though they occur simultaneously. For steel deck diaphragms, some designers use sub-diaphragms similar to the approach used for wood diaphragms. More commonly for steel deck diaphragms, the static simplification of the load path for support of out-of-plane wall forces has wall anchorage forces transferred to the end of the deck sheets for out-of-plane forces parallel to the direction that the deck sheets span and into the joists for out-of-plane forces perpendicular to the direction that the joists span.

For buildings with concrete and masonry walls, Section 12.11.2.2 of ASCE/SEI 7-10 requires continuous diaphragm ties that resist the out-of-plane top of wall connection forces. Many engineers interpret the provision to require that the force at the edge of the wall be transferred across the entire diaphragm through the continuity ties. Other engineers interpret the requirement as allowing the force in the continuity tie to be reduced as the force is transferred into the main diaphragm. This approach is very common when analyzing existing buildings. If using this approach of variable tie force, the required tie strength is small near the center of the diaphragm assuming equal wall mass at each diaphragm edge acting with motions in phase. To address the small tie force, engineers often use a minimum tie force equal to that required by Section 12.1.3 (SEAOC 2008 and SEAOC 2010).

Section 12.1.3 ASCE/SEI 7-10 requires that all parts of buildings between seismic separation joints be interconnected. If the minimum force level determined using this section is applied, the ties must also be designed for a seismic force, F_p, equal to 0.133 times short period acceleration, S_{DS}, times the weight of the smaller portion of the building being connected to the larger portion but not less than 5% of the weight of the smaller portion. For one-story buildings, the weight includes the wall and roof weights. Therefore, the maximum tie force will be located where the weight to each side of the tie is equal. For symmetrical buildings, this will be the center of the diaphragm.

RP5-3.6 Deformation Compatibility

ASCE/SEI 7-10, Section 12.11.1, requires that "interconnection of structural wall elements and connections to supporting framing systems shall have sufficient ductility, rotational capacity, or sufficient strength to resist shrinkage, thermal changes, and differential foundation settlement when combined with seismic forces." Section 12.12.2 requires that "the deflection in the plane of the diaphragm, as determined by engineering analysis, shall not exceed the permissible deflection of the attached elements." Despite these requirements, diaphragm deflections are rarely computed for this building type, so these deformation compatibility requirements are rarely checked.

RP5-3.7 Diaphragm Design for Strength

The current design approach does not require a hierarchy of shear strength between the diaphragm and walls. Because the walls are stronger than the diaphragm and diaphragm connections to the wall for most practical design cases, the connections for the diaphragms yield prior to yielding of the vertical elements of the SFRS. Thus, the performance of this type of building is very dependent on the overstrength and ductility of the diaphragm and its connectors.

RP5-3.7.1 Wood Diaphragms

Wood structural panels are commonly nailed to wood framing or to nailers that are fastened to the top of steel joists or beams. At the perimeter of the diaphragm, the wood panels are nailed to wood ledgers and sometimes fastened directly to steel ledgers using pneumatic actuated pin fasteners. Less commonly used fasteners are staples for attaching structural wood panels to wood framing or powder actuated fasteners for attaching structural wood panels directly to the steel framing members.

Wood diaphragms are designed in accordance with *Special Design Provisions for Wind and Seismic* (SDPWS-2008) (AF&PA, 2009). Wood diaphragms included in SDPWS consist of wood structural panels such as oriented-strand board or plywood nailed to wood members or wood nailers. It does not address staples used as fasteners. Wood diaphragms are described as unblocked if some panel edges are unsupported by framing members or blocked if all panel edges are supported. Unblocked diaphragms are used in low and moderate seismic regions and are generally not used for RWFD buildings. Blocked structural wood panel diaphragms are commonly used for RWFD buildings in some western states. The aspect ratio (diaphragm span length to depth) for blocked diaphragms must be less than 4:1. For short and moderate diaphragm spans, a single line of nails is used along panel edges. The fastener spacing along panel edges vary from a maximum spacing of 6 in. to a minimum spacing of 3 in. except at diaphragm boundaries and continuous panel edges parallel to loading for which the spacing is a minimum of 2 in. on center. Panel edges nailed at 3 in. on center and greater may be supported by nominal 2 in. wide lumber. For nail spacing less than 3 in. on center and at all diaphragm boundaries, the lumber must be nominally at least 3 in. wide to mitigate splitting. The spacing of nails to intermediate supports is 12 in. on center maximum. The nominal strength of blocked diaphragms varies from a minimum of 370 pounds/linear foot (plf) to a maximum of 1,640 plf. The nominal strength must be reduced by a strength reduction factor of 0.80 for load and resistance factored design (LRFD) or by 1/2 to obtain a factor of safety of 2 for allowable stress design (ASD).

For longer diaphragm spans in RWFD buildings designed for high-seismic risk, high-load diaphragm nailing may be used to obtain shear strengths more than the maximum for a typical blocked diaphragm. The high-load diaphragm nailing patterns were developed as part of a testing program in the 1970s in which the goal was to determine the diaphragm nailing required to develop the strength of the wood panels (SEAOC, 2008); however, the high-load nailing patterns in the table do not develop the strength of the panels. The high-load nail patterns consist of two and three lines of nails along panel edges. Nail spacing along the lines at typical staggered panel edges varies from a maximum of 6 in. to a minimum of 3 in. on center with nail locations for adjacent lines being staggered. At diaphragm boundaries and continuous panel edges, nail spacing varies from a maximum spacing of 4 in. to a minimum spacing of

2-1/2 in. on center. Framing members are required to be nominally 3 or 4 in. wide depending on the number of lines and spacing of the nails. The nominal strengths vary from a minimum of 1,210 plf to a maximum of 3,130 plf. A strength reduction factor of 0.80 applies to design strength for LRFD and a factor of safety of 2 applies to ASD.

The nailing pattern is usually specified in zones that account for increasing shear demand from the center of the diaphragm to the edges. In areas of high seismic demands such as California, as many as six nailing zones are used for a larger diaphragm.

RP5-3.7.2 Steel Deck Diaphragms

For steel deck diaphragms, deck sheets are attached to open web steel joists or steel beams using arc-spot welds, powder-actuated fasteners, or self-drilling screws. Deck sheets are laid over multiple steel framing members, usually to cover three or more spans, and bottom surfaces of the deck flutes are attached to the framing members. In building specifications the pattern in which the deck is to be attached to framing members is described as the deck width followed by the number of fasteners within the width, i.e., 36/7 indicates the deck sheet is 36 in. wide and seven connectors attach the deck to each framing member. Various patterns are shown in Figure 1. Where the end of one sheet meets the end of the next sheet, the sheets are typically overlapped and the deck-to-framing connections attach both sheets to the underlying framing.

The edges of deck sheets can be either nested or interlocked, as shown in Figure 1. Nested deck is common in the Eastern U.S. but is also used in the Western U.S. Interlocking deck is primarily used in the Western U.S. For nested deck, not only do the ends of sheets overlap but so do adjacent edges of deck; therefore, the corner deck-to-framing connectors pass through four sheets and then attach to the underlying framing. For nested deck, the corner panel connector is shared by all four deck sheets meeting at that corner, and the edge deck-to-framing connectors are shared by the two overlapping sheets. For interlocking deck, the corner connectors are only shared by the two sheets that overlap one another at ends of deck sheets, and the edge connectors are not shared by the adjacent sheets. Therefore, for the same deck-to-framing connection pattern, interlocking deck averages one extra connector for each deck sheet width. The extra connector results in a less than proportionate increase in diaphragm shear strength due to the details of the connections as described below. For a nested deck, shear force at a connector is transferred directly from one sheet to the adjacent connected sheet through the edge connector. For the interlocking deck, shear force is transferred from the edge connectors into the steel frame and from the steel framing to the adjacent deck sheet at the additional connector. The difference in strength is only the difference in strength of transferring shear directly from one sheet to the next versus the shear strength of a connector transferring from the deck to the framing.

The sides of adjacent deck sheets are interconnected with button punches, top seam welds, self-drilling screws, or a variety of proprietary connectors and punches. These inter-panel connections along the sheet edges are referred to as sidelaps. Button punching requires an interlocking deck, so it is used in the Western U.S. Top seam welds can be used on either interlocking deck or nested deck though in the case of the nested deck, the sidelap connection is more of a fillet weld along the edge of one of the sheets. Screws need to be installed at 90 degrees to the deck surface, so they are mostly installed in nested deck but can also be installed horizontally into specially formed interlocking deck. The proprietary sidelap connectors and punches are mostly used in the Western U.S. In the Western U.S., sidelap connector spacing is specified, while in the Eastern U.S., the number of sidelap connectors for each deck span is specified.

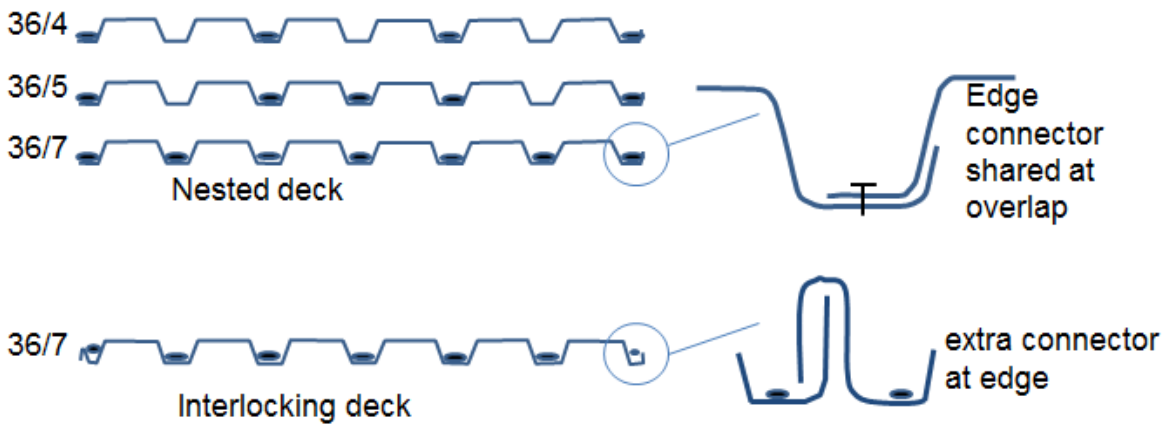

FIGURE 1 Fastener Configurations for Nested and Interlocking Deck

Steel deck diaphragms are designed using deck suppliers' evaluation services reports (ESRs) or using the design approach in the Steel Deck Institute's Diaphragm Design Manual (SDI-DDM) (SDI 2004). The diaphragm shear design values in ESRs are based on monotonic testing of relatively small diaphragms that rarely contain end lap connections. Shear strength values for 20 and 22 gage deck with spans in the range of 5 to 7 ft are generally in the range of 200 plf to 1,600 plf for allowable stress design, which includes a factor of safety of 2.5 for mechanical fasteners and 3.0 for welds for design for earthquakes. For load and resistance factor design (LRFD), strengths are generally in the range of 300 plf to 2,600 plf, which includes a strength reduction factor of 0.65 for mechanical connectors and 0.55 for welds.

Zoning of connectors for steel deck diaphragms is common in regions where seismic forces are high but the number of zones used is often limited to three. In regions of low and moderate seismic demand, diaphragm connector zoning is also used but less commonly than in regions of higher seismicity.

RP5-4 EVALUATION OF CURRENT DESIGN APPROACH

Although the current design approach is based on the assumption of inelastic response in the vertical elements (walls, rigid frames), yielding of the diaphragm commonly dominates the inelastic response of the buildings to earthquakes. Archetype buildings using the current design approach were designed, and P695 analyses (FEMA P695, 2009) were applied to these designs to provide a baseline of performance and to demonstrate that changes to the design approach are necessary. The FEMA P695 methodology is used to reliably quantify building system performance and provide guidance in the selection of appropriate design criteria when ASCE/SEI 7-10 linear design methods are applied. The primary objectives of FEMA P695 are to obtain an acceptably low probability of collapse of the SFRS under maximum considered earthquake (MCE) ground motions, and to provide uniform protection against collapse across various structural systems. An appropriate P695 evaluation must use a representative nonlinear model that includes both detailed design information of the system as well as comprehensive test data on the post-yield performance of system components and subassemblies.

A proposed structural system, or in this case a proposed design methodology of an existing system, is evaluated through the use of collapse fragility curves. Incremental Dynamic Analyses (IDA) on a representative sample of nonlinear numerical building models that account for the range of the design space are conducted to build the collapse fragility curves using a pre-determined ensemble of earthquake ground motions. The number of archetypes selected is based on building an appropriate representation of the typical RWFD structure including the range of variation reasonably expected and likely to affect performance. The archetypes are assigned to performance groups for the evaluation process. The collapse margin ratio (CMR) is determined from the IDA and fragility curves. The CMR is defined as the

median spectral collapse intensity at the fundamental elastic period of the building archetype under analysis, $S_{CT}[T]$ obtained from nonlinear dynamic analyses divided by the ground motion spectral demand $S_{MT}[T]$ at the maximum considered earthquake (MCE) intensity level at the same fundamental elastic period. The collapse margin ratio is multiplied by a spectral shape factor (SSF) to obtain an adjusted collapse margin ratio (ACMR). The spectral shape factor is a function of the fundamental period, the period-based ductility, μ_T, and the applicable seismic design category of the archetype under analysis. The ACMR for both individual archetypes and the archetype performance groups are compared to acceptable ACMRs that accounts for uncertainties judged to be within the evaluation process. The acceptable ACMR for a performance group targets less than 10% probability of collapse in an MCE event, and the acceptable ACMR for individual archetypes targets less than 20% probability of collapse in an MCE event.

RP5-4.1 DESCRIPTION OF ARCHETYPES

Evaluations were performed on archetypes designed for high and moderate seismic risk. For the evaluations, high-seismic risk is defined as having design acceleration parameters S_{DS} equal to 1.0 and S_{D1} equal to 0.60. These acceleration parameters are used for the SDC D_{max} evaluation in accordance with FEMA P695. Moderate-seismic risk is defined as having design acceleration parameters S_{DS} equal to 0.499 and S_{D1} equal to 0.199, which are the boundary values for SDCs C and D and is referred to as SDC C_{max} for the evaluations.

For these evaluations, archetypes were designed with either steel deck or wood panel diaphragms. The archetype naming convention is shown in Figure 2. Summary tables and tables with detailed descriptions of diaphragm zones for the archetypes are in Appendix A. The walls for these archetypes are reinforced-concrete wall panels 25 ft in width, 33 ft tall measured from the top of the slab-on-grade, and 9-1/4 in. thick for high seismic risk and 7-1/4 in. thick for moderate seismic risk. The roof level is 30 ft above the top of the slab-on-grade with the walls cantilevering as a parapet 3 ft higher than the roof level.

The archetypes are grouped by diaphragm type, either wood or steel deck, and whether the diaphragm is relatively large or small. The archetypes have plan aspect ratios of 1:1, 2:1 and 1:2. Large diaphragms are 400 ft long and either 400 ft or 200 ft wide. The small diaphragms with aspect ratios of 2:1 and 1:2 are 200 ft long by 100 ft wide, and for the 1:1 aspect ratios the diaphragms are 100 ft by 100 ft. The wood diaphragms are wood structural panels nailed to wood nailers that are attached to open web steel joists. The steel deck diaphragms are attached to the joists with arc spot welds, powder actuated fasteners, or self-drilling screws. Adjacent steel deck sheets are attached along their sides (sidelaps) with top seam welds, button punches, or self-drilling screws. Many steel deck diaphragms include proprietary sidelap connections in the western portion of the U.S., which includes regions of high seismicity. Archetypes are not included with the proprietary sidelap connections because cyclic test data for the response of these connectors is not available. The steel deck diaphragms were designed using 22 and 20 gage deck because connection data was available for connectors with these deck gages. Note that thicker gage deck results in less ductile connections so the steel deck diaphragm results presented herein are limited to only diaphragms with 22 or 20 gage deck.

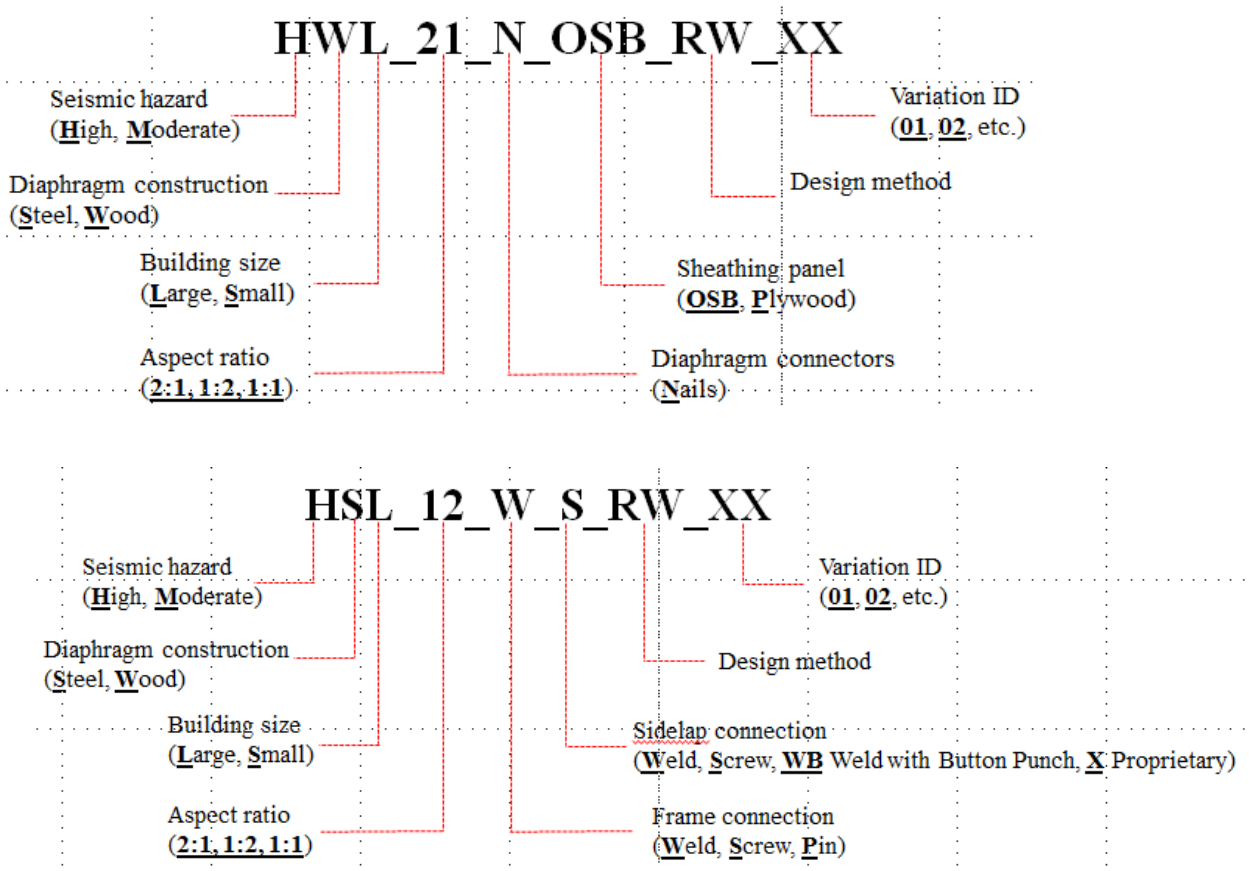

FIGURE 2 Archetype Naming Convention

The archetypes were designed as intermediate precast shear walls with a response modification factor of 4. The period for each direction of each archetype was computed using the approximate period equation, Eq. 3-1, for T_a. For the 30 ft roof height of the archetypes, the approximate period is 0.26 sec. This value is less than the transition period, T_s, equal to 0.60 sec for high-seismic risk (SDC D) archetypes and 0.40 sec for moderate seismic-risk (SDC C_{max}) archetypes. Therefore, the archetypes for the existing design approach, i.e., current code, are designed using a base shear coefficient of 0.25 for the high-seismic risk (SDC D) archetypes and for a base shear coefficient of 0.125 for the moderate seismic risk (SDC C_{max}) cases.

The diaphragms for the archetypes are zoned with different fastener spacings similar to zoning commonly used in practice. For the wood diaphragms, the diaphragms are zoned as follows:

- Large wood diaphragms with 1:1 aspect ratio – four zones of concentric squares for high-seismic risk and two zones of concentric squares for moderate seismic risk.
- Large wood diaphragm with 2:1 and 1:2 aspect ratio for high-seismic risk – six zones total with the first two zones near the center of diaphragm as concentric rectangles and the remaining zones banded for loading in the transverse direction
- Large wood diaphragm with 2:1 and 1:2 aspect ratio for moderate seismic risk – three banded zones for loading in the transverse direction
- Small wood diaphragm with 1:1 aspect ratio – two zones of concentric squares
- Small wood diaphragms with 2:1 and 1:2 aspect ratio – five banded zones for high-seismic risk and two banded zones for moderate seismic risk for loading in the transverse direction

For the steel deck diaphragms, the diaphragms are zoned as follows:

- Large steel deck diaphragm with 1:1 aspect ratio – three zones of concentric squares
- Large steel deck diaphragm with 2:1 and 1:2 aspect ratio – three zones banded for transverse direction loading
- Small steel deck diaphragms with 1:1 aspect ratio – one zone used for entire diaphragm
- Small steel deck diaphragms with 2:1 and 1:2 aspect ratio – two zones banded for transverse direction loading

RP5-4.2 Modeling Framework

The computational time necessary to perform nonlinear response history analyses, i.e., the time it takes for the computer to run the analyses, is too long to allow for analyses of detailed finite element models of each archetype, so an approach was developed that allows for a relatively simplified model to be used. The approach includes three steps and is illustrated in Figure 3:

1. Create a data base of connectors that have been cyclically tested and based on the test results determine the hysteretic parameters of Wayne Stewart (Stewart 1987) or SAWS (Folz and Filiatrault, 2001) nonlinear cyclic springs for each connector and shown in Figure 4. Examples for nailed and welded connectors are illustrated in Figures 5 and 6.
2. Create a mathematical model in MATLAB of one-half of each archetype's diaphragm that accounts for the stiffness of the panels, diaphragm chords, and each diaphragm connector. Divide the diaphragm model into horizontal segments and load the diaphragm by a cyclic point load at its mid-span. Combine the response of the elements and connectors within each diaphragm segment to form a single nonlinear hysteretic spring that represents the cyclic response of the segment. This step is illustrated in Figure 7. Variable connector spacing is accounted for in this model.
3. Create a model in RUAUMOKO2D (Carr, 2007) that consists of one-half of the archetype and includes a spring and mass for each horizontal diaphragm segment, beam elements with nonlinear hinges to represent the out-of-plane wall response, and springs and masses to represent the in-plane wall at the end of the diaphragm. A representation of the simplified model is shown in Figure 8. P-delta effects are incorporated into the model by applying the roof weight on leaning columns between the ground and the roof diaphragm. Localized effects that account for shear concentration in sub-diaphragms or regions receiving wall anchorage forces are not accounted for in this analysis.

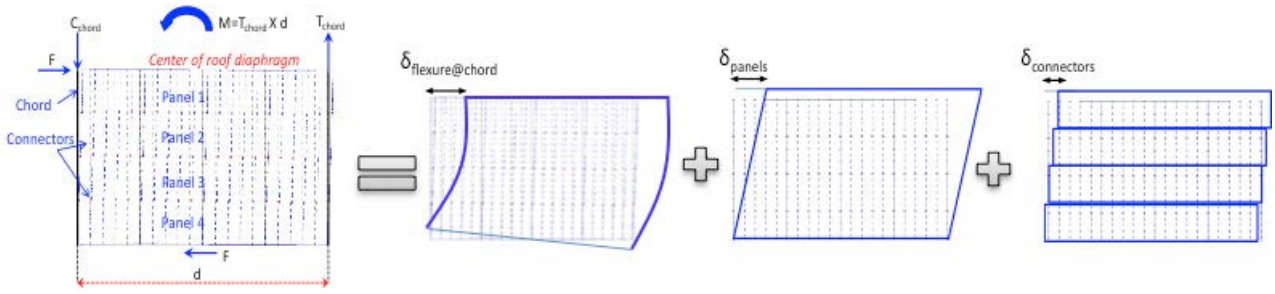

FIGURE 7 In-plane displacement components of the analytical inelastic roof diaphragm model

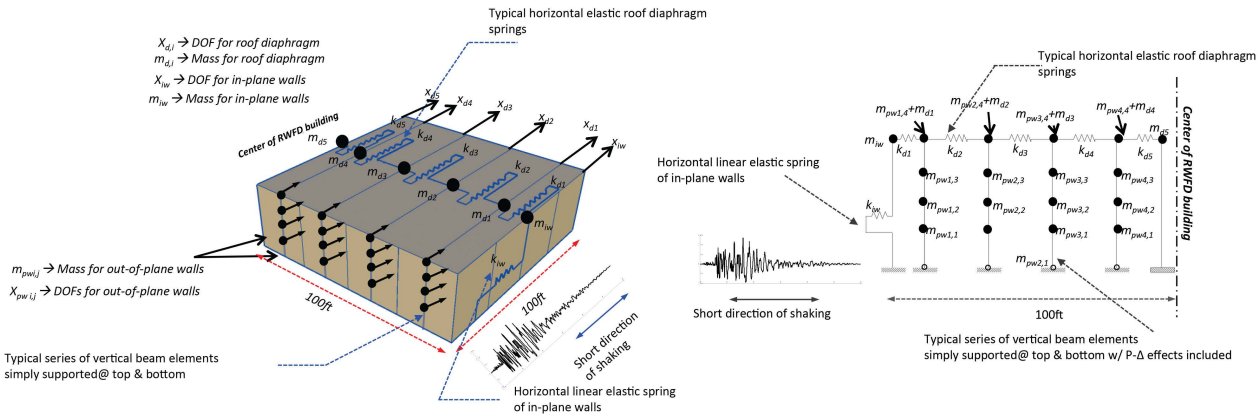

FIGURE 8 Illustration of a simplified rigid wall flexible diaphragm (RWFD) building model developed in the RUAUMOKO2D platform

Cyclic test data for the 10d common nails are from Coyne (2007), Fonseca and Campbell (2002), and Christovasilis, et al (2009). Cyclic data for button punch, screw, and top seam weld sidelap connectors between deck sheets are from Rogers and Tremblay (2003b). Cyclic data for welds, powder actuated fasteners, and screws that connect steel deck to steel plates are from Guenfoud, et al. (2010) and from Rogers and Tremblay (2003a). A list of the database of cyclic test data for nails and steel deck connectors is included in Tables B1, B2, and B3 of Appendix B.

RP5-4.3 Modeling Framework Validation

The two-dimensional model of the diaphragm, Step 2, was validated by comparing predicted results to cyclic diaphragm test results of Tremblay et al. (2004). The predicted and tested shear for monotonic loading are normalized to the applicable maximum shear and compared in Figure 9. The results for shear versus deformation for one main cycle predicted by the diaphragm sub model versus the test results are compared in Figure 10. Results for the simplified model, Step 3, are compared to those of a detailed finite element model by Olund (2009). The periods are obtained from eigenvalue analyses using the simplified building model and are initial elastic periods. The natural periods of the simplified model for the first and second modes are about 3% longer than those predicted by Olund's detailed model.

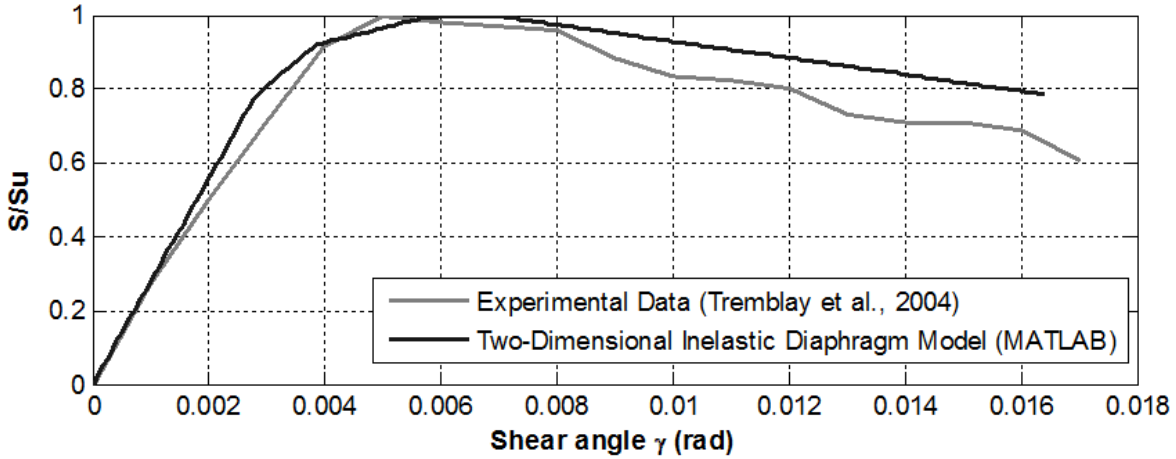

FIGURE 9 Validation/comparison of inelastic roof diaphragm for monotonic loading

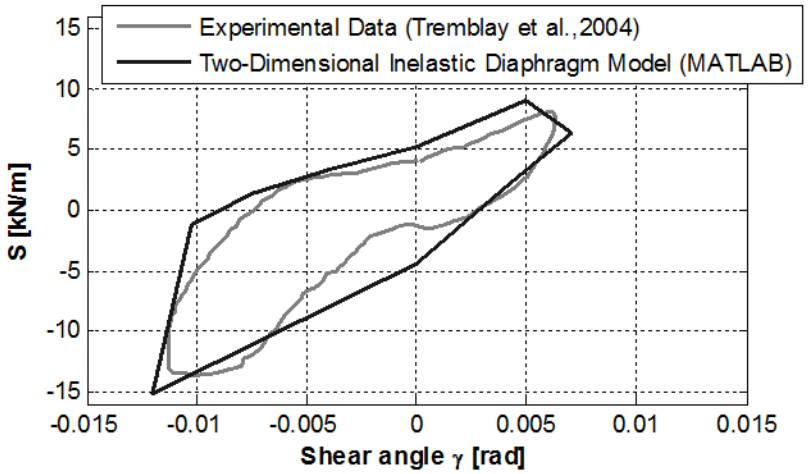

FIGURE 10 Validation/comparison of inelastic roof diaphragm for cyclic loading (one main cycle)

The collapse assessment of the rigid wall flexible diaphragm (RWFD) building was evaluated by conducting Incremental Dynamic Analyses (IDA) (Vamvatsikos and Cornell, 2002) using the FEMA P695 Far Field Ground Motion Ensemble (FEMA P695, 2009) and computing the median collapse intensity. To monitor the state of the structure at the end of each nonlinear time history dynamic analysis, the diaphragm (roof) drift ratio was considered as the damage measure (DM), while the intensity measure (IM) was defined by the spectral acceleration ($S_a(T_1)$) at the fundamental period of the RWFD building; T_1 is the fundamental period obtained from eigenvalue analyses of the initially elastic simplified building model. Olund (2009) set the limit state for a RWFD as a roof drift equal to 3%. For the purpose of comparing results of Olund's detailed model to those of the simplified building model the limit state is set equal to 3% roof drift, but for analysis results reported later in this report, the limit state is equated to a load-displacement (P-delta) sidesway instability. As shown in Figure 11, the simplified building model slightly underestimates (by approximately 9%) the median collapse intensity compared to the detailed FEM developed by Olund (2009).

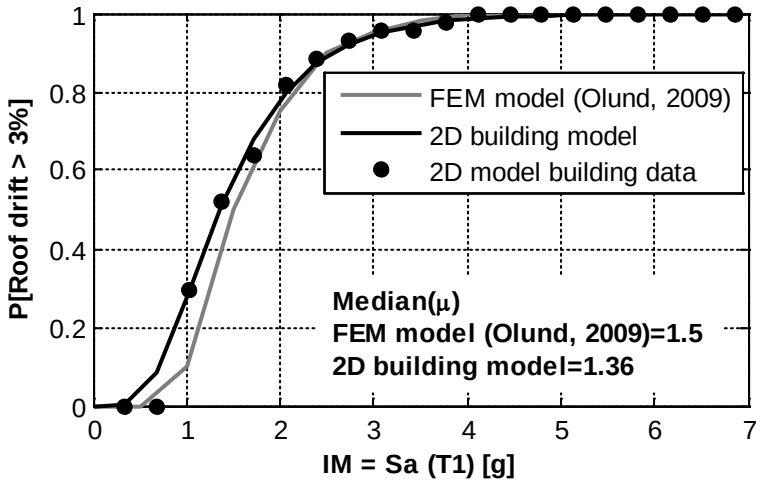

FIGURE 11 Incremental dynamic analysis results/comparison

A limitation of the modeling framework is that it cannot account for the simultaneous loading of framing connectors at ends of steel deck sheets from the in-plane diaphragm shears and the continuity tie

or out-of-plane wall anchorage forces. Therefore, the archetypes designed and analyzed are based on the requirements to resist shear only. However, the magnitudes of these two sources of loading are not compatible with one another. Specifically, out-of-plane wall forces are not reduced to account for ductility and the connections supporting the wall are expected to behave elastically, while the forces acting on these same connectors from diaphragm shear resistance are based on an assumption that the connections will yield. There seems to be a philosophical conflict in the intended behavior of the fastener when exposed to both diaphragm shear forces and wall anchorage forces, which occur simultaneously in some regions of the diaphragm. For steel deck diaphragms, consideration should be given to supporting the out-of-plane wall forces with separate continuity ties rather than transferring them into the deck sheets.

RP5-4.4 FEMA P695 Analysis Results for Current Design

Incremental Dynamic Analyses (IDA) (Vamvatsikos and Cornell, 2002) using the FEMA P695 Far Field Ground Motion Ensemble (FEMA P695, 2009) were performed using the simplified building models to compute the median collapse intensity. For the analysis results, the median collapse intensity is defined as the median spectral intensity at the fundamental period that causes side-sway P-delta instability. Summaries of collapse results for individual wood and steel deck diaphragm archetypes are included in Appendix C. Values for the median collapse intensity, $S_{CT}[T]$, ground motion spectral demand, $S_{MT}[T]$, building drift ratios (BDR) for the design level earthquake and maximum considered earthquake, the spectral shape factor (SSF), fundamental elastic period, and period based ductility, μ_T, are provided. The BDR, which equals the sum of the wall drift ratio (WDR) and the diaphragm drift ratio (DDR), is used as measure of building damage for this study. Collapse margin ratios (CMRs), adjusted collapse margin ratios (ACMRs), and acceptable ACMRs for the individual archetypes and the archetype groups are also included in Appendix C. The acceptable ACMRs are computed using the uncertainty (beta) factors listed in Table 2. Note that the value for the design requirement uncertainty is based on an assumed improved design procedure so a larger value might be more appropriate for evaluating the current design approach. The combined uncertainty, β_{Total}, is computed as the square root sum of the squares of the individual uncertainties. For β_{Total} equal to 0.66, the acceptable ACMR is 1.73 and 2.30 for 20% and 10% probability of collapse at Maximum Considered Earthquake (MCE) ground motion, respectively. The acceptable ACMR applicable for the performance of individual archetypes is 1.73, and the acceptable ACMR of performance groups is 2.30. Summaries of the collapse margin ratio results for the performance groups of wood and steel archetypes are provided in Tables 3 and 4.

The current design approach did not pass the P695 collapse criteria for the small archetype performance groups with wood diaphragms. Each small wood diaphragm archetype had an individual ACMR that exceeded the acceptable value of 1.73 indicating each archetype passed the criterion. However, the small archetype performance groups for both high- and moderate-seismic risk had ACMR values of 2.11 and 1.98, respectively, which is less than the acceptable ACMR of 2.30, so these performance groups did not pass the criterion. The small archetypes had short periods and remained in the short period range as yielding occurred. In this region, period shifts can result in resonance with large spikes in the short period range that can lead to much larger spectral accelerations and displacements than predicted using the design spectrum plateau. This issue of short-period structures having higher seismic demands leading to the lowest level of collapse performance has been well documented, starting with Newmark and Hall (1973). Section 9.5.1 of FEMA P695 (2009) describes this issue with short-period structures in greater detail.

The larger archetype wood diaphragm performance groups had ACMRs of 2.68 and 2.80 for the high- and moderate risk performance groups, which exceed the acceptable ACMR of 2.30 to pass the criterion. Each large wood diaphragm archetype had an individual ACMR that exceeded the acceptable value of 1.73. The large wood archetypes performed better because the elastic periods were often off of the design response spectrum's plateau but the diaphragm was designed as though it was on the plateau of the spectrum. Also, as the diaphragm yields its period lengthens, which in general leads to lower forces.

Both the large and small steel deck diaphragm performance groups did not pass the criteria. For individual archetypes with high-seismic risk 5 of 7 large archetypes and 1 of 9 small archetypes had ACMRs less than the acceptable ACMR of 1.73, and for individual archetypes with moderate-seismic risk 3 of 12 large archetypes and 3 of 9 small archetypes had ACMRs less than acceptable. The ACMRs for the large archetype groups of 1.71 and 1.87 for high-seismic risk and 1.95 and 1.88 for moderate seismic risk performed slightly worse than the small archetype groups. The small archetype groups had values of 2.23 and 1.92 for high-seismic risk and a value of 1.86 for moderate seismic risk. The reason for the difference relative to what was observed for the wood diaphragms is that the larger steel diaphragms were relatively stiffer than the larger wood diaphragms and had periods that were on or close to the design spectrum plateau. Differences in ACMRs of the archetypes with various combinations of welds, PAFs, screws and button punches were not significant enough to distinguish definitive differences in performance of the connectors.

Table 2 Beta factors for determining acceptable collapse margin ratios

Description	Beta factor	Value
Record-to-record uncertainty	β_{TR}	0.40
Design requirements uncertainty	B_{DR}	0.20
Test data uncertainty	β_{TD}	0.35
Modeling uncertainty	B_{MDL}	0.35
Combined uncertainty	β_{Total}	0.66

Table 3 Summary of collapse margin ratio results for wood diaphragm archetype performance groups for current design

Performance Group	Seismicity	Size	Computed ACMR	Acceptable ACMR	Pass/Fail
PG-1E	High	Large	2.68	2.30	Pass
PG-2E	High	Small	2.11		Fail
PG-3E	Moderate	Large	2.80		Pass
PG-4E	Moderate	Small	1.98		Fail

Table 4 Summary of collapse margin ratio results for steel deck diaphragm archetype performance groups

Performance Group	Seismicity	Size	Framing Connectors	Sidelaps	Computed ACMR	Acceptable ACMR	Pass/Fail
PG-5E	High	Large	Welds	Welds/button punches	1.71	2.30	Fail
PG-6E	High	Large	PAFs/screws	Screws	1.87		Fail
PG-7E	High	Small	Welds	Button punches	2.23		Fail
PG-8E	High	Small	PAFs/screws	Screws	1.92		Fail
PG-9E	Moderate	Large	Welds/PAFs/screws	Screws	1.95		Fail
PG-10E	Moderate	Large	Welds/PAFs/screws	Welds	1.88		Fail
PG-11E	Moderate	Small	Welds/PAFs/screws	Screws	1.86		Fail

The results indicate that the current design rules are not adequate based on the FEMA P695 methodology for both wood structural panel and steel deck diaphragms. Therefore, a modified or new design approach is needed. The results also indicate that if a single response modification factor were to be used for the diaphragm parallel to current design of SFRS, its value would need to be less than 4. For the wood diaphragms, considering that the lowest ratio of ACMR to acceptable ACMR (1.98/2.3) is 0.86 leads to the expectation that current design using an R-factor (0.86x4) of about 3 to 3.5 is appropriate. For steel deck diaphragms, consider that the lowest ratio of ACMR to acceptable ACMR (1.71/2.3) is 0.74 leads to the expectation that current design using an R-factor of about 2.5 to 3 may be appropriate for

20 and 22 ga steel deck diaphragms. However, analyses should be performed to determine the appropriate R values. This expectation is not appropriate for steel deck diaphragms with gages of 18 or thicker as they are anticipated to result in less ductile diaphragms.

The analysis results also showed that the diaphragm's inelastic behavior was concentrated at the ends of the diaphragm. The global ductility of the diaphragm is lower than the ductility of the connectors because connector yielding is not spread well into the diaphragm. Response of these buildings would improve if a means of spreading connection yielding deeper into the diaphragm were developed. For the steel deck diaphragms, the response would also be improved if the post-yield stiffness of the connector were positive to a larger displacement value. Tests indicate positive post-yield stiffness only to 1 or 2 mm. The exact displacement needed for improved behavior is not known at this time but a value such as 10 mm is expected to be more than adequate.

RP5-4.5 Fundamental Period of the Archetypes

The results of the simplified building model analyses show that the fundamental period of each archetype is dominated by the diaphragm response. The elastic fundamental periods for the archetypes were obtained from the analyses and are included in Tables C1 and C3 of Appendix C. A summary of the elastic periods are included in Table 5.

Table 5 Summary of Elastic Periods for Archetypes

Wood diaphragm span length	Period for high-seismic archetypes	Period for moderate-seismic archetypes
400 ft	0.85 to 0.87 sec	0.90 to 0.92 sec
200 ft	0.49 to 0.54 sec	0.55 to 0.58 sec
100 ft	0.36 to 0.38 sec	0.43 to 0.45 sec
Steel diaphragm span length		
400 ft	0.49 to 0.56 sec	0.61 to 0.73 sec
200 ft	0.35 to 0.42 sec	0.51 to 0.59 sec
100 ft	0.21 to 0.26 sec	0.28 to 0.33 sec

Using the elastic periods from the analyses of the high-seismic wood diaphragm archetypes and the high-seismic steel deck diaphragm archetypes, empirical formulas were developed for the fundamental periods of wood and steel deck diaphragms, respectively. The following formula is proposed for computing the fundamental period, T_{wood}, of the wood diaphragm buildings with concrete or masonry shear walls.

$$T_{wood} = \frac{0.0019}{\sqrt{C_w}} h_n + 0.002L \qquad \text{(Eq. 4-1)}$$

Where, L is the diaphragm span in feet between vertical elements of the seismic-force-resisting system,

C_w is a coefficient defined by Equation 12.8-10 in ASCE/SEI 7-10

$$C_w = \frac{100}{A_B} \sum_{i=1}^{x} \frac{A_i}{\left[1+0.83\left(\frac{h_i}{D_i}\right)^2\right]} \qquad \text{(Eq. 4-2)}$$

A_B is the area of the base of the building in ft^2,

A_i is the web area of the in-plane shear wall i in ft^2,

D_i is the length of the in-plane shear wall i in ft^2, and

h_i is the height of the in-plane shear wall i in ft^2.

h_n is the height of the roof framing in ft.

The following formula is proposed for computing the fundamental period, T_{steel}, of the steel deck diaphragm buildings.

$$T_{steel} = \frac{0.0019}{\sqrt{C_w}} h_n + 0.001L \qquad \text{(Eq. 4-3)}$$

The proposed period equations are plotted along with the periods determined from the simplified building model analyses in Figure 12 for the wood diaphragm archetypes and in Figure 13 for the steel diaphragm archetypes. Although the periods are derived from analyses of single-span diaphragms, the deformations were shear dominated. Therefore, the period equations are valid for multi-span diaphragms. The archetypes used to develop these formulas included heavy walls.

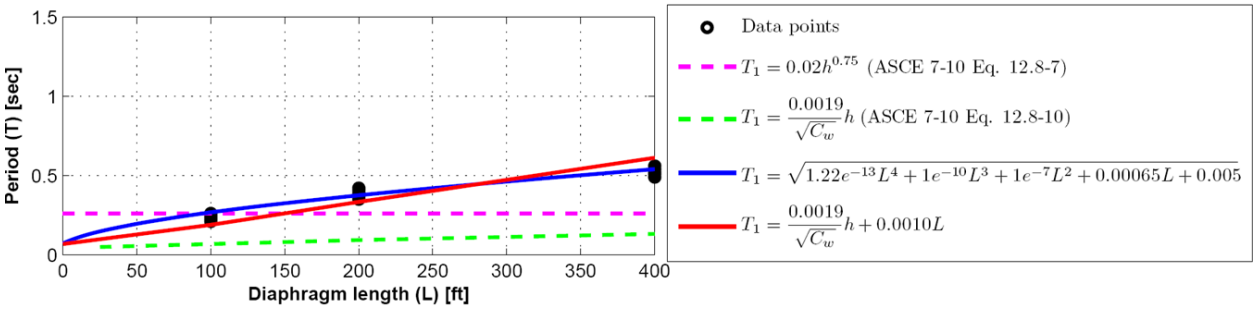

FIGURE 13 Comparison of fundamental periods from analyses of steel deck archetypes to those predicted by the proposed formula (Eq. 4-3), ASCE/SEI 7-10 equations, and a best fit curve

RP5-4.6 Out-of-plane Wall Anchorage Forces

A study was performed to determine the magnitude of the force required to anchor the top of walls for out-of-plane forces. Archetype HSL_21_W_WB_RW4 was analyzed to determine the out-of-plane wall forces. This archetype is 400 ft long by 200 ft wide with the roof height at 30 ft. The wall panels are 9-1/4 in. thick and 33 ft tall. The roof diaphragm is steel deck with welded framing connectors, top seam weld sidelap connectors in the outer two zones and button punches at the center zone. The top of wall anchorage force computed in accordance with Eq. 3-4, i.e., ASCE/SEI 7-10, is 1,680 lbs/ft, which is based on the design level earthquake. The model of the archetype was loaded with the forty-four ground-motion records from FEMA P695 and amplified to spectral acceleration intensities up to 2.5g. The median out-of-plane wall anchorage forces for the forty-four records at the roof level are shown in

Figures 14 and 15 respectively for the transverse and longitudinal direction of loading. In the figures, the blue lines represent the model that accounts for out-of-plane wall flexibility and the red line represents the behavior if the wall is treated infinitely rigid out-of-plane. The MCE intensities are where the dashed vertical blue lines cross the curves.

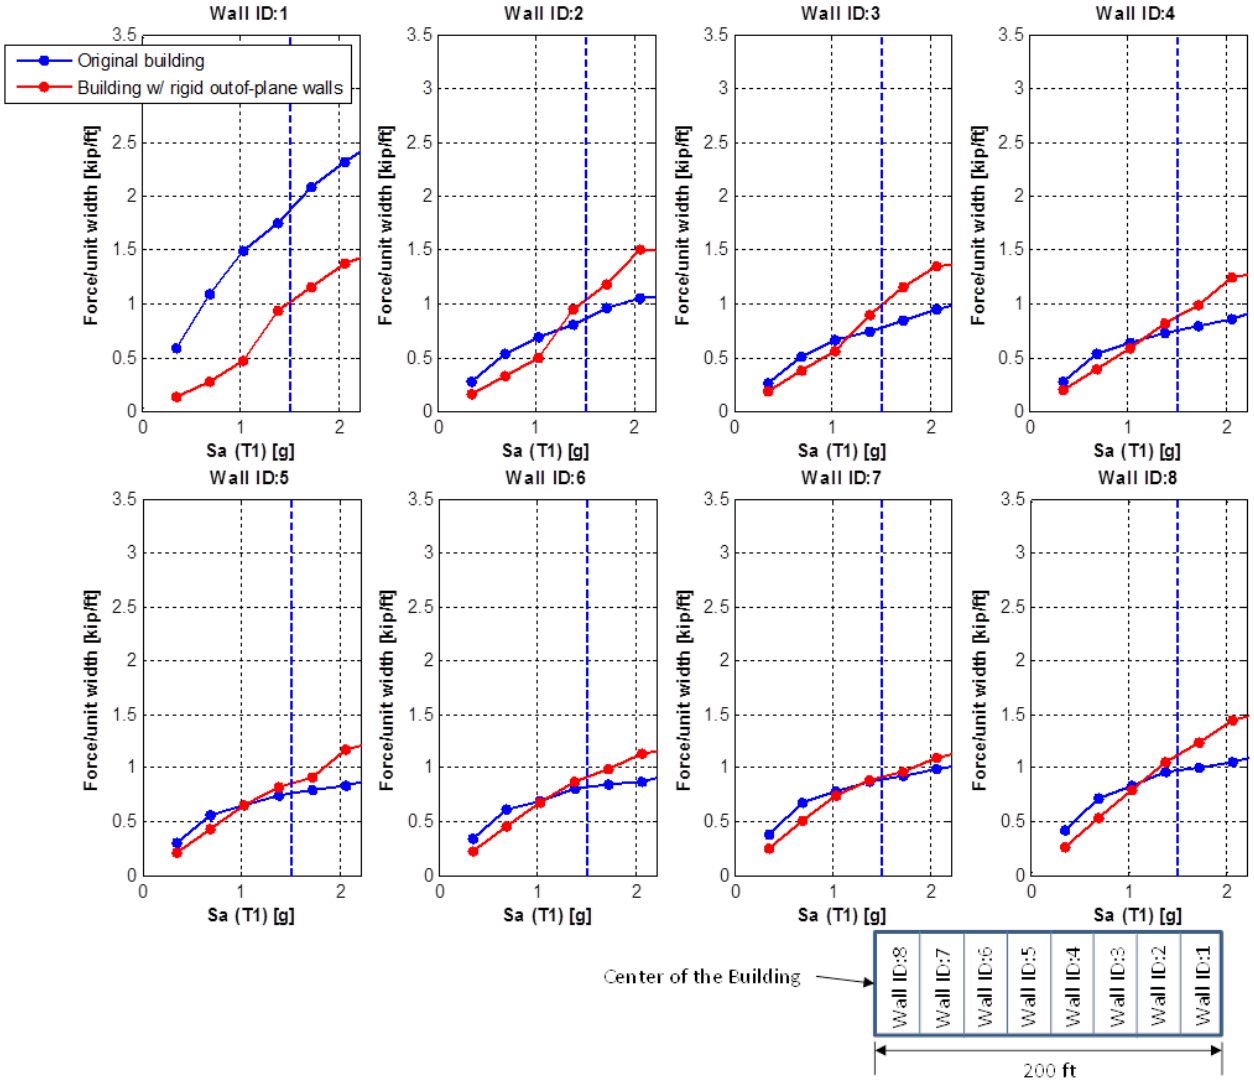

FIGURE 14 Median out-of-plane wall anchorage force for transverse direction of loading

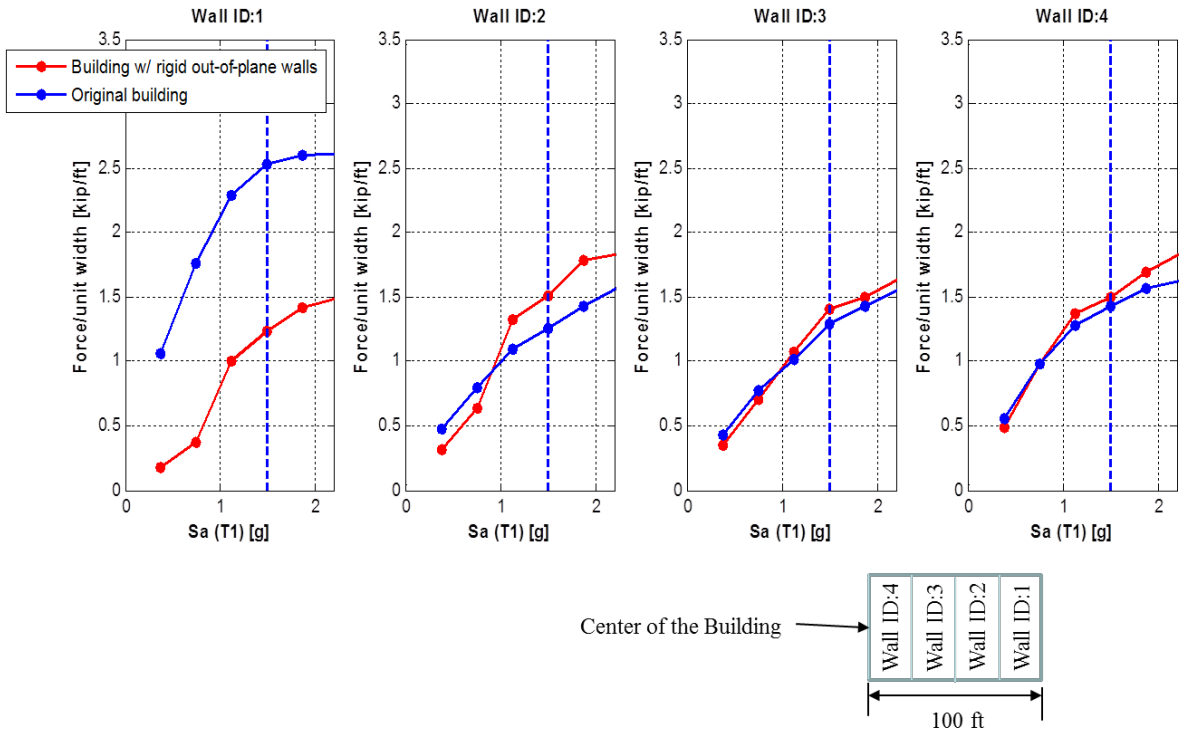

FIGURE 15 Median out-of-plane wall anchorage force for the longitudinal direction of loading

The study showed that forces are higher for walls loaded out-of-plane when the diaphragm is loaded in the longitudinal direction than they are for walls loaded out-of-plane when the diaphragm is loaded in the transverse direction. At the center of the diaphragm span, the out-of-plane wall anchorage forces are about 1.2 kips/ft for the transverse direction loading and 1.5 kips/ft in the longitudinal direction loading for MCE level of shaking. Out-of-plane anchorage forces in the longitudinal direction are likely greater than in the transverse direction because the diaphragm has more overstrength in the longitudinal versus the transverse direction. The study also showed that anchorage forces were higher at the corners than in the middle of the diaphragm. This occurs because input motions between the bottom and the top of the wall panels are more likely to be in-phase adjacent to the corners, which dynamically amplifies the wall accelerations near the corner. Also, the panel flexibility affects the load developed near the corners more than away from the corners. Forces generated in the analyses are less than the required design forces computed in accordance with ASCE/SEI 7-10 using Eq. 3-4 except at the corner in the longitudinal direction. The results suggest that the formula for out-of-plane wall anchorage should be revised to eliminate the k_a variable and change the 0.4 coefficient to 0.8.

RP5-5 PROPOSED DESIGN APPROACH

An approach to design rigid wall-flexible diaphragm buildings for earthquake effects is proposed. The approach consists of two design paths: (1) one in which yielding is expected in the vertical elements, and (2) a second in which diaphragm yielding is expected. The design path for which diaphragm yielding is expected includes proportionally strengthened end regions, which has the potential to spread yielding deeper into the diaphragm as described in Section 5.4. The proposed approach is based on the results of a study in which the performance of an archetype was improved by weakening the diaphragm away from the end region Koliou, et al. (2014). For the purposes of this white paper ductile diaphragms are wood structural panels with common nails for connectors. At this time, the proposed design approach is meant to apply to RWFD buildings with wood diaphragms, though portions of the approach could be applied to

the design of RWFD buildings with steel deck diaphragms as well. The proposed design approach is not intended to apply to standing seam metal roofs or similar metal roofs that are attached to framing members with clips that allow for relative movement between the metal roofing and the framing. It is also not intended to apply to steel deck attached to wood framing.

RP5-5.1 Description of Proposed Design Approach

The proposed design approach allows for two design paths based on whether

- vertical elements are to yield and dissipate energy or
- the diaphragm is to yield and dissipate energy.

These paths are described in the Sections 5.1.1 and 5.1.2. Regardless of which design path is chosen certain design requirements apply. These requirements are included in Section 5.1.3.

RP5-5.1.1 Vertical Element Yielding Design Path

If the vertical elements are to yield and dissipate energy, the diaphragm design force level should be based on the force level for the vertical elements but amplified by the overstrength factor, Ω_o, for the SFRS. The overstrength factor, Ω_o, is 2-1/2 for the wall systems listed in Table 1. If the system is an intermediate precast shear wall with R equal to 4 and Ω_o equal to 2-1/2, the effective R_{dia} for the diaphragm design is 1.6. Accounting for the diaphragm overstrength and designing the diaphragm for an effective diaphragm response modification factor, R_{dia}, equal to 1.6 results in limited ductility demand for design earthquake ground motions. Designing for yielding of the vertical elements applies to RWFD buildings with regular or irregular plan geometries. In using such a low effective diaphragm response modification factor, consideration could be given to using a greater magnitude strength reduction factor on the diaphragm design strength, but this would require a study to determine the appropriate value to use. Until such a study is performed, the current strength reduction factor, ϕ, of 0.8 for wood diaphragms should be used. Note that all limitations and requirements for the vertical system in ASCE/SEI 7-10 apply when following this design path.

Diaphragm chords and collectors should be designed using the forces generated using the effective diaphragm response modification factor, R_{dia}. An additional diaphragm overstrength factor does not need to be applied to the design of the collectors.

Designing a RWFD building that will actually yield the vertical elements is difficult because the vertical elements usually have significant overstrength, particularly concrete wall systems. Obtaining yielding and energy dissipation in a wall system rather than the roof diaphragm generally requires designing and detailing wall-to-foundation or wall-to-slab connections that yield as wall panels and their connections are loaded by overturning moments.

If a RWFD building has more than one type of vertical element, for example tilt-up walls on the perimeter with special concentrically steel braced frames at an interior expansion joint, the diaphragm design should be based on the system with the lowest response modification factor, R, and that systems overstrength factor.

RP5-5.1.2 Diaphragm Yielding Design Path

This design path is only appropriate for RWFD buildings with regular shaped wood diaphragms at this time. If the diaphragm is regularly-shaped in plan such that it can be divided into rectangular plan areas supported on each edge, the following design procedure can be used in which diaphragm yielding and energy dissipation is expected. The following requirements apply.

1. The vertical elements of the SFRS, i.e., shear walls and frames, should be designed for in-plane forces using the response modification factor, R, for the type of system being engineered but not

greater than 4. The detailing requirements and system limitations still apply even though the R factor may have been reduced.

2. Diaphragm design shears are determined in the transverse direction using a response modification factor of the diaphragm, Rdia, equal to 4.5, an approximate period from Eq. 4-1 of this report, and the formulas for Cs in Section 12.8.1 of ASCE/SEI 7-10. For buildings with steel-braced frames for the vertical elements instead of walls, the first term in Eq. 4-1 may be replaced by 0.02hn0.75 where hn is the height of the roof framing in ft.
3. The diaphragm design shears computed in Item 2 for the transverse direction are increased by a factor of 1.5 for the end 10% of length regions of the diaphragm span. This is shown in Figure 16. In addition to designing the end regions for 1.5 times the force, the contract documents should specify diaphragm design strength in the end regions at least 1.5 times the design strength specified for the remainder of the diaphragm.
4. Diaphragm design shears for the longitudinal direction shall be computed using a response modification factor of the diaphragm equal to 4.5 with the shears increased by a factor of 1.5 in the end 10% of diaphragm width regions.
5. Diaphragm chords shall be designed for the diaphragm flexure resulting from diaphragm loads equal to those computed using Rdia.
6. Collectors and their connections are designed for the forces computed from the design diaphragm shears being collected and amplified by a diaphragm overstrength factor, Ωodia. An applicable value for the diaphragm overstrength factor is currently being developed. In the meantime a value of 2.5 is appropriate.

RP5-5.1.3 Design Requirements Applicable to All RWFD Buildings

The following requirements apply to diaphragm design of both design paths.

1. Out-of-plane wall forces and out-of-plane top of wall anchorage forces shall be designed in accordance with Section 12.11 of ASCE/SEI 7-10 except that ka shall be set equal to 2 for all diaphragm spans. Wood ledgers may not be loaded in cross-grain bending as part of the wall anchorage connection and wood structural panels may not resist tensile or compressive wall anchorage loads.
2. Connections and members that support out-of-plane anchorage forces at the tops of walls must be capable of resisting the design force while undergoing expected building deformations including those from diaphragm deflections. The roof displacement may cause rotation at these connections that opens and closes the angle between the roof and the wall, as shown in Figure 17. For connections similar to that shown in Figure 17, prying force develops due to force eccentricities and due to distortion. For the vertical leg of the ledger angle shown in the figure, a force eccentricity exists between the tension in the horizontal leg of the angle and the connectors that attach the angle to the wall. The top of the vertical leg of the angle is being separated from the wall face and this causes the bottom of the angle to bear against the wall surface. The result is additional prying forces at connectors attaching the vertical angle leg to the wall. Prying can also occur between the structural wood panel and the horizontal leg of the angle due to the distortion between the wall and roof diaphragm. As distortion reduces the geometric angle between the plane of the roof deck and the plane of the wall, the structural wood panel will bear against the end of the horizontal leg of the ledger angle. This will be resisted by tension in the connectors between the panel or deck and the horizontal leg of the angle. As distortion increases this geometric angle, the edge of the panel or deck will bear against the top of the horizontal leg of the ledger angle, which will also cause tension at the connectors between the panel or deck and the horizontal angle leg. A study is needed to determine how to compute the total diaphragm displacement. In the meantime, the elastic diaphragm deflection should be computed using the SDPWS-2008 approach at the design force level and then this displacement should be multiplied by the effective diaphragm response modification factor, R_{dia}, to obtain the total

diaphragm displacement. For example, if the wall yielding path is chosen using R equal to 4 and Ω_o equal to 2.5, the elastic diaphragm displacement should be multiplied by 1.6. The elastic displacement of the wall should be multiplied by the C_d factor to obtain the total wall deflection. The deformation compatibility check should include both the wall and diaphragm deflection. For the diaphragm yielding design path, the elastic wall and diaphragm deflections should be computed based on a force level reduced by R_{dia} equal to 4.5. These elastic deflections should each be amplified by a factor equal to R_{dia} and the two added together to obtain the total deflection that must be considered for deflection compatibility. Note that the actual total displacement of the wall is likely to be smaller and the total displacement of the diaphragm larger than predicted but the combined total displacement will likely be close to the actual value that should be anticipated.

3. Continuity ties that extend across the diaphragm shall be provided in each direction.

    - Out-of-plane wall anchorage forces must be transferred deep into the diaphragm interior using continuity ties to properly develop resistance. The ties must be connected to the main diaphragm to transfer the out-of-plane wall anchorage forces into the main diaphragm. It is reasonable that the design force for a continuous tie reduces as it develops into the diaphragm; however, the tie force shall not be reduced below that required of Section 12.1.3 of ASCE/SEI 7-10.
    - For diaphragms with sub-diaphragms, out-of-plane wall anchorage forces shall be transferred into sub-diaphragms as currently allowed and from sub-diaphragms to continuity ties that extend across the diaphragm.

RP5-5.2 Limitations of the Proposed Design Path for Diaphragm Yielding

The proposed approach is limited to buildings of regular plan geometry that can be divided into rectangular diaphragm segments. Each diaphragm segment must be supported on all 4 sides, i.e., this does not apply to diaphragms that cantilever or resist load in rotation. The approach is not applicable to irregular-shaped diaphragms that are not devisable into rectangular sections because defining how to spread ductility in the diaphragm for the potential non-rectangular configurations is beyond the scope of this project. For irregular shapes and as an alternative for rectangular-shaped diaphragms, a design approach in which R_{dia} on the order of 2 to 3 is used without strengthened edges might be appropriate but would require additional analyses to confirm the adequacy of such an approach. The approach in which in-plane yielding of vertical elements is expected and the diaphragm is designed for diaphragm shears using the R factor for the vertical system but amplified by the overstrength factor, Ω_o, is applicable.

The proposed approach is only applicable to diaphragms that will perform equivalent to the diaphragms studied to develop the design procedure. For wood diaphragms, the connectors studied were common nails that connect the structural wood panel to wood framing members or nailers on steel framing. Steel deck diaphragms were also studied but as will be discussed in Section 5.3, the proposed approach should not be used for them at this time.

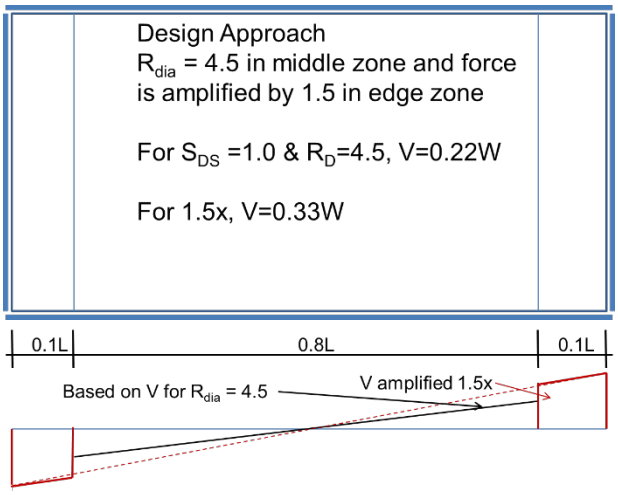

FIGURE 16 Description of approach for a period on the plateau of the design spectrum

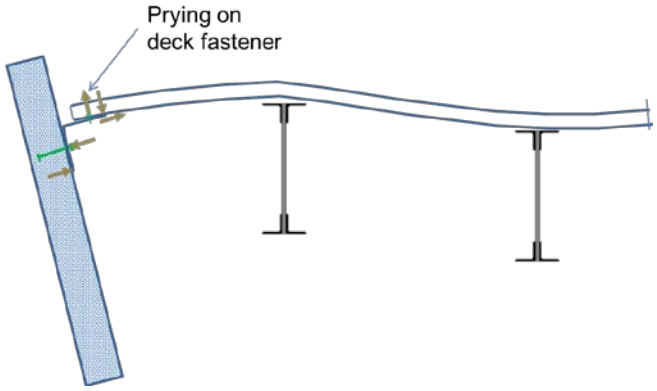

FIGURE 17 Deformations and change in angle between roof diaphragm and wall and prying on the connection to ledger

The proposed procedure also assumes that wall panels do not have pilasters. Currently, new construction of RWFD buildings rarely includes pilasters, especially for warehouse and retail use where pilasters obstruct installation of racks. Occasionally, they are included in gymnasiums and other rigid wall-flexible diaphragm buildings. Where they are used, the wall panels should be design for two-way action and the concentration of wall force at the top of the pilaster should be accounted for. This is usually addressed by adequately connecting the girder resting on the pilaster for higher out-of-plane forces and including these forces in the design of the girder.

RP5-5.3 Applicability of Proposed Design Approach to RWFD Buildings with Steel Deck Diaphragms

At this time the proposed design approach is not intended to apply to RWFD buildings with steel deck diaphragms. There are several reasons for not recommending its use even though it has been studied (Koliou, 2014). Reasons include (1) tests results of a large scale diaphragm showed significantly less distribution of yielding than the analyses show when loaded parallel to deck edges (Massarelli, et al., 2012), (2) steel deck diaphragms were never intended to be yielding elements as such design strengths are based on monotonic tests, (3) data for reverse cyclically loaded connections is sparse and missing for many commonly used deck gages, (4) the post-yield stiffness of connectors is positive for only a short deformation, 1 to 2 mm, (5) few reverse cyclically loaded diaphragm tests have been performed while

FEMA P695 requires comprehensive test data, and (6) many diaphragms in high seismic regions are designed using proprietary sidelaps for which no test data was available to include in the study. Additionally, the behavior of connectors simultaneously resisting forces from diaphragm shear with ductile connector behavior expected and forces from out-of-plane wall anchorage in which elastic connector behavior is expected must be understood. This issue will likely require design limitations that have yet to be identified.

This study included 20 and 22 ga steel deck diaphragms with puddle welds, powder actuated fasteners, and self-drilling screws for framing connectors. Sidelap connectors included in the study were button punches, self-drilling screws, and top seam welds. There is a potential that the proposed design approach could be applied to 20 and 22 ga diaphragms with the connectors studied. However, the concern of yielding not spreading as reported by Massarelli, et al. (2012) when the diaphragm is loaded parallel to the direction the deck sheets span must be understood and addressed. It could also be applied to new or proprietary connectors with positive post-yield stiffness to an acceptable deformation limit. Currently that limit is not known exactly but a value of 10 mm is likely sufficient.

Once a set of non-proprietary connections can be shown to result in acceptable diaphragm performance, additional connectors could be approved using the procedures of FEMA P795 (2011) *Quantification of Building Performance Factors: Component Equivalency Methodology*.

If the proposed procedure were to be applicable to diaphragms with welded connections the weld quality must be consistent with the weld quality used for the cyclic testing that led to the applicability. Detailed welding requirements should be developed as part of developing a design procedure from the proposed design approach. Recommendations for welding are provided in Guenfoud, et al. (2010). The factors to control for arc-spot welds (puddle welds) are high current setting, electrode type (E6011), and proper welding technique. Recommendations are made to increase the welding times relative to those recommended in SDI Manual (2004) for 1/8 in electrodes.

RP5-5.4 Discussion of Diaphragm Yielding

The design path for which diaphragm yielding is expected has the potential to provide improved diaphragm yielding relative to that of a diaphragm designed with current design procedures. However, the degree of improvement is dependent on how diaphragm shear strength is distributed for each design. For the proposed design approach in which the diaphragm yielding path is chosen, yielding generally starts in the general diaphragm field near the interface with the strengthened perimeter. Diaphragm yielding can then spread towards the center of the diaphragm span and to a lesser degree into the perimeter zone in which the diaphragm design strength is amplified.

Diaphragm yielding spreads towards the center of the diaphragm span because of (1) the post-yield strength characteristics of the common nails and (2) the distribution of forces acting on the diaphragm. The common nails exhibit positive post yield stiffness and substantial increases in strength that allows higher forces and yielding to develop in the diaphragm in the direction of the center of the diaphragm span. Additionally, the magnitude of average diaphragm shears along the length of the diaphragm span is not linear as typically assumed for design, including the proposed procedure. Instead, the diaphragm shear distribution from response-history analyses show the peak shears along the diaphragm span are more evenly distributed.

The degree to which the yielding spreads towards the diaphragm span center depends on the distribution of diaphragm shears for a particular time-history and the changes in diaphragm nailing along the length of the diaphragm. The most distributed yielding occurs if the diaphragm nailing has many zones that follow a linearly varying distribution of diaphragm shear strength with the weakest zone at the center and increasing in strength until it reaches the perimeter zone for which an over-strength factor is applied to the design.

The reason that diaphragm yielding may extend into the strengthened perimeter zone is that force is generated from the mass of walls and the roof. The diaphragm shears in this zone can continue to increase even if yielding occurs outside this zone. Although some yielding occurs in the strengthened perimeter zone, the intention of the design approach is too prevent concentrated yielding and significant diaphragm degradation in this region.

RP5-5.5 Quality of Design, Construction and Inspection

Like many seismic-force-resisting systems, the effectiveness of the proposed approach will be dependent on complying with design requirements. However, the design requirements are relatively simple in comparison to many other systems. The main change from current design is how strength is proportioned along the diaphragm span. As mentioned in Section 5.3, improved distribution of yielding can be obtained by using multiple zones of diaphragm strength but the procedure is not dependent on providing multiple zones of yielding.

Diaphragm designs using the proposed design approach are no more likely to be constructed improperly than current diaphragm designs. A common concern is the use of wrong nailing patterns or wrong nail type. If this is a concern, inspection of the nailing pattern and type of nails used should be included in the project inspection requirements. For larger footprint buildings, the roof diaphragm is usually part of panelized framing constructed on the ground and lifted into place. There is a small chance that panels could be placed in the wrong locations; however, inspection should include checking the nails in the panels where they are constructed and confirming that they are placed correctly within the roof structure.

RP5-5.6 Diaphragm Modifications and Deterioration

After initial construction, diaphragm strength can be affected by modifications and deterioration. The most common modification that reduces strength is adding openings through the diaphragm, which will reduce the strength approximately in proportion to the size of the openings in a line relative to the overall depth of the diaphragm. Large openings or many small ones can further reduce the strength and cause a concentration of deformations. This is also a concern with the current design approach. Openings near the center of the diaphragm are likely to have little or no effect on performance, and openings close to and within the strengthened region are likely to have a detrimental effect.

Deterioration of a diaphragm can occur due to roof leaks. Such damage is usually concentrated at or near the diaphragm to wall connections and at openings through the diaphragm. Deterioration is a concern but it is no more likely for the proposed design than it is for existing design.

RP5-6 EVALUATION OF PROPOSED DESIGN APPROACH

To validate the proposed design approach, archetype buildings were designed and P695 analyses were performed.

RP5-6.1 Description of Archetypes

Evaluations were performed on archetypes designed for high and moderate seismic risk as defined in Section 4.1. For these evaluations, archetypes were designed with either steel deck or wood panel diaphragms. Summary tables with detailed descriptions of diaphragm zones for the archetypes are in Appendix D for the wood diaphragms. The results of the steel deck diaphragms are included in Koliou (2014). The walls for these archetypes are reinforced-concrete wall panels 25 ft in length, 33 ft tall measured from the top of slab-on-grade, and 9-1/4 in. thick for high seismic risk and 7-1/4 in. thick for moderate seismic risk. The roof level is at 30 ft above the top of slab-on-grade with parapet walls cantilevering 3 ft higher than the roof level.

The archetypes are grouped by whether the diaphragm is large or small. The archetypes have plan aspect ratios of 1:1, 2:1 and 1:2. Large diaphragms are 400 ft long and either 400 ft or 200 ft wide. The small diaphragms with aspect ratios of 2:1 and 1:2 are 200 ft long by 100 ft wide, and for the 1:1 aspect ratios the diaphragms are 100 ft by 100 ft. The wood diaphragms are wood structural panels nailed to nailers that are attached to open web steel joists.

RP5-6.2 P695 Analysis Results for Proposed Design Approach

Incremental Dynamic Analyses (IDA) (Vamvatsikos and Cornell, 2002) using the FEMA P695 Far Field Ground Motion Ensemble (FEMA P695, 2009) were performed using the simplified models to compute the median collapse intensity. Summaries of collapse results for individual wood diaphragm archetypes are included in Appendix E. Adjusted collapse margin ratios (ACMR) and acceptable ACMR values for the individual archetypes and the archetype groups are also included in Appendix E. The acceptable ACMR values are computed using the beta factors listed in Table 2. The combined uncertainty, β_{Total}, is computed as the square root sum of the squares of the individual uncertainties. For β_{Total} equal to 0.66, the acceptable ACMR is 1.73 and 2.30 for 20% and 10% probability of collapse at Maximum Considered Earthquake (MCE) ground motion, respectively. The acceptable ACMR applicable for the performance of individual archetypes is 1.73, and the ACMR of performance groups is 2.30. Summaries of the adjusted collapse margin ratio results for the performance groups of wood archetypes are provided in Table 6. The acceptable ACMR of at least 2.30 is achieved for each performance group.

Table 6 Summary of collapse margin ratio results for wood structural panel diaphragms archetype performance groups

Performance Group	Seismicity	Size	Computed ACMR	Acceptable ACMR	Pass/Fail
PG-1N	High	Large	3.68	2.30	Pass
PG-2N	High	Small	2.51		Pass
PG-3N	Moderate	Large	3.90		Pass
PG-4N	Moderate	Small	3.07		Pass

The elastic periods for the archetypes designed in accordance with the proposed approach are listed in Table 7. In almost all cases the range of periods are 0 to 20% longer than the equivalent periods in Table 5 for the archetypes designed using the current code design approach.

The archetypes with larger diaphragms did better than the archetypes with small diaphragms, and the archetypes designed for moderate seismicity performed better than the ones designed for high seismicity. The small archetypes designed for high seismicity had the lowest ACMR. The range of fundamental elastic periods indicated in Table 7 is less than the transition period of 0.6 sec for most of these 100 and 200 ft long diaphragms. Thus, these archetypes are experiencing the short period issue described in Section 4.4 regarding the FEMA P695 analyses for the archetypes using the current design approach. The ACMR for small archetypes designed for moderate seismicity have longer periods than those designed for high seismicity and the transition period is only 0.4 sec. The short period issue is less of a factor for the small buildings designed for moderate seismicity. The elastic period values in Table 7 are all well above the transition period for the wood archetypes that are 400 ft long, thus, the high ACMRs for the large wood diaphragm performance groups, PG1 and PG3.

Table 7 Summary of Elastic Periods for Archetypes Designed Using the Proposed Approach

Wood diaphragm span length		Period for high-seismic archetypes	Period for moderate-seismic archetypes
400 ft		0.92 to 0.96 sec	0.92 to 0.93 sec
200 ft		0.53 to 0.65 sec	0.57 to 0.61 sec
100 ft	0.39 to 0.42 sec	0.45 to 0.46 sec	

The ranges of building drift ratios for the performance groups are provided in Table 8. The building drift ratio is the sum of the wall drift ratio (WDR) and the diaphragm drift ratio (DDR) and serves as a damage index. The WDR is computed as the in-plane wall deformation divided by the height of the roof, and the DDR is computed as the diaphragm displacement divided by one-half of the diaphragm span. In general shorter diaphragm spans result in larger BDRs, especially for the wood diaphragms. This likely results from the wall drift ratio (WDR) being a larger percentage of the BDR for the smaller buildings.

Table 8 Range of building drift ratios (BDRs) for the wood diaphragm performance groups

Performance Group	Seismicity	Size	Median BDR @ DE (%)	Median BDR @ MCE (%)
PG-1N	High	Large	0.34 to 0.52	0.54 to 0.81
PG-2N	High	Small	0.79 to 0.85	1.14 to 1.31
PG-3N	Moderate	Large	0.34 to 0.39	0.55 to 0.65
PG-4N	Moderate	Small	0.53 to 0.61	0.90 to 1.21

RP5-7 SUMMARY

The existing design approach for one-story buildings with flexible roof diaphragms was evaluated and found to be inadequate according to the criteria of the FEMA P695 methodology. An issue with the existing approach is that it does not spread inelastic response (yielding) into the diaphragm. A new approach for the design of these buildings with wood diaphragms has been proposed that includes recognizing the diaphragm's own dynamic response. It requires strengthened regions at the ends of the diaphragm. Strengthening the diaphragm edges improves the distribution of yielding within the diaphragm. A simplified modeling framework was developed to perform the required incremental dynamic analyses. Simplified period formulas that account for both diaphragm and vertical element deformations were developed and incorporated into the proposed procedure.

	4 ply – 22 ga deck to 0.25 in. plate	4	

RP5-APPENDIX C

Results for the FEMA P695 collapse analyses for the current design approach are presented in this appendix. The following notations and abbreviations are used in the tables:

ACMR – Adjusted Collapse Margin Ratio where: $ACMR = SSF_i \times CMR_i$

BDR – Building Drift Ratio where: $BDR(\%) = DDR(\%) + WDR(\%)$

CMR – Collapse Margin Ratio where: $CMR_i = \frac{S_{CT}}{S_{MT}}$

DE – Design Earthquake

DDR – Diaphragm Drift Ratio (%) where: $DDR(\%) = \frac{X_{mid,roof}}{L_{roof}/_2} \times 100$

$X_{mid,roof}$ is the diaphragm deflection at mid length

L_{roof} is the diaphragm span

MCE – Maximum Considered Earthquake

SSF – Spectral Shape Function

S_{CT} [T]– Median collapse intensity obtained from nonlinear dynamic analysis at the fundamental elastic period

S_{MT} [T]– Ground motion spectral demand at maximum considered earthquake (MCE) intensity level at the fundamental elastic period

WDR(%) – In-plane Wall Drift Ratio where: $WDR(\%) = \frac{X_{in-plane\ walls}}{h_{wall}} \times 100$

$X_{in\text{-}plane\ walls}$ is the deflection at the roof level of the in-plane walls

h_{wall} is the height of roof above the foundation

μ_T – Period based ductility where: $\mu_T = \frac{\delta_u}{\delta_{y,eff}}$

δ_u is the ultimate building drift ratio (BDR)

$\delta_{y,eff}$ is the effective yield building drift ratio (BDR)

FEMA

FEMA P-1050-2 Vol II
Catalog No. 15169-2

Proposal ASCE-003_-2012-11-29-Hooper – Expanded Commentary to ASCE/SEI 7- 10

SCOPE: Adopt Expanded Commentary to ASCE 7-10, which covers Chapters 11-22 of the 2014 NEHRP Provisions. This proposal includes only commentary language.

PROPOSAL FOR CHANGE:

The attached content is the entirety of the final draft of the Expanded Commentary to ASCE/SEI 7-10. The proposed change is to adopt the Expanded Commentary, because it supports ASCE 7-10, which has already been adopted as the basis for the 2014 Edition of the NEHRP Recommended Seismic Provisions.

REASON FOR PROPOSAL:

The 2014 NEHRP Provisions will use ASCE 7-10 as the base document, making modifications to that text as necessary. This proposal would adopt the Expanded Commentary to ASCE 7-10, providing a complete version of the Provisions' base document.

DRAFT

ATTACHMENT: Commentary

EXPANDED COMMENTARY TO ASCE/SEI 7-10

based on

2009 NEHRP RECOMMENDED SEISMIC PROVISIONS FOR NEW BUILDINGS AND OTHER STRUCTURES (FEMA P-750)

DRAFT

Page intentionally left blank.

DRAFT

Chapter C11
SEISMIC DESIGN CRITERIA

C11.1 GENERAL

Many of the technical changes made to the seismic provisions of the 2010 edition of this standard are primarily based on Part 1 of the 2009 edition of the *NEHRP Recommended Provisions for the Development of Seismic Regulations for New Buildings and Other Structures*, which is prepared by the Building Seismic Safety Council (BSSC) under sponsorship of the Federal Emergency Management Agency (FEMA) as part of its contribution to the National Earthquake Hazards Reduction Program (NEHRP). The National Institute of Standards and Technology (NIST) is the lead agency for NEHRP, the federal government's long-term program to reduce the risks to life and property posed by earthquakes in the U.S. Since 1985, the NEHRP Provisions have been updated every 3 to 5 years. The efforts by BSSC to produce the NEHRP Provisions were preceded by work performed by the Applied Technology Council (ATC) under sponsorship of the National Bureau of Standards (NBS) – now NIST – that originated after the 1971 San Fernando Valley earthquake These early efforts demonstrated the design rules of that time for seismic resistance but had some serious shortcomings. Each subsequent major earthquake has taught new lessons. The NEHRP agencies (FEMA, NIST, NSF, USGS), ATC, BSSC, ASCE, and others have endeavored to work individually and collectively to improve each succeeding document to provide the state-of-the-art earthquake engineering design and construction provisions and to ensure that the provisions have nationwide applicability.

Content of Commentary. The enhanced commentary to ASCE/SEI 7-10 is based substantially on Part 2, Commentary, of the *NEHRP Recommended Provisions for the Development of Seismic Regulations for New Buildings and Other Structures* (FEMA P-750), Building Seismic Safety Council, Federal Emergency Management Agency, 2009 edition. For additional background on the earthquake provisions contained in Chapter 11 through 23 of ASCE/SEI 7-10, the reader is referred to:

- *Recommended Lateral Force Requirements and Commentary*, Seismology Committee, Structural Engineers Association of California, 1999

Nature of Earthquake "Loads." Earthquakes load structures indirectly through ground motion. As the ground shakes, a structure responds. The response vibration produces structural deformations with associated strains and stresses. The computation of dynamic response to earthquake ground shaking is complex. The design forces prescribed in this standard are intended only as approximations to generate internal forces suitable for proportioning the strength and stiffness of structural elements and for estimating the deformations (when multiplied by the deflection amplification factor, C_d) that would occur in the same structure in the event of the design-*level* earthquake ground motion (not MCE_R).

The basic methods of analysis in the standard employ the common simplification of a response spectrum. A response spectrum for a specific earthquake ground motion provides the maximum value of response for elastic single-degree-of-freedom oscillators as a function of period without the need to reflect the total response history for every period of interest. The design response spectrum specified in Section 11.4 and used in the basic methods of analysis in Chapter 12 is a smoothed and normalized approximation for many different recorded ground motions.

The design limit state for resistance to an earthquake is unlike that for any other load within the scope of ASCE/SEI 7. The earthquake limit state is based upon system performance, not member performance, and considerable energy dissipation through repeated cycles of inelastic straining is assumed. The reason is the large demand exerted by the earthquake and the associated high cost of providing enough strength to maintain linear elastic response in ordinary buildings. This unusual limit state means that several conveniences of elastic behavior, such as the principle of superposition, are not applicable, and makes it difficult to separate design provisions for loads from those for resistance. This is the reason Chapter 14 of the standard contains so many provisions that modify customary requirements for proportioning and detailing structural members and systems. It is also the reason for the construction quality assurance requirements.

Use of Allowable Stress Design Standards. The conventional design of nearly all masonry structures and many wood and steel structures has been accomplished using Allowable Stress Design (ASD). Although the fundamental basis for the earthquake loads in Chapters 11 through 23 is a strength limit state beyond first yield of the structure,

DRAFT

the provisions are written such that conventional ASD methodscan be used by the design engineer. Conventional ASD methodsmay be used in one of two fashions:

1. The earthquake load as defined in Chapters 11 through 23 may be used directly in allowable stress load combinations of Section 2.4 and the resulting stresses compared directly with conventional allowable stresses.

2. The earthquake load may be used in strength design load combinations and resulting stresses compared with amplified allowable stresses (for those materials for which the design standard gives the amplified allowable stresses, e.g., masonry).

Federal Government Construction. The Interagency Committee on Seismic Safety in Construction has prepared an order executed by the President (Executive Order 12699) that all federally owned or leased building construction, as well as federally regulated and assisted construction, should be constructed to mitigate seismic hazards and that the *NEHRP Provisions* are deemed to be the suitable standard. It is expected that this standard would be deemed equivalent, but the reader should bear in mind that there are certain differences.

C11.1.1 Purpose

The purpose of Section 11.1.1 is to clarify that the detailing requirements and limitations prescribed in this section and referenced standards are still required even when the design load combinations involving the wind forces of Chapters 26 through 29 produce greater effects than the design load combinations involving the earthquake forces of Chapters 11 through 23. This is required so the structure resists, in a ductile manner, potential seismic loads in excess of the prescribed wind loads. A proper, continuous load path is an obvious design requirement, but experience has shown that it often is overlooked and that significant damage and collapse can result. The basis for this design requirement is two-fold:

1. To ensure that the design has fully identified the seismic-force-resisting system and its appropriate design level and

2. To ensure that the design basis is fully identified for the purpose of future modifications or changes in the structure.

Detailed requirements for analyzing and designing this load path are given in the appropriate design and materials chapters.

C11.1.2 Scope

Certain structures are exempt for the following reasons:

Exemption 1 –Detached wood-frame dwellings not exceeding two stories above grade plane constructed in accordance with the prescriptive provisions of the *International Residential Code* (IRC) for light-frame wood construction, including all applicable IRC seismic provisions and limitations are deemed capable of resisting the anticipated seismic forces. Detached one- and two-story wood-frame dwellings generally have performed well even in regions of higher seismicity. Therefore, within its scope, the IRC adequately provides the level of safety required for buildings. The structures that do not meet the prescriptive limitations of the IRC are required to be designed and constructed in accordance with the International Building Code (IBC) and the ASCE/SEI-7 provisions adopted therein.

Exemption 2 – Agricultural storage structures generally are exempt from most code requirements because such structures are intended only for incidental human occupancy and represent an exceptionally low risk to human life.

Exemption 3 – Bridges, transmission towers, nuclear reactors, and other structures with special configuration and uses are not covered. The regulations for buildings and building-like structures presented in this document do not adequately address the design and performance of such special structures.

ASCE/SEI 7-10 is not retroactive and usually applies to existing structures only when there is an addition, change of use, or alteration. Minimum acceptable seismic resistance of existing buildings is a policy issue normally set by the authority having jurisdiction. Appendix 11B of the standard contains rules of application for basic conditions. ASCE/SEI 31, *Seismic Evaluation of Buildings* and ASCE/SEI 41, *Seismic Rehabilitation of Existing Buildings*, provide technical guidance but do not contain policy recommendations. A chapter in the *International Building Code* (IBC) applies to alteration, repair, addition, and change of occupancy of existing buildings, and the

DRAFT

International Code Council maintains the *International Existing Building Code* (IEBC) and an associated commentary.

C11.1.3 Applicability

Industrial buildings may be classified as nonbuilding structures in certain situations for the purposes of determining seismic design coefficients and factors, system limitations, height limits, and associated detailing requirements. Many industrial building structures have geometries and/or framing systems that are different from the broader class of occupied structures addressed by Chapter 12, and the limited nature of the occupancy associated with these buildings reduces the hazard associated with their performance in earthquakes. Therefore, when the occupancy is limited primarily to maintenance and monitoring operations, these structures may be designed in accordance with the provisions of Section 15.5 for nonbuilding structures similar to buildings. Examples of such structures include, but are not limited to, boiler buildings, aircraft hangars, steel mills, aluminum smelting facilities, and other automated manufacturing facilities, whereby the occupancy restrictions for such facilities should be uniquely reviewed in each case. These structures may be clad or open structures.

C11.1.4 Alternate Materials and Alternate Means and Methods of Construction

It is not possible for a design standard to provide criteria for the use of all possible materials and their combinations and methods of construction, either existing or anticipated. This section serves to emphasize that the evaluation and approval of alternate materials and methods require a recognized and accepted approval system. The requirements for materials and methods of construction contained within the document represent the judgment of the best use of the materials and methods based on well-established expertise and historical seismic performance. It is important that any replacement or substitute be evaluated with an understanding of all the ramifications of performance, strength, and durability implied by the standard.

Until needed standards and agencies are created, authorities having jurisdiction need to operate on the basis of the best evidence available to substantiate any application for alternates. If accepted standards are lacking, applications for alternative materials or methods should be supported by test data obtained from tests data requirements in Section 1.3.1.2 The tests should simulate expected load and deformation conditions to which the system, component or assembly may be subjected during the service life of the structure. These conditions, when applicable, should include several cycles of full reversals of loads and deformations in the inelastic range.

C11.2 DEFINITIONS

Attachments, Components, and Supports: The distinction between attachments, components, and supports is necessary to the understanding of the requirements for nonstructural components and nonbuilding structures. Common cases associated with nonstructural elements are illustrated in Fig. C11-1. The definitions of components, supports, and attachments are generally applicable to components with a defined envelope in the as-manufactured condition and for which additional supports and attachments are required to provide support in the as-built condition. This distinction may not always be clear, particularly when the component is equipped with prefabricated supports; therefore, judgment must be used in the assignment of forces to specific elements in accordance with the provisions of Chapter 13.

DRAFT

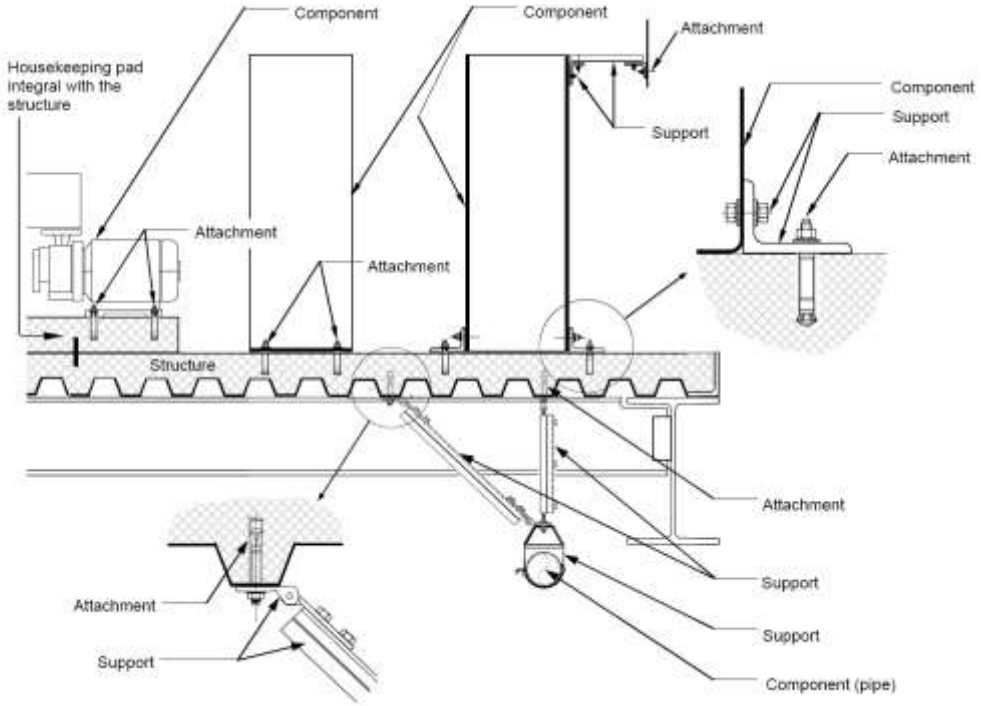

Figure C11- 1 Examples of Components, Supports, and Attachments

***Base*:** The following factors affect the location of the seismic base:

- location of the grade relative to floor levels,
- soil conditions adjacent to the building,
- openings in the basement walls,
- location and stiffness of vertical elements of the seismic force-resisting system,
- location and extent of seismic separations,
- depth of basement,
- manner in which basement walls are supported,
- proximity to adjacent buildings, and
- slope of grade.

For typical buildings on level sites with competent soils, the base is generally close to the grade plane. For a building without a basement, the base is generally established near the ground level slab elevation as shown in Fig. C11-2. Where the vertical elements of the seismic force-resisting system are supported on interior footings or pile caps, the base is the top of these elements. Where the vertical elements of the seismic force-resisting system are supported on top of perimeter foundation walls, the base is typically established at the top of the foundation walls. Often vertical elements are supported at various elevations on the top of footings, piles caps, and perimeter foundation walls. Where this occurs, the base is generally established as the lowest elevation of the tops of elements supporting the vertical elements of the seismic force-resisting system.

DRAFT

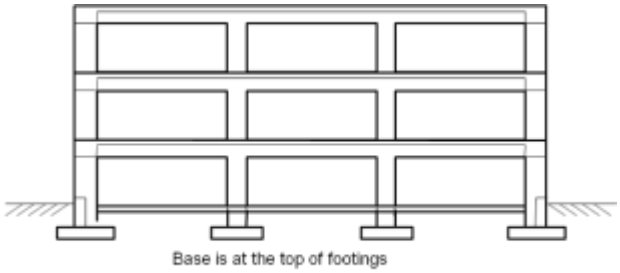

Figure C11- 2 Base for a Level Site

For a building with a basement located on a level site, it is often appropriate to locate the base at the floor closest to grade, as shown in Fig. C11-3. If the base is to be established at the level located closest to grade, the soil profile over the depth of the basement should not be liquefiable in the MCE_G ground motion. The soil profile over the depth of the basement also should not include quick and highly sensitive clays or weakly cemented soils prone to collapse in the MCE_G ground motion. Where liquefiable soils or soils susceptible to failure or collapse in an MCE_G ground motion are located within the depth of the basement, the base may need to be located below these soils rather than close to grade. Stiff soils are required over the depth of the basement because seismic forces will be transmitted to and from the building at this level and over the height of the basement walls. The engineer of record is responsible for establishing whether the soils are stiff enough to transmit seismic forces near grade. For tall or heavy buildings or where soft soils are present within the depth of the basement, the soils may compress laterally too much during an earthquake to transmit seismic forces near grade. For these cases, the base should be located at a level below grade.

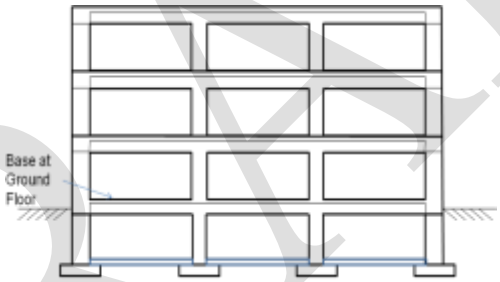

Figure C11- 3 Base at Ground Floor Level

In some cases, the base may be at a floor level above grade. For the base to be located at a floor level above grade, stiff foundation walls on all sides of the building should extend to the underside of the elevated level considered the base. Locating the base above grade is based on the principles for the two-stage equivalent lateral force procedure for a flexible upper portion of a building with one-tenth the stiffness of the lower portion of the building as permitted in Section 12.2.3.2. For a floor level above grade to be considered the base, it generally should not be above grade more than one-half the height of the basement story, as shown in Fig. C11-4. Figure C11-4 illustrates the concept of base level being located at the top of a floor level above grade, which is also includes light-frame floor systems that rest on top of stiff basement walls or stiff crawl space stem walls of concrete or masonry construction.

DRAFT

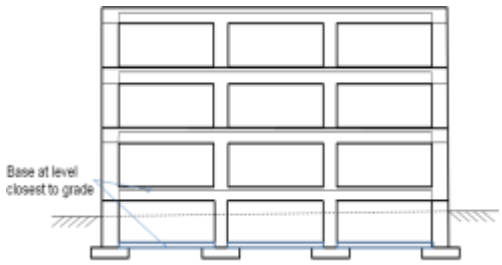

Figure C11- 4 Base at Level Closest to Grade Elevation

A condition where the basement walls that extend above grade on a level site may not provide adequate stiffness is where the basement walls have many openings for items such as light wells, areaways, windows, and doors, as shown in Fig. C11-5. Where the basement wall stiffness is inadequate, the base should be taken as the level close to but below grade. If all of the vertical elements of the seismic force-resisting system are located on top of basement walls and there are many openings in the basement walls, it may be appropriate to establish the base at the bottom of the openings. Another condition where the basement walls may not be stiff enough is where the vertical elements of the seismic force-resisting system are long concrete shear walls extending over the full height and length of the building, as shown in Fig. C11-6. For this case, the appropriate location for the base is the foundation level of the basement walls.

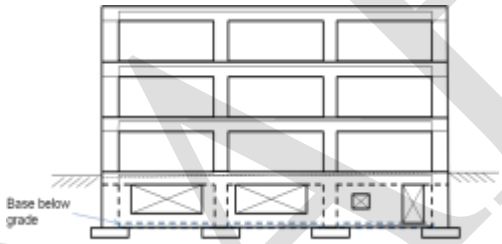

Figure C11- 5 Base Below Substantial Openings in Basement Wall

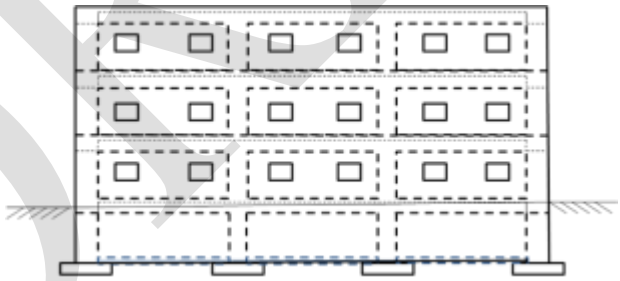

Figure C11- 6 Base at Foundation Level where there are Full-Length Exterior Shear Walls

Where the base is established below grade, the weight of the portion of the story above the base that is partially above and below grade must be included as part of the effective seismic weight. If the equivalent lateral force procedure is used, this can result in disproportionately high forces in upper levels due to a large mass at this lowest level above the base. The magnitude of these forces can often be mitigated by using the two-stage equivalent lateral force procedure where allowed or by using a dynamic analysis to determine force distribution over the height of the building. If a dynamic analysis is used, it may be necessary to include multiple modes to capture the required mass participation unless soil springs are incorporated into the model. Incorporation of soil springs into the model will generally reduce seismic forces in the upper levels. With one or more stiff stories below more flexible stories, the dynamic behavior of the structure may result in the portion of the base shear from the first mode being less than the portion of base shear from higher modes.

DRAFT

Other conditions may also necessitate establishing the base below grade for a building with a basement that is located on a level site. Such conditions include where seismic separations extend through all floors including those located close to and below grade, the floor diaphragms close to and below grade are not tied to the foundation wall, the floor diaphragms including the diaphragm for the floor close to grade are flexible, and other buildings are located nearby.

For a building with seismic separations extending through the height of the building including levels close to and below grade, the separate structures will not be supported by the soil against a basement wall on all sides in all directions. If there is only one joint through the building, assigning the base to the level close to grade may still be appropriate if the soils over the depth of the basement walls are stiff and the diaphragm is rigid. Stiff soils are required so that the seismic forces can be transferred between the soils and basement walls in both bearing and side friction. If the soils are not stiff, adequate side friction may not develop for movement in the direction perpendicular to the joint.

For large footprint buildings, seismic separation joints may extend through the building in two directions and there may be multiple parallel joints in a given direction. For individual structures within these buildings, substantial differences in the location of the center of rigidity for the levels below grade relative to levels above grade can lead to torsional response. For such buildings, the base should usually be at the foundation elements below the basement or the highest basement slab level where the separations are no longer provided.

Where floor levels are not tied to foundation walls, the base may need to be located well below grade at the foundation level. An example is a building with tie-back walls and post-tensioned floor slabs. For such a structure, the slabs may not be tied to the wall to allow relative movement between them. In other cases a soft joint may be provided. If shear forces cannot be transferred between the wall and a ground level or basement floor, the location of the base will depend on whether forces can be transferred through bearing between the floor diaphragm and basement wall and between the basement wall and the surrounding soils. Floor diaphragms bearing against the basement walls must resist the compressive stress from earthquake forces without buckling. If a seismic or expansion joint is provided in one of these buildings, the base will almost certainly need to be located at the foundation level or a level below grade where the joint no longer exists.

If the diaphragm at grade is flexible and does not have substantial compressive strength, the base of the building may need to be located below grade. This condition is more common with existing buildings. Newer buildings with flexible diaphragms should be designed for compression to avoid the damage that will otherwise occur.

The proximity to other structures can also affect where the base should be located. If other buildings with basements are located adjacent to one or more sides of a building, it may be appropriate to locate the base at the bottom of the basement. The closer the adjacent building is to the building, the more likely it is that the base should be below grade.

For sites with sloping grade, many of the same considerations for a level site are applicable. For example, on steeply sloped sites the earth may be retained by a tie-back wall so that the building does not have to resist the lateral soil pressures. For such a case, the building will be independent of the wall, so the base should be located at a level close to the elevation of grade on the side of the building where it is lowest, as shown in Fig. C11-7. Where the building's vertical elements of the seismic force-resisting system also resist lateral soil pressures, as shown in Fig. C11-8, the base should also be located at a level close to the elevation of grade on the side of the building where grade is low. For these buildings, the seismic force-resisting system below highest grade is often much stiffer than the system used above it, as shown in Fig. C11-9, and the seismic weights for levels close to and below highest grade are greater than for levels above highest grade. Use of a two-stage equivalent lateral force procedure can be useful for these buildings.

DRAFT

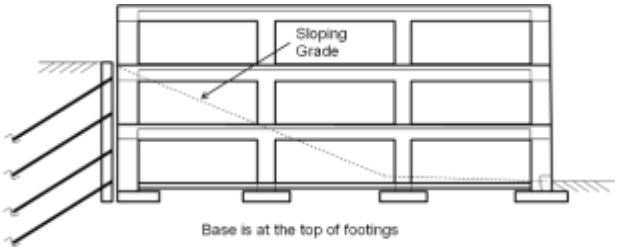

Figure C11- 7 Building with Tie-Back or Cantilevered Retaining Wall that is Separate from the Building

1

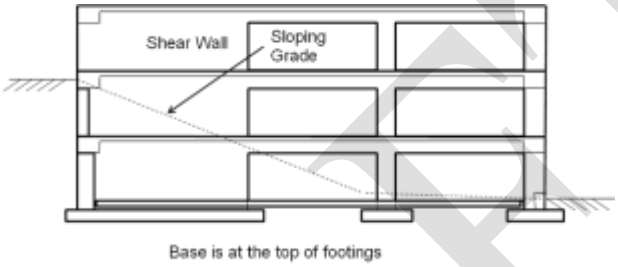

Figure C11- 8 Building with Vertical Elements of the Seismic Force-Resisting System Supporting Lateral Earth Pressures

2

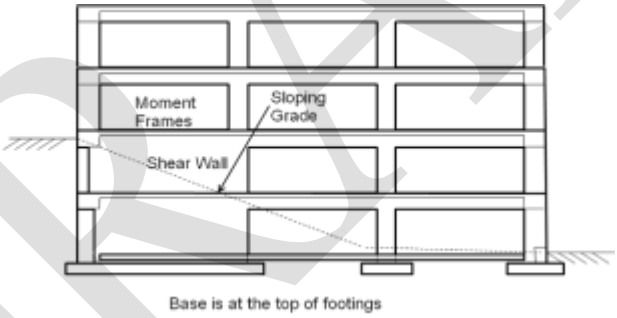

Figure C11- 9 Building with Vertical Elements of the Seismic Force-Resisting System Supporting Lateral Earth Pressures

3 Where the site is moderately sloped such that it does not vary in height by more than a story, stiff walls often extend
4 to the underside of the level close to the elevation of high grade, and the seismic force-resisting system above grade
5 is much more flexible above grade than it is below grade. If the stiff walls extend to the underside of the level close
6 to high grade on all sides of the building, locating the base at the level closest to high grade may be appropriate. If
7 the stiff lower walls do not extend to the underside of the level located closest to high grade on all sides of the
8 building, the base should be assigned to the level closest to low grade. If there is doubt as to where to locate the
9 base, it should conservatively be taken at the lower elevation.

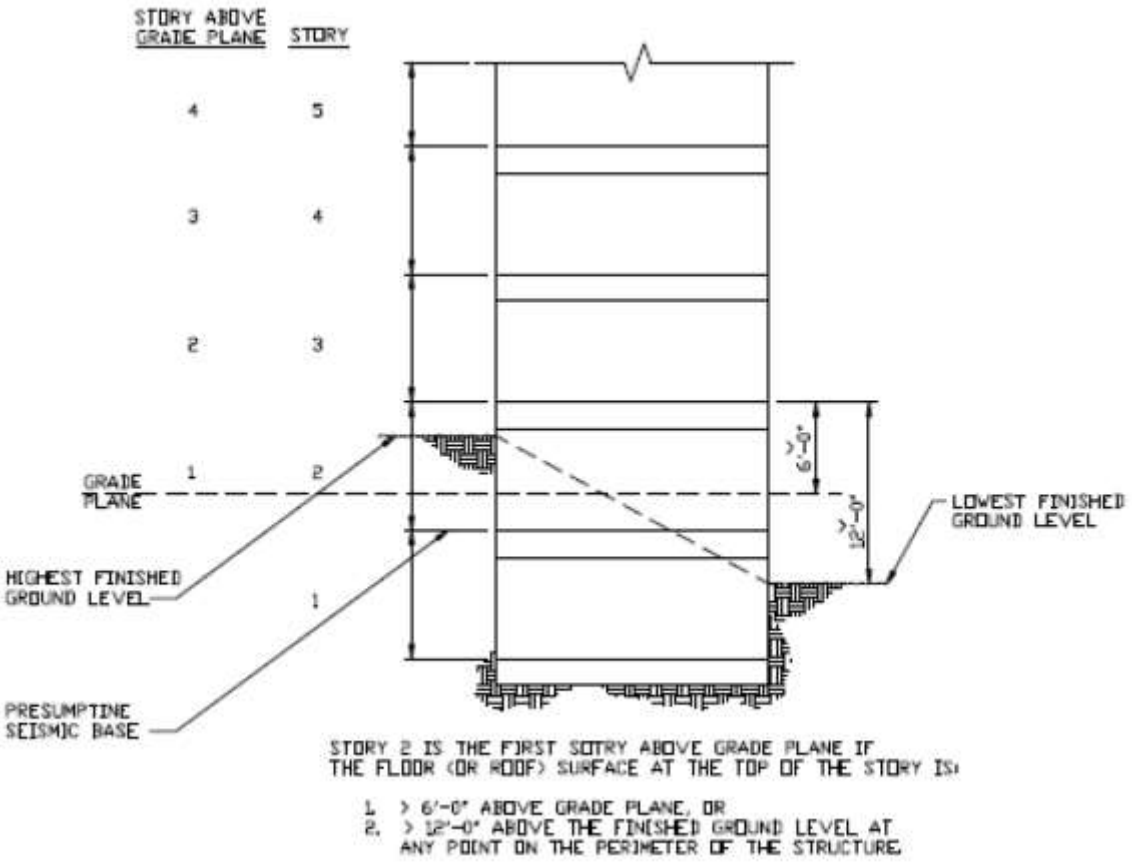

Figure C11- 10 Illustration of Definition of Story Above Grade Plane

C11.4 SEISMIC GROUND MOTION VALUES

The seismic ground motion values of Section 11.4 are defined by 0.2 s and 1 s spectral response accelerations (5% of critical damping) for the mapped values of risk-targeted maximum considered earthquake (MCE_R) ground motions provided in Chapter 22. The United States Geological Survey (USGS) prepared the mapped values of MCE_R ground motions of Chapter 22 in accordance with (1) the site-specific ground motion procedures of Section 21.2, (2) updates of the United States national seismic hazard maps (Peterson et. al., 2008), and (3) results of related research (Huang et al., 2008). The mapped values of MCE_R ground motion parameters S_s and S_1 are derived as the lesser of the probabilistic MCE_R spectral response acceleration (Section 21.2.1) and deterministic MCE_R spectral response acceleration (Section 21.2.2) at any location. The deterministic MCE_R spectral response acceleration has a lower limit as shown in Figure 21.2-1. The USGS calculated the probabilistic (MCE_R) spectral response acceleration using the iterative procedure (Method 2) of Section 21.2.1.2 (Luco et al., 2007). Mapped values of MCE_R ground motions are governed by probabilistic MCE_R response spectral acceleration, except at high hazard sites located relatively close to an active fault.

The basis for the mapped values of the MCE_R ground motions in ASCE/SEI 7-10 is significantly different from that of the mapped values of MCE ground motions in previous editions of ASCE/SEI 7. These differences include use of (1) probabilistic ground motions that are based on uniform collapse risk, rather than uniform hazard, (2) deterministic ground motions that are based on the 84th percentile (approximately 1.8 times median), rather than 1.5 times median response spectral acceleration for sites near active faults, and (3) ground motion intensity that is based on maximum, rather than the average (geometrical mean), response spectra acceleration in the horizontal plane. Except for determining the MCE_G PGA values in Chapters 11 and 21, the mapped values are given as MCE_R spectral response accelerations.

The approach adopted in Section 11.4 is intended to provide for a more uniform collapse risk for structures designed using the risk-targeted maximum considered earthquake (MCE_R) ground motions. The MCE_R ground motions are expected to result in structures with a 1% probability of collapse in 50 years, based on the probabilistic seismic hazard at each site and a probabilistic estimate of the margin against collapse inherent in structures designed to the seismic provisions in the standard (collapse fragility). In previous editions of ASCE/SEI 7, the lower bound margin was judged, based on experience, to correspond to a factor of about 1.5 in ground motions. In ASCE/SEI 7-10 the uncertainty in this margin is accounted for with the collapse fragility defined in Section 21.2.1.2. Nevertheless, the design earthquake ground motion is based on 1/1.5 (or 2/3) of MCE_R ground motion for consistency with previous editions of the standard. This factor has been taken into account in developing the MCE_R ground motions.

Probabilistic (MCE_R) ground motions are based on the assumption that buildings designed in accordance with ASCE/SEI 7-10 have a collapse probability of not more than 10 percent, on average, if MCE_R ground motions occur at the building site. The conditional probability of 10 percent is an idealized collapse safety goal of FEMA P-695 (FEMA, 2009). The FEMA P-695 study investigated the collapse probability of a limited number of different types of seismic force-resisting systems and found that systems designed in accordance with ASCE/SEI 7-10 generally conform to the 10 percent collapse safety goal. While stronger shaking could occur, it was judged economically impractical to design for such ground motions and that MCE_R ground motions based on a 1 percent probability of collapse in 50 years provides an acceptable level of seismic safety.

In regions of high seismicity, such as in many areas of California, the seismic hazard is typically controlled by large-magnitude events occurring on a limited number of well-defined fault systems. Probabilistic ground motions calculated for a 1 percent probability of collapse in 50 years can be significantly larger than deterministic ground motions based on the characteristic magnitudes of earthquakes on these known active faults. Probabilistic ground motions tend to be greater when major active faults produce characteristic earthquakes every few hundred years, rather than at longer return periods. For these regions, it is considered more appropriate to determine MCE_R ground motions directly by deterministic methods based on a conservative estimate of the ground shaking associated with characteristic earthquakes of well-defined fault systems. In order to provide an appropriate level of conservatism in the design process, 84th percentile ground motions are used to define deterministic (MCE_R) ground motion which are estimated as median ground motions for characteristic events multiplied by 1.8 (Huang, et al., 2008).

The smaller deterministic (MCE_R) ground motions result in a probability of collapse in 50 years greater than the targeted 1 percent of probabilistic (MCE_R) ground motions, but the assumption of not more than a 10 percent probability of collapse if the MCE_R ground motion occurs at the building site still applies. It was judged economically impractical to design buildings in high seismic regions located near active faults for more than 84th percentile ground motions of characteristic earthquakes, and that a 10 percent probability of collapse if these ground motions occur at the building site provides an acceptable level of safety.

C11.4.1 Mapped Acceleration Parameters

In the general procedure, seismic design values are computed from mapped values of the spectral response acceleration at short periods, S_S, and at 1 second, S_1, for Class B sites. These S_s and S_1 values may be obtained directly from Figures 22-1 through 22-6 (in Chapter 22). However, these maps themselves do not permit precise determination of S_s and S_1 values, especially in high seismic regions, so the mapped values may be obtained directly from the United States Geological Survey (USGS) website: http://earthquake.usgs.gov/designmaps or through the ASCE Structural Engineering Institute web site http://content.seinstitute.org.

S_S is the mapped value of the 5-percent-damped MCE_R spectral response acceleration for short-period structures founded on Site Class B (firm rock) sites. The short-period acceleration has been determined at a period of 0.2 second because it was concluded that 0.2 second was reasonably representative of the shortest effective period of buildings and structures that are designed using the standard, considering the effects of soil compliance, foundation rocking, and other factors typically neglected in structural analysis.

Similarly, S_1 is the mapped value of the 5-percent-damped MCE_R spectral response acceleration at a period of 1 second on Site Class B. The spectral response acceleration at periods other than 1 second typically can be derived from the acceleration at 1 second. Consequently, for MCE_R ground shaking on Site Class B sites, these two response acceleration parameters, S_S and S_1, are sufficient when adjusted for site effects to define an entire response spectrum for the period range of importance for most buildings and structures using the generic shape of the MCE_R response spectrum shown in Figure 21.2-1.

DRAFT

C11.4.3 Site Coefficients and Risk-Targeted Maximum Considered Earthquake (MCE_R) Spectral Response Acceleration Parameters

Using the general procedure to obtain acceleration response parameters that are appropriate for sites with a classification other than Site Class B, the S_S and S_1 values must be modified as indicated in Section 11.4.3. This modification is performed using two coefficients, F_a and $F_{v,}$ that respectively scale the S_S and S_1 values determined for Site Class B to values appropriate for other site classes. The MCE_R spectral response accelerations adjusted for site class are designated S_{MS} and S_{M1}, respectively, for short-period and 1-second-period response.

The site coefficients, F_a and F_v, presented respectively in Tables 11.4-1 and 11.4-2 for the various site classes are based on the results of empirical analyses of strong-motion data and analytical studies of site response.

The amount of ground-motion amplification by a soil deposit relative to bedrock depends on the wave-propagation characteristics of the soil, which can be estimated from measurements or inferences of shear-wave velocity and in turn the shear modulus for the materials as a function of the level of shaking. In general, softer soils with lower shear-wave velocities exhibit greater amplifications than stiffer soils with higher shear-wave velocities. Increased levels of ground shaking result in increased soil stress-strain nonlinearity and increased soil damping which, in general, reduces the amplification, especially for shorter periods. Furthermore, for soil deposits of sufficient thickness, soil amplification is generally greater at longer periods than at shorter periods.

An extensive discussion of the development of the F_a and F_v site coefficients is presented by Dobry, et al. (2000). Since the development of these coefficients and the development of a community consensus regarding their values in 1992, earthquake events have provided additional strong-motion data from which to infer site amplifications. Analyses conducted on the basis of these more recent data are reported by a number of researchers including Crouse and McGuire (1996), Harmsen (1997), Dobry et al. (1999), Silva et al. (2000), Joyner and Boore (2000), Field (2000), Steidl (2000), Rodriquez-Marek et al. (2001), Borcherdt (2002), and Stewart et al. (2003). Although the results of these studies vary, the site amplification factors are generally consistent with those in Tables 11.4-1 and 11.4-2.

C11.4.4 Design Spectral Acceleration Parameters

As described in C11.4, structural design in ASCE/SEI 7-10 is performed for earthquake demands that are 2/3 of the MCE_R response spectra. As set forth in Section 11.4.4, two additional parameters, S_{DS} and S_{D1}, are used to define the acceleration response spectrum for this design level event. These parameters are 2/3 of the respective S_{MS} and S_{M1} values and define a design response spectrum for sites of any characteristics and for natural periods of vibration less than the transition period, T_L. Values of S_{MS}, S_{M1}, S_{DS}, and S_{D1} can also be obtained from the USGS website cited above.

C11.4.5 Design Response Spectrum

The design response spectrum (Figure 11.4-1) consists of several segments. The constant-acceleration segment covers the period band from T_o to T_s; response accelerations in this band are constant and equal to S_{DS}. The constant-velocity segment covers the period band from T_s to T_L, and the response accelerations in this band are proportional to $1/T$ with the response acceleration at 1-sec period equal to S_{D1}. The long-period portion of the design response spectrum is defined on the basis of the parameter, T_L, the period that marks the transition from the constant-velocity segment to the constant-displacement segment of the design response spectrum. Response accelerations in the constant-displacement segment, where $T \geq T_L$, are proportional to $1/T^2$. Values of T_L are provided on maps in Figures 22-12 through 22-16.

The T_L maps were prepared following a two-step procedure. First, a correlation between earthquake magnitude and T_L was established. Then, the modal magnitude from deaggregation of the ground-motion seismic hazard at a 2-second period (1-second period for Hawaii) was mapped. Details of the procedure and the rational for it are found in Crouse et al. (2006).

C11.4.7 Site-Specific Ground Motion Procedures

Site-specific ground motions are permitted for design of any structure, and required for design of certain structuresand certain site soil conditions. The objective of a site-specific ground-motion analysis is to determine ground motions for local seismic and site conditions with higher confidence than is possible using the general procedure of Sections 11.4.

DRAFT

As noted earlier, the site-specific procedures of Chapter 21 are the same as those used by the USGS to develop the mapped values of MCE_R ground motions shown in Figures 22-1 through 22-6 of Chapter 22. Unless significant differences in local seismic and site conditions are determined by a site-specific analysis of earthquake hazard, site-specific ground motions would not be expected to differ significantly from those of the mapped values of MCE_R ground motions prepared by the USGS.

C11.5 IMPORTANCE FACTOR AND RISK CATEGORY

Large earthquakes are rare events that include severe ground motions. Such events are expected to result in damage to structures even if they were designed and built in accordance with the minimum requirements of the standard. The consequence of structural damage or failure is not the same for the various types of structures located within a given community. Serious damage to certain classes of structures, such as critical facilities (e.g., hospitals), will disproportionally affect a community. The fundamental purpose of this section and subsequent requirements that depend on this section is to improve the ability of a community to recover from a damaging earthquake by tailoring the seismic protection requirements to the relative importance of a structure. That purpose is achieved by requiring improved performance for structures that:

1. Are necessary to response and recovery efforts immediately following an earthquake,
2. Present the potential for catastrophic loss in the event of an earthquake, or
3. House a very large number of occupants or occupants less able to care for themselves than the average.

The first basis for seismic design in the standard is that structures will have a suitably low likelihood of collapse in rare events defined as the maximum considered earthquake (MCE) ground motion. A second basis is that life threatening damage, primarily from failure of nonstructural components in and on structures, will be unlikely in a the design earthquake ground motion (defined as two-thirds of the MCE). Given the occurrence of ground motion equivalent to the MCE, a population of structures built to meet these design objectives will probably still experience substantial damage in many structures, rendering these structures unfit for occupancy or use. Experience in past earthquakes around the world has demonstrated that there will be an immediate need to treat injured people, to extinguish fires and prevent conflagration, to rescue people from severely damaged or collapsed structures, and to provide shelter and sustenance to a population deprived of its normal means. These needs are best met when structures essential to response and recovery activities remain functional.

The standard addresses these objectives by requiring that each structure be assigned to one of the four risk categories presented in Chapter 1 and by assigning an importance factor, I_e, to the structure based upon that risk category. (The two lowest categories, I and II are combined for all purposes within the seismic provisions). The risk category is then used as one of two components in determining the Seismic Design Category (see Section C11.6) and is a primary factor in setting drift limits for building structures under the design earthquake ground motion (see Section C12.12).

Figure C11-11 shows the combined intent of these requirements for design. The vertical scale is the likelihood of the ground motion with the MCE being the rarest considered. The horizontal scale is the level of performance intended for the structure and attached nonstructural components, which range from collapse to operational. The basic objective of collapse prevention at the MCE for ordinary structures (Risk Category II) is shown at the lower right by the solid triangle; protection from life-threatening damage at the design earthquake ground motion (defined by the standard as two-thirds of the MCE) is shown by the open triangle. The performance implied for higher risk categories III and IV is shown by squares and circles, respectively. The performance anticipated for less severe ground motion is shown by dotted symbols.

Figure C11- 11 Expected performance as related to risk category (RC) and level of ground motion

C11.5.1 Importance Factor I_e

The importance factor, I_e, is used throughout the standard in quantitative criteria for strength. In most of those quantitative criteria, the importance factor is shown as a divisor on the factor R or R_p to reduce damage for important structures in addition to preventing collapse in larger ground motions. The R and R_p factors adjust the computed linear elastic response to a value appropriate for design; in many structures, the largest component of that adjustment is ductility (the ability of the structure to undergo repeated cycles of inelastic strain in opposing directions). For a

given strength demand, reducing the effective *R* factor (by means of the importance factor) increases the required yield strength, thus reducing ductility demand and related damage.

C11.5.2 Protected Access for Risk Category IV Structures

Those structures considered essential facilities for response and recovery efforts must be accessible to carry out their purpose. For example, if the collapse of a simple canopy at a hospital could block ambulances from the emergency room admittance area, then the canopy must meet the same structural standard as the hospital. The protected access requirement must be considered in the siting of essential facilities in densely built urban areas.

C11.6 SEISMIC DESIGN CATEGORIES

Seismic design categories (SDCs) provide a means to step progressively from simple, easily performed design and construction procedures and minimums to more sophisticated, detailed, and costly requirements as both the level of seismic hazard and the consequence of failure escalate. The SDCs are used to trigger requirements that are not scalable; such requirements are either on or off. For example, the basic amplitude of ground motion for design is scalable – the quantity simply increases in a continuous fashion as one moves from a low hazard area to a high hazard area. However, a requirement to avoid weak stories is not particularly scalable. Requirements such as this create step functions. There are many such requirements in the standard, and the SDCs are used systematically to group these step functions. (Further examples include whether seismic anchorage of nonstructural components is required or not, whether particular inspections will be required or not, and structural height limits applied to various seismic force-resisting systems.)

In this regard, SDCs perform one of the functions of the seismic zones used in earlier U.S. building. However, SDCs also depend on a building's occupancy and, therefore, its desired performance. Further, unlike the traditional implementation of seismic zones, the ground motions used to define the SDCs include the effects of individual site conditions on probable ground-shaking intensity.

In developing the groundmotion limits and design requirements for the various Seismic Design Categories, the equivalent modified Mercalli intensity (MMI) scale was considered. There are now correlations of the qualitative MMI with quantitative characterizations of ground motions. The reader is encouraged to consult any of a great many sources that describe the MMIs. The following list is a very coarse generalization:

MMI V	No real damage
MMI VI	Light nonstructural damage
MMI VII	Hazardous nonstructural damage
MMI VIII	Hazardous damage to susceptible structures
MMI IX	Hazardous damage to robust structures

When the current design philosophy was adopted (the 1997 edition of the *NEHRP Recommended Provisions*, FEMA 302, and *Commentary*, FEMA 303), the upper limit for SDC A was set at roughly one-half of the lower threshold for MMI VII and the lower limit for SDC D was set at roughly the lower threshold for MMI VIII. However, the lower limit for SDC D was more consciously established by equating that design value (two-thirds of the MCE) to one-half of what had been the maximum design value in building codes over the period of 1975 to 1995. As more correlations between MMI and numerical representations of ground motion have been created, it is reasonable to make the following correlation between the MMI at MCE ground motion and the Seismic Design Category (all this discussion is for ordinary occupancies):

MMI V	SDC A
MMI VI	SDC B
MMI VII	SDC C
MMI VIII	SDC D
MMI IX	SDC E

An important change was made to the determination of SDC when the current design philosophy was adopted. Earlier editions of the *NEHRP Provisions* utilized the peak velocity-related acceleration, A_v, to

determine a building's Seismic Performance Category. However, this coefficient does not adequately represent the damage potential of earthquakes on sites with soil conditions other than rock. Consequently, the 1997 *NEHRP Provisions* adopted the use of response spectral acceleration parameters S_{DS} and S_{D1}, which include site soil effects for this purpose.

Except for the lowest level of hazard (SDC A), the SDC also depends on the risk categories. For a given level of ground motion, the SDC is one category higher for Risk Category IV structures than for lower-risk structures. This has the effect of increasing the confidence that the design and construction requirements will deliver the intended performance in the extreme event.

Note that the tables in the standard are at the design level, defined as two-thirds of the MCE level. Also recall that the MMIs are qualitative by their nature and that the above correlation will be more or less valid depending on which numerical correlation for MMI is used. The numerical correlations for MMI roughly double with each step so correlation between design earthquake ground motion and MMI is not as simple or convenient.

In sum, at the MCE level, SDC A structures should not see motions that are normally destructive to structural systems, whereas the MCE level motions for SDC D structures can destroy vulnerable structures. The grouping of step function requirements by SDC is such that there are a few basic structural integrity requirements imposed at SDC A graduating to a suite of requirements at SDC D based upon observed performance in past earthquakes, analysis, and laboratory research.

The nature of ground motions within a few kilometers of a fault can be very different from more distant motions. For example, some near fault motions will have strong velocity pulses, associated with forward rupture directivity, that tend to be highly destructive to irregular structures even if they are well detailed. For ordinary occupancies, the boundary between SDCs D and E is set to define sites likely to be close enough to a fault that these unusual ground motions may be present. Note that this boundary is defined in terms of mapped bedrock outcrop motions affecting response at 1 second, not site adjusted values, in order to better discriminate between sites near and far from faults. Short-period response is not normally as affected as the longer period response. The additional design criteria imposed on structures in SDCs E and F specifically are intended to provide acceptable performance under these very intense near-fault ground motions.

For most buildings, the SDC is determined without consideration of the building's period. Structures are assigned to a SDC based on the more severe condition determined from 1-second acceleration and short-period acceleration. This is done for several reasons. Perhaps the most important of these is that it is often difficult to estimate precisely the period of a structure using default procedures contained in the standard. Consider, for example, the case of rigid wall/flexible diaphragm buildings including low-rise reinforced masonry and concrete tilt-up buildings with either untopped metal deck or wood diaphragms. The formula in the standard for determining the period of vibration of such buildings is based solely on the structural height, h_n, and the length of wall present. These formulas typically indicate very short periods for such structures, often on the order of 0.2 second or less. However, the actual dynamic behavior of these buildings often is dominated by the flexibility of the diaphragm – a factor neglected by the formula for approximate fundamental period. Large buildings of this type can have actual periods on the order of 1 second or more. In order to avoid misclassifying a building's SDC by inaccurately estimating the fundamental period, the standard generally requires that the more severe SDC determined on the basis of short- and long-period shaking be used.

Another reason for this requirement is a desire to simplify building regulation by requiring all buildings on a given soil profile in a particular region to be assigned to the same SDC regardless of the structural type. This has the advantage of permitting uniform regulation in the selection of seismic force-resisting systems, inspection and testing requirements, seismic design requirements for nonstructural components, and similar aspects of the design process regulated on the basis of SDC, within a community.

Notwithstanding the above, it is recognized that classification of a building as SDC C instead of B or D can have significant impact on the cost of construction. Therefore, the standard includes an exception permitting the classification of buildings that can reliably be classified as having short structural periods on the basis of short-period shaking alone.

Local or regional jurisdictions enforcing building regulations may desire to consider the effect of the maps, typical soil conditions, and Seismic Design Categories on the practices in their jurisdictional areas. For reasons of uniformity of practice or reduction of potential errors, adopting ordinances could stipulate particular values of

DRAFT

ground motion, particular site classes, or particular Seismic Design Categories for all or part of the area of their jurisdiction. For example:

1. An area with a historical practice of high seismic zone detailing might mandate a minimum SDC of D regardless of ground motion or site class.
2. A jurisdiction with low variation in ground motion across the area might stipulate particular values of ground motion rather than requiring use of the maps.
3. An area with unusual soils might require use of a particular Site Class unless a geotechnical investigation proves a better Site Class.

C11.7 DESIGN REQUIREMENTS FOR SEISMIC DESIGN CATEGORY A

The 2002 edition of the standard included a new provision of minimum lateral force for Seismic Design Category A structures. The minimum load is a structural integrity issue related to the load path. It is intended to specify design forces in excess of wind loads in heavy low-rise construction. The design calculation in Section 1.4.3 of the standard is simple and easily done to ascertain if seismic or the wind load governs. This provision requires a minimum lateral force of 1 percent of the total gravity load assigned to a story to assure general structural integrity.

Seismic Design Category A is assigned when the MCE ground motions are below those normally associated with hazardous damage. Damaging earthquakes are not unknown or impossible in such regions, however, and ground motions close to such events may be large enough to produce serious damage. Providing a minimum level of resistance reduces both the radius over which the ground motion exceeds structural capacities and resulting damage in such rare events. There are reasons beyond seismic risk for minimum levels of structural integrity.

The requirements for SDC A in Section 1.4 are all minimum strengths for structural elements stated as forces at the level appropriate for direct use in the strength design load combinations of Section 2.3. The two fundamental requirements are a minimum strength for a structural system to resist lateral forces (Section 1.4.3) and a minimum strength for connections of structural members (Section 1.4.4).

For many buildings the wind force will control the strength of the lateral-force-resisting system but, for low-rise buildings of heavy construction with large plan aspect ratio, the minimum lateral force specified in Section 1.4.3 may control. Note that the requirement is for strength and not for toughness, energy dissipation capacity, or some measure of ductility. The force level is not tied to any postulated seismic ground motion. The boundary between SDCs A and B is based on a spectral response acceleration of 25 percent of gravity (MCE level) for short-period structures; clearly the 1 percent acceleration level (Equation 1.4-1) is far smaller. For ground motions below the A/B boundary, the spectral displacements generally are on the order of a few inches or less depending on period. Experience has shown that even a minimal strength is beneficial in providing resistance to small ground motions, and it is an easy provision to implement in design. The low probability of motions greater than the MCE is a factor in taking the simple approach without requiring details that would produce a ductile response. Another factor is that larger design forces are specified in Section 1.4.4 for connections between main elements of the lateral force load path.

The minimum connection force is specified in three ways: a general minimum horizontal capacity for all connections; a special minimum for horizontal restraint of in line beams and trusses, which also includes the live load on the member; and a special minimum for horizontal restraint of concrete and masonry walls perpendicular to their plane (Section 1.4.5). The 5 percent coefficient used for the first two is a simple and convenient value that provides some margin over the minimum strength of the system as a whole. .

C11.8 GEOLOGIC HAZARDS AND GEOTECHNICAL INVESTIGATION

In addition to this commentary, Part 3 of the 2009 *NEHRP Recommend Provisions* includes additional and more detailed discussion and guidance on evaluation of geologic hazards and determination of seismic lateral pressures.

C11.8.1 Site Limitation for Seismic Design Categories E and F

Because of the difficulty of designing a structure for the direct shearing displacement of fault rupture and the relatively high seismic activity of SDCs E and F, locating a structure on an active fault having the potential to cause rupture of the ground surface at the structure is prohibited.

DRAFT

C11.8.2 Geotechnical Investigation Report Requirements for Seismic Design Categories C through F

Earthquake motion is only one factor in assessing potential for geologic and seismic hazards. All of the listed hazards can lead to surface ground displacements with potential adverse consequences to structures. Finally, hazard identification alone has little value unless mitigation options are also identified.

C11.8.3 Additional Geotechnical Investigation Report Requirements for Seismic Design Categories D through F

New provisions for computing peak ground acceleration for soil liquefaction and stability evaluations have been introduced in this section. Of particular note in this section is the explicitly-stated requirement that liquefaction must now be evaluated for the MCE_G ground motion .These provisions include maps of the Maximum Considered Earthquake geometric mean (MCE_G) peak ground acceleration for Site Class B bedrock (PGA), plus a site-coefficient (F_{PGA}) table to convert the PGA value to one adjusted for Site Class effects (PGA_M).

PGA Provisions

Paragraph 2 of Section 11.8.3 states that peak ground acceleration shall be determined based on either a site-specific study taking into account soil amplification effects or using Eq.11.8-1 for which MCE_G peak ground acceleration is obtained from national maps of peak ground acceleration for bedrock Site Class B (PGA) multiplied by a site coefficient (F_{PGA}) to obtain peak ground acceleration for other site classes (PGA_M). This methodology for determining peak ground acceleration for liquefaction evaluations improves the methodology in ASCE 7-05 by using mapped PGA rather than the approximation for PGA by the ratio $S_S/2.5$. Furthermore, in the Central and Eastern U.S. (CEUS), the ratio $S_S/2.5$ tends to underestimate PGA. $S_S/2.5$ is applicable for bedrock Site Class B and thus could be used as input at depth to a site response analysis under the provisions of ASCE 7-05. The use of Eq. 11.8-1 provides an alternative to conducting site response analysis using rock PGA by providing a site-adjusted ground surface acceleration (PGA_M) that can directly be applied in the widely-used empirical correlations for assessing liquefaction potential. Correlations for evaluating liquefaction potential are elaborated on in Resource Paper RP 12, *Evaluation of Geologic Hazards and Determination of Seismic Lateral Earth Pressures,* published in the 2009 NEHRP Provisions.

Maps of MCE_G PGA for Site Class B bedrock, similar to maps of S_S and S_1, are shown in Figures 22-7 to 22-11 in Chapter 22. Similar to adjustments for the bedrock spectral response accelerations for site response through the F_a and F_v coefficients, bedrock motions for PGA are adjusted for these same site effects using a site coefficient, F_{PGA}, that depends on the level of ground shaking in terms of PGA and the stiffness of the soil, typically defined in terms of the shear-wave velocity in the upper 30 meters of geologic profile, V_{s30}. Values of F_{PGA} are presented in Table 11.8-1, and the adjustment is made through Equation 11.8-1, i.e., $PGA_M = F_{PGA}$ PGA, where PGA_M is peak ground acceleration adjusted for site class. The values of F_{PGA} in Table 11.8-1 are identical to the F_a values in Table 11.4-1. These F_a values are the same as those in ASCE 7-05 and ASCE 7-02. The method of determining Site Class, used in the determination of F_a, is also identical to that in the present and previous ASCE 7 documents.

There is an important difference in the derivation of the PGA maps and the maps of S_S and S_1 in ASCE 7-10. Unlike previous editions of ASCE 7, the S_S and S_1 maps in ASCE 7-10 have been derived for the "maximum direction shaking" and are now risk-based rather than hazard-based. On the other hand, the PGA maps have been derived based on the geometric mean of the two horizontal components of motion. The geomean was used in the PGA maps rather than the PGA for the maximum direction shaking to assure that there is consistency between the determination of PGA and the basis of the simplified empirical field procedure for estimating liquefaction potential based on results of Standard Penetration Tests (SPT), cone penetrometer tests (CPT), and other similar field investigative methods. When these correlations were originally derived, the geomean (or similar metric) of peak ground acceleration at the ground surface was used to identify the cyclic stress ratio for sites with or without liquefaction. The resulting envelopes of data define the liquefaction cyclic resistance ratio (CRR). Rather than re-evaluating these case histories for the "maximum direction shaking", it was decided to develop maps of the geomean PGA and continue using the existing empirical methods.

Liquefaction Evaluation Requirements

Beginning with ASCE 7-02, it has been the intent that liquefaction potential be evaluated at MCE ground motion levels. There was ambiguity in the previous requirement in ASCE 7-05 as to whether liquefaction potential should be evaluated for the MCE or the design earthquake. Paragraph 2 of Section 11.8.3 of ASCE 7-05 stated that liquefaction potential be evaluated for the design earthquake, while also stating that in the absence of a site specific study, peak ground acceleration shall be assumed equal to $S_S/2.5$ (S_S being the MCE short-period response spectral acceleration on Site Class B rock). There has also been a difference in provisions between ASCE 7-05 and the 2006

DRAFT

edition of the IBC in which Section 1802.2.7 stated that liquefaction shall be evaluated for the design earthquake ground motions and the default value of peak ground acceleration in the absence of a site specific study was given as $S_{DS}/2.5$ (S_{DS} being the short-period site-adjusted design response spectral acceleration). ASCE 7-10, Paragraph 2 of Section 11.8.3 and Equation 11.8-1 now require explicitly that liquefaction potential be evaluated based upon the MCE_G peak ground acceleration.

The explicit requirement in ASCE-7-10 to evaluate liquefaction for MCE ground motion rather than design earthquake ground motion assures that the full potential for liquefaction is addressed during the evaluation of structure stability, rather than a lesser level when the design earthquake is used. This change also assures that, for the MCE ground motion, the performance of the structure is considered under a consistent hazard level for the effects of liquefaction, such as collapse prevention or life safety, depending on the Risk Category for the structure (see Figure C11-11). By evaluating liquefaction for the MCE rather than the design earthquake peak ground acceleration, the ground motion for the liquefaction assessment increases by a factor of 1.5. This increase in peak ground acceleration to the MCE level means that sites that previously were nonliquefiable could now be liquefiable, and sites where liquefaction occurred to a limited extent under the design earthquake could undergo more liquefaction, in terms of depth and lateral extent. Some mechanisms that are directly related to the development of liquefaction, such as lateral spreading and flow or ground settlement, could also increase in severity.

This change in peak ground acceleration level for the liquefaction evaluation addressed an issue that has existed and periodically been discussed since the design earthquake concept was first suggested in the 1990s. The design earthquake ground motion was obtained by multiplying the MCE ground motion by a factor of 2/3 to account for a margin in capacity in most buildings. Various calibration studies at the time of code development concluded that for the design earthquake most buildings had a reserve capacity of over 1.5 relative to collapse. This reserve capacity allowed the spectral accelerations for the MCE to be reduced using a factor of 2/3, while still achieving safety from collapse. On the other hand, liquefaction potential is evaluated at the selected MCE_G peak ground acceleration and typically determined to be acceptable if the factor of safety is greater than 1.0, meaning that there is no implicit safety margin on liquefaction potential. By multiplying peak ground acceleration by a factor of 2/3, liquefaction would be assessed at an effective return period or probability of exceedance different than that for the MCE. However, ASCE 7-10 now requires that liquefaction be evaluated for the MCE.

Paragraph 3 of Section 11.8.3 of the ASCE 7-10 Standard states the various potential consequences of liquefaction that must be assessed; soil downdrag and loss in lateral soil reaction for pile foundations are additional consequences that have been included in this paragraph. This section of the new provisions, as in previous editions, does not present specific seismic criteria for the design of the foundation or substructure, but Paragraph 4 does state that the geotechnical report must include discussion of possible measures to mitigate these consequences.

A liquefaction resource document has been prepared in support of these revisions to Section 11.8.3. The resource document, *Evaluation of Geologic Hazards and Determination of Seismic Lateral Earth Pressures*, includes a summary of methods that are currently being used to evaluate liquefaction potential, and the limitations of these methods. This summary appears as Resource Paper, RP-12, in the 2009 NEHRP Provisions. The resource document summarizes alternatives for evaluating liquefaction potential, methods for evaluating the possible consequences of liquefaction (e.g., loss of ground support, increased lateral earth pressures, etc.) and methods of mitigating the liquefaction hazard. The resource document also identifies alternate methods of evaluating liquefaction hazards, such as analytical and physical modeling. Reference is made to the use of non-linear effective stress methods for modeling the build-up in pore water pressure during seismic events at liquefiable sites.

Evaluation of Dynamic Seismic Lateral Earth Pressures

The dynamic lateral earth pressure on basement and retaining walls during earthquake ground shaking is considered to be an earthquake load, E, for use in design load combinations. This dynamic earth pressure is superimposed on the pre-existing static lateral earth pressure during ground shaking. The pre-existing static lateral earth pressure is considered to be an H load.

Chapter C12
SEISMIC DESIGN REQUIREMENTS FOR BUILDING STRUCTURES

C12.1 STRUCTURAL DESIGN BASIS

The performance expectations for structures designed in accordance with ASCE/SEI 7-10 are described in Sections C11.1 and C11.5. Structures designed in accordance with the standard are likely to have a low probability of collapse but suffer serious structural damage if subjected to the maximum considered earthquake (MCE) or stronger ground motion.

Although the seismic requirements of the standard are stated in terms of forces and loads, there are no external forces applied to the structure during an earthquake as, for example, is the case during a wind storm. The design forces are intended only as approximations to generate internal forces suitable for proportioning the strength and stiffness of structural elements and for estimating the deformations (when multiplied by the deflection amplification factor, C_d) that would occur in the same structure in the event of design earthquake (not MCE_R) ground motion.

C12.1.1 Basic Requirements

Chapter 12 of the standard sets forth a set of coordinated requirements that must be used together. The basic steps in structural design of a building structure for acceptable seismic performance are as follows:

1. Select gravity- and seismic-force-resisting systems appropriate to the anticipated intensity of ground shaking. Section 12.2 sets forth limitations depending on the Seismic Design Category.
2. Configure these systems to produce a continuous, regular, and redundant load path so that the structure acts as an integral unit in responding to ground shaking. Section 12.3 addresses configuration and redundancy issues.
3. Analyze a mathematical model of the structure subjected to lateral seismic motions and gravity forces. Sections 12.6 and 12.7 set forth requirements for the method of analysis and for construction of the mathematical model. Sections 12.5, 12.8, and 12.9 set forth requirements for conducting a structural analysis to obtain internal forces and displacements.
4. Proportion members and connections to have adequate lateral and vertical strength and stiffness. Section 12.4 specifies how the effects of gravity and seismic loads are to be combined to establish required strengths, and Section 12.12 specifies deformation limits for the structure.

One to three story structures with shear wall or braced frame systems of simple configuration may be eligible for design under the simplified alternative procedure contained in Section 12.14. Any other deviations from the requirements of Chapter 12 are subject to approval by the authority having jurisdiction (AHJ) and must be rigorously justified as specified in Section 11.1.4.

The baseline seismic forces used for proportioning structural elements (individual members, connections, and supports) are static horizontal forces derived from an elastic response spectrum procedure. A basic requirement is that horizontal motion can come from any direction relative to the structure, with detailed requirements for evaluating the response of the structure provided in Section 12.5. For most structures, the effect of vertical ground motions is not analyzed explicitly, it is implicitly included by adjusting the load factors (up and down)for permanent dead loads, as specified in Section 12.4. Certain conditions requiring more detailed analysis of vertical response are defined in Chapters 13 and 15 for nonstructural components and nonbuilding structures are defined in Chapters 13 and 15, respectively.

The basic seismic analysis procedure uses response spectra that are representative of, but substantially reduced from, the anticipated ground motions. As a result, at the MCE_R level of ground shaking, structural elements are expected to yield, buckle, or otherwise behave inelastically. This approach has substantial historical precedent. In past earthquakes, structures with appropriately ductile, regular, and continuous systems which were designed using *reduced* design forces have performed acceptably. In the standard, such design forces are computed by dividing the forces that would be generated in a structure behaving elastically when subjected to the design earthquake ground

DRAFT

motion by the response modification coefficient, *R*, and this design ground motion is taken as two-thirds of the MCE_R ground motion.

The intent of *R* is to reduce the demand determined assuming the structure remains elastic at the design earthquake to target the development of the first significant yield. This reduction accounts for the displacement ductility demand, R_d, required by the system and the inherent overstrength, Ω, of the seismic-force-resisting system (SFRS) – see Fig. C12.1-1. Significant yield is the point where complete plastification of a critical region of the SFRS first occurs(e.g., formation of the first plastic hinge in a moment frame)and the stiffness of the SFRS to further increases in lateral forces decreases as continued inelastic behavior spreads within the SFRS. This approach is consistent with member-level ultimate strength design practices. As such, first significant yield should not be misinterpreted as the point where first yield occurs in any member (e.g., 0.7 times the yield moment of a steel beam or either initial cracking or initiation of yielding in a reinforcing bar in a reinforced concrete beam or wall).

Figure C12.1-1 shows the lateral force versus deformation relation for an archetypal moment frame used as a SFRS. First significant yield is shown as the lowest plastic hinge on the force-deformation diagram. Because of particular design rules and limits, including material strengths in excess of nominal or project specific design requirements, structural elements will be stronger by some degree than that required by analysis. The SFRS is therefore expected to reach first significant yield for forces in excess of design forces. With increased lateral loading, additional plastic hinges form and the resistance increases at a reduced rate (following the solid curve) until the maximum strength is reached, representing a fully yielded system. The maximum strength developed along the curve is substantially higher than that at first significant yield, and this margin is referred to as the system overstrength capacity. The ratio of these strengths is denoted as Ω. Further, the figure illustrates the potential variation that can exist between the actual elastic response of a system and that considered using the limits on the fundamental period (assuming 100% mass participation in the fundamental mode – see C12.8.6). While not a concern for strength design, this variation can have an effect on the expect drifts.

DRAFT

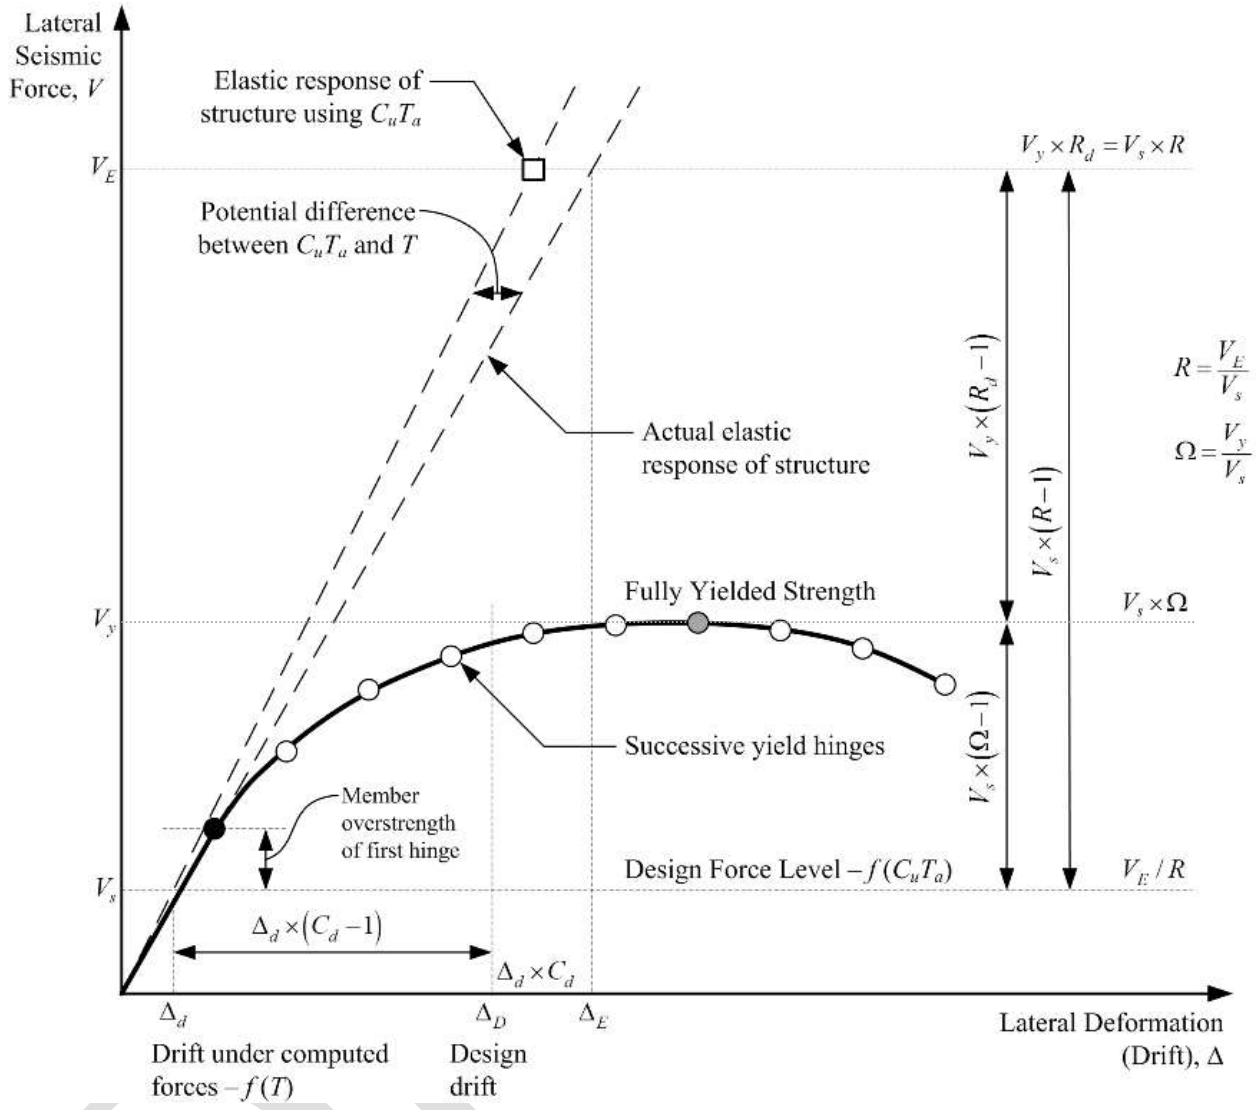

Figure C12.1- 1 Inelastic force-deformation curve.

The system overstrength described above is the direct result of overstrength of the elements that form the SFRS, and to a lesser extent the lateral force distribution used to evaluate the inelastic force-deformation curve. These two effects interact with applied gravity loads to produce sequential plastic hinges as illustrated in the figure. This member overstrength is the consequence of several sources. First, material overstrength (i.e., actual material strengths higher than the nominal material strengths specified in the design) may increase the member overstrength significantly. For example, a recent survey shows that the mean yield strength of ASTM A36 steel is about 30 to 40 percent higher than the specified yield strength used in design calculations. Second, member design strengths usually incorporate a strength reduction or resistance factor, ϕ to produce a low probability of failure under design loading. It is common to not include this factor in the member load-deformation relation when evaluating the seismic response of a structure in a nonlinear structural analysis. Third, designers can introduce additional strength by selecting sections or specifying reinforcing patterns that exceed those required by the computations. Similar situations occur where prescriptive minimums of the standard, or of the referenced design standards, control the design. Finally, the design of many flexible structural systems (e.g., moment resisting frames) can be controlled by

the drift rather than strength with sections selected to control lateral deformations rather than to provide the specified strength.

The result is that structures typically have a much higher lateral strength than that specified as the minimum by the standard, and first significant yielding of structures may occur at lateral load levels that are 30 to 100 percent higher than the prescribed design seismic forces. If provided with adequate ductile detailing, redundancy and regularity, full yielding of structures may occur at load levels that are two to four times the prescribed design force levels.

Most structural systems have some elements whose action cannot provide reliable inelastic response or energy dissipation. Similarly, some elements are required to remain essentially elastic in order to maintain the structural integrity of the structure (e.g., columns supporting a discontinuous SFRS). Such elements and actions must be protected from undesirable behavior by considering that the actual forces within the structure can be significantly larger than those at first significant yield. The standard specifies an overstrength factor, Ω_0, to amplify the prescribed seismic forces for use in design of such elements and for such actions. This approach is a simplification to determining the maximum forces that could be developed in a system and the distribution of these forces within the structure. Thus, this specified overstrength factor is neither an upper nor a lower bound; it is simply an approximation specified to provide a nominal degree of protection against undesirable behavior.

The elastic deformations calculated under these reduced forces (see C12.8.6) are multiplied by the deflection amplification factor, C_d, to estimate the deformations likely to result from the design earthquake ground motion. This factor was first introduced in ATC 3-06 (ATC 1984). . For a vast majority of systems C_d is less than R, with a few notable exceptions where inelastic drift is strongly coupled with an increased risk of collapse (e.g., reinforced concrete bearing walls). Research over the past 30 years has illustrated that inelastic displacements may be significantly greater than Δ_E for many structures and less than Δ_E for others. Where C_d is substantially less than R, the system is considered to have damping greater than the nominal 5 percent of critical damping. As set forth in Section 12.12 and Chapter 13, the amplified deformations are used to assess story drifts and to determine seismic demands on elements of the structure that are not part of the seismic-force-resisting system and on nonstructural components within structures.

Figure C12.1-1 illustrates the significance of seismic design parameters contained in the standard including the response modification coefficient, R; the deflection amplification factor, C_d; and the overstrength factor, Ω_0. The values of these parameters, provided in Table 12.2-1, as well as the criteria for story drift and P-delta effects, have been established considering the characteristics of typical properly designed structures. The provisions of the standard anticipate a SFRS with redundant characteristics wherein significant system strength above the level of first significant yield can be obtained by plastification at other critical locations in the structure prior to the formation of a collapse mechanism. If excessive "optimization" of a structural design is performed with lateral resistance provided by only a few elements, the successive yield hinge behavior depicted in Figure C12.1-1 will not be able to form, the actual overstrength (Ω) will be small, and use of the seismic design parameters in the standard may not provide the intended seismic performance.

The response modification coefficient, R, represents the ratio of the forces that would develop under the specified ground motion if the structure had an entirely linear-elastic response to the prescribed design forces (see Figure C12.1-1). The structure must be designed so that the level of significant yield exceeds the prescribed design force. The ratio R_d, expressed as $R_d = V_E/V_S$, where V_E is the elastic seismic force demand and V_S is the prescribed seismic force demand, is always larger than 1.0; thus, all structures are designed for forces smaller than those the design ground motion would produce in a structure with a completely linear-elastic response. This reduction is possible for a number of reasons. As the structure begins to yield and deform inelastically, the effective period of response of the structure lengthens, which results in a reduction in strength demand for most structures. Furthermore, the inelastic action results in a significant amount of energy dissipation (hysteretic damping) in addition to other sources of damping present below significant yield. The combined effect, which is known as the ductility reduction, explains why a properly designed structure with a fully yielded strength (V_y in Figure C12.1-1) that is significantly lower than V_E can be capable of providing satisfactory performance under the design ground motion excitations.

The energy dissipation resulting from hysteretic behavior can be measured as the area enclosed by the force-deformation curve of the structure as it experiences several cycles of excitation. Some structures have far more energy dissipation capacity than others. The extent of energy dissipation capacity available depends largely on the amount of stiffness and strength degradation the structure undergoes as it experiences repeated cycles of inelastic deformation. Figure C12.1-2 shows representative load deformation curves for two simple substructures such as a

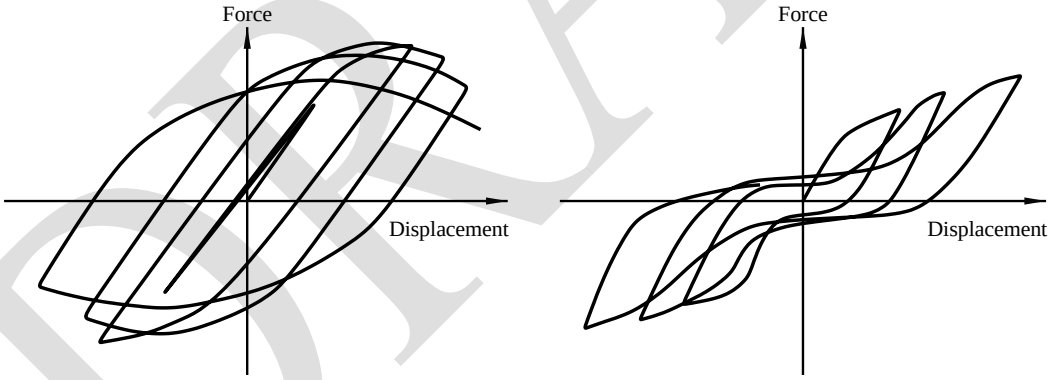
beam-column assembly in a frame. Hysteretic curve (a) in the figure is representative of the behavior of substructures that have been detailed for ductile behavior. The substructure can maintain nearly all of its strength and stiffness over several large cycles of inelastic deformation. The resulting force-deformation "loops" are quite wide and open, resulting in a large amount of energy dissipation. Hysteretic curve (b) represents the behavior of a substructure that has much less energy dissipation than that for the substructure (a) but has a greater change in response period. The structural response is determined by a combination of energy dissipation and period modification.

The principles of this section outline the conceptual intent behind the seismic design parameters used by the standard. However, these parameters are based largely on engineering judgment of the various materials and performance of structural systems in past earthquakes and cannot be directly computed using the relationships presented in Figure C12.1-1. The seismic design parameters chosen for a specific project or system should be chosen with care. For example, lower values should be used for structures possessing a low degree of redundancy wherein all the plastic hinges required for the formation of a mechanism may be formed essentially simultaneously and at a force level close to the specified design strength. This situation can result in considerably more detrimental *P*-delta effects. Since it is difficult for individual designers to judge the extent to which the value of *R* should be adjusted based on the inherent redundancy of their designs, Section 12.3.4 provides the redundancy factor, ρ, that is typically determined by being based on the removal of individual seismic-force-resisting elements.

Higher-order seismic analyses are permitted for any structure and are required for some structures (see Section 12.6); lower limits based on the equivalent lateral force procedure may, however, still apply.

C12.1.2 Member Design, Connection Design, and Deformation Limit

Given that key elements of the seismic-force-resisting system will likely yield in response to ground motions as discussed in Section C12.1.1, it might be expected that structural connections would be required to develop the strength of connected members. Although that is a logical procedure, it is not a general requirement. The actual requirement varies by system and generally is specified in the standards for design of the various structural materials cited by reference in Chapter 14. Good seismic design requires careful consideration of this issue.



a. Ductile hysteresis loops b. Pinched hysteresis loops

Figure C12.1- 2 Typical hysteretic curves.

C12.1.3 Continuous Load Path and Interconnection

In effect, Section 12.1.3 calls for the seismic design to be complete and in accordance with the principles of structural mechanics. The loads must be transferred rationally from their point of origin to the final point of resistance. This should be obvious, but it often is overlooked by those inexperienced in earthquake engineering. Design consideration should be given to potentially adverse effects where there is a lack of redundancy. Given the many unknowns and uncertainties in the magnitude and characteristics of earthquake loading, in the materials and systems of construction for resisting earthquake loadings and in the methods of analysis, good earthquake

DRAFT

engineering practice has been to provide as much redundancy as possible in the seismic-force-resisting system of buildings. Redundancy plays an important role in determining the ability of the building to resist earthquake forces. In a structural system without redundant elements, every element must remain operative to preserve the integrity of the building structure. On the other hand, in a highly redundant system, one or more redundant elements may fail and still leave a structural system that retains its integrity and can continue to resist lateral forces, albeit with diminished effectiveness.

While a redundancy requirement is included in Section 12.3.4, overall system redundancy can be improved by making all joints of the vertical load-carrying frame moment resisting and incorporating them into the seismic-force-resisting system. These multiple points of resistance can prevent a catastrophic collapse due to distress or failure of a member or joint. (The overstrength characteristics of this type of frame are discussed in Section C12.1.1.)

The minimum connection forces are not intended to be applied simultaneously to the entire seismic-force-resisting system.

C12.1.4 Connection to Supports

The requirement is similar to that given in Section 1.4 on connections to supports for general structural integrity. See Section C1.4.

C12.1.5 Foundation Design

Most foundation design criteria are still stated in terms of allowable stresses, and the forces computed in the standard are all based on the strength level of response. When developing strength-based criteria for foundations, all the factors cited in Section 12.1.5 require careful consideration. Section C12.13 provides specific guidance.

C12.1.6 Material Design and Detailing Requirements

The design limit state for resistance to an earthquake is unlike that for any other load within the scope of the standard. The earthquake limit state is based on overall system performance, not member performance, where repeated cycles of inelastic straining are accepted as an energy dissipating mechanism. Provisions that modify customary requirements for proportioning and detailing structural members and systems are provided to produce the desired performance.

C12.2 STRUCTURAL SYSTEM SELECTION

C12.2.1 Selection and Limitations

For the purpose of seismic analysis and design requirements, seismic-force-resisting systems are grouped into categories as shown in Table 12.2-1. These categories are subdivided further for various types of vertical elements used to resist seismic forces. In addition, the sections for detailing requirements are specified.

Specification of response modification coefficients, R, requires considerable judgment based on knowledge of actual earthquake performance as well as research studies. The coefficients and factors in Table 12.2-1 continue to be reviewed in light of recent research results. The values of R for the various systems were selected considering observed performance during past earthquakes, the toughness (ability to dissipate energy without serious degradation) of the system, and the amount of damping typically present in the system when it undergoes inelastic response. FEMA P-695 (Applied Technology Council, 2009) has been developed with the purpose of establishing and documenting a methodology for quantifying seismic force-resisting system performance and response parameters for use in seismic design. While R is a key parameter being addressed, related design parameters such as the overstrength factor, Ω_0, and the deflection amplification factor, C_d, also are addressed. Collectively, these terms are referred to as "seismic design coefficients (or factors)". Future systems will likely derive their seismic design coefficients (or factors) using this methodology and existing system coefficients (or factors) also may be reviewed in light of this new procedure.

Height limits have been specified in codes and standards for over 50 years. The structural system limitations and limits on structural height, h_n, specified in Table 12.2-1 evolved from these initial limitations and were further modified by the collective expert judgment of the NEHRP Provisions Update Committee (PUC) and the ATC-3 project team (the forerunners of the PUC). They have continued to evolve over the past 30 years based on observations and testing, but the specific values are based on subjective judgment.

DRAFT

In a bearing wall system, major load-carrying columns are omitted and the walls carry a major portion of the gravity (dead and live) loads. The walls supply in-plane lateral stiffness and strength to resist wind and earthquake loads as well as other lateral loads. In some cases, vertical trusses are employed to augment lateral stiffness. In general, lack of redundancy for support of vertical and horizontal loads causes values of R to be lower for this system compared to R values of other systems.

In a building frame system, gravity loads are carried primarily by a frame supported on columns rather than by bearing walls. Some portions of the gravity load may be carried on bearing walls, but the amount carried should represent a relatively small percentage of the floor or roof area. Lateral resistance is provided by shear walls or braced frames. Light-framed walls with shear panels are intended for use only with wood and steel building frames. Although gravity-load-resisting systems are not required to provide lateral resistance, most of them do. To the extent that the gravity-load-resisting system provides additional lateral resistance, it will enhance the building's seismic performance capability, so long as it is capable of resisting the resulting stresses and undergoing the associated deformations.

In a moment-resisting frame system, moment-resisting connections between the columns and beams provide lateral resistance. In Table 12.2-1, such frames are classified as ordinary, intermediate, or special. In high seismic design categories, the anticipated ground motions are expected to produce large inelastic demands so special moment frames designed and detailed for ductile response in accordance with Chapter 14 are required. In low seismic design categories, the inherent overstrength in typical structural designs is such that the anticipated inelastic demands are somewhat reduced, and less ductile systems may be employed safely. Since these less ductile ordinary framing systems do not possess as much toughness, lower values of R are specified.

The values for R, Ω_0, and C_d at the composite systems in Table 12.2-1 are similar to those for comparable systems of structural steel and reinforced concrete. Use of the tabulated values is allowed only when the design and detailing requirements in Section 14.3 are followed.

In a dual system, a three-dimensional space frame made up of columns and beams provides primary support for gravity loads. Primary lateral resistance is supplied by shear walls or braced frames, and secondary lateral resistance is provided by a moment frame complying with the requirements of Chapter 14.

Where a beam-column frame or slab-column frame lacks special detailing, it cannot act as an effective backup to a shear wall subsystem so there are no dual systems with ordinary moment frames. Instead, Table 12.2-1 permits the use of a shear wall-frame interactive system with ordinary reinforced concrete moment frames and ordinary reinforced concrete shear walls. Use of this defined system, which requires compliance with Section 12.2.5.8, offers a significant advantage over a simple combination of the two constituent ordinary reinforced concrete systems. Where those systems are simply combined, Section 12.2.3.3 would require use of seismic design parameters for an ordinary reinforced concrete moment frame.

In a cantilevered column system, stability of mass at the top is provided by one or more columns with base fixity acting as a single-degree-of-freedom system.

Cantilever column systems are essentially a special class of moment-resisting frame except that they do not possess the redundancy and overstrength that most moment-resisting frames derive from sequential formation of yield or plastic hinges. Where a typical moment-resisting frame must form multiple plastic hinges in members in order to develop a yield mechanism, a cantilever column system develops hinges only at the base of the columns to form a mechanism. As a result, their overstrength is limited to that provided by material overstrength and by design conservatism.

It is permitted to construct cantilever column structures using any of the systems that can be used to develop moment frames including ordinary and special steel; and ordinary, intermediate and special concrete; detailing systems as well as timber frames. The system limitations for cantilever column systems reflect the type of moment frame detailing provided but with a limit on structural height, h_n, of 35 feet.

The value of R for cantilever column systems is derived from moment-resisting frame values where R is divided by Ω_0 but is not taken as less than 1 or greater than 2 1/2. This accounts for the lack of sequential yielding in such systems. C_d is taken as equal to R, recognizing that damping is quite low in these systems and inelastic displacement of these systems will not be less than the elastic displacement.

DRAFT

C12.2.2 Combinations of Framing Systems in Different Directions

Different seismic force-resisting systems can be utilized along each of the two orthogonal axes of the structure as long as the respective values of R, Ω_0, and C_d are used. Depending on the combination selected, it is possible that one of the two systems will limit the extent of the overall system with regard to structural system limitations or structural height, h_n, and the more restrictive of these will govern.

C12.2.3 Combinations of Framing Systems in the Same Direction

The intent of the provision requiring use of the most stringent seismic design parameters (R, Ω_0 and C_d) is to prevent mixed seismic force-resisting systems that could concentrate inelastic behavior in the lower stories.

C12.2.3.1 R, Ω_0, and C_d Values for Vertical Combinations

This section expands upon Section 12.2.3 by specifying the requirements specific to the cases where (a) the value of R for the lower seismic force-resisting system is lower than for the upper system, and (b) the value of R for the upper seismic force-resisting system is lower than for the lower system.

The two cases are intended to account for all possibilities of vertical combinations of seismic force-resisting systems in the same direction. For a structure with a vertical combination of three or more seismic force-resisting systems in the same direction, Section 12.2.3.1 is required to be applied to the adjoining pairs of systems until the vertical combinations meet the requirements therein.

There are also exceptions to these requirements for conditions that do not affect the dynamic characteristics of the structure or that will not result in concentration of inelastic demand in critical areas.

C12.2.3.2 Two Stage Analysis Procedure

A two stage equivalent lateral force procedure is permitted where the lower portion of the structure has a minimum of 10 times the stiffness of the upper portion of the structure. In addition, the period of the entire structure is not permitted to be greater than 1.1 times the period of the upper portion considered as a separate structure supported at the transition from the upper to the lower portion. An example would be a concrete podium under a wood- or steel-framed upper portion of a structure. The upper portion may be analyzed for seismic forces and drifts using the values of R, Ω_o, and C_d for the upper portion as a separate structure. The seismic forces (e.g., shear and overturning) at the base of the upper portion are applied to the top of the lower portion and scaled up by the ratio of $(R/\rho)_{upper}$ to $(R/\rho)_{lower}$. The lower portion, which now includes the seismic forces from the upper portion, may then be analyzed using the values of R, Ω_o, and C_d for the lower portion of the structure.

C12.2.3.3 R, Ω_0, and C_d Values for Horizontal Combinations

For nearly all conditions, the least value of R of different seismic force-resisting systems in the same direction must be used in design. This requirement reflects the expectation that the entire system will undergo the same deformation with its behavior controlled by the least ductile system. However, for light-frame construction or flexible diaphragms meeting the listed conditions, the value of R for each independent line of resistance can be used. This exceptional condition is consistent with light-frame construction that utilizes the ground for parking with residential use above.

C12.2.4 Combination of Framing Detailing Requirements

This requirement is provided so that the seismic force-resisting system with the highest value of R has the necessary ductile detailing throughout. The intent is that details common to both systems be designed to remain functional throughout the response to earthquake load effects in order to preserve the integrity of the seismic force-resisting system.

C12.2.5 System Specific Requirements

C12.2.5.1 Dual System

The moment frame of a dual system must be capable of resisting at least 25 percent of the design seismic forces; this percentage is based on judgment. The purpose of the 25 percent frame is to provide a secondary seismic force-resisting system with higher degrees of redundancy and ductility in order to improve the ability of the building to support the service loads (or at least the effect of gravity loads) after strong earthquake shaking. The primary system (walls or bracing) acting together with the moment frame must be capable of resisting all of the design seismic forces. The following analyses are required for dual systems:

DRAFT

1. The moment frame and shear walls or braced frames must resist the design seismic forces considering fully the force and deformation interaction of the walls or braced frames and the moment frames as a single system. This analysis must be made in accordance with the principles of structural mechanics considering the relative rigidities of the elements and torsion in the system. Deformations imposed upon members of the moment frame by their interaction with the shear walls or braced frames must be considered in this analysis.
2. The moment frame must be designed with sufficient strength to resist at least 25 percent of the design seismic forces.

C12.2.5.2 Cantilever Column Systems

Cantilever column systems are singled out for special consideration because of their unique characteristics. These structures often have limited redundancy and overstrength and concentrate inelastic behavior at their bases. As a result, they have substantially less energy dissipation capacity than other systems. A number of apartment buildings incorporating this system experienced very severe damage and, in some cases, collapsed in the 1994 Northridge earthquake. Because the ductility of columns having large axial stress is limited, cantilever column systems may not be used where individual column axial demands from seismic load effects exceed 15 percent of their available axial strength, including slenderness effects.

Elements providing restraint at the base of cantilever columns must be designed for seismic load effects including overstrength so that the strength of the cantilever columns is developed.

C12.2.5.3 Inverted Pendulum-Type Structures

Inverted pendulum-type structures do not have a unique entry in Table 12.2-1 since they can be formed from many structural systems. Inverted pendulum-type structures have more than half of their mass concentrated near the top (producing one degree of freedom in horizontal translation) and rotational compatibility of the mass with the column (producing vertical accelerations acting in opposite directions). Dynamic response amplifies this rotation; hence, the bending moment induced at the top of the column can exceed that computed using the procedures of Section 12.8. The requirement to design for a top moment that is one-half of the base moment calculated in accordance with Section 12.8 is based on analyses of inverted pendulums covering a wide range of practical conditions.

C12.2.5.4 Increased Structural Height Limit for Steel Eccentrically Braced Frames, Steel Special Concentrically Braced Frames, Steel Buckling-restrained Braced Frames, Steel Special Plate Shear Walls and Special Reinforced Concrete Shear Walls

The first criterion for an increased limit on structural height, h_n, precludes extreme torsional irregularity since premature failure of one of the shear walls or braced frames could lead to excessive inelastic torsional response. The second criterion, which is similar to the redundancy requirements, is to limit the structural height of systems that are too strongly dependent on any single line of shear walls or braced frames. The inherent torsion resulting from the distance between the center of mass and the center of rigidity must be included, but accidental torsional effects are neglected for ease of implementation.

C12.2.5.5 Special Moment Frames in Structures Assigned to Seismic Design Categories D through F

Special moment frames, either alone or as part of a dual system, are required to be used in Seismic Design Categories D through F where the structural height, h_n, exceeds 160 feet (or 240 feet for buildings that meet the provisions of Section 12.2.5.4) as indicated in Table 12.2-1. In shorter buildings where special moment frames are not required to be used, the special moment frames may be discontinued and supported on less ductile systems as long as the requirements of Section 12.2.3 for framing system combinations are followed.

For the situation where special moment frames are required, they should be continuous to the foundation. In cases where the foundation is located below the building's base, provisions for discontinuing the moment frames can be made as long as the seismic forces are properly accounted for and transferred to the supporting structure.

C12.2.5.6 Steel Ordinary Moment Frames

Steel ordinary moment frames (OMFs) are less ductile than steel special moment frames; consequently, their use is prohibited in structures assigned to Seismic Design Categories D, E and F (see Table 12.2.-1). Structures with steel OMFs, however, have exhibited acceptable behavior in past earthquakes where the structures were sufficiently limited in their structural height, number of stories and seismic mass. The provisions in the standard reflect these observations. The exception is discussed separately (below). Table C12.2.5.6-C12.2.5.7 summarizes the provisions.

DRAFT

C12.2.5.6.1 Seismic Design Category D or E

Single-story steel OMFs are permitted, provided (a) the structural height, h_n, is a maximum of 65 ft (20 m), (b) the dead load supported by and tributary to the roof is a maximum of 20 psf (0.96 kN/m^2), and (c) the dead load of the exterior walls more than 35 ft (10.6 m) above the seismic base tributary to the moment frames is a maximum of 20 psf (0.96 kN/m^2).

In structures of light-frame construction, multistory steel OMFs are permitted, provided (a) the structural height, h_n, is a maximum of 35 ft (10.6 m), (b) the dead load of the roof and each floor above the seismic base supported by and tributary to the moment frames are each a maximum of 35 psf (1.68 kN/m^2), and (c) the dead load of the exterior walls tributary to the moment frames is a maximum of 20 psf (0.96 kN/m^2).

Exception: Recognizing that industrial structures, such as aircraft maintenance hangars and assembly buildings, with steel OMFs have performed well in past earthquakes with strong ground motions (EQE 1983, 1985, 1986a, 1986b, 1986c and 1987), the exception permits single-story steel OMFs to be unlimited in height provided: (a) the structure is limited to the enclosure of equipment or machinery, (b) its occupants are limited to maintaining and monitoring the equipment, machinery and their associated processes, (c) the sum of the dead load and equipment loads supported by and tributary to the roof is a maximum of 20 psf (0.96 kN/m^2), and (d) the dead load of the exterior wall system including exterior columns more than 35 ft (10.6 m) above the seismic base is a maximum of 20 psf (0.96 kN/m^2). Though the latter two load limits (items c and d) are similar to those described in Section C12.2.5.6.1, there are meaningful differences.

The exception further recognizes that these facilities often require large equipment or machinery, and associated systems, not supported by or considered tributary to the roof, that support the intended operational functions of the structure, such as top running bridge cranes, jib cranes, and liquid storage containment and distribution systems; to list a few. To limit the seismic interaction between the seismic force-resisting systems and these components, the exception requires the weight of equipment or machinery that is not self-supporting (i.e., not freestanding) for all loads (i.e., dead, live, seismic, etc.) to be included when determining compliance with the roof or exterior wall load limits. This *equivalent* equipment load shall be in addition to the loads listed above.

To determine the equivalent equipment load, the exception requires the weight to be considered fully (100%) tributary to an area not exceeding 600 ft^2 (55.8 m^2). This limiting area can be taken either to an adjacent exterior wall for cases where the weight is supported by an exterior column (which may also span to the first interior column) or to the adjacent roof for cases where the weight is supported entirely by an interior column or columns, but not both; nor can a fraction of the weight be allocated to each zone. Equipment loads within overlapping tributary areas should be combined in the same limiting area. Other provisions in the standard as well as past editions, require satisfying wall load limits tributary to the moment frame, but this requirement is not included in the exception in that it is based on a component-level approach that does not consider the interaction between systems in the structure. As such, the limiting area is considered to be a reasonable approximation of the tributary area of a moment frame segment for the purpose of this conversion. While this weight allocation procedure may not represent an accurate physical distribution, it is considered to be a reasonable method for verifying compliance with the specified load limits in order to limit seismic interactions. The engineer must still be attentive to actual mass distributions when computing seismic loads. Further information is discussed in C11.1.3.

C12.2.5.6.2 Seismic Design Category F

Single-story steel OMFs are permitted, provided they meet Conditions (a) and (b) described in Section C12.2.5.6.1 above for single-story frames, and (c) the dead load of the exterior walls tributary to the moment frames is a maximum of 20 psf (0.96 kN/m^2).

C12.2.5.7 Steel Intermediate Moment Frames

Steel intermediate moment frames (IMFs) are more ductile than steel ordinary moment frames (OMFs) but less ductile than steel special moment frames; consequently, restrictions are placed on their use in structures assigned to Seismic Design Category D and their use is prohibited in structures assigned to Seismic Design Categories E and F (see Table 12.2-1). As with steel OMFs, steel IMFs have also exhibited acceptable behavior in past earthquakes where the structures were sufficiently limited in their structural height, number of stories and seismic mass. The provisions in the standard reflect these observations. The exceptions are discussed separately (below). Table C12.2.5.6-C12.2.5.7 summarizes the provisions.

DRAFT

C12.2.5.7.1 Seismic Design Category D

Single-story steel IMFs are permitted without limitations on dead load of the roof and exterior walls, provided the structural height, h_n, is a maximum of 35 ft (10.6 m). An increase to 65 ft (20 m) is permitted for h_n, provided (a) the dead load supported by and tributary to the roof is a maximum of 20 psf (0.96 kN/m^2), and (b) the dead load of the exterior walls more than 35 ft (10.6 m) above the seismic base tributary to the moment frames is a maximum of 20 psf (0.96 kN/m^2).

The exception permits single-story steel IMFs to be unlimited in height, provided they meet all of the conditions described in the Exception to Section C12.2.5.6.1 above for the same structures.

C12.2.5.7.2 Seismic Design Category E

Single-story steel IMFs are permitted, provided they meet all of the conditions described in Section C12.2.5.6.1 above for single-story OMFs.

The exception permits single-story steel IMFs to be unlimited in height, provided they meet all of the conditions described in Section C12.2.5.6.1 above for the same structures.

Multistory steel IMFs are permitted, provided they meet all of the conditions described in Section C12.2.5.6.1 above for multistory OMFs, except the structure is not required to be of light-frame construction.

C12.2.5.7.3 Seismic Design Category F.

Single-story steel IMFs are permitted, provided (a) the structural height, h_n, is a maximum of 65 ft (20 m), (b) the dead load supported by and tributary to the roof is a maximum of 20 psf (0.96 kN/m^2), and (c) the dead load of the exterior walls tributary to the moment frames is a maximum of 20 psf (0.96 kN/m^2).

Multistory steel IMFs are permitted, provided they meet all of the conditions described in the Exception to Section C12.2.5.6.1 above for multistory OMFs in structures of light-frame construction.

DRAFT

Table C12.2.5.6-C12.2.5.7 Summary of Conditions for OMFs and IMFs in Structures assigned to Seismic Design Category D, E or F (refer to the standard for additional requirements)

Section	Frame	SDC	Max. Number Stories	Light-Frame Construction	Max. h_n	Max. roof/floor DL (psf)	Exterior Wall DL	
							Max. (psf)	Wall[(1)] Height (ft)

1. Applies to portion of wall above listed wall height.
"NL" means "No Limit;" "NA" means "Not Applicable"

C12.2.5.8 Shear Wall-Frame Interactive Systems

For structures assigned to Seismic Design Category A or B (where seismic hazard is low), it is usual practice to design shear walls and frames of a shear wall-frame structure to resist lateral forces in proportion to their relative rigidities, considering interaction between the two subsystems at all levels. As discussed in Section C12.2.1, this typical approach would require use of a lower response modification coefficient, *R*, than that defined for shear wall-frame interactive systems. Where the special requirements of this section are satisfied, more reliable performance is expected, justifying a higher value of *R* .

C12.3 DIAPHRAGM FLEXIBILITY, CONFIGURATION IRREGULARITIES, AND REDUNDANCY

C12.3.1 Diaphragm Flexibility

Most seismic-force-resisting systems have two distinct parts: the horizontal system that distributes lateral forces to the vertical elements and the vertical system that transmits lateral forces between the floor levels and the base of the structure.

The horizontal system may consist of diaphragms or a horizontal bracing system. For the majority of buildings, diaphragms offer the most economical and positive method of resisting and distributing seismic forces in the horizontal plane. Typically, diaphragms consist of metal deck (with or without concrete), concrete slabs, and wood sheathing/decking. While most diaphragms are flat, consisting of the floors of buildings, they also may be inclined, curved, warped, or folded configurations, and most diaphragms have openings.

The diaphragm stiffness relative to the stiffness of the supporting vertical seismic-force-resisting system ranges from flexible to rigid and is important to define. Provisions defining diaphragm flexibility are given in Sections 12.3.1.1 through 12.3.1.3. If a diaphragm cannot be idealized as either flexible or rigid, explicit consideration of its stiffness must be included in the analysis.

DRAFT

The diaphragms in most buildings braced by wood light-frame shear walls are semi-rigid. Because semi-rigid diaphragm modeling is beyond the capability of available software for wood light-frame buildings, it is anticipated that this requirement will be met by evaluating force distribution using both rigid and flexible diaphragm models and taking the worse case of the two. While this is in conflict with common design practice, which typically includes only flexible diaphragm force distribution for wood light-frame buildings, it is one method of capturing the effect of the diaphragm stiffness.

C12.3.1.1 Flexible Diaphragm Condition

Section 12.3.1.1 defines broad categories of diaphragms that may be idealized as flexible regardless of whether the diaphragm meets the calculated conditions of Section 12.3.1.3. These include:

a. Construction with relatively stiff vertical framing elements such as steel braced frames and concrete or masonry shear walls;

b. One-and two-family dwellings; and

c. Light-frame construction (e.g., construction consisting of light-frame walls and diaphragms) with or without nonstructural toppings of limited stiffness.

For Item c above, compliance with story drift limits along each line of shear walls is intended as an indicator that the shear walls are substantial enough to share load on a tributary area basis and not require torsional force redistribution.

C12.3.1.2 Rigid Diaphragm Condition

Span-to-depth ratio limits are included in the deemed-to-comply condition as an indirect measure of the flexural contribution to diaphragm stiffness.

C12.3.1.3 Calculated Flexible Diaphragm Condition

A diaphragm is permitted to be idealized as flexible if the calculated diaphragm deflection (typically at mid span) between supports (lines of vertical elements) is greater than two times the average story drift of the vertical lateral-force-resisting elements located at the supports of the diaphragm span.

C12.3.2 Irregular and Regular Classification

The configuration of a structure can significantly affect its performance during a strong earthquake producing the ground motion contemplated in the standard. Structural configuration can be divided into two aspects: horizontal and vertical. Most seismic design provisions were derived for buildings having regular configurations, but earthquakes have shown repeatedly that buildings having irregular configurations suffer greater damage. This situation prevails even with good design and construction.

There are several reasons for the poor behavior of irregular structures. In a regular structure, the inelastic response, including energy dissipation and damage, produced by strong ground shaking tends to be well distributed throughout the structure. However, in irregular structures, inelastic behavior can be concentrated by irregularities and result in rapid failure of structural elements in these areas. In addition, some irregularities introduce unanticipated demands into the structure, which designers frequently overlook when detailing the structural system. Finally, the elastic analysis methods typically employed in the design of structures often cannot predict the distribution of earthquake demands in an irregular structure very well, leading to inadequate design in the areas associated with the irregularity. For these reasons, the standard encourages regular structural configurations and prohibits gross irregularity in buildings located on sites close to major active faults where very strong ground motion and extreme inelastic demands are anticipated. Note that the termination of seismic force resisting elements at the foundation is not considered to be a discontinuity.

C12.3.2.1 Horizontal Irregularity

A building may have a symmetric geometric shape without re-entrant corners or wings but still be classified as irregular in plan because of its distribution of mass or vertical seismic-force-resisting elements. Torsional effects in earthquakes can occur even where the centers of mass and rigidity coincide. For example, ground motion waves acting on a skew with respect to the building axis can cause torsion. Cracking or yielding in an asymmetric fashion also can cause torsion. These effects also can magnify the torsion due to eccentricity between the centers of mass and rigidity. Torsional structural irregularities (Types 1a and 1b) are defined to address this concern.

A square or rectangular building with minor re-entrant corners would still be considered regular, but large re-entrant corners creating a crucifix form would produce an irregular structural configuration (Type 2). The response of the

DRAFT

wings of this type of building generally differs from the response of the building as a whole, and this produces higher local forces than would be determined by application of the standard without modification. Other winged plan configurations (e.g., H-shapes) are classified as irregular even if symmetric due to the response of the wings.

Significant differences in stiffness between portions of a diaphragm at a level are classified as Type 3 structural irregularities since they may cause a change in the distribution of seismic forces to the vertical components and create torsional forces not accounted for in the distribution normally considered for a regular building.

Where there are discontinuities in the path of lateral force resistance, the structure cannot be considered to be regular. The most critical discontinuity defined is the out-of-plane offset of vertical elements of the seismic-force-resisting system (Type 4). Such offsets impose vertical and lateral load effects on horizontal elements that are difficult to provide for adequately.

Where vertical lateral-force-resisting elements are not parallel to the major orthogonal axes of the seismic force-resisting system, the equivalent lateral force procedure of the standard cannot be applied appropriately so the structure is considered to have an irregular structural configuration (Type 5).

Figure C12.3-1 illustrates horizontal structural irregularities.

DRAFT

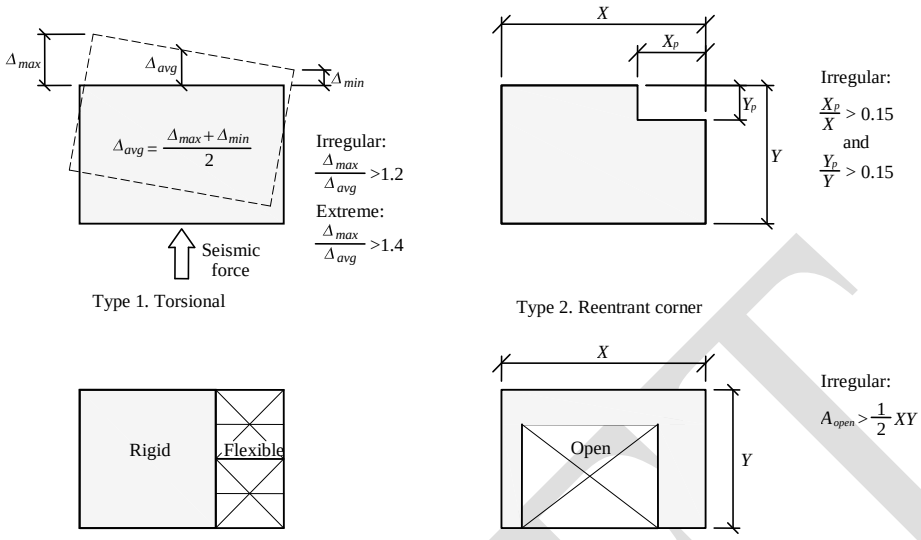

Figure C12.3-1 Horizontal structural irregularity examples.

C12.3.2.2 Vertical Irregularity

Vertical irregularities in structural configuration affect the responses at the various levels and induce loads at these levels that differ significantly from the distribution assumed in the equivalent lateral force procedure given in Section 12.8.

A moment-resisting frame building might be classified as having a soft story irregularity (Type 1a or 1b) if one story is much taller than the adjoining stories and the design did not compensate for the resulting decrease in stiffness that normally would occur.

A building is classified as having a weight (mass) irregularity (Type 2) where the ratio of mass to stiffness in adjacent stories differs significantly. This typically occurs where a heavy mass (e.g., an interstitial mechanical floor) is placed at one level.

A vertical geometric irregularity (Type 3) applies regardless of whether the larger dimension is above or below the smaller one.

Vertical lateral-force-resisting elements at adjoining stories that are offset from each other in the vertical plane of the elements and impose overturning demands on supporting structural elements such as beams, columns, trusses, walls or slabs are classified as in-plane-discontinuity irregularities (Type 4).

DRAFT

Buildings with a weak-story irregularity (Type 5a or 5b) tend to develop all of their inelastic behavior and consequent damage at the weak story, possibly leading to collapse.

Figure C12.3-2 illustrates examples of vertical structural irregularities.

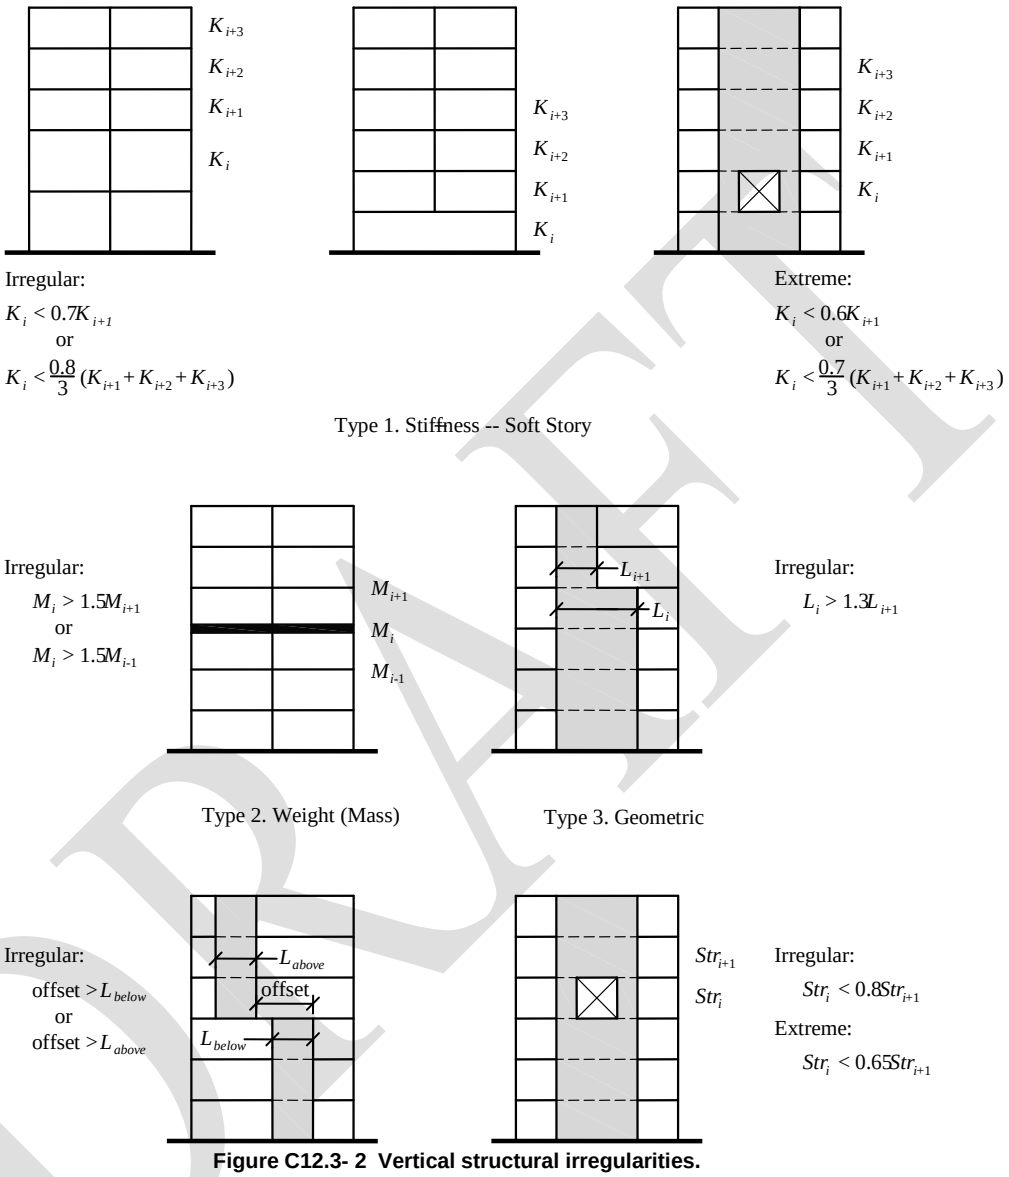

Figure C12.3- 2 Vertical structural irregularities.

C12.3.3 Limitations and Additional Requirements for Systems with Structural Irregularities

C12.3.3.1 Prohibited Horizontal and Vertical Irregularities in Seismic Design Categories D through F

The prohibitions and limits due to structural irregularities in this section stem from poor performance in past earthquakes and the potential to concentrate large inelastic demands in certain portions of the structure. Even where such irregularities are permitted, they should be avoided whenever possible in all structures.

C12.3.3.2 Extreme Weak Stories

Since extreme weak story irregularities are prohibited in Section 12.3.3.1 for buildings located in Seismic Design Categories D, E and F, the limitations and exceptions in this section apply only to buildings assigned to Seismic Design Category B or C. Weak stories of structures assigned to Seismic Design Category B or C that are designed

DRAFT

for seismic forces amplified by the overstrength factor, Ω_0, are exempted because reliable inelastic response is expected.

C12.3.3.3 Elements Supporting Discontinuous Walls or Frames

The purpose of requiring elements (e.g., beams, columns, trusses, slabs, walls, etc) that support discontinuous walls or frames to be designed to resist seismic load effects including overstrength factor is to protect the gravity load-carrying system against possible overloads caused by overstrength of the seismic force-resisting system. Either columns or beams may be subject to such failure, therefore, both should include this design requirement. Beams may be subject to failure due to overloads in either the downward or upward directions of force. Examples include reinforced concrete beams, the weaker top laminations of glued laminated beams, or unbraced flanges of steel beams or trusses. Hence, the provision has not been limited simply to downward force, but instead to the larger context of "vertical load." Additionally, walls that support isolated point loads from frame columns or discontinuous perpendicular walls or walls with significant vertical offsets, as shown in Figures C12.3.3-1 through C12.3.3-2, can be subject to the same type of failure due to overload.

The connection between the discontinuous element and the supporting member must be adequate to transmit the forces required for the design of the discontinuous element. For example, where the discontinuous element is required to comply with the seismic load effects including overstrength factor in Section 12.4.3, as is the case for a steel column in a braced frame or a moment frame, its connection to the supporting member is required to be designed to transmit the same forces. These same seismic load effects are not required for shear walls and, as such, the connection between the shear wall and the supporting member would only need to be designed to transmit the loads associated with the shear wall.

For wood light-frame shear wall construction, the final sentence of Section 12.3.3.3 results in the shear and overturning connections at the base of a discontinued shear wall (i.e. shear fasteners and tie-downs) being designed using the load combinations of Section 2.3 or 2.4 rather than the load combinations with overstrength factor of Section 12.4.3(See Figure C12.3-5). The intent of the first sentence of Section 12.3.3.3 is to protect the system providing resistance to forces transferred from the shear wall by designing the system for amplified seismic load effects; strengthening of the shear wall anchorage to this system is not required in order to meet this intent.

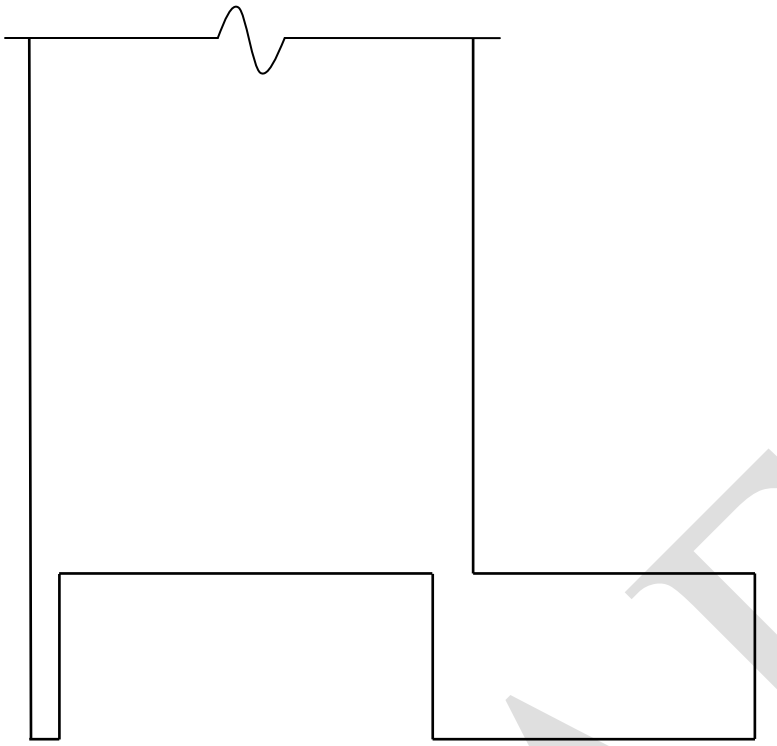

Figure C12.3-4: Vertical in-plane-discontinuity irregularity from walls with significant offsets(Type 4)

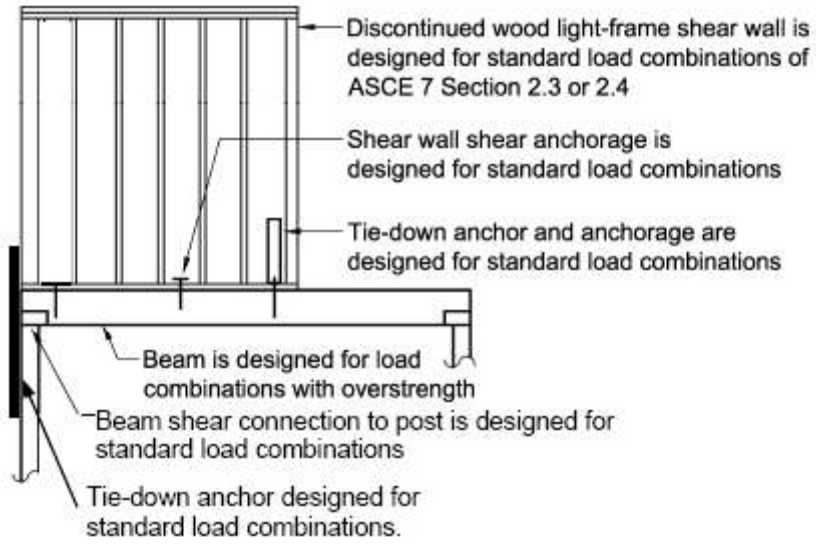

Figure C12.3- 5 Discontinued Wood Light-Frame Shear Wall

C12.3.3.4 Increase in Forces Due to Irregularities for Seismic Design Categories D through F

The listed irregularities may result in loads that are distributed differently than assumed in the equivalent lateral force procedure of Section 12.8, especially as related to the interconnection of the diaphragm with vertical elements of the seismic-force-resisting system. The 25 percent increase in force is intended to account for this difference. Where the force is calculated using the seismic load effects including overstrength factor, no further increase is warranted.

C12.3.4 Redundancy

The standard introduces a revised redundancy factor, ρ, for structures assigned to Seismic Design Category D, E, or F to quantify redundancy. The value of this factor is either 1.0 or 1.3. This factor has the effect of reducing the response modification coefficient, R, for less redundant structures, thereby increasing the seismic demand. The factor is specified in recognition of the need to address the issue of redundancy in the design.

The desirability of redundancy, or multiple lateral-force-resisting load paths, has long been recognized. The redundancy provisions of this section reflect the belief that an excessive loss of story shear strength or development of an extreme torsional irregularity (Type 1b) may lead to structural failure. The value of ρ determined for each direction may differ.

C12.3.4.1 Conditions Where Value of ρ is 1.0

This section provides a convenient list of conditions where ρ is 1.0.

C12.3.4.2 Redundancy Factor, ρ, for Seismic Design Category D through F

There are two approaches to establishing a redundancy factor, ρ, of 1.0. Where neither condition is satisfied, ρ is taken equal to 1.3. It is permitted to take ρ equal to 1.3 without checking either condition. A reduction in the value of ρ from 1.3 is not permitted for structures assigned to Seismic Design Category D that have an extreme torsional irregularity (Type 1b). Seismic Design Categories E and F are not also specified because extreme torsional irregularities are prohibited (see Section 12.3.3.1).

The first approach is a check of the elements outlined in Table 12.3-3 for cases where the seismic design story shear exceeds 35 percent of the base shear. Parametric studies (conducted by Building Seismic Safety Council Technical Subcommittee 2 but unpublished) were used to select the 35 percent value. Those studies indicated that stories with story shears of at least 35 percent of the base shear include all stories of low-rise buildings (buildings up to 5 to 6 stories) and about 87 percent of the stories of tall buildings. The intent of this limit is to exclude penthouses of most buildings and the uppermost stories of tall buildings from the redundancy requirements.

This approach requires the removal (or loss of moment resistance) of an individual lateral-force-resisting element to determine its effect on the remaining structure. If the removal of elements, one-by-one, does not result in more than a 33 percent reduction in story strength or an extreme torsional irregularity, ρ may be taken as 1.0. For this evaluation, the determination of story strength requires an in-depth calculation. The intent of the check is to use a simple measure (elastic or plastic) to determine whether an individual member has a significant effect on the overall system. If the original structure has an extreme torsional irregularity to begin with, the resulting ρ is 1.3. Figure C12.3-5 presents a flowchart for implementing the redundancy requirements.

As indicated in the table, braced frame, moment frame, shear wall, and cantilever column systems must conform to redundancy requirements. Dual systems also are included but, in most cases, are inherently redundant. Shear walls or wall piers with a height-to-length aspect ratio greater than 1.0 within any story have been included; however, the required design of collector elements and their connections for Ω_0 times the design force may address the key issues. In order to satisfy the collector force requirements, a reasonable number of shear walls usually is required. Regardless, shear wall systems are addressed in this section so that either an adequate number of wall elements is included or the proper redundancy factor is applied. For wall piers, the height is taken as the height of the adjacent opening and generally is less than the story height.

The second approach is a deemed-to-comply condition wherein the structure is regular and has a specified arrangement of seismic-force-resisting elements to qualify for ρ of 1.0. As part of the parametric study, simplified braced frame and moment frame systems were investigated to determine their sensitivity to the analytical redundancy criteria. This simple deemed-to-comply condition is consistent with the results of the study.

DRAFT

C12.4 SEISMIC LOAD EFFECTS AND COMBINATIONS

C12.4.1 Applicability

Structural elements designated by the engineer as part of the seismic-force-resisting system typically are designed directly for seismic load effects. None of the seismic forces associated with the design base shear are formally assigned to structural elements that are not designated as part of the seismic-force-resisting system, but such elements must be designed using the load conditions of Section 12.4 and must accommodate the deformations resulting from application of seismic loads.

C12.4.2 Seismic Load Effect

Section 12.4 presents the required combinations of seismic forces with other loads. The load combinations are taken from the basic load combinations of Chapter 2 of the standard with further elaboration of the seismic load effect, *E*. The seismic load effect includes horizontal and vertical components. The horizontal seismic loads effects, E_h, are caused by the response of the structure to horizontal seismic ground motions, while the vertical seismic load effects are caused by the response of the structure to vertical seismic ground motions. The basic load combinations in Chapter 2 were duplicated and reformulated in Section 12.4 to clarify the intent of the provisions for the vertical seismic load effect term E_v.

The concept of using an equivalent static load coefficient applied to the dead load to represent vertical seismic load effects was first introduced in ATC 3-06, where it was defined as simply +/- 0.2 D. The load combinations where the vertical seismic load coefficient was to be applied assumed strength design load combinations. Neither ATC 3-06 nor in the early versions of the NEHRP Provisions clearly explained how the values of 0.2 were determined but it is reasonable to assume that it was based on the judgment of the writers of those documents. It is accepted by the writers of this standard that vertical ground motions do occur and the value of $+/- 0.2S_{DS}$ was determined based on consensus judgment. Many issues enter into the development of the vertical coefficient including phasing of vertical ground motion, appropriate R factors, etc. that make determination of a more precise value difficult. Although no specific rationale or logic is provided in editions of the NEHRP Provisions on how the value of $0.2S_{DS}$ was determined, one possible way to rationalize the selection of the $0.2S_{DS}$ value is to recognize it is equivalent to (2/3) (0.3) S_{DS}, where the 2/3 factor represents the often-assumed ratio between the vertical and horizontal components of motion, and the 0.3 factor represents the 30% in the 100%-30% orthogonal load combination rule used for horizontal motions.

While details regarding defining vertical ground motion spectra are currently well known, the committee elected not to define a vertical ground motion spectra in this standard because the approach provided by the equivalent static coefficient $0.2S_{DS}$ is adequate. For situations where one wishes to explicitly include the vertical component of ground motion in design analysis, one may utilize the vertical ground motion spectra definition that is provided in the "New Chapter 23, Vertical Ground Motions for Seismic Design" in the 2009 edition of the NEHRP Recommended Seismic Provisions

C12.4.2.1 Horizontal Seismic Load Effect

Horizontal seismic load effects, E_h, are determined in accordance with Equation 12.4-3 as $E_h = \rho Q_E$. Q_E is the seismic load effect of horizontal seismic forces from *V* or F_p. The purpose for E_h is to approximate the horizontal seismic load effect from the design basis earthquake to be used in load combinations including *E*, for the design of lateral force-resisting elements including diaphragms, vertical elements of seismic force-resisting systems as defined in Table 12.2-1, the design and anchorage of elements such as structural walls and the design of nonstructural components.

C12.4.2.2 Vertical Seismic Load Effect

The vertical seismic load effect, E_v, is determined with Equation 12.4-4 as $E_v = 0.2 S_{DS} D$. E_v is permitted to be taken as zero in Equations 12.4-1, 12.4-2, 12.4-5 and 12.4-6 if S_{DS} is equal to or less than 0.125 and in Equation 12.4-2 for determining demands on the soil structure interface of foundations. E_v increases the load on beams and columns supporting seismic elements and increases the axial load in the P-M interaction of walls resisting seismic load effects.

C12.4.2.3 Seismic Load Combinations

The seismic load effect, *E*, is combined with the effects of other loads as set forth in Chapter 2 of the standard. For strength design, the load combinations in Section 2.3.2 that include *E* are modified in Section 12.4.2.3 to include the horizontal and vertical seismic load effects of Sections 12.4.2.1 and 12.4.2.2, respectively. Similarly, the basic load

DRAFT

combinations for allowable stress design in Section 2.4.1 that include E are also modified in Section 12.4.2.3 to include the same seismic load effects.

For structures subject to the effects of flood loads or ice loads, Chapter 2 of the standard requires the consideration of additional load combinations and should be consulted to determine which combinations include *E*.

C12.4.3 Seismic Load Effect Including Overstrength Factor

Some elements of properly detailed structures are not capable of safely resisting ground-shaking demands through inelastic behavior. To ensure safety, these elements must be designed with sufficient strength to remain elastic. The overstrength factor, Ω_0, approximates the inherent overstrength in typical structures having different seismic force-resisting systems.

C12.4.3.1 Horizontal Seismic Load Effects With Overstrength Factor

Horizontal seismic load effects with overstrength factor, E_{mh}, are determined in accordance with Equation 12.4-7 as $E_{mh} = \Omega_o Q_E$. Q_E is the effect of horizontal seismic forces from V, F_{px} or F_p. The purpose for E_{mh} is to approximate the maximum seismic load for the design of critical elements including discontinuous systems, transfer beams and columns supporting discontinuous systems, and collectors.

Exception: Seismic load effects, *E*, multiplied by Ω_0, are an approximation of the maximum force these elements are ever likely to experience. The standard permits the seismic load effects including overstrength factor to be taken as less than the amount computed by applying Ω_0 to the design seismic forces where it can be determined that yielding of other elements in the structure will limit the amount of load that can be delivered to the element and, therefore, the amount of force that can develop in the element.

As an example, the axial load in a column of a moment-resisting frame will result from the shear forces in the beams that connect to this column. The axial loads due to seismic load effects need never be taken as greater than the sum of the shears in these beams at the development of a full structural mechanism, considering the probable strength of the materials and strain-hardening effects. For frames controlled by beam hinge-type mechanisms this would typically be $2\ M_{pb} / L$ for steel frames where M_{pb} is the nominal plastic flexural strength of the beam as defined in AISC 341-10, and M_{pr} / l_n for concrete frames where M_{pr} is the probable flexural strength of the beam and l_n is the clear span length as defined in ACI 318-08.

In this context, the capacity of the element is its expected or median anticipated strength considering potential variation in material yield strength and strain-hardening effects. When calculating the capacity of elements for this purpose, material strengths should not be reduced by strength reduction or resistance factors, ϕ.

C12.4.3.2 Load Combinations With Overstrength Factor

The seismic load effect including overstrength factor, E_m, is combined with other loads as set forth in Chapter 2 using the load combinations as set forth in Section 12.4.3.2. The purpose for load combinations with overstrength factor is to approximate the maximum seismic load combination for the design of critical elements including discontinuous systems, transfer beams and columns supporting discontinuous systems, and collectors.

C12.4.3.3 Allowable Stress Increase for Load Combinations With Overstrength

The allowable stress increase for load combinations with overstrength is to provide compatibility with past practice.

C12.4.4 Minimum Upward Force for Horizontal Cantilevers for Seismic Design Categories D through F

In Seismic Design Categories D, E, and F, horizontal cantilevers are designed for an upward force that results from an effective vertical acceleration of 1.2 times gravity. This is to provide some minimum strength in the upward direction and to account for possible dynamic amplification of vertical ground motions resulting from the vertical flexibility of the cantilever. The requirement is not applied to downward forces on cantilevers, for which the typical load combinations are used.

C12.5 DIRECTION OF LOADING

Seismic forces are delivered to a building through ground accelerations that may approach from any direction relative to the orthogonal directions of the building; therefore, seismic effects are expected to develop in both directions simultaneously. The standard requires structures to be designed for the most critical loading effects from seismic forces applied in any direction. The procedures outlined in this section are deemed to satisfy this requirement.

DRAFT

For horizontal structural elements such as beams and slabs, orthogonal effects may be minimal; however, design of vertical elements of the seismic-force-resisting system that participate in both orthogonal directionswill likely be governed by these effects.

C12.5.1 Direction of Loading Criteria

For structures with orthogonal seismic force-resisting systems, the most critical load effects can typically be computed using a pair of orthogonal directions that coincide with the principal axes of the structure. Structures with nonparallel or nonorthogonal systems may require a set of orthogonal direction pairs to determine the most critical load effects. If a three-dimensional mathematical model is used, the analyst must be attentive to the orientation of the global axes in the model in relation to the principal axes of the structure.

C12.5.2 Seismic Design Category B

Recognizing that design of structures assigned to Seismic Design Category (SDC) B is often controlled by nonseismic load effects and, therefore, will not be sensitive to orthogonal loadings regardless of any horizontal structural irregularities, it is permitted to determine the most critical load effects by considering that the maximum response can occur in any single direction; simultaneous application of response in the orthogonal direction is not required. Typically, the two directions used for analysis will coincide with the principle axes of the structure.

C12.5.3 Seismic Design Category C

Design of structures assigned to SDC C often parallels the design of structures assigned to SDC B and, therefore, as a minimum conforms to Section 12.5.2. While it is not likely that design of the seismic force-resisting systems in regular structures assigned to SDC C will be sensitive to orthogonal loadings, special consideration must be given to structures with nonparallel or nonorthogonal systems (Type 5 horizontal structural irregularity) to avoid overstressing by different directional loadings. In this case, the standard provides two methods to approximate simultaneous orthogonal loadings, and requires a three-dimensional mathematical model of the structure for analysis in accordance with Section 12.7.3.

The orthogonal combination procedure in Item (a) of Section 12.5.3 combines the effects from 100 percent of the seismic load applied in one direction with 30 percent of the seismic load applied in the perpendicular direction. This general approximation – the "30% rule" – was introduced by Rosenblueth and Contreras (1977) based on earlier work by A.S. Veletsos and also N.M. Newmark (cited in Rosenblueth and Contreras), as an alternative to performing the more rational, yet computationally demanding, response history analysis, and is applicable to any elastic structure. Combining effects for seismic loads in each direction and accidental torsion in accordance with Sections 12.8.4.2 and 12.8.4.3 results in 16 load combinations:

Orthogonal load combinations

$Q_E = +/- Q_{E_X+AT} +/- 0.3Q_{E_Y}$

$Q_E = +/- Q_{E_X-AT} +/- 0.3Q_{E_Y}$

$Q_E = +/- Q_{E_Y+AT} +/- 0.3Q_{E_X}$

$Q_E = +/- Q_{E_Y-AT} +/- 0.3Q_{E_X}$

where :

Q_{E_Y} = effect of Y-direction load at the center of mass (Section 12.8.4.2)

Q_{E_X} = effect of X-direction load at the center of mass (Section 12.8.4.2)

AT = accidental torsion computed in accordance with Sections 12.8.4.2 and 12.8.4.3

Though the standard permits combining effects from forces applied independently in any pair of orthogonal directions (to approximate the effects of concurrent loading), accidental torsion need not be considered in the direction that produces the lesser effect per Section 12.8.4.2. This provision is sometimes disregarded when using a mathematical model for three-dimensional analysis that can automatically include accidental torsion, which then results in 32 load combinations.

The maximum effect of seismic forces, Q_E, from orthogonal load combinations is modified by the redundancy factor, ρ, or the overstrength factor, Ω_0, where required, and the effects of vertical seismic forces, E_V, are considered in accordance with Section 12.4, to obtain the seismic load effect, E.

DRAFT

These orthogonal combinations should not be confused with uniaxial modal combination rules such as the square root of the sum of the squares (SRSS) or complete quadratic combination (CQC) method. In past standards, an acceptable alternative to the above was to use the SRSS method to combine effects of the two orthogonal directions, where each term computed is assigned the sign that resulted in the most conservative result. This method is no longer in common use. While both approaches described for considering orthogonal effects are approximations, it is important to note that they were developed with consideration of results for a square building.

Orthogonal effects can alternatively be considered by performing three-dimensional response history analyses (see Chapter 16) with application of orthogonal ground motion pairs applied simultaneously in any two orthogonal directions. If the structure is located within 3 miles of an active fault, the ground motion pair should be rotated to the fault-normal and fault-parallel directions of the causative fault.

C12.5.4 Seismic Design Categories D through F

Direction of loading for structures assigned to SDC D, E or F conforms to Section 12.5.3 for structures assigned to SDC C. If a Type 5 horizontal structural irregularity exists then orthogonal effects are similarly included in design. Recognizing the higher seismic risk associated with structures assigned to SDC D, E or F, the standard provides additional requirements for vertical members coupled between intersecting seismic force-resisting systems.

C12.6 ANALYSIS SELECTION PROCEDURE

Table 12.6-1 provides the permitted analysis procedures for all seismic design categories. The table is applicable only to buildings without seismic isolation (Chapter 17) or passive energy devices (Chapter 18) for which there are additional requirements in Sections 17.4 and 18.2.4, respectively.

The four basic procedures provided in Table 12.6-1 are the equivalent lateral force (ELF, Section 12.8), the modal response spectrum (MRS, Section 12.9), the linear response history (LRH, Section 16.1) and the nonlinear response history (NRH, Section 16.2) analysis procedures. Nonlinear static pushover analysis is not provided as an "approved" analysis procedure in the standard.

The ELF procedure is allowed for all buildings assigned to Seismic Design Category B or C; and for all buildings assigned to Seismic Design Category D, E or F except for the following :

- Structures with structural height, h_n, > 160 ft (48.8 m) and $T > 3.5T_s$.
- Structures with structural height, h_n, > 160 ft (48.8 m) and $T \leq 3.5\ T_s$, but with one or more of the structural irregularities in Table 12.3.1 or 12.3-2.
- Structures with structural height, h_n, < 160 ft (48.8 m) and with one or more of the following structural irregularities: torsion or extreme torsion (Table 12.3-1); or soft story, extreme soft story, weight (mass), or vertical geometric (Table 12.3-2).

$T_s = S_{D1} / S_{DS}$ is the period at which the horizontal and descending parts of the design response spectrum intersect (Figure 11-4.1). The value of T_s will depend on the site class because S_{DS} and S_{D1} include such effects. Where the ELF procedure is not allowed, the analysis must be performed using modal response spectrum or response history analysis.

The use of the ELF procedure is limited to buildings with the listed structural irregularities because the procedure is based on an assumption of a gradually varying distribution of mass and stiffness along the height and negligible torsional response. The basis for the 3.5 T_s limitation is that the higher modes become more dominant in taller buildings (Lopez and Cruz 1996, Chopra 2007), and as a result, the ELF procedure may underestimate the seismic base shear and may not correctly predict the vertical distribution of seismic forces in taller buildings.

As Table C12.6-1 demonstrates, the value of 3.5 T_s generally increases as ground motion intensity increases and as soils become softer. Assuming a fundamental period of approximately 0.1 times the number of stories, the maximum structural height, h_n, for which the ELF procedure applies ranges from about 10 stories for low seismic hazard sites with firm soil to 30 stories for high seismic hazard sites with soft soil. Since this trend was not intended, the 160 ft height limit is introduced.

DRAFT

Table C12.6-1 Values of 3.5 T_s for Various Cities and Site Classes

Location	S_S (g)	S_1 (g)	3.5 T_s (seconds) for Site Class

C12.7 MODELING CRITERIA

C12.7.1 Foundation Modeling

Structural systems consist of three interacting subsystems: the structural framing (girders, columns, walls, diaphragms), the foundation (footings, piles, caissons), and the supporting soil. The ground motion that a structure experiences, as well as the response to that ground motion, depends on the complex interaction between these subsystems.

Those aspects of ground motion that are affected by site characteristics are assumed to be independent of the structure-foundation system as these effects would occur in the free-field in the absence of the structure. Hence, site effects are considered separately (Sections 11.4.2 through 11.4.4 and Chapters 20 and 21).

Given a site-specific ground motion or response spectrum, the dynamic response of the structure will depend on the foundation system and on the characteristics of the soil that support the system. The dependence of the response on the structure-foundation-soil system is referred to as soil-structure interaction. Such interactions will usually, but not always, result in a reduction of seismic base shear. This reduction is due to the flexibility of the foundation-soil system and an associated lengthening of the fundamental period of vibration of the structure. In addition, the soil system may provide an additional source of damping. However, that total displacement typically increases with soil-structure interaction.

If the foundation is considered to be rigid, the computed base shears usually will be conservative, and it is for this reason that rigid foundation analysis is permitted. The designer may neglect soil-structure interaction; or, may consider it explicitly in accordance with Section 12.13.3 or implicitly in accordance with Chapter 19.

As an example, consider a moment frame building without a basement and with moment-frame columns supported on footings designed to support shear and axial loads, i.e., pinned column bases. If foundation flexibility is not considered, the columns should be restrained horizontally and vertically, but not rotationally. Consider a moment-frame building with a basement. For this building, horizontal restraint may be provided at the level closest to grade, as long as the diaphragm is designed to transfer the shear out of the moment frame. Because the columns extend through the basement, they may also be restrained rotationally and vertically at this level. However, it is often preferable to extend the model through the basement and provide the vertical and rotational restraints at the foundation elements, which is more consistent with the actual building geometry.

C12.7.2 Effective Seismic Weight

During an earthquake, the structure accelerates laterally, and these accelerations of the structural mass produce inertial forces. These inertial forces, accumulated over the height of the structure, produce the seismic base shear.

When a building vibrates during an earthquake, only that portion of the mass or weight that is physically tied to the structure needs to be considered as effective. Hence, live loads (e.g., loose furniture, loose equipment, and human occupants) need not be included. However, certain types of live loads such as storage loads may develop inertial forces, particularly where they are densely packed.

DRAFT

Also considered as contributing to effective seismic weight are:

1. All permanent equipment (e.g., air conditioners, elevator equipment, and mechanical systems);
2. Partitions to be erected or rearranged as specified in Section 4.3.2 (greater of actual partition weight and 10 psf of floor area);
3. 20 percent of significant snow load (p_f > 30 psf); and
4. The weight of landscaping and similar materials.

The full snow load need not be considered because maximum snow load and maximum earthquake load are unlikely to occur simultaneously and loose snow does not move with the roof.

C12.7.3 Structural Modeling

The development of a mathematical model of a structure is always required because the story drifts and the design forces in the structural members cannot be determined without such a model. In some cases, the mathematical model can be as simple as a free-body diagram as long as the model can appropriately capture the strength and stiffness of the structure.

The most realistic analytical model is three-dimensional, includes all sources of stiffness in the structure and the soil-foundation system as well as P-delta effects, and allows for nonlinear inelastic behavior in all parts of the structure-foundation-soil system. Development of such an analytical model is very time consuming, and such analysis is rarely warranted for typical building designs performed in accordance with the standard. Instead of performing a nonlinear analysis, inelastic effects are accounted for indirectly in the linear analysis methods by means of the response modification coefficient, R, and the deflection amplification factor, C_d.

Using modern software, it often is more difficult to decompose a structure into planar models than it is to develop a full three-dimensional model so three-dimensional models are now commonplace. Increased computational efficiency also allows efficient modeling of diaphragm flexibility. Three-dimensional models are required where the structure has horizontal torsional (Type 1), out-of-plane offset (Type 4), or nonparallel system (Type 5) irregularities.

Analysis using a three-dimensional model is not required for structures with flexible diaphragms that have horizontal out-of-plane offset irregularities. This is because the irregularity will impose seismic load effects in a direction other than the direction under consideration (orthogonal effects) due to eccentricity in the vertical load path caused by horizontal offsets of the vertical lateral-force-resisting elements from story to story. This is not likely to occur, however, with flexible diaphragms to an extent that warrants such modeling. The eccentricity in the vertical load path will cause a redistribution of seismic design forces from the vertical elements in the story above to the vertical elements in the story below in essentially the same direction. The effect on the vertical elements in the orthogonal direction in the story below will be minimal. Three-dimensional modeling may still be required for structures with flexible diaphragms due to other types of horizontal irregularities (e.g., nonparallel system).

In general, the same three-dimensional model may be utilized for the equivalent lateral force, the modal response spectrum, and the linear response history analysis procedures. Modal response spectrum and linear response history analyses require a realistic modeling of structural mass; the response history method also requires an explicit representation of inherent damping. Five percent of critical damping is automatically included in the modal response spectrum approach. See Chapter 16 and the related commentary for additional information on linear and nonlinear response history analysis procedures.

It is well known that deformations in the panel zones of the beam-column joints of steel moment frames are a significant source of flexibility. Two different mechanical models for including such deformations are summarized in Charney and Marshall (2006). These methods apply to both elastic and inelastic systems. For elastic structures, centerline analysis provides reasonable, but not always conservative, estimates of frame flexibility. Fully rigid end zones should not be used, as this will always result in an overestimation of lateral stiffness in steel moment-resisting frames. Partially rigid end zones may be justified in certain cases such as where doubler plates are used to reinforce the panel zone.

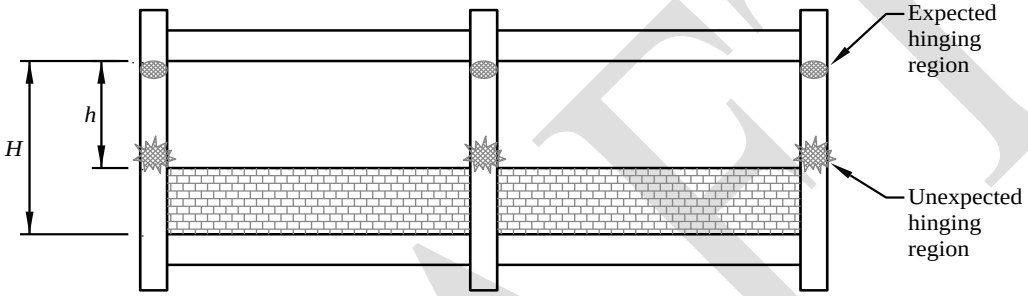
Including the effect of composite slabs in the stiffness of beams and girders may be warranted in some circumstances. Where composite behavior is included, due consideration should be paid to the reduction in effective composite stiffness for portions of the slab in tension (Schaffhausen and Wegmuller, 1977; Liew, et al., 2001)

DRAFT

For reinforced concrete buildings, it is important to address the effects of axial, flexural, and shear cracking in modeling the effective stiffness of the structural elements. Determining appropriate effective stiffness of the structural elements should take into consideration the anticipated demands on the elements, their geometry, and the complexity of the model. Recommendations for computing cracked section properties may be found in Paulay and Priestley (1992) and similar texts.

C12.7.4 Interaction Effects

The interaction requirements are intended to prevent unexpected failures in members of moment-resisting frames. Figure C12.7-1 illustrates a typical situation where masonry infill is used, and this masonry is fitted tightly against reinforced concrete columns. Since the masonry is much stiffer than the columns, hinges in a column form at the top of the column and at the top of the masonry rather than at the top and bottom of the column. If the column flexural capacity is M_p, the shear in the columns increases by the factor H/h, and this may cause an unexpected nonductile shear failure in the columns. Many building collapses have been attributed to this effect.



Expected plastic hinge capacity = M_p

Expected column shear = $2M_p/H$

Actual column shear = $2M_p/h$

Figure C12.7- 1 Undesired interaction effects.

C12.8 EQUIVALENT LATERAL FORCE PROCEDURE

The equivalent lateral force (ELF) procedure provides a simple way to incorporate the effects of inelastic dynamic response into a linear static analysis. This procedure is useful in preliminary design of all structures and is allowed for final design of the vast majority of structures. The procedure is valid only for structures without significant discontinuities in mass and stiffness along the height, where the dominant response to ground motions is in the horizontal direction without significant torsion.

The ELF procedure has three basic steps:

1. Determine the seismic base shear, V;
2. Distribute V vertically along the height of the structure; and
3. Distribute V horizontally across the width and breadth of the structure.

Each of these steps is based on a number of simplifying assumptions. A broader understanding of these assumptions may be obtained from any structural dynamics textbook that emphasizes seismic applications.

C12.8.1 Seismic Base Shear

Treating the structure as a single-degree-of-freedom system with 100% mass participation in the fundamental mode, Equation 12.8-1 simply expresses V as the product of the effective seismic weight, W, and the seismic response coefficient, C_s, which is a period-dependent, spectral pseudo-acceleration, in g units. C_s is modified by the response modification coefficient, R, and the importance factor, I_e, as appropriate, to account for inelastic behavior and to provide for improved performance for high occupancy or essential structures.

DRAFT

C12.8.1.1 Calculation of Seismic Response Coefficient

The standard prescribes five equations for determining C_s. Equations 12.8-2, 12.8-3 and 12.8-4 are illustrated in Figure C12.8-1.

Equation 12.8-2 controls where $0.0 < T < T_s$ and represents the constant acceleration part of the design response spectrum (see Section 11.4.5). In this region, C_s is independent of period. Although the theoretical design response spectrum shown in Figure 11.4-1 illustrates a transition in pseudo-acceleration to the peak ground acceleration as the fundamental period, T, approaches zero from T_0, this transition is not used in the ELF procedure. One reason is that simple reduction of the response spectrum by (1/R) in the very short period region would exaggerate inelastic effects.

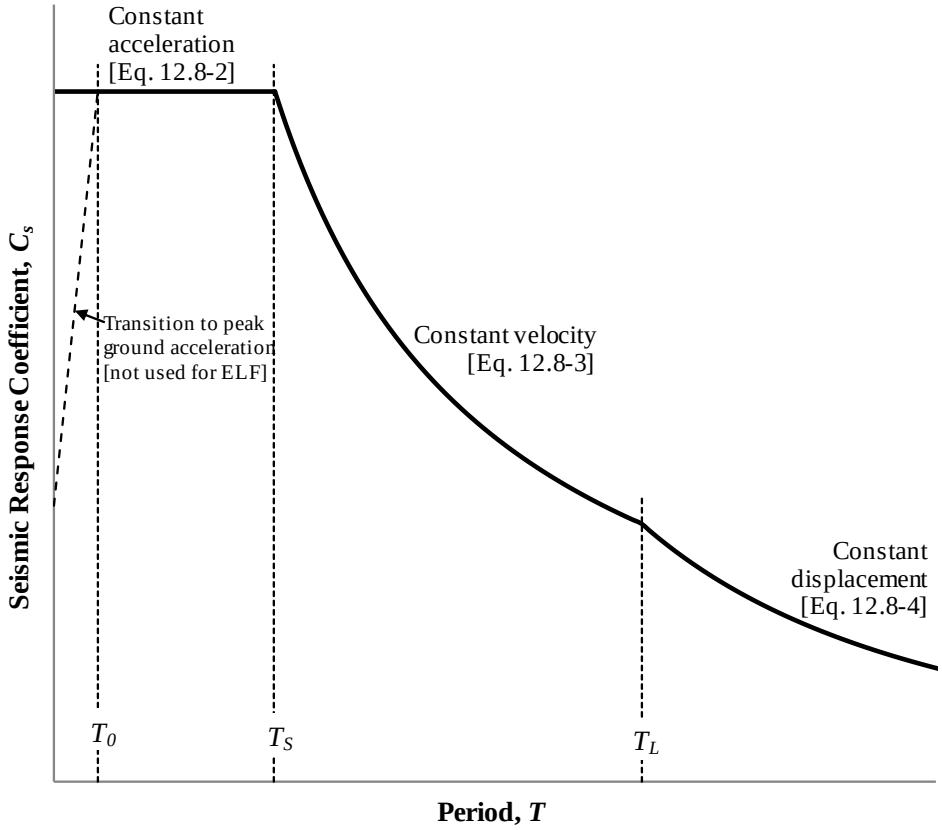


Figure C12.8-1 Seismic response coefficient versus period.

Equation 12.8-3, representing the constant velocity part of the spectrum, controls where $T_s < T < T_L$. In this region, the seismic response coefficient is inversely proportional to period, and the pseudo-velocity (pseudo-acceleration divided by circular frequency, ω, assuming steady-state response) is constant. T_L, the long-period transition period, represents the transition to constant displacement and is provided in Figures 22-12 through 22-16. T_L ranges from 4 seconds in the north-central conterminous states and western Hawaii to 16 seconds in the Pacific Northwest and in western Alaska.

Equation 12.8-4, representing the constant displacement part of the spectrum, controls where $T > T_L$. Given the current mapped values of T_L, this equation only affects long-period structures. The transition period has recently received increased attention as displacement response spectra from the 2010 M8.8 Chilean earthquake indicate a considerably lower transition period is possible in locations controlled by subduction zone earthquakes.

The final two equations represent minimum base shear levels for design. Equation 12.8-5 is the minimum base shear and primarily effects sites in the far-field. This equation provides an allowable strength of approximately 3 percent of the weight of the structure. This minimum base shear was originally enacted in 1933 by the state of California (Riley Act). Based on research conducted in the ATC-63 project (Applied Technology Council, 2009), it was determined that this equation provides an adequate level of collapse resistance for long-period structures when used in conjunction with other provision of the standard.

Equation 12.8-6 applies to sites near major active faults (as reflected by values of S_1) where pulse-type effects can increase long-period demands.

C12.8.1.2 Soil-Structure Interaction Reduction

Soil-structure interaction, which can significantly influence the dynamic response of a structure during an earthquake, is addressed in Chapter 19.

C12.8.1.3 Maximum Ss Value in Determination of Cs

The maximum value of S_s was created as hazard maps were revised in 1997. The cap on S_s reflects engineering judgment about performance of code-complying buildings in past earthquakes so the structural height, period, and regularity conditions required for use of the limit are very important qualifiers.

C12.8.2 Period Determination

The fundamental period, *T*, for an elastic structure is used to determine the design base shear, *V*, as well as the exponent, *k*, that establishes the distribution of *V* along the height of the structure (see Section 12.8.3). *T* may be computed using a mathematical model of the structure that incorporates the requirements of Section 12.7 in a properly substantiated analysis. Generally, this type of analysis is performed using a computer program that incorporates all deformational effects (e.g., flexural, shear and axial) and accounts for the effect of gravity load on the stiffness of the structure. For many structures, however, the sizes of the primary structural members are not known at the outset of design. For preliminary design, as well as instances where a substantiated analysis will not be used, the standard provides formulas to compute an approximate fundamental period, T_a, (see Section 12.8.2.1). These periods represent lower-bound estimates of *T* for different structure types. Period determination is typically computed for a mathematical model that is fixed at the base. That is, the base where seismic effects are imparted into the structure is globally restrained (e.g., horizontally, vertically, and rotationally). Column base modeling (i.e., pinned or fixed) for frame-type seismic force-resisting systems is a function of frame mechanics, detailing and foundation (soil) rigidity; and attention should be given to the adopted assumption. However, this is not the same conceptual restraint for the structure as is stated above. Soil flexibility may be considered for computing *T* (typically assuming a rigid foundation element). The engineer should be attentive to the equivalent linear soil-spring stiffness used to represent the deformational characteristics of the soil at the base (see Section 12.13.3). Similarly, pinned column bases in frame-type structures are sometimes used to conservatively account for soil flexibility under an assumed rigid foundation element. Period shifting of a fixed-base model of a structure due to soil-structure interaction is permitted in accordance with Chapter 19.

The fundamental mode of a structure with a geometrically complex arrangement of seismic force-resisting systems determined with a three-dimensional model may be associated to the torsional mode of response of the system, with mass participating in both horizontal directions (orthogonal) concurrently. The analyst must be attentive to this mass participation and recognize that the period used to compute the design base shear should be associated to the mode with the largest mass participation in the direction being considered. Often in this situation these periods will be close to each other. Significant separation between the torsional mode period (when fundamental) and the shortest translational mode period may be an indicator of an ill-conceived structural system or potential modeling error.The standard requires that the fundamental period, *T*, used to determine the design base shear, *V*, does not exceed the approximate fundamental period, T_a, times the upper limit coefficient, C_u, provided in Table 12.8-1. This period limit prevents the use of an unusually low base shear for design of a structure that is, analytically, overly flexible due to mass and stiffness inaccuracies in the analytical model. C_u has two effects on T_a. First, recognizing that project specific design requirements and design assumptions can influence *T*, C_u lessens the conservatism inherent in the empirical formulas for T_a to more closely follow the mean curve (see Figure C12.8-2). Second, the values for C_u recognize that the formulas for T_a are targeted to structures in high seismic hazard locations. Most likely, the stiffness of a structure will decrease in areas of lower seismicity and this decrease is accounted for in the values of C_u. The response modification coefficient, *R*, typically decreases to account for reduced ductility demands and the relative wind effects increase in lower seismic hazard locations. The design engineer must therefore be attentive to the value used for design of seismic force-resisting systems in structures that are controlled by wind effects. While

DRAFT

the value for C_u will most likely be independent of the governing design forces in high wind areas, project-specific serviceability requirements may add considerable stiffness to a structure and decrease the value of C_u from considering seismic effects alone. This effect should be assessed where design forces for seismic and wind effects are nearly equal. Lastly, if T from a properly substantiated analysis (Section 12.8.2) is less than $C_u T_a$, then the lower value of T and $C_u T_a$ should be used for the design of the structure.

DRAFT

1

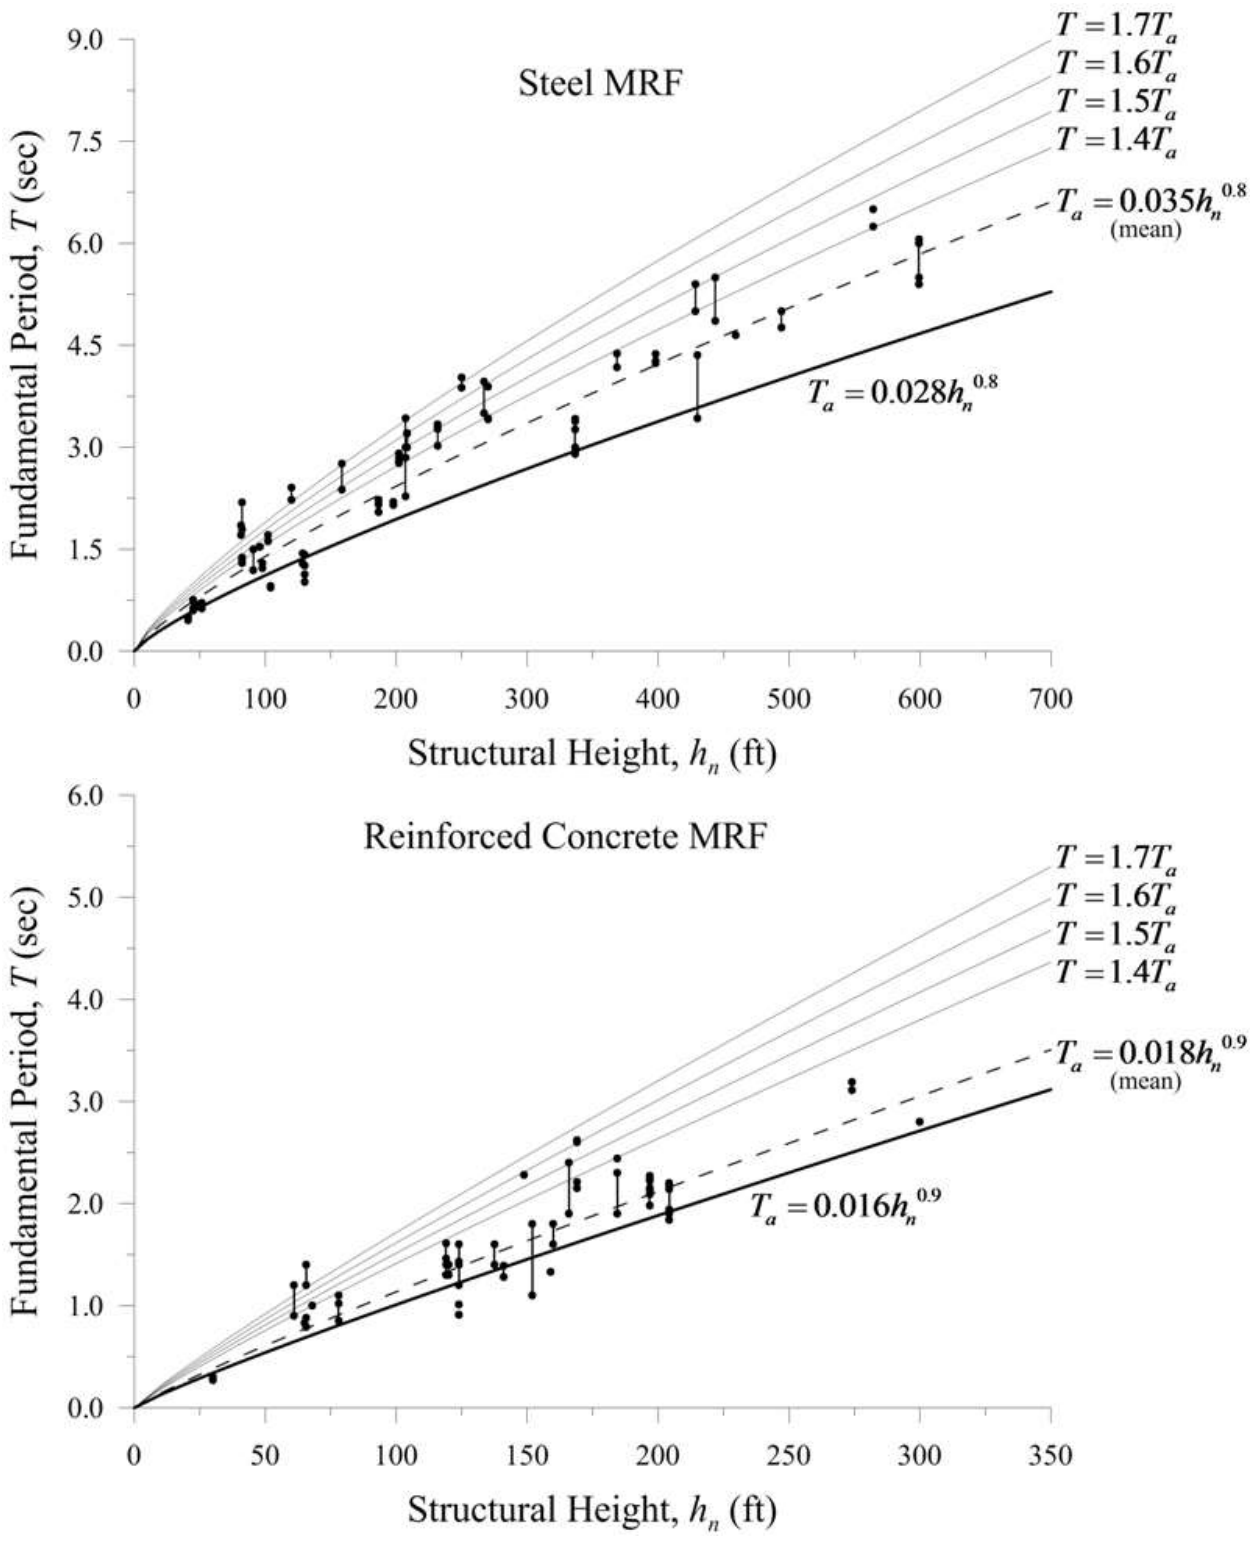

Figure C12.8-2 Variation of fundamental period with structural height.

C12.8.2.1 Approximate Fundamental Period

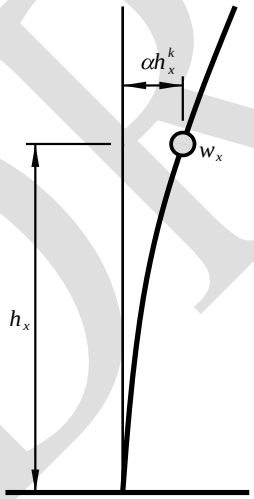
Equation 12.8-7 is an empirical relationship determined through statistical analysis of the measured response of building structures in small- to moderate-sized earthquakes, including response to wind effects (Chopra and Goel, 1997 and 1998). Figure C12.8-2 illustrates such data for various building structures with steel and reinforced concrete moment-resisting frames. Historically, the exponent, *x*, in Equation 12.8-7 has been taken as 0.75 and was based on the assumption of a linearly varying mode shape while using Rayleigh's method. The exponents provided in the standard, however, are based on actual response data from building structures, thus, more accurately reflecting the influence of mode shape on the exponent. Since the empirical expression is based on the lower bound of the data, it produces a lower bound estimate of the period for a building structure of a given height. This lower bound period, when used in Equations 12.8-3 and 12.8-4 to compute the seismic response coefficient, C_s, provides a conservative estimate of the seismic base shear, *V*.

C12.8.3 Vertical Distribution of Seismic Forces

Equation 12.8-12 is based on the simplified first mode shape shown in Figure C12.8-3. In the figure, F_x is the inertial force at level *x*, which is simply the absolute acceleration at level *x* times the mass at level *x*. The base shear is the sum of these inertial forces, and Equation 12.8.12 simply gives the ratio of the lateral seismic force at level *x*, F_x, to the total design lateral force or shear at the base, *V*.

The deformed shape of the structure in Figure C12.8-3 is a function of the exponent *k*, which is related to the fundamental period of the structure, *T*. The variation of *k* with *T* is illustrated in Figure C12.8-4. The exponent *k* is intended to approximate the effect of higher modes, which are generally more dominant in structures with a longer fundamental period of vibration. Lopez and Cruz (1996) discuss the factors that influence higher modes of response. Although the actual first mode shape for a structure is also a function of the type of seismic-force-resisting system, that effect is not reflected in these equations. Also, as *T* is limited to $C_u T_a$ for design, this mode shape may differ from that corresponding to the statistically-based empirical formula for the approximate fundamental period, T_a. A drift analysis in accordance with Section 12.8.6 can be conducted using the actual period (see C12.8.6). As such, *k* will change to account for the variation between *T* and the actual period.

The horizontal forces computed using Equation 12.8-11 do not reflect the actual inertial forces imparted on a structure at any particular point in time. Instead, they are intended to provide lateral seismic forces at individual levels that are consistent with enveloped results from more accurate analyses (Chopra and Newmark, 1980).



$$F_x = \omega^2 \alpha h_x^k \frac{w_x}{g}$$

$$V_b = \sum_{i=1}^{n} \omega^2 \alpha h_i^k \frac{w_i}{g}$$

$$C_{vx} = \frac{F_x}{V_b} = \frac{w_x h_x^k}{\sum_{i=1}^{n} w_i h_i^k}$$

Figure C12.8-3 Basis of Equation 12.8-12.

C12.8.4 Horizontal Distribution of Forces

Within the context of an ELF analysis, the horizontal distribution of lateral forces in a given story to various seismic-force-resisting elements in that story depends on the type, geometric arrangement, and vertical extents of the structural elements and on the shape and flexibility of the floor or roof diaphragm. Because some elements of the

DRAFT

seismic-force-resisting system are expected to respond inelastically to the design ground motion, the distribution of forces to the various structural elements and other systems also depends on the strength of the yielding elements and their sequence of yielding (see C12.1.1). Such effects cannot be captured accurately by a linear elastic static analysis (Paulay, 1997), and a nonlinear dynamic analysis is too computationally cumbersome to be applied to the design of most buildings. As such, approximate methods are used to account for uncertainties in horizontal distribution in an elastic static analysis, and to a lesser extent in elastic dynamic analysis.

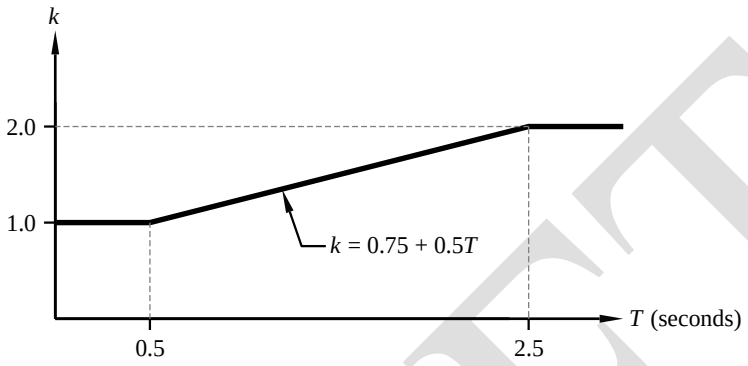


Figure C12.8- 4 Variation of exponent k with period T.

Of particular concern in regards to the horizontal distribution of lateral forces is the torsional response of the structure during the earthquake. The standard requires that the inherent torsional moment be evaluated for every structure with diaphragms that are not flexible (see C12.8.4.1). Although primarily a factor for torsionally irregular structures, this mode of response has also been observed in structures that are designed to be nearly symmetric in plan and layout of seismic-force-resisting systems (De La Liera and Chopra, 1994). This torsional response in the case of a torsionally regular structure is due to a variety of "accidental" torsional moments due to increased eccentricities between the centers of rigidity and mass that exist due to uncertainties in quantifying the mass and stiffness distribution of the structure, as well as torsional components of earthquake ground motion that are not included explicitly in code-based designs (Newmark and Rosenbleuth, 1971). Consequently, the accidental torsional moment can affect any structure, and potentially more so for a torsionally irregular structure. The standard requires that the accidental torsional moment be considered for every structure (see C12.8.4.2) as well as the amplification of this torsion for structures with torsional irregularity (see C12.8.4.3).

C12.8.4.1 Inherent Torsion

Where a rigid diaphragm is in the analytical model, the mass tributary to that floor or roof can be idealized as a lumped mass located at the resultant location on the floor or roof – termed the center of mass (CoM). This point represents the resultant of the inertial forces on the floor or roof. This diaphragm model simplifies structural analysis by reducing what would be many degrees of freedom in the two principal directions of a structure to three degrees of freedom (two horizontal and one rotational about the vertical axis). Similarly, the resultant stiffness of the structural members providing lateral stiffness to the structure tributary to a given floor or roof can be idealized as the center of rigidity (CoR).

It is difficult to accurately determine the center of rigidity for a multistory building because the center of rigidity for a particular story depends on the configuration of the seismic-force-resisting elements above and below that story and may be load dependent (Chopra and Goel, 1991). Furthermore, the location of the CoR is more sensitive to inelastic behavior than the CoM. If the CoM of a given floor or roof does not coincide with the CoR of that floor or roof, an inherent torsional moment, M_t, is created by the eccentricity between the resultant seismic force and the CoR. In addition to this *idealized* inherent torsional moment, the standard requires an accidental torsional moment, M_{ta}, be considered (see C.12.8.4.2).

Similar principles can be applied to models of semi-rigid diaphragms that explicitly model the in-plane stiffness of the diaphragm, except that the deformation of the diaphragm needs to be included in computing the distribution of

DRAFT

the resultant seismic force and inherent torsional moment to the seismic force-resisting system.

This inherent torsion is included automatically when performing a three-dimensional analysis using either a rigid or semi-rigid diaphragm. If a two-dimensional planar analysis is used, where permitted, the CoR and CoM for each story must be determined explicitly and the applied seismic forces must be adjusted accordingly.

For structures with flexible diaphragms (as defined in Section 12.3), vertical elements of the seismic force-resisting system are assumed to resist inertial forces from the mass that is tributary to the elements with no explicitly computed torsion. No diaphragm is perfectly flexible, therefore some torsional forces will develop even when they are neglected.

C12.8.4.2 Accidental Torsion

The locations of the centers of mass and rigidity for a given floor or roof typically cannot be established with a high degree of accuracy due to mass and stiffness uncertainty and deviations in design, construction, and loading from the idealized case. To account for this inaccuracy, the Standard requires the consideration of a minimum eccentricity of five percent of the width of a structure perpendicular to the direction being considered to any static eccentricity computed using idealized locations of the centers of mass and rigidity. Where a structure has a geometrically complex or non-rectangular floor plan, the eccentricity is computed using the diaphragm extents perpendicular to the direction of loading (see C12.5).

One approach to account for this variation in eccentricity is to shift the CoM each way from its calculated location and apply the seismic lateral force at each shifted location as separate seismic load cases. It is typically conservative to assume that the CoM offsets at all floors and roof occur simultaneously and in the same direction. This offset will produce an "accidental" static torsional moment, M_{ta}, at each story. Most computer programs can automate this offset for three-dimensional analysis by automatically applying these static moments in the auto-generated seismic load case (along the global coordinate axes used in the computer model – see C12.5). Alternatively, user-defined torsional moments can be applied as separate load cases and then added to the seismic lateral force load case. For two-dimensional analysis, the accidental torsional moment is distributed to each seismic force-resisting system as an applied static lateral force in proportion to its relative elastic lateral stiffness and distance from the CoR.

Shifting the CoM is a static approximation and thus does not affect the dynamic characteristics of the structure, as would be the case were the CoM to be physically moved by, for example, altering the horizontal mass distribution and mass moment of inertia. While this "dynamic" approach can be used to adjust the eccentricity, it can be too computationally cumbersome for static analysis and therefore is reserved for dynamic analysis (see C12.9.5).

The above discussion is applicable only to a rigid diaphragm model. A similar approach can be used for a semi-rigid diaphragm model except that the accidental torsional moment is decoupled into nodal moments or forces that are placed throughout the diaphragm. The amount of nodal actions will depend on how sensitive the diaphragm is to in-plane deformation. As the in-plane stiffness of the diaphragm decreases, tending towards a flexible diaphragm, the nodal inputs decrease proportionally.

The physical significance of this mass eccentricity should not be confused with the physical meaning of the eccentricity required for representing non-uniform wind pressures acting on a structure. However, this accidental torsion also incorporates to a lesser extent the potential torsional motion inputted into structures with very large footprints from differences in ground motion within the footprint of the structure.

Torsionally irregular structures whose fundamental mode is potentially dominated by the torsional mode of response can be more sensitive to dynamic amplification of this accidental torsional moment. Consequently, the 5 percent minimum can underestimate the accidental torsional moment. In these cases, the standard requires the amplification of this moment for design when using an elastic static analysis procedure, including satisfying the drift limitations (see C12.8.4.3).

Accidental torsion results in forces that are combined with those obtained from the application of the seismic design story shears, V_x, including inherent torsional moments. All elements are designed for the maximum effects determined considering positive accidental torsion, negative accidental torsion, and no accidental torsion (see Section C12.5). Where consideration of earthquake forces applied concurrently in any two orthogonal directions is required by the standard, it is permitted to apply the 5%eccentricity of the center of mass along the single orthogonal direction that produces the greater effect, but need not be applied simultaneously in the orthogonal direction.

DRAFT

C12.8.4.3 Amplification of Accidental Torsional Moment

For structures with torsional or extreme torsional irregularity (Type 1a or 1b horizontal structural irregularity) and analyzed using the equivalent lateral force procedure, the standard requires amplification of the accidental torsional moment to account for increases in the torsional moment due to potential yielding of the perimeter seismic-force-resisting systems (i.e., shifting of the center of rigidity) as well as other factors potentially leading to dynamic torsional instability. For verifying torsional irregularity requirements in Table 12.3-1, *story drifts* resulting from the applied loads, that include both the inherent and accidental torsional moments, are used with no amplification of the accidental torsional moment ($A_x = 1$). The same process is used when computing the amplification factor, A_x, except that *displacements* (relative to the base) at the level being evaluated are used in lieu of story drifts. Displacements are used here to indicate that amplification of the accidental torsional moment is primarily a system-level phenomenon, proportional to the increase in acceleration at the extreme edge of the structure, and not explicitly related to an individual story and the components of the seismic-force-resisting system contained therein.

Equation 12.8-14 was developed by the SEAOC Seismology Committee to encourage engineers to design buildings with good torsional stiffness and was first introduced in the UBC-88. Figure C12.8-5 illustrates the effect of Equation 12.8-14 for a symmetric rectangular building with various aspect ratios (L/B) where the seismic-force-resisting elements are positioned at a variable distance (defined by α) from the center of mass in each direction. Each element is assumed to have the same stiffness. The structure is loaded parallel to the short direction with an eccentricity of 0.05 L.

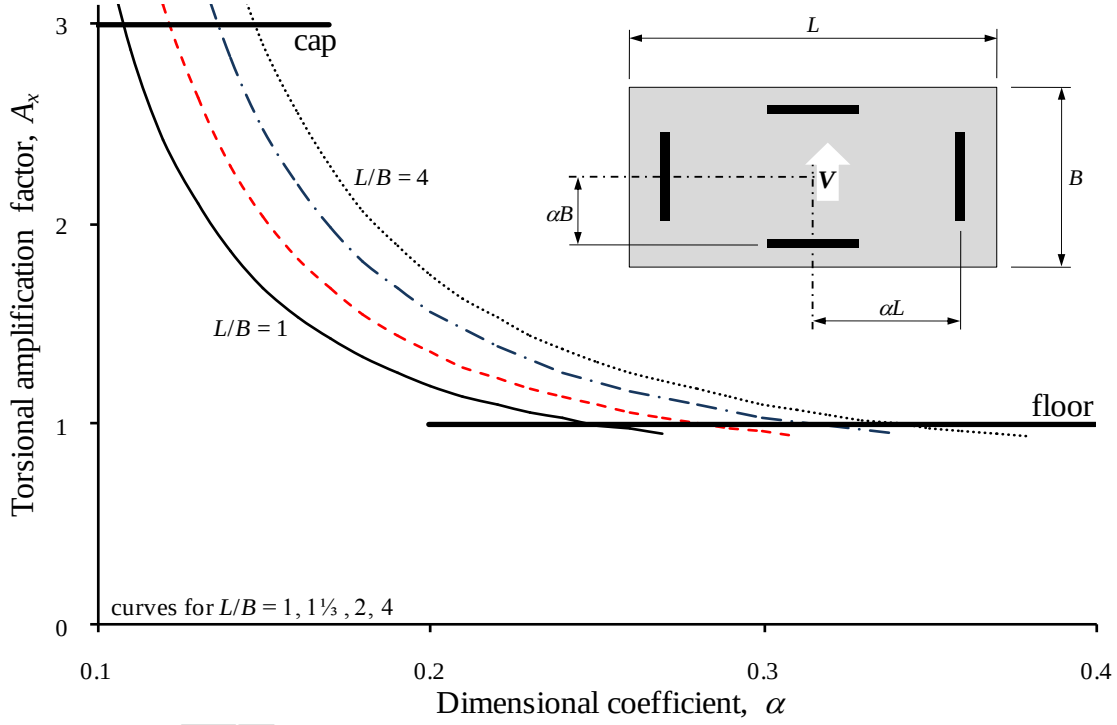

Figure C12.8- 5 Torsional amplification factor for symmetric rectangular buildings.

For α equal to 0.5, these elements are at the perimeter of the building, and for α equal to 0.0, they are at the center (providing no torsional resistance). For a square building ($L/B = 1.00$), A_x is greater than 1.0 where α is less than 0.25 and increases to its maximum value of 3.0 where α is equal to 0.11. For a rectangular building with L/B equal to 4.00, A_x is greater than 1.0 where α is less than 0.34 and increases to its maximum value of 3.0 where α is equal to 0.15.

C12.8.5 Overturning

The overturning effect on a vertical lateral-force-resisting element is computed based on the calculation of lateral seismic force, F_x, times the height from the base to the level of the horizontal lateral-force-resisting element that transfers F_x to the vertical element, summed over each story. Each vertical lateral-force-resisting element resists its portion of overturning based on its relative stiffness with respect to all vertical lateral-force-resisting elements in a building or structure. The seismic forces used are those from the equivalent lateral force procedure determined in Section 12.8.3 or based on a dynamic analysis of the building or structure. The overturning forces may be resisted by dead loads, and shall be combined with dead and live loads or other loads, in accordance with the load combinations of Section 12.4.2.3.

C12.8.6 Story Drift Determination

Equation 12.8-15 is used to estimate inelastic deflections (δ_x), which are then used to calculate design story drifts, Δ. These story drifts must be less than the allowable story drifts, Δ_a, of Table 12.12-1. For structures without torsional irregularity, computations are performed using deflections of the centers of mass of the floors bounding the story. If the eccentricity between the centers of mass of two adjacent floors, or a floor and a roof, is more than 5% of the width of the diaphragm extents, it is permitted to compute the deflection for the bottom of the story at the point on the floor that is vertically aligned with the location of the center of mass of the top floor or roof. This situation can arise where a building has story offsets and the diaphragm extents of the top of the story are smaller than the extents of the bottom of the story. For structures assigned to Seismic Design Category C, D, E, or F that are torsionally irregular, the standard requires that deflections be computed along the edges of the diaphragm extents using two vertically aligned points.

Figure C12.8-6 illustrates the force-displacement relationships between elastic response, response to reduced design-level forces, and the expected inelastic response. If the structure remained elastic during an earthquake, the force developed would be V_E, and the corresponding displacement would be δ_E. Note that V_E does not include R, which accounts primarily for ductility and system overstrength. According to the equal displacement approximation rule of seismic response, the maximum displacement of an inelastic system is approximately equal to that of an elastic system with the same initial stiffness. This condition has been observed for structures idealized with bilinear inelastic response and a fundamental period, T, greater than T_s (see Section 11.4.5). For shorter period structures, peak displacement of an inelastic system tends to exceed that of the corresponding elastic system. Since the forces are reduced by R, the resulting displacements are representative of an elastic system and need to be amplified to account for inelastic response.

DRAFT

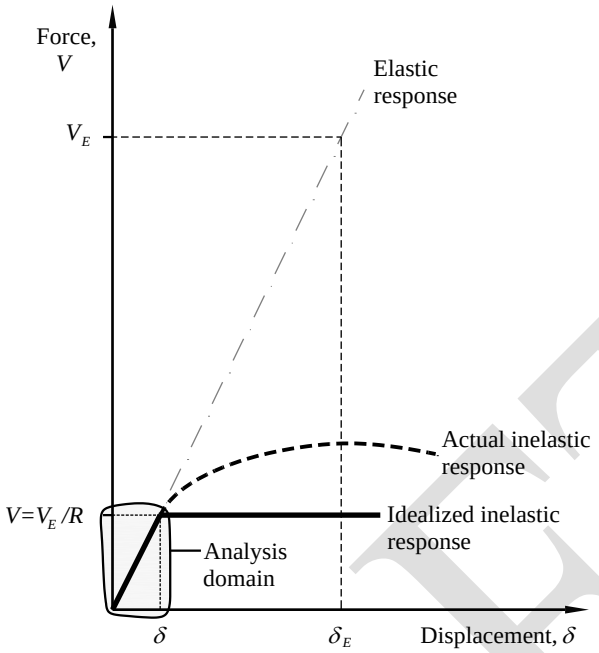

Figure C12.8- 6 Displacements used to compute drift.

The deflection amplification factor, C_d, in Equation 12.8-15 amplifies the displacements computed from an elastic analysis using prescribed forces to represent the expected inelastic displacement for the design-level earthquake, and is typically less than R (see C12.1.1). It is important to note that C_d is a story-level amplification factor and does not represent displacement amplification of the elastic response of a structure, either modeled as an *effective* single-degree-of-freedom structure (fundamental mode) or a constant amplification to represent the deflected shape of a multiple-degree-of-freedom structure; in effect, implying that the mode shapes do not change during inelastic response. Furthermore, drift-level forces are different than design-level forces used for strength compliance of the structural elements. Drift forces are typically lower as the computed fundamental period can be used to compute the base shear (see Section C12.8.6.2).

When conducting a drift analysis the analyst should be attentive to the applied gravity loads used in combination with the strength-level earthquake forces so that consistency between the forces used in the drift analysis and those used for stability verification (P-Δ) in Section 12.8.7 is maintained, including consistency in computing the fundamental period if a second-order analysis is used. Further discussion is provided in C12.8.7.

The design forces used to compute the elastic deflection (δ_{xe}) include the importance factor, I_e, so Equation 12.8-15 includes I_e in the denominator. This is appropriate since the allowable story drifts (except for masonry shear wall structures) in Table 12.12-1 are more stringent for higher risk categories.

C12.8.6.1 Minimum Base Shear for Computing Drift

Except for period limits (as described in Section C12.8.6.2), all of the requirements of Section 12.8 must be satisfied when computing drift for an ELF analysis except the minimum base shear determined from applying Equation 12.8-5 does not need to be considered. This equation represents a minimum strength that needs to be provided to a system (see Section C12.8.1.1). Equation 12.8-6 needs to be considered, when triggered, as it represents the increase in the response spectrum in the long period range from near-fault effects.

C12.8.6.2 Period for Computing Drift

Where the design response spectrum of Section 11.4.5 or the corresponding equations of Section 12.8.1 are used and the fundamental period of the structure, T, is less than the long period transition period, T_L, displacements increase with increasing period (even though forces may decrease). Section 12.8.2 applies an upper limit on T so that design forces are not underestimated, but if the lateral forces used to compute drifts are inconsistent with the forces

DRAFT

corresponding to T, then displacements can be overestimated. To account for this variation in dynamic response, the standard allows the determination of displacements using forces that are consistent with the *computed* fundamental period of the structure without the upper limit of Section 12.8.2.

The analyst must still be attentive to the period used to compute drift forces. The same analytical representation (see Section C12.7.3) of the structure used for strength design must also be used for computing displacements. Similarly, the same analysis method (Table 12.6-1) used to compute design forces must also be used to compute drift forces. It is generally appropriate to use 85 percent of the computed fundamental period to account for mass and stiffness inaccuracies as a precaution against overly flexible structures, but need not be taken less than that used for strength design. The more flexible the structure, the more likely it is that P-delta effects will ultimately control the design (see Section C12.8.7). Computed values of T that are significantly greater than (perhaps more than 1.5 times in high seismic areas) $C_u T_a$ may indicate a modeling error. Similar to the discussion in Section C.12.8.2, the analyst should assess the value of C_u used where serviceability constraints from wind effects add significant stiffness to the structure.

C12.8.7 P-Delta Effects

Figure C12.8-7 shows an idealized static force-displacement response for a simple one-story structure (e.g., idealized as an inverted pendulum-type structure). As the top of the structure displaces laterally, the gravity load, P, supported by the structure acts through that displacement and produces an increase in overturning moment by P times the story drift, Δ, that must be resisted by the structure – the so-called "P-Delta (P-Δ) effect". This effect also influences the lateral displacement response of the structure from an applied lateral force, F.

The response of the structure not considering the P-Δ effect is depicted by Condition 0 in the figure with a slope of K_0 and lateral first-order yield force F_{0y}. This characterizes the *first-order* response of the structure (the response of the structure from an analysis not including P Delta effects). Where the P-Δ effect is included (depicted by Condition 1 in the figure), the related quantities are K_1 and F_{1y}. This characterizes the *second-order* response of the structure (the response of the structure from an analysis including P Delta effects).

The geometric stiffness of the structure, K_G, in this example is equal to the gravity load, P, divided by the story height, h_{sx}. K_G is used to represent the change in lateral response by analytically reducing the elastic stiffness, K_0. K_G is negative where gravity loads cause compression in the structure. Since the two response conditions in the figure are for the same structure, the inherent yield displacement of the structure is the same ($\Delta_{0y} = \Delta_{1y} = \Delta_y$).

Two consequential points taken from the figure are (1) the increase in required strength and stiffness of the seismic force-resisting system where the P-Δ effect influences the lateral response of the structure must be accounted for in design; and (2) the P-Δ effect can create a negative stiffness condition during post-yield response, which could initiate instability of the structure. Where the post-yield stiffness of the structure may become negative, dynamic displacement demands can increase significantly (Gupta and Krawinkler, 2000).

One approach that can be used to assess the influence of the P-Δ effect on the lateral response of a structure is to compare the first-order response to the second-order response, which can be done using an elastic stability coefficient, θ, defined as the absolute value of K_G divided by K_0.

$$\theta = \frac{|K_G|}{K_0} = \left| \frac{P\Delta_{0y}}{F_{0y} h_{sx}} \right| \qquad \text{C12.8-1}$$

Given the above, and the geometric relationships shown in Figure C12.8-7, it can be shown that the force producing yield in condition 1 (with P-Δ effects) is

$$F_{1y} = F_{0y}(1-\theta) \qquad \text{C12.8-2}$$

and that for a force, F, less than or equal to F_{1y}

$$\Delta_1 = \frac{\Delta_0}{1-\theta} \qquad \text{C12.8-3}$$

Therefore, the stiffness ratio, K_0 / K_1, is

$$\frac{K_0}{K_1} = \frac{1}{1-\theta} \qquad \text{C12.8-4}$$

In the previous equations:

F_{0y} = the lateral first-order yield force

F_{1y} = the lateral second-order yield force

h_{sx} = the story height (or structure height in this example)

K_G = the geometric stiffness

K_0 = the elastic first-order stiffness

K_1 = the elastic second-order stiffness

P = the total gravity load supported by the structure

Δ_0 = the lateral first-order drift

Δ_{0y} = the lateral first-order yield drift

Δ_1 = the lateral second-order drift

Δ_{1y} = the lateral second-order yield drift

θ = the elastic stability coefficient

A physical interpretation of this effect is that in order to achieve the second-order response depicted in the figure, the seismic force-resisting system must be designed to have the increased stiffness and strength depicted by the first-order response. As θ approaches unity, Δ_1 approaches infinity and F_1 approaches zero, defining a state of static instability.

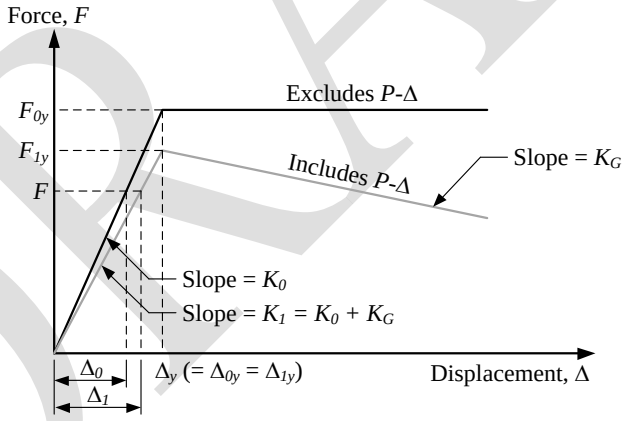

Figure C12.8- 7 Idealized Response of a One-Story Structure With and Without P-Δ

The intent of Section 12.8.7 is to determine whether *P-Δ* effects are significant when considering the first-order response of a structure and, if so, to increase the strength and stiffness of the structure to account for *P-Δ* effects. Some material-specific design standards require *P*-Δ effects to always be included in the elastic analysis of a structure and strength design of its members. The amplification of first-order member forces in accordance with Section 12.8.7 should not be misinterpreted to mean that these other requirements can be disregarded nor should they be applied concurrently. Therefore, Section 12.8.7 is primarily used to verify compliance with the allowable drifts and check against potential post-earthquake instability of the structure, while provisions in material-specific design standards are used to increase member forces for design, if provided. In so doing, the analyst should be attentive to the stiffness of each member used in the mathematical model so that synergy between standards is

DRAFT

maintained.

Equation 12.8-16 is used to determine the elastic stability coefficient, θ, of each story of a structure.

$$\theta = \left| \frac{P\Delta_0}{F_0 h_{sx}} \right| = \frac{P\Delta I_e}{V_x h_{sx} C_d} \qquad \text{C12.8-5}$$

where h_{sx}, I_e and V_x are the same as defined in the standard and

F_0 = the force in a story causing $\Delta_0 = \Sigma F_x = V_x$

Δ_0 = the elastic lateral story drift = $\Delta I_e / C_d$

Δ = the inelastic story drift determined in accordance with Section 12.8.6

P = the total *point-in-time* gravity load supported by the structure (see below)

Structures with θ less than 0.10 generally are expected to have a positive monotonic post-yield stiffness. Where θ for any story exceeds 0.10, P-Δ effects must be considered for the entire structure using one of the two approaches in the standard. Either first-order displacements and member forces (see above) are multiplied by $1/(1-\theta)$ or the P-Δ effect is explicitly included in the structural analysis and the resulting θ is multiplied by $1/(1+\theta)$ to verify compliance with the first-order stability limit. Most commercial computer programs can perform second-order analysis. The analyst must therefore be attentive to the algorithm incorporated in the software and cognizant of any limitations; including suitability of iterative and non-iterative methods, inclusion of second-order effects (P-Δ and P-δ) in automated modal analyses, and appropriateness of superposition of design forces.

Gravity load drives the increase in lateral displacements from the equivalent lateral forces. The standard requires the total vertical design load, and the largest vertical design load for combination with earthquake loads is given by combination 5 from section 2.3.2, which is transformed in section 12.4.2.3 to be:

$$(1.2 + 0.2S_{DS})\ D + 1.0\ L + 0.2\ S + 1.0\ E$$

where the 1.0 factor on L is actually 0.5 for many common occupancies. The provision of 12.8.7 allows the factor on dead load D to be reduced to 1.0 for the purpose of P-Delta analysis under seismic loads. The vertical seismic component need not be considered for checking θ_{max}.

As explained in commentary for Chapter 2, the 0.5 and 0.2 factors on L and S, respectively, are intended to capture the arbitrary point in time values of those loads. The factor 1.0 results in the dead load effect being fairly close to best estimates of the arbitrary point in time value for dead load. L is defined in Chapter 4 of the standard to include the reduction in live load based upon floor area. Many commercially available computer programs do not include live load reduction in the basic structural analysis. In such programs, live reduction is applied only in the checking of design criteria; this results in a conservative calculation with regard to the requirement of the standard.

The seismic story shear, V_x (in accordance with Section 12.8.4), used to compute θ includes the importance factor, I_e. Further, the design story drift, Δ (in accordance with Section 12.8.6), does not include this factor. Therefore, I_e, has been added to Equation 12.8-16 to correct an apparent omission in previous editions of the standard. Nevertheless, the standard has always required V_x and Δ used in this equation to be those occurring simultaneously.

Equation 12.8-17 establishes the maximum stability coefficient, θ_{max}, permitted. The intent of this requirement is to protect structures from the possibility of instability triggered by post-earthquake residual deformation. The danger of such failures is real and may not be eliminated by apparently available overstrength. This is particularly true of structures designed in regions of lower seismicity.

For the idealized system shown in the figure, assume the maximum displacement is $C_d \Delta_0$. Assuming the unloading stiffness, K_u, is equal to the elastic stiffness, K_0, the residual displacement is

$$\left(C_d - \frac{1}{\beta} \right) \Delta_0 \qquad \text{C12.8-6}$$

Additionally, assume that there is a factor of safety, FS, of 2 against instability at the maximum residual drift, $\Delta_{r,max}$. Evaluating the overturning and resisting moments ($F_0 = V_0$ in this example),

DRAFT

$$P\Delta_{r,\max} \le \frac{V_0}{\beta FS} h \text{ where } \beta = \frac{V_0}{V_{0y}} \le 1.0 \qquad \text{C12.8-7}$$

Therefore,

$$\frac{P\left[\Delta_0 \left(\beta C_d - 1\right)\right]}{V_0 h} \le 0.5 \rightarrow \theta_{\max} \left(\beta C_d - 1\right) = 0.5 \rightarrow \theta_{\max} = \frac{0.5}{\beta C_d - 1}$$

Conservatively assume that $\beta C_d - 1 \approx \beta C_d$

$$\theta_{\max} = \frac{0.5}{\beta C_d} \le 0.25 \qquad \text{C12.8-9}$$

In the previous equations:

- C_d = the displacement amplification factor
- FS = the factor of safety
- h_{sx} = the story height (or height of the structure in this example)
- P = the total *point-in-time* gravity load supported by the structure
- V_0 = the first-order story shear demand
- V_{0y} = the first-order yield strength of the story
- β = the ratio of shear demand to shear capacity
- Δ_0 = the elastic lateral story drift
- $\Delta_{r,max}$ = the maximum residual drift at $V_0 = 0$
- θ_{max} = the maximum elastic stability coefficient

The standard requires that the computed stability coefficient, θ, not exceed 0.25 or 0.5 / β C_d, where β C_d is an adjusted ductility demand that takes into account the variation between the story strength demand and the story strength supplied. The story strength demand is simply V_x. The story strength supplied may be computed as the shear in the story that occurs simultaneously with the attainment of the development of first significant yield of the overall structure. To compute first significant yield, the structure should be loaded with a seismic force pattern similar to that used to compute story strength demand and iteratively increased until first yield. Alternatively, a simple and conservative procedure is to compute the ratio of demand to strength for each member of the seismic force-resisting system in a particular story and then use the largest such ratio as β.

The principal reason for inclusion of β is to allow for a more equitable analysis of those structures in which substantial extra strength is provided, whether as a result of added stiffness for drift control, code-required wind resistance, or simply a feature of other aspects of the design. Some structures inherently possess more strength than required, but instability is not typically a concern. For many flexible structures, the proportions of the structural members are controlled by drift requirements rather than strength requirements; consequently, β is less than 1.0 because the members provided are larger and stronger than required. This has the effect of reducing the inelastic component of total seismic drift and, thus, β is placed as a factor on C_d.

Accurate evaluation of β would require consideration of all pertinent load combinations to find the maximum ratio of demand to capacity due to seismic load effects in each and every member. A conservative simplification is to divide the total demand with seismic load effects included by the total capacity; this covers all load combinations in which dead and live load effects add to seismic load effects. If a member is controlled by a load combination where dead load counteracts seismic load effects, to be correctly computed, β must be based only on the seismic component, not the total; note that the gravity load, P, in the P-Δ computation would be less in such a circumstance and, therefore, θ would be less. The importance of the counteracting load combination does have to be considered, but it rarely controls instability.

Although the P-Δ procedure in the standard reflects a simple static idealization as shown in Figure C12.8-7, the real

DRAFT

issue is one of dynamic stability. To adequately evaluate second-order effects during an earthquake, a nonlinear response history analysis should be performed that reflects variability of ground motions and system properties, including initial stiffness, strain hardening stiffness, initial strength, hysteretic behavior, and magnitude of point-in-time gravity load, P. Unfortunately, the dynamic response of structures is highly sensitive to such parameters, causing considerable dispersion to appear in the results (Vamvatsikos, 2002). This dispersion, which increases dramatically with stability coefficient θ, is due primarily to the incrementally increasing residual deformations (ratcheting) that occur during the response. Residual deformations may be controlled by increasing either the initial strength or the secondary stiffness. See Gupta and Krawinkler (2000) for additional information.

C12.9 MODAL RESPONSE SPECTRUM ANALYSIS

In the modal response spectrum analysis method, the structure is decomposed into a number of single-degree-of-freedom systems, each having its own mode shape and natural period of vibration. The number of modes available is equal to the number of mass degrees of freedom of the structure, so the number of modes can be reduced by eliminating mass degrees of freedom. For example, rigid diaphragm constraints may be used to reduce the number of mass degrees of freedom to one per story for planar models, and to three per story (two translations and rotation about the vertical axis) for three-dimensional structures. However, where the vertical elements of the seismic-force-resisting system have significant differences in lateral stiffness, rigid diaphragm models should be used with caution as relatively small in-plane diaphragm deformations can have a significant effect on the distribution of forces.

For a given direction of loading, the displacement in each mode is determined from the corresponding spectral acceleration, modal participation, and mode shape. Because the sign (positive or negative) and the time of occurrence of the maximum acceleration are lost in creating a response spectrum, there is no way to recombine modal responses exactly. However, statistical combination of modal responses produces reasonably accurate estimates of displacements and component forces. The loss of signs for computed quantities leads to problems in interpreting force results where seismic effects are combined with gravity effects, produces forces that are not in equilibrium, and makes it impossible to plot deflected shapes of the structure.

C12.9.1 Number of Modes

The key motivation to perform modal response spectrum analysis is to determine how the actual distribution of mass and stiffness of a structure affects the elastic displacements and member forces. Where at least 90 percent of the model mass participates in the response, the distribution of forces and displacements is sufficient for design. The scaling required by Section 12.9.4 controls the overall magnitude of design values so that incomplete mass participation does not produce nonconservative results.

The number of modes required to achieve 90 percent modal mass participation is usually a small fraction of the total number of modes. See Lopez and Cruz (1996) for further discussion of the number of modes to use for modal response spectrum analysis.

C12.9.2 Modal Response Parameters

The design response spectrum (whether the general spectrum from Section 11.4.5 or a site-specific spectrum determined in accordance with Section 21.2) is representative of linear elastic structures. Division of the spectral ordinates by the response modification coefficient, R, accounts for inelastic behavior, and multiplication of spectral ordinates by the importance factor, I_e, provides the additional strength needed to improve the performance of important structures. The displacements that are computed using the response spectrum that has been modified by R and I_e (for strength) must be amplified by C_d and reduced by I_e to produce the expected inelastic displacements. (See Section C12.8.6.)

C12.9.3 Combined Response Parameters

Most computer programs provide for either the SRSS or the CQC method (Wilson, et al., 1981) of modal combination. The two methods are identical where applied to planar structures, or where zero damping is specified for the computation of the cross-modal coefficients in the CQC method. The modal damping specified in each mode for the CQC method should be equal to the damping level that was used in the development of the design response spectrum. For the spectrum in Section 11.4.5, the damping ratio is 0.05.

The SRSS or CQC method is applied to loading in one direction at a time. Where Section 12.5 requires explicit consideration of orthogonal loading effects, the results from one direction of loading may be added to 30 percent of the results from loading in an orthogonal direction. Wilson (2000) suggests that a more accurate approach is to use

the SRSS method to combine 100 percent of the results from each of two orthogonal directions where the individual directional results have been combined by SRSS or CQC, as appropriate.

The CQC-4 method (as modified by ASCE 4) is also specified and is an alternative to the required use of the CQC method where there are closely spaced modes with significant cross-correlation of translational and torsional response. The CQC-4 method varies slightly from the CQC method through the use of a parameter that forces a correlation in modal responses where they are partially or completely in-phase with the input motion. This difference primarily affects structures with short fundamental periods, *T*, that have significant components of response that are in-phase with the ground motion. In these cases, using the CQC method can be nonconservative. A general overview of the various modal response combination methods can be found in U.S Nuclear Regulatory Commission (1999).

C12.9.4 Scaling Design Values of Combined Response

The modal base shear, V_t, may be less than the ELF base shear, *V*, because: (a) the calculated fundamental period, *T*, may be longer than that used in computing *V*, (b) the response is not characterized by a single mode, or (c) the ELF base shear assumes 100 percent mass participation in the first mode, which is always an overestimate.

C12.9.4.1 Scaling of Forces

The scaling required by Section 12.9.4.1 provides, in effect, a minimum base shear for design. This minimum base shear is provided because the computed fundamental period may be the result of an overly flexible (incorrect) analytical model. The possible 15 percent reduction in design base shear may be considered as an incentive for using a modal response spectrum analysis in lieu of the equivalent lateral force procedure.

C12.9.4.2 Scaling of Drifts

Displacements from the modal response spectrum are not scaled because the use of an overly flexible model will result in conservative estimates of displacement that need not be further scaled.

C12.9.5 Horizontal Shear Distribution

Torsion effects in accordance with Section 12.8.4 must be included in the modal response spectrum analysis (MRSA) as specified in Section 12.9 by requiring use of the procedures in Section 12.8 for the determination of the seismic base shear, *V*. There are two basic approaches for consideration of accidental torsion.

The first approach follows the static procedure discussed in C12.8.4.2, where the total seismic lateral forces obtained from the MRSA – using the computed locations of the centers of mass and rigidity – are statically applied at an artificial point offset from the center of mass to compute the accidental torsional moments. Most computer programs can automate this procedure for three-dimensional analysis. Alternatively, the torsional moments can be statically applied as separate load cases and added to the results obtained from the MRSA.

As this approach is a static approximation, amplification of the accidental torsion in accordance with Section 12.8.4.3 is required. MRSA results in a single, positive response thus inhibiting direct assessment of torsional response. One method to circumvent this is to determine the maximum and average displacements for each mode participating in the direction being considered and then apply modal combination rules (primarily the CQC method) to obtain the total displacements used to check torsional irregularity and compute the amplification factor, A_x. The analyst should be attentive as to how accidental torsion is included for individual modal responses.

The second approach, which applies primarily to three-dimensional analysis, is to modify the dynamic characteristics of the structure so that dynamic amplification of the accidental torsion is directly considered. This can be done, for example, by either reassigning the lumped mass for each floor and roof (rigid diaphragm) to alternate points offset from the initially calculated center of mass and modifying the mass moment of inertia or physically relocating the initially calculated center of mass on each floor and roof by modifying the horizontal mass distribution (typically presumed uniformly distributed). This approach increases the computational demand significantly as all possible configurations would have to be analyzed, primarily two additional analyses for each principal axis of the structure. The advantage of this approach is that the dynamic effects of direct loading and accidental torsion are assessed automatically. Practical disadvantages are the increased bookkeeping required to track multiple analyses and the cumbersome calculations of the mass properties.

Where this “dynamic” approach is used, amplification of the accidental torsion in accordance with Section 12.8.4.3 is not required because repositioning the center of mass increases the coupling between the torsional and lateral modal responses, directly capturing the amplification of the accidental torsion.

DRAFT

Most computer programs that include accidental torsion in a MRSA do so statically (first approach discussed above) and do not physically shift the center of mass. The designer should be aware of the methodology used for consideration of accidental torsion in the selected computer program.

C12.9.6 P-delta Effects

The requirements of Section 12.8.7, including the stability coefficient limit, θ_{max}, apply to modal response spectrum analysis.

C12.9.7 Soil Structure Interaction Reduction

The standard permits including soil-structure interaction (SSI) effects in a modal response spectrum analysis in accordance with Chapter 19. The increased use of modal analysis for design stems from computer analysis programs automatically performing such an analysis. However, common commercial programs do not give analysts the ability to customize modal response parameters. This hinders the ability to include SSI effects in an automated modal analysis.

C12.10 DIAPHRAGMS, CHORDS, AND COLLECTORS

C12.10.1 Diaphragm Design

Diaphragms are generally treated as horizontal deep beams or trusses that distribute lateral forces to the vertical elements of the seismic-force-resisting system. As deep beams, diaphragms must be designed to resist the resultant shear and bending stresses. Diaphragms are commonly compared to girders, with the roof or floor deck analogous to the girder web in resisting shear, and the boundary elements (chords) analogous to the flanges of the girder in resisting flexural tension and compression. As in girder design, the chord members (flanges) must be sufficiently connected to the body of the diaphragm (web) to prevent separation and to force the diaphragm to work as single unit.

Diaphragms may be considered flexible, semi-rigid, or rigid. The flexibility or rigidity of the diaphragm determines how lateral forces will be distributed to the vertical elements of the seismic-force-resisting system. See Section C12.3.1. Once the distribution of lateral forces is determined, shear and moment diagrams are used to compute the diaphragm shear and chord forces. Where diaphragms are not flexible, inherent and accidental torsion must be considered in accordance with Section 12.8.4.

Diaphragm openings may require additional localized reinforcement (sub-chords and collectors) to resist the subdiaphragm chord forces above and below the opening and to collect shear forces where the diaphragm depth is reduced. (See Figure C12.10-1.) Collectors on each side of the opening drag shear into the subdiaphragms above and below the opening. The subchord and collector reinforcement must extend far enough into the adjacent diaphragm to develop the axial force through shear transfer. The required development length is determined by dividing the axial force in the sub-chord by the shear capacity (in force/unit length) of the main diaphragm.

Chord reinforcement at reentrant corners must extend far enough into the main diaphragm to develop the chord force through shear transfer. (See Figure C12.10-2.) Continuity of the chord members also must be considered where the depth of the diaphragm is not constant.

In wood and metal deck diaphragm design, framing members are often used as continuity elements, serving as sub-chords and collector elements at discontinuities. These continuity members also are often used to transfer wall out-of-plane forces to the main diaphragm, where the diaphragm itself does not have the capacity to resist the anchorage force directly. For additional discussion, see Sections C12.11.2.2.3 and C12.11.2.2.4.

DRAFT

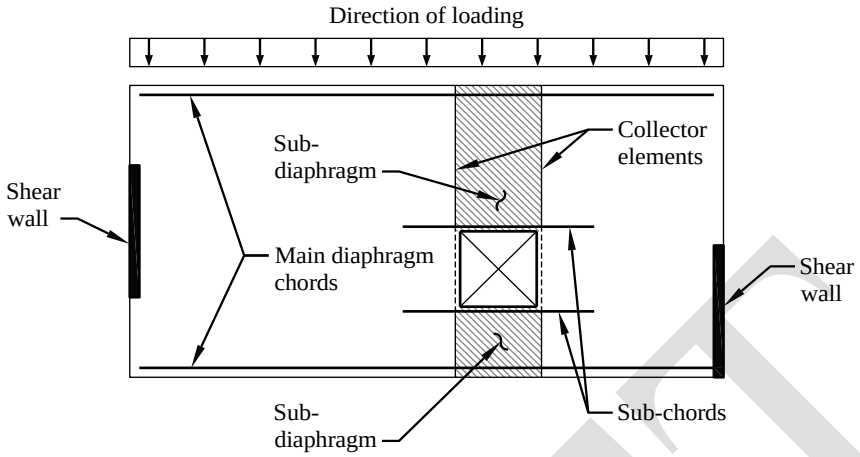

Figure C12.10- 1 Diaphragm with an opening.

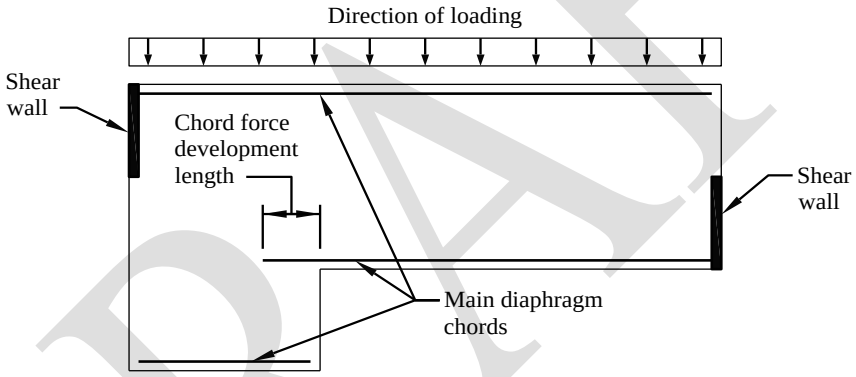

Figure C12.10- 2 Diaphragm with a re-entrant corner.

C12.10.1.1 Diaphragm Design Forces

Diaphragms must be designed to resist inertial forces, as specified in Equation 12.10-1, and to transfer design seismic forces due to horizontal offsets or changes in stiffness of the vertical resisting elements. Inertial forces are those seismic forces that originate at the specified diaphragm level, while the transfer forces originate above the specified diaphragm level. The redundancy factor, ρ, used for design of the seismic-force-resisting elements also applies to diaphragm transfer forces, thus completing the load path.

C12.10.2.1 Collector Elements Requiring Load Combinations with Overstrength Factor for Seismic Design Categories C through F

The overstrength requirement of this section is intended to keep inelastic behavior in the ductile elements of the seismic-force-resisting system (consistent with the response modification coefficient, *R*,) rather than in collector elements.

C12.11 STRUCTURAL WALLS AND THEIR ANCHORAGE

As discussed in Section C1.4, structural integrity is important not only in earthquake-resistant design but also in resisting high winds, floods, explosion, progressive failure, and even such ordinary hazards as foundation settlement. The detailed requirements of this section address wall-to-diaphragm integrity.

DRAFT

C12.11.1 Design for Out-of-Plane Forces

Because they are often subjected to local deformations caused by material shrinkage, temperature changes, and foundation movements, wall connections require some degree of ductility in order to accommodate slight movements while providing the required strength.

Although nonstructural walls are not subject to this requirement, they must be designed in accordance with Chapter 13.

C12.11.2 Anchorage of Concrete or Masonry Structural Walls

There are numerous instances in U.S. earthquakes of tall, single-story, and heavy walls becoming detached from supporting roofs, resulting in collapse of walls and supported bays of roof framing (Hamburger and McCormick, 2004). The response involves dynamic amplification of ground motion by response of vertical system and further dynamic amplification from flexible diaphragms. The design forces for seismic design category D and higher have been developed over the years in response to studies of specific failures. It is generally accepted that the rigid diaphragm value is reasonable for structures subjected to high ground motions. For a simple idealization of the dynamic response, these values imply that the combined effects of inelastic action in the main framing system supporting the wall, the wall (acting out of plane), and the anchor itself correspond to a reduction factor of 4.5 from elastic response to an MCE motion and therefore the value of the response modification coefficient, *R*, associated with nonlinear action in the wall or the anchor itself is 3.0. Such reduction is generally not achievable in the anchorage itself, thus it must come from yielding elsewhere in the structure, for example, the vertical elements of the seismic force resisting system, the diaphragm, or walls acting out of plane. The minimum forces are based upon the concept that less yielding will occur with smaller ground motions and less yielding will be achievable for systems with smaller values of *R*, which are permitted in structures assigned to Seismic Design Categories B and C. The minimum value of *R* in structures assigned to Seismic Design Category D, except cantilever column systems and light-frame walls sheathed with materials other than wood structural panels, is 3.25; whereas the minimum values of *R* for Categories B and C are 1.5 and 2.0, respectively.

Where the roof framing is not perpendicular to anchored walls, provision needs to be made to transfer both the tension and sliding components of the anchorage force into the roof diaphragm. Where a wall cantilevers above its highest attachment to, or near, a higher level of the structure, the reduction factor based upon height within the structure, $(1 + 2z/h)/3$, may result in a lower anchorage force than appropriate. In such an instance, using a value of 1.0 for the reduction factor may be more appropriate.

C12.11.2.1 Anchorage of Concrete or Masonry Structural Walls to Flexible Diaphragms

Diaphragm flexibility can amplify out-of-plane accelerations so the wall anchorage forces in this condition are twice those defined in Section 12.11.1.

C12.11.2.2 Additional Requirements for for Anchorage of Concrete or Masonry Structural Walls to Diaphragms in Structures Assigned to Seismic Design Categories C through F.

C12.11.2.2.1 Transfer of Anchorage Forces into Diaphragm

This requirement, which aims to prevent the diaphragm from tearing apart during strong shaking by requiring transfer of anchorage forces across the complete depth of the diaphragm, was prompted by failures of connections between tilt up concrete walls and wood panelized roof systems in the 1971 San Fernando earthquake.

Depending upon diaphragm shape and member spacing, numerous suitable combinations of subdiaphragms and continuous tie elements and smaller sub-subdiaphragms connecting to larger subdiaphragms and continuous tie elements are possible. The configuration of each subdiaphragm (or sub-subdiaphragm) provided must comply with the simple 2.5-to-1 length-to-width ratio, and the continuous ties must have adequate member and connection strength to carry the accumulated wall anchorage forces.

C12.11.2.2.2 Steel Elements of Structural Wall Anchorage System

A multiplier of 1.4 has been specified for strength design of steel elements in order to obtain a fracture strength of almost 2 times the specified design force (where φ_t is 0.75 for tensile rupture).

C12.11.2.2.3 Wood Diaphragms

Material standards for wood structural panel diaphragms permit the sheathing to resist shear forces only; use of diaphragm sheathing to resist direct tension or compression forces is not permitted. Therefore, seismic out-of-plane anchorage forces from structural walls must be transferred into framing members (such as beams, purlins, or subpurlins) using suitable straps or anchors. For wood diaphragms, it is common to use local framing and sheathing

DRAFT

elements as subdiaphragms to transfer the anchorage forces into more concentrated lines of drag or continuity framing that carry the forces across the diaphragm and hold the building together. Figure C12.11-1 shows a schematic plan of typical roof framing using subdiaphragms.

Fasteners that attach wood ledgers to structural walls are intended to resist shear forces from diaphragm sheathing attached to the ledger that act longitudinally along the length of the ledger but not shear forces that act transversely to the ledger, which tend to induce splitting in the ledger due to cross-grain bending. Separate straps or anchors generally are provided to transfer out-of-plane wall forces into perpendicular framing members.

C12.11.2.2.4 Metal Deck Diaphragms

In addition to transferring shear forces, metal deck diaphragms often can resist direct axial forces in at least one direction. However, corrugated metal decks cannot transfer axial forces in the direction perpendicular to the corrugations and are prone to buckling if the unbraced length of the deck as a compression element is large. To manage diaphragm forces perpendicular to the deck corrugations, it is common for metal decks to be supported at 8- to 10-foot intervals by joists that are connected to walls in a manner suitable to resist the full wall anchorage design force and to carry that force across the diaphragm. In the direction parallel to the deck corrugations, subdiaphragm systems are considered near the walls; if the compression forces in the deck become large relative to the joist spacing, small compression reinforcing elements are provided to transfer the forces into the subdiaphragms.

C12.11.2.2.5 Embedded Straps

Steel straps may be used in systems where heavy structural walls are connected to wood or steel diaphragms as the wall-to-diaphragm connection system. In systems where steel straps are embedded in concrete or masonry walls, the straps are required to be bent around reinforcing bars in the walls, which will improve their ductile performance in resisting earthquake load effects (e.g., the straps will pull the bars out of the wall before the straps fail by pulling out without pulling the reinforcing bars out). Consideration should be given to the probability that light steel straps have been worked in past earthquakes and developed cracks or fractures at the wall-to-diaphragm framing interface because of gaps in the framing adjacent to the walls.

C12.11.2.2.6 Eccentrically Loaded Anchorage System

Wall anchors often are loaded eccentrically, either because the anchorage mechanism allows eccentricity, or because of anchor bolt or strap misalignment. This eccentricity reduces the anchorage connection capacity and hence must be considered explicitly in design of the anchorage. Figure C12.11-2 shows a one-sided roof-to-wall anchor that is subjected to severe eccentricity due to a misplaced anchor rod. If the detail were designed as a concentric two-sided connection, this condition would be easier to correct.

C12.11.2.2.7 Walls with Pilasters

The anchorage force at pilasters must be calculated considering two-way bending in wall panels. It is customary to anchor the walls to the diaphragms assuming one-way bending and simple supports at the top and bottom of the wall. However, where pilasters are present in the walls, their stiffening effect must be taken into account. The panels between pilasters are typically supported along all panel edges. Where this occurs, the reaction at the top of the pilaster is the result of two-way action of the panel and is applied directly to the anchorage supporting the top of the pilaster. The anchor load at the pilaster generally is larger than the typical uniformly distributed anchor load between pilasters. Figure C12.11-3 shows the tributary area typically used to determine the anchorage force for a pilaster.

Anchor points adjacent to the pilaster must be designed for the full tributary loading, conservatively ignoring the effect of the adjacent pilaster.

DRAFT

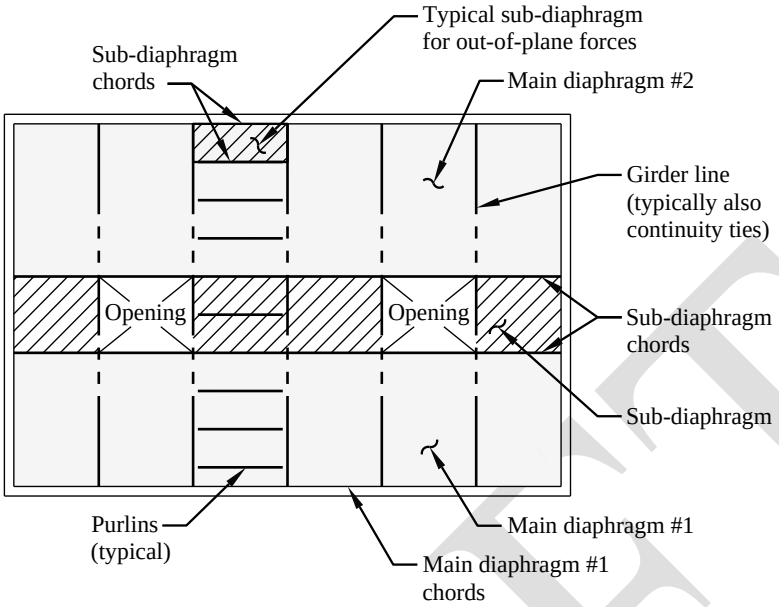

Figure C12.11- 1 Typical subdiaphragm framing.

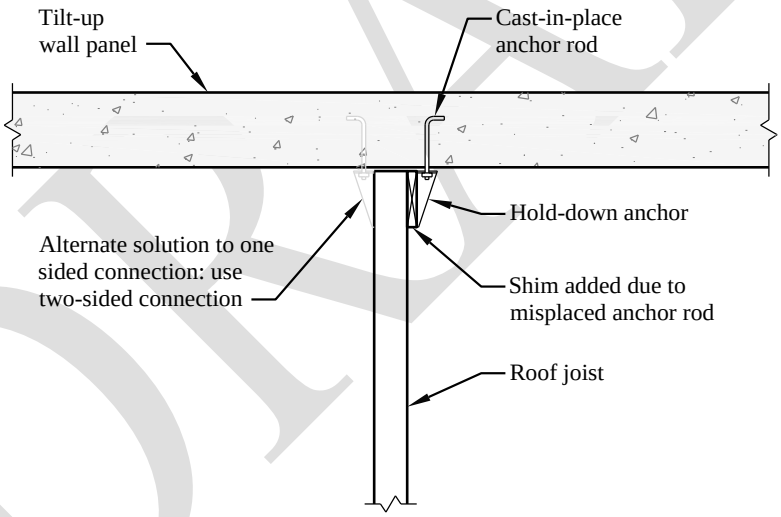

Figure C12.11- 2 Plan view of wall anchor with misplaced anchor rod.

C12.12 DRIFT AND DEFORMATION

As used in the standard, deflection is the absolute lateral displacement of any point in a structure relative to its base, and design story drift, Δ, is the difference in deflection along the height of a story (i.e., the deflection of a floor relative to that of the floor below). The drift, Δ, is calculated according to the procedures of Section 12.8.6 (Sections 12.9.2 and 16.1 give procedures for calculating displacements for modal response spectrum and linear response history analysis procedures, respectively; the definition of Δ in Section 11.3 should be used).

DRAFT

Calculated story drifts generally include torsional contributions to deflection (i.e., additional deflection at locations of the center of rigidity at other than the center of mass due to diaphragm rotation in the horizontal plane). The provisions allow these to be neglected where they are not significant, such as in cases where the calculated drifts are much less than the allowable story drifts, Δ_a, no torsional irregularities exist, and more precise calculations are not required for structural separations (see Sections C12.12.3 and C12.12.4).

The deflections and design story drifts are calculated using for the design earthquake ground motion, which is two-thirds of the risk-targeted maximum considered earthquake (MCE_R) ground motion. The resulting drifts are therefore likely to be underestimated.

The design base shear, V, used to calculate Δ is reduced by the response modification coefficient, R. Multiplying displacements by the deflection amplification factor, C_d, is intended to correct for this reduction and approximate inelastic drifts corresponding to the design response spectrum unreduced by R. However, it is recognized that use of values of C_d less than R underestimates deflections (Uang and Maarouf, 1994). See also C12.8.6.2 and C12.9.4 for the appropriate base shear for computing displacements.

For these reasons the displacements calculated may not correspond well to MCE_R ground motions. However, they are appropriate for use in evaluating the structure's compliance with the story drift limits put forth in Table 12.12.1 of the standard.

There are many reasons to limit drift; the most significant are to address the structural performance of member inelastic strain and system stability and to limit damage to nonstructural components, which can be life-threatening. Drifts provide a direct but imprecise measure of member strain and structural stability. Under small lateral deformations, secondary stresses due to the P-delta effect are normally within tolerable limits. (See Section C12.8.7.) The drift limits provide indirect control of structural performance.

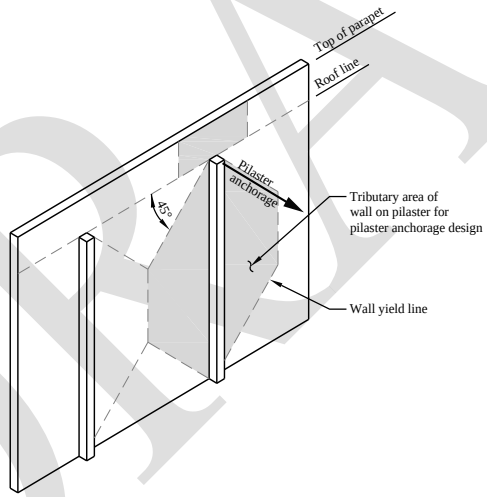

Figure C12.11- 3 Tributary area used to determine anchorage force at pilaster.

Buildings subjected to earthquakes need drift control to limit damage to partitions, shaft and stair enclosures, glass, and other fragile nonstructural components. The drift limits have been established without regard to economic considerations such as a comparison of present worth of future repairs with additional structural costs to limit drift. These are matters for building owners and designers to address.

The allowable story drifts, Δ_a, of Table 12.12-1 reflect the consensus opinion of the ASCE 7 Committee taking into account the life safety and damage control objectives described above. Since the displacements induced in a structure include inelastic effects, structural damage as the result of a design-level earthquake is likely. This may be seen from the values of Δ_a stated in Table 12.12-1. For other structures assigned to Risk Category I or II, the value of Δ_a is 0.02 h_{sx}, which is about ten times the drift ordinarily allowed under wind loads. If deformations well in

DRAFT

excess of Δ_a were to occur repeatedly, structural elements of the seismic force-resisting system could lose so much stiffness or strength that they compromise the safety and stability of the structure.

To provide better performance for structures assigned to Risk Category III or IV, their allowable story drifts, Δ_a, generally are more stringent than for those assigned to Risk Category I or II . However, those limits are still greater than the damage thresholds for most nonstructural components. Therefore, while the performance of structures assigned to Risk Category III or IV should be improved, there may be considerable damage from a design-level earthquake.

The allowable story drifts, Δ_a, for structures a maximum of four stories above the base are relaxed somewhat, provided the interior walls, partitions, ceilings, and exterior wall systems have been designed to accommodate story drifts. The type of structure envisioned by Footnote c would be similar to a prefabricated steel structure with metal skin.

The values of Δ_a set forth in Table 12.12-1 apply to each story. For some structures, satisfying strength requirements may produce a system with adequate drift control. However, the design of moment-resisting frames and of tall, narrow shear walls or braced frames often is governed by drift considerations. Where design spectral response accelerations are large, seismic drift considerations are expected to control the design of midrise buildings.

C12.12.3 Structural Separation. This section addresses the potential for impact from adjacent structures during an earthquake. Such conditions may arise due to construction on or near a property line or due to the introduction of separations within a structure (typically called "seismic joints") for the purpose of permitting their independent response to earthquake ground motion. Such joints may effectively eliminate irregularities and large force transfers between portions of the building with different dynamic properties.

The standard requires the distance to be "sufficient to avoid damaging contact under total deflection." It is recommended that the distance be computed using the square root of the sum of the squares of the lateral deflections. Such a combination method treats the deformations as linearly independent variables. The deflections used are the expected displacements (e.g., the anticipated maximum inelastic deflections including the effects of torsion and diaphragm deformation). Just as these displacements increase with height, so does the required separation. If the effects of impact can be shown not to be detrimental, the required separation distances can be reduced.

For very rigid shear wall structures with rigid diaphragms whose lateral deflections cannot be reasonably estimated, the NEHRP *Recommended Seismic Provisions* (BSSC, 2009) suggest that older code requirements for structural separations of at least 1 inch (25 mm) plus 1/2 inch (13 mm) for each 10 feet (3 m) of height above 20 feet (6 m) be followed.

C12.12.4 Members Spanning between Structures. Where a portion of the structure is seismically separated from its support, the design of the support requires attention to ensure that support is maintained as the two portions move independently during earthquake ground motions. To prevent loss of gravity support for members that bridge between the two portions, the relative displacement must not be underestimated. Displacements computed for verifying compliance with drift limits (Equation 12.8-15), and structural separations (Equation 12.12-1), may be insufficient for this purpose.

The provision gives four requirements to ensure that displacement is not underestimated.

1. The deflections calculated using Equation 12.8-15 are multiplied by 1.5 R/C_d to correct for likely underestimation of displacement by the equation. The factor of 1.5 corrects for the 2/3 factor that is used in the calculation of seismic base shear, V, by reducing the base shear from the value based on the MCE_R ground motion (Section 11.4.4). Multiplying by R/C_d corrects for the fact that values of C_d less than R underestimate deflections (Uang and Maarouf, 1994).

2. The deflections are calculated for torsional effects, including amplification factors. Diaphragm rotation can add significantly to the center-of-mass displacements calculated using Equation 12.8-15.

3. Displacement due to diaphragm deformations are required to be calculated, as in some types of construction where the deformation during earthquake ground motions of the diaphragm can be considerable.

4. The absolute sum of displacements of the two portions is used instead of a modal combination, such as with Eq. 12.12-2, which would represent a probable value.

DRAFT

It is recognized that displacements so calculated are likely to be conservative. However, the consequences of loss of gravity support are likely to be severe and some conservatism is deemed appropriate.

C12.12.5 Deformation Compatibility For Seismic Design Categories D Through F. In regions of high seismicity, many designers apply ductile detailing requirements to elements that are intended to resist seismic forces but neglect such practices for nonstructural components, or for structural components that are designed to resist only gravity forces but must undergo the same lateral deformations as the designated seismic force-resisting system. Even where elements of the structure are not intended to resist seismic forces and are not detailed for such resistance, they can participate in the response and may suffer severe damage as a result. This provision requires the designer to provide a level of ductile detailing or proportioning to all elements of the structure appropriate to the calculated deformation demands at the design story drift, Δ. This may be accomplished by applying details in gravity members similar to that used in members of the seismic force-resisting system or by providing sufficient *strength in those members, or by providing sufficient stiffness in the overall structure to preclude ductility demands in those members*.

In the 1994 Northridge earthquake, such participation was a cause of several failures. A preliminary reconnaissance report of that earthquake (EERI, 1994) states:

> *Of much significance is the observation that six of the seven partial collapses (in modern precast concrete parking structures) seem to have been precipitated by damage to the gravity load system. Possibly, the combination of large lateral deformation and vertical load caused crushing in poorly confined columns that were not detailed to be part of the lateral load resisting system. Punching shear failures were observed in some structures at slab-to-column connections such as at the Four Seasons building in Sherman Oaks. The primary lateral load resisting system was a perimeter ductile frame that performed quite well. However, the interior slab-column system was incapable of undergoing the same lateral deflections and experienced punching failures.*

This section addresses such concerns. Rather than relying on designers to assume appropriate levels of stiffness, this section explicitly requires that the stiffening effects of adjoining rigid structural and nonstructural elements be considered and that a rational value of member and restraint stiffness be used for the design of structural components that are not part of the seismic-force-resisting system.

This section also includes a requirement to address shears that can be induced in structural components that are not part of the seismic-force-resisting system, since sudden shear failures have been catastrophic in past earthquakes.

The exception is intended to encourage the use of intermediate or special detailing in beams and columns that are not part of the seismic-force-resisting system. In return for better detailing, such beams and columns are permitted to be designed to resist moments and shears from unamplified deflections. This reflects observations and experimental evidence that well-detailed structural components can accommodate large drifts by responding inelastically without losing significant vertical load-carrying capacity.

C12.13 FOUNDATION DESIGN

C12.13.3 Foundation Load-Deformation Characteristics

For linear static and dynamic analysis methods, where foundation flexibility is included in the analysis the load-deformation behavior of the supporting soil should be represented by an equivalent elastic stiffness using soil properties that are compatible with the soil strain levels associated with the design earthquake motion. The strain-compatible shear modulus, G, and the associated strain-compatible shear wave velocity, vs, needed for the evaluation of equivalent elastic stiffness are specified in Chapter 19 of the standard or can be based on a site-specific study. While inclusion of soil flexibility tends to lengthen the fundamental period of the structure, it should not change the maximum period limitations applied when calculating the required base shear of a structure.

A mathematical model incorporating a combined superstructure and foundation system is necessary to assess the effect of foundation and soil deformations on the superstructure elements. Typically, frequency-independent linear springs are included in the mathematical model to represent the load-deformation characteristics of the soil and the foundation components are either explicitly modeled (e.g., mat foundation supporting a configuration of structural walls) or are assumed to be rigid (e.g., spread footing supporting a column). In specific cases, a spring may be used to model both the soil and foundation component (e.g., grade beams or individual piles).

For dynamic analysis, the standard requires a parametric evaluation with upper and lower bound soil parameters to account for the uncertainty in as-modeled soil stiffness and in-situ soil variability, and to evaluate the sensitivity of these variations on the superstructure. Sources of uncertainty include variability in the rate of loading including the

DRAFT

cyclic nature of building response, level of strain associated with loading at the design earthquake (or stronger), idealization of potentially nonlinear soil properties as elastic, and variability in the estimated soil properties. To a lesser extent, this variation accounts for variability in the performance of the foundation components, primarily when a rigid foundation is assumed or distribution of cracking of concrete elements is not explicitly modeled.

Commonly-used analysis procedures tend to segregate the "structural" components of the foundation (e.g., footing, grade beam, pile, pile cap) from the supporting (e.g., soil) components. The "structural" components are typically analyzed using standard Strength Design load combinations and methodologies, whereas the adjacent soil components are analyzed using Allowable Stress Design (ASD) practices, in which earthquake forces (that have been reduced by R) are considered using ASD load combinations, to make comparisons of design forces versus allowable capacities. These "allowable" soil capacities are typically based on expected strength divided by a factor of safety, for a given level of potential deformations.

When design of the superstructure and foundation components is performed using strength-level load combinations, this traditional practice of using allowable stress design to verify soil compliance can become problematic for assessing the behavior of foundation components. The 2009 NEHRP Recommended Provisions contain two resource papers (RP 4 and RP 8) that provide guidance on the application of ultimate strength design (USD) procedures in the geotechnical design of foundations and the development of foundation load-deformation characterizations for both linear and nonlinear analysis methods. Additional guidance on these topics is contained in Standard ASCE/SEI 41-06.

12.13.4 Reduction of Foundation Overturning.

Overturning effects at the soil-foundation interface are permitted to be reduced by 25 percent for foundations of structures that satisfy both of the following conditions:

a. The structure is designed in accordance with the Equivalent Lateral Force Analysis as set forth in Section 12.8.

b. The structure is not an inverted pendulum or cantilevered column type structure.

Overturning effects at the soil-foundation interface are permitted to be reduced by 10 percent for foundations of structures designed in accordance with the modal analysis requirements of Section 12.9.

C12.13.5 Requirements for Structures Assigned to Seismic Design Category C

C12.13.5.1 Pole-Type Structures

The high contact pressures that develop between an embedded pole and soil as a result of lateral loads make pole-type structures sensitive to earthquake motions. Pole bending strength and stiffness, as well as the soil lateral bearing capacity and the permissible deformation at grade level are key considerations in the design. For further discussion of pole-soil interaction, see Section C12.13.6.7.

C12.13.5.2 Foundation Ties

One important aspect of adequate seismic performance is that the foundation system acts as an integral unit, not permitting one column or wall to move appreciably to another. To attain this performance, the standard requires that pile caps to be tied together. This is especially important where the use of deep foundations is driven by the existence of soft surface soils.

Multistory buildings often have major columns that run the full height of the building adjacent to smaller columns that support only one level; the calculated tie force should be based on the heavier column load.

The standard permits alternate methods of tying foundations together when appropriate. Relying on lateral soil pressure on pile caps to provide the required restraint is not a recommended method because ground motions are highly dynamic and may occasionally vary between structure support points during a design-level seismic event.

C12.13.5.3 Pile Anchorage Requirements

The pile anchorage requirements are intended to prevent brittle failures of the connection to the pile cap under moderate ground motions. Moderate ground motions can result in pile tension forces or bending moments that could compromise shallow anchorage embedment. Loss of pile anchorage could result in increased structural displacements from rocking, overturning instability, and loss of shearing resistance at the ground surface. A concrete bond to a bare steel pile section usually is unreliable but connection by means of deformed bars properly developed from the pile cap into concrete confined by a circular pile section is permitted.

DRAFT

C12.13.6 Requirements for Structures Assigned to Seismic Design Categories D through F

C12.13.6.1 Pole-Type Structures

See Section C12.13.5.1.

C12.13.6.2 Foundation Ties

See Section C12.13.5.2. For Seismic Design Categories D through F, the requirement is extended to spread footings on soft soils (Site Class E or F).

C12.13.6.3 General Pile Design Requirements

Design of piles is based on the same response modification coefficient, *R*, used in design of the superstructure; since inelastic behavior will result, piles should be designed with ductility similar to that of the superstructure. When strong ground motions occur, inertial pile-soil interaction may produce plastic hinging in piles near the bottom of the pile cap, and kinematic soil-pile interaction will result in bending moments and shearing forces throughout the length of the pile, being higher at interfaces between stiff and soft soil strata. These effects are particularly severe in soft soils and liquefiable soils so Section 14.2.3.2.1 requires special detailing in areas of concern.

The shears and curvatures in piles caused by inertial and kinematic interaction may exceed the bending capacity of conventionally designed piles, resulting in severe damage. Analysis techniques to evaluate pile bending are discussed by Margason and Holloway (1977) and Mylonakis (2001), and these effects on concrete piles are further discussed by Shepard (1983). For homogeneous, elastic media and assuming the pile follows the soil, the free-field curvature (soil strains without a pile present) can be estimated by dividing the peak ground acceleration by the square of the shear wave velocity of the soil. Considerable judgment is necessary in using this simple relationship for a layered, inelastic profile with pile-soil interaction effects. Norris (1994) discusses methods to assess pile-soil interaction.

Where determining the extent of special detailing, the designer must consider variation in soil conditions and driven pile lengths, so that adequate ductility is provided at potentially high curvature interfaces. Confinement of concrete piles to provide ductility and maintain functionality of the confined core pile during and after the earthquake may be obtained by use of heavy spiral reinforcement or exterior steel liners.

C12.13.6.4 Batter Piles

Partially embedded batter piles have a history of poor performance in strong ground shaking, as shown by Gerwick and Fotinos (1992). Failure of battered piles has been attributed to design that neglects loading on the piles from ground deformation or assumes that lateral loads are resisted by axial response of piles without regard to moments induced in the pile at the pile cap (Lam and Bertero, 1990). Because batter piles are considered to have limited ductility, they must be designed using the load combinations with overstrength factor. Moment-resisting connections between pile and pile cap must resolve the eccentricities inherent in batter pile configurations. This concept is illustrated clearly by EQE Engineering (1991).

C12.13.6.5 Pile Anchorage Requirements

Piles should be anchored to the pile cap to permit energy dissipating mechanisms, such as pile slip at the pile-soil interface, while maintaining a competent connection. This section of the standard sets forth a capacity design approach to achieve that objective. Anchorages occurring at pile cap corners and edges should be reinforced to preclude local failure of plain concrete sections due to pile shears, axial loads, and moments.

C12.13.6.6 Splices of Pile Segments

A capacity design approach, similar to that for pile anchorage, is applied to pile splices.

C12.13.6.7 Pile Soil Interaction

Short piles and long slender piles embedded in the earth behave differently when subjected to lateral forces and displacements. The response of a long slender pile depends on its interaction with the soil considering the nonlinear response of the soil. Numerous design aid curves and computer programs are available for this type of analysis, which is necessary to obtain realistic pile moments, forces, and deflections and is common in practice (Ensoft, 2004b). More sophisticated models, which also consider inelastic behavior of the pile itself, can be analyzed using general-purpose nonlinear analysis computer programs or closely approximated using the pile-soil limit state methodology and procedure given by Song, et al. (2005).

Short piles (with length-to-diameter ratios no more than 6) can be treated as a rigid body simplifying the analysis. A method assuming a rigid body and linear soil response for lateral bearing is given in the current building codes. A more accurate and comprehensive approach using this method is given in a study by Czerniak (1957).

DRAFT

C12.13.6.8 Pile Group Effects

The effects of groups of piles, where closely spaced, must be taken into account for vertical and horizontal response. As groups of closely spaced piles move laterally, failure zones for individual piles overlap, and horizontal strength and stiffness response of the pile-soil system is reduced. Reduction factors or "*p*-multipliers" are used to account for these groups of closely spaced piles. For a pile center-to-center spacing of three pile diameters, reduction factors of 0.6 for the leading pile row and 0.4 for the trailing pile rows are recommended by Rollins, et al. (1999). Computer programs are available to analyze group effects assuming nonlinear soil and elastic piles (Ensoft, 2004a).

C12.14 SIMPLIFIED ALTERNATIVE STRUCTURAL DESIGN CRITERIA FOR SIMPLE BEARING WALL OR BUILDING FRAME SYSTEMS

C12.14.1 General

In recent years, engineers and building officials have become concerned that the seismic design requirements in codes and standards, while intended to make structures perform more reliably, have become so complex and difficult to understand and implement that they may be counterproductive. Since the response of buildings to earthquake ground shaking is very complex (especially for irregular structural systems), realistically accounting for these effects can lead to complex requirements. There is a concern that the typical designers of small, simple buildings, which may represent more than 90 percent of construction in the United States, have difficulty understanding and applying the general seismic requirements of the standard.

The simplified procedure presented in this section of the standard applies to low-rise, stiff buildings. The procedure, which was refined and tested over a five-year period, was developed to be used for a defined set of buildings deemed to be sufficiently regular in structural configuration to allow a reduction of prescriptive requirements. For some design elements, such as foundations and anchorage of nonstructural components, other sections of the standard must be followed, as referenced within Section 12.14.

C12.14.1.1 Simplified Design Procedure

Reasons for the limitations of the simplified design procedure of Section 12.14 are as follows:

1. The procedure was developed to address adequate seismic performance for standard occupancies. Since it was not developed for higher levels of performance associated with structures assigned to Risk Category III and IV , no importance factor (I_e) is employed.
2. Site Class E and F soils require specialized procedures that are beyond the scope of the procedure.
3. The procedure was developed for stiff, low-rise buildings, where higher-mode effects are negligible.
4. Only stiff systems where drift is not a controlling design criterion may employ the procedure. Because of this limitation, drifts are not computed. The response modification coefficient, *R*, and the associated system limitations are consistent with those found in the general Chapter 12 requirements.
5. In order to achieve a balanced design and a reasonable level of redundancy, two lines of resistance are required in each of the two major axis directions. Because of this stipulation, no redundancy factor (ρ) is applied.
6. To reduce the potential for dominant torsional response, at least one line of resistance must be placed on each side of the center of mass.
7. Large overhangs for flexible diaphragm buildings can produce a response that is inconsistent with the assumptions associated with the procedure.
8. A system that satisfies these layout and proportioning requirements avoids torsional irregularity, so calculation of accidental torsional moments is not required.
9. An essentially orthogonal orientation of lines of resistance effectively uncouples response along the two major axis directions, so orthogonal effects may be neglected.
10. Where the simplified design procedure is chosen, it must be used for the entire design, in both major axis directions.
11. Since in-plane and out-of-plane offsets generally create large demands on diaphragms, collectors, and discontinuous elements, which are not addressed by the procedure, these irregularities are prohibited.
12. Buildings that exhibit weak-story behavior violate the assumptions used to develop the procedure.

DRAFT

C12.14.3 Seismic Load Effects and Combinations

The equations for seismic load effects and load combinations in the simplified design procedure are consistent with those for the general procedure, with one notable exception: the overstrength factor (corresponding to Ω_0 in the general procedure) is set at 2.5 for all systems as indicated in Section 12.14.3.2.1. Given the limited systems that can use the simplified design procedure, specifying unique overstrength factors was deemed unnecessary.

C12.14.7 Design and Detailing Requirements

The design and detailing requirements outlined in this section are similar to those for the general procedure. The few differences include the following:

1. Forces used to connect smaller portions of a structure to the remainder of the structures are taken as 0.20 times the short- period design spectral response acceleration, S_{DS}, rather than the general procedure value of 0.133 (Section 12.14.7.1).

2. Anchorage forces for concrete or masonry structural walls for structures with diaphragms that are not flexible are computed using the requirements for nonstructural walls (Section 12.14.7.5).

C12.14.8 Simplified Lateral Force Analysis Procedure

C12.14.8.1 Seismic Base Shear

The seismic base shear in the simplified design procedure, as given by Equation 12.14-11, is a function of the short-period design spectral response acceleration, S_{DS}. The value for F in the base shear equation addresses changes in dynamic response for buildings that are two or three stories above grade plane (see Section 11.2 for definitions of "grade plane" and "story above grade plane"). As in the general procedure (Section 12.8.1.3), S_{DS} may be computed for short, regular structures with S_S taken no greater than 1.5.

C12.14.8.2 Vertical Distribution

The seismic forces for multistory buildings are distributed vertically in proportion to the weight of the respective floor. Given the slightly amplified base shear for multi-story buildings, this assumption, along with the limit of three stories above grade plane for use of the procedure, produces results consistent with the more traditional triangular distribution without introducing that more sophisticated approach.

C12.14.8.5 Drift Limits and Building Separation

For the simplified design procedure, which is restricted to stiff shear wall and braced frame buildings, drift need not be calculated. Where drifts are required (such as for structural separations and cladding design) a conservative drift value of 1 percent is specified.

Chapter C13
SEISMIC DESIGN REQUIREMENTS FOR NONSTRUCTURAL COMPONENTS

C13.1 GENERAL

Chapter 13 defines minimum design criteria for architectural, mechanical, electrical, and other nonstructural systems and components recognizing structure use, occupant load, the need for operational continuity, and the interrelation of structural and architectural, mechanical, electrical, and other nonstructural components. Nonstructural components are designed for design earthquake ground motions as defined in Section 11.2 and determined in Section 11.4.4 of the standard. In contrast to structures, which are implicitly designed for a low probability of collapse when subjected to the maximum considered earthquake (MCE) ground motions, there are no implicit performance goals associated with the MCE for nonstructural components. Performance goals associated with the design earthquake are discussed in Section C13.1.3.

Suspended or attached nonstructural components that could detach either in full or in part from the structure during an earthquake are referred to as falling hazards and may represent a serious threat to property and life safety. Critical attributes that influence the hazards posed by these components include their weight, their attachment to the structure, their failure or breakage characteristics (e.g., non-shatterproof glass), and their location relative to occupied areas (e.g., over an entry or exit, a public walkway, an atrium, or a lower adjacent structure). Architectural components that pose potential falling hazards include parapets, cornices, canopies, marquees, glass, large ornamental elements (e.g., chandeliers), and building cladding. In addition, suspended mechanical and electrical components (e.g., mixing boxes, piping, and ductwork) may represent serious falling hazards. Figures C13.1-1 through C13.1-4 show damage to nonstructural components in past earthquakes.

DRAFT

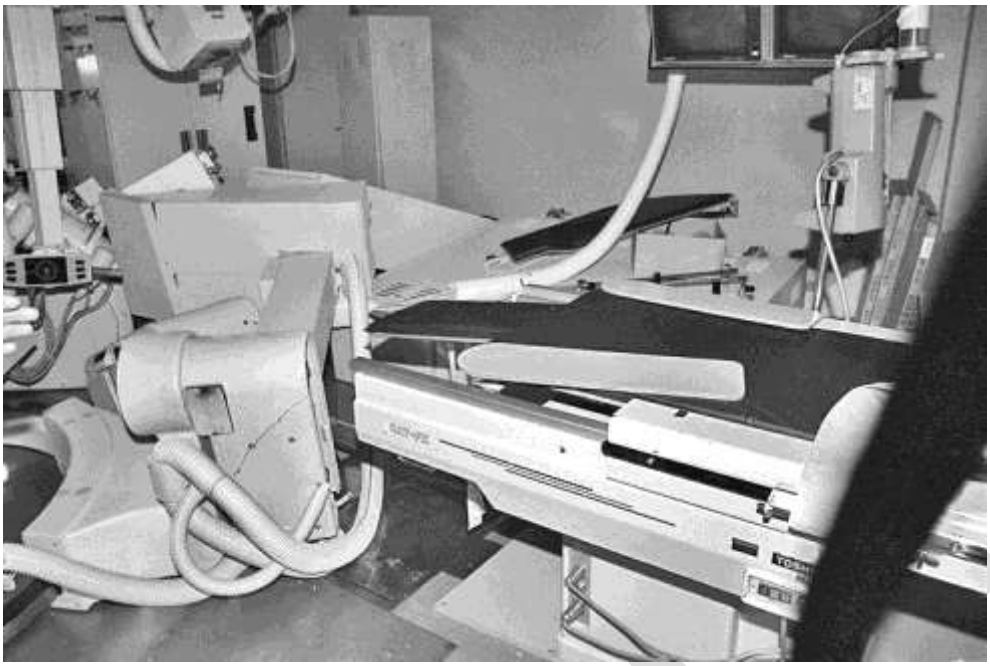

Figure C13.1- 1 Hospital imaging equipment that fell from overhead mounts.

Figure C13.1- 2 Collapsed light fixtures.

Figure C13.1- 3 Collapsed duct and HVAC diffuser.

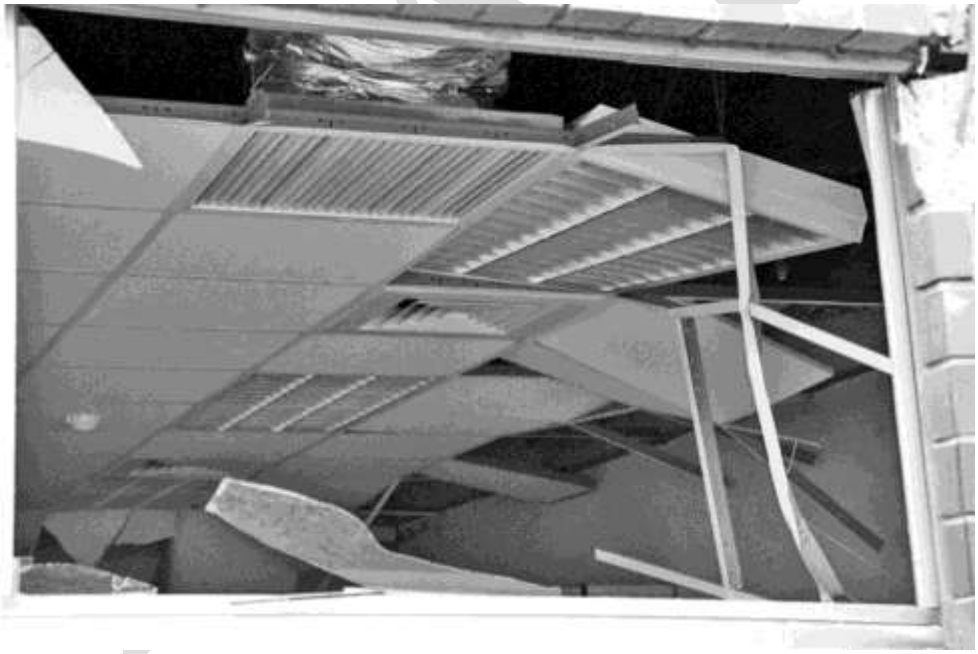

Figure C13.1- 4 Damaged ceiling system.

Components whose collapse during an earthquake could result in blockage of the means of egress deserve special consideration. The term "means of egress" is used commonly in building codes with respect to fire hazard. Consideration of egress may include intervening aisles, doors, doorways, gates, corridors, exterior exit balconies, ramps, stairways, pressurized enclosures, horizontal exits, exit passageways, exit courts, and yards. Items whose

failure could jeopardize the means of egress include walls around stairs and corridors, veneers, cornices, canopies, heavy partition systems, ceilings, architectural soffits, light fixtures, and other ornaments above building exits or near fire escapes. Examples of components that generally do not pose a significant falling hazard include fabric awnings and canopies. Architectural, mechanical, and electrical components that, if separated from the structure, will fall in areas that are not accessible to the public (e.g., into a mechanical shaft or light well) also pose little risk to egress routes.

For some architectural components such as exterior cladding elements, wind design forces may exceed the calculated seismic design forces. Nevertheless, seismic detailing requirements may still govern the overall structural design. Where this is a possibility, it must be investigated early in the structural design process.

The seismic design of nonstructural components may involve consideration of nonseismic requirements that are affected by seismic bracing. For example, accommodation of thermal expansion in pressure piping systems often is a critical design consideration and seismic bracing for these systems must be arranged in a manner that accommodates thermal movements. Particularly in the case of mechanical and electrical systems, the design for seismic loads should not compromise the functionality, durability, or safety of the overall design; this requires collaboration between the various disciplines of the design and construction team.

For various reasons (e.g., business continuity), it may be desirable to consider higher performance than that required by the building code. For example, to achieve continued operability of a piping system, it is necessary to prevent unintended operation of valves or other inline components in addition to preventing collapse and providing leak tightness. Higher performance also is required for components containing substantial quantities of hazardous contents (as defined in Section 11.2). These components must be designed to prevent uncontrolled release of those materials.

The requirements of Chapter 13 are intended to apply to new construction and tenant improvements installed at any time during the life of the structure, provided they are listed in Table 13.5-1 or 13.6-1. Further, they are intended to reduce (not eliminate) the risk to occupants and to improve the likelihood that essential facilities remain functional. While property protection (in the sense of investment preservation) is a possible consequence of implementation of the standard, it is not currently a stated or implied goal; a higher level of protection may be advisable if such protection is desired or required.

C13.1.1 Scope

The requirements for seismic design of nonstructural components apply to the nonstructural component as well as to its supports and attachments to the main structure. In some cases as defined in Section 13.2, it is necessary to consider explicitly the performance characteristics of the component. The requirements are intended to apply only to permanently attached components – not to furniture, temporary items, or mobile units. Furniture, such as tables, chairs, and desks, may shift during strong ground shaking but generally pose minimal hazards provided they do not obstruct emergency egress routes. Storage cabinets, tall bookshelves, and other items of significant mass do not fall into this category and should be anchored or braced in accordance with this chapter.

DRAFT

Figure C13.1- 5 Toppled storage cabinets.

Temporary items are those that remain in place for short periods of time (months, not years). Components that are expected to remain in place for periods of a year or longer, even if they are designed to be movable, should be considered permanent for the purposes of this section. Modular office systems are considered permanent since they ordinarily remain in place for long periods. In addition, they often include storage units that have significant capacity and may topple in an earthquake. They are subject to the provisions of Section 13.5.8 for partitions if they exceed 6 feet in height. Mobile units include components that are moved from one point in the structure to another during ordinary use. Examples include desktop computers, office equipment, and other components that are not permanently attached to the building utility systems (Figure C13.1-5). Components that are mounted on wheels to facilitate periodic maintenance or cleaning but that otherwise remain in the same location (e.g., server racks) are not considered moveable for the purposes of anchorage and bracing. Likewise, skid-mounted components (as shown in Figure C13.1-6) as well as the skids themselves are considered permanent equipment.

In all cases, equipment must be anchored if it is permanently attached to utility services (electricity, gas, and water). For the purposes of this requirement, "permanently attached" should be understood to include all electrical connections except NEMA 5-15 and 5-20 straight-blade connectors (duplex receptacles).

C13.1.2 Seismic Design Category

The requirements for nonstructural components are based in part on the Seismic Design Category to which they are assigned. As the Seismic Design Category is established considering factors not unique to specific nonstructural components, all nonstructural components occupying or attached to a structure are assigned to the same Seismic Design Category as the structure.

C13.1.3 Component Importance Factor

Performance expectations for nonstructural components often are defined in terms of the functional requirements of the structure to which the components are attached. While specific performance goals for nonstructural components have yet to be defined in building codes, the component importance factor (I_p) implies performance levels for specific cases. For noncritical nonstructural components (those with an importance factor, I_p, of 1.0) the following behaviors are anticipated for shaking having different levels of intensity:

1. Minor earthquake ground motions – minimal damage; not likely to affect functionality
2. Moderate earthquake ground motions – some damage that may affect functionality

DRAFT

3. Design earthquake ground motions – major damage but significant falling hazards are avoided; likely loss of functionality.

Figure C13.1- 6 Skid-mounted components.

Components with importance factors greater than 1.0 are expected to remain in place, sustain limited damage, and, when necessary, function following an earthquake (see Section C13.2.2). These components can be located in structures that are not assigned to Risk Category IV. For example, fire sprinkler piping systems have an importance factor, I_p, of 1.5 in all structures since these essential systems should function following an earthquake. Egress stairways are assigned an Ip of 1.5 as well, although in many cases the design of these stairways is dictated by differential displacements, not inertial force demands.

The component importance factor is intended to represent the greater of the life-safety importance of the component and the hazard-exposure importance of the structure. It indirectly influences the survivability of the component via required design forces and displacement levels as well as component attachments and detailing. While this approach provides some degree of confidence in the seismic performance of a component, it may not be sufficient in all cases. For example, individual ceiling tiles may fall from a ceiling grid that has been designed for larger forces. This may not represent a serious falling hazard if the ceiling tiles are made of lightweight materials, but it may lead to blockage of critical egress paths or disruption of the facility function. When higher levels of confidence in performance are required, the component is classified as a designated seismic system (Section 11.2), and, in certain cases, seismic qualification of the component or system is necessary. Seismic qualification approaches are provided in Sections 13.2.5 and 13.2.6. In addition, seismic qualification approaches presently in use by the Department of Energy (DOE) can be applied.

Risk Category IV structures are intended to be functional following a design earthquake; critical nonstructural components and equipment in such structures are designed with I_p equal to 1.5. This requirement applies to most components and equipment since damage to vulnerable unbraced systems or equipment may disrupt operations following an earthquake even if they are not directly classified as essential to life safety. The nonessential/nonhazardous components themselves are not affected by this requirement, and requirements focus on the supports and attachments. UFC 3-310-04 has additional guidance for improved performance.

C13.1.4 Exemptions

Several classes of nonstructural components are exempted from the requirements of Chapter 13. The exemptions are made on the assumption that, either due to their inherent strength and stability, or the lower level of earthquake demand (accelerations and relative displacements), or both, these nonstructural components and systems can achieve the performance goals described earlier in this commentary without explicitly satisfying the requirements of this chapter.

The requirements are intended to apply only to permanent components, not furniture and temporary or mobile equipment. Furniture (with the exception of more massive elements like storage cabinets) may shift during strong ground shaking, but pose minimal hazards. Equipment must be anchored if it is permanently attached to the structure utility services, such as electricity, gas, or water. For the purposes of this requirement, "permanently attached" includes all electrical connections except plugs for duplex receptacles.

See 13.1.1 for a discussion of temporary components.

Mobile units include components that are moved from one point in the structure to another during ordinary use. Examples include desktop computers, office equipment, and other components that are not permanently attached to the building utility systems. Components mounted on wheels to facilitate periodic maintenance or cleaning but which otherwise remain in the same location are not considered movable for the purposes of anchorage and bracing.

Furniture resting on floors such as tables, chairs, and desks may shift during strong ground shaking, but generally pose minimal hazards provided they do not obstruct emergency egress routes. Examples also include desktop computers, office equipment, and other components that are not permanently attached to the building utility systems.

With the exception of parapets supported by bearing walls or shear walls, all components in Seismic Design Categories A and B are exempt, due to the low levels of ground shaking expected. Parapets are not exempt because experience has shown that these items can fail and pose a significant falling hazard, even at low-level shaking levels.

The exemption for mechanical and electrical components in Seismic Design Categories D, E, or F based on weight and location of the center of mass is particularly applicable to vertical equipment racks and similar components. Where detailed information regarding the center of mass of the intended installation is unavailable, a conservative estimate based on potential equipment configurations should be used.

While the exemptions listed in 13.1.4 are intended to waive bracing requirements for non-structural components that are judged to pose negligible life safety hazard, in some cases it may nevertheless be advisable to consider bracing (in consultation with the owner) for exempted components to minimize repair costs and/or disproportionate loss (e.g., art works of high value).

C13.1.5 Application of Nonstructural Component Requirements to Nonbuilding Structures

At times, a nonstructural component should be treated as a nonbuilding structure. When the physical characteristics associated with a given class of nonstructural components vary widely, judgment is needed to select the appropriate design procedure and coefficients. For example, cooling towers vary from small packaged units with an operating weight of 2,000 pounds or less to structures the size of buildings. Consequently, design coefficients for the design of "cooling towers" are found both in Table 13.6-1 and Table 15.4-2. Small cooling towers are best designed as nonstructural components using the provisions of Chapter 13 while large ones are clearly nonbuilding structures that are more appropriately designed using the provisions of Chapter 15. Similar issues arise for other classes of nonstructural component (e.g., boilers and bins). Guidance on determining whether an item should be treated as a nonbuilding structure or nonstructural component for the purpose of seismic design is provided in Bachman and Dowty (2008).

Pre-manufactured modular mechanical units are considered nonbuilding structures supporting nonstructural components. The entire system (all modules assembled) can be shake table qualified or qualified separately as subsystems. Modular mechanical units house various nonstructural components that are subject to all the design requirements of Chapter 13.

The specified weight limit for nonstructural components (25 percent relative to the combined weight of the structure and component) relates to the condition at which dynamic interaction between the component and the supporting structural system is potentially significant. Section 15.3.2 contains requirements for addressing this interaction in design.

DRAFT

C13.1.6 Reference Documents

Professional and trade organizations have developed nationally recognized codes and standards for the design and construction of specific mechanical and electrical components. These documents provide design guidance for normal and upset (abnormal) operating conditions and for various environmental conditions. Some of these documents include earthquake design requirements in the context of the overall mechanical or electrical design. It is the intent of the standard that seismic requirements in referenced documents be used. The developers of these documents are familiar with the expected performance and failure modes of the components; however, the documents may be based on design considerations not immediately obvious to a structural design professional. For example, in the design of industrial piping, stresses due to seismic inertia forces typically are not added to those due to thermal expansion.

Where reference documents have been adopted specifically by this standard as meeting the force and displacement requirements of this chapter with or without modification, they are considered to be a part of the standard.

There is a potential for misunderstanding and misapplication of reference documents for the design of mechanical and electrical systems. A registered design professional familiar with both the standard and the reference documents used should be involved in the review and acceptance of the seismic design.

Even when reference documents for nonstructural components lack specific earthquake design requirements, mechanical and electrical equipment constructed in accordance with industry-standard reference documents have performed well historically when properly anchored. Nevertheless, it is expected that manufacturers of mechanical and electrical equipment will consider seismic loads in the design of the equipment itself even when not explicitly required by this chapter.

While some reference documents provide requirements for seismic capacity appropriate to the component being designed, the seismic demands used in design may not be less than those specified in the standard.

Specific guidance for selected mechanical and electrical components and conditions is provided in Section 13.6.

Unless exempted in Section 13.1.4, components should be anchored to the structure, and to promote coordination,required supports and attachments should be detailed in the construction documents. Reference documents may contain explicit instruction for anchorage of nonstructural components. The anchorage requirements of Section 13.4 must be satisfied in all cases, however, in order to ensure a consistent level of robustness in the attachments to the structure.

C13.1.7 Reference Documents Using Allowable Stress Design

Many nonstructural components are designed using specifically developed reference documents that are based on allowable stress loads and load combinations and generally permit increases in allowable stresses for seismic loading. Although Section 2.4.1 of the standard does not permit increases in allowable stresses, Section 13.1.7 explicitly defines the conditions for stress increases in the design of nonstructural components where reference documents provide a basis for earthquake-resistant design.

C13.2 GENERAL DESIGN REQUIREMENTS

C13.2.1 Applicable Requirements for Architectural, Mechanical, and Electrical Components, Supports, and Attachments

Compliance with the requirements of Chapter 13 may be accomplished by project-specific design or by a manufacturer's certification of seismic qualification of a system or component. When compliance is by manufacturer's certification, the items must be installed in accordance with the manufacturer's requirements. Evidence of compliance may be provided in the form of a signed statement from a representative of the manufacturer or from the registered design professional indicating that the component or system is seismically qualified. One or more of the following options for evidence of compliance may be applicable:

1. An analysis (e.g., of a distributed system such as piping) that includes derivation of the forces used for the design of the system, the derivation of displacements and reactions, and the design of the supports and anchorages.

2. A test report, including the testing configuration and boundary conditions used. Where testing is intended to address a class of components, the range of items covered by the testing performed should also include the justification of similarities of the items that make this certification valid.

DRAFT

3. An experience data report.

Components addressed by the standard include individual simple units and assemblies of simple units for which reference documents establish seismic analysis or qualification requirements. Also addressed by the standard are complex architectural, mechanical, and electrical systems for which reference documents either do not exist or exist for only elements of the system. In the design and analysis of both simple components and complex systems, the concepts of flexibility and ruggedness often can assist the designer in determining the necessity for analysis and, when analysis is necessary, the extent and methods by which seismic adequacy may be determined. These concepts are discussed in Section C13.6.1.

C13.2.2 Special Certification Requirements for Designated Seismic Systems

This section addresses the qualification of active designated seismic equipment, its supports, and attachments with the goal of improving survivability and achieving a high level of confidence that a facility will be functional following a design earthquake. Where components are interconnected, the qualification should provide the permissible forces (e.g., nozzle loads) and, as applicable, anticipated displacements of the component at the connection points to facilitate assessment for consequential damage in accordance with Section 13.2.3. Active equipment has parts that rotate, move mechanically, or are energized during operation. Active designated seismic equipment constitutes a limited subset of designated seismic systems. Failure of active designated seismic equipment itself may pose a significant hazard. For active designated seismic equipment, failure of structural integrity or loss of function are to be avoided.

Examples of active designated seismic equipment include mechanical (HVAC and refrigeration) or electrical (power supply distribution) equipment, medical equipment, fire pump equipment, and uninterruptible power supplies for hospitals.

There are practical limits on the size of a component that can be qualified via shake table testing. Components too large to be qualified by shake table testing need to be qualified by a combination of structural analysis and qualification testing or empirical evaluation through a subsystem approach. Subsystems of large, complex components (e.g., very large chillers or skid-mounted equipment assemblies) can be qualified individually and the overall structural frame of the component evaluated by structural analysis.

Evaluating post-earthquake operational performance for active equipment by analysis generally involves sophisticated modeling with experimental validation and may not be reliable. Therefore, the use of analysis for active or energized components is not permitted unless a comparison can be made to components that have been otherwise deemed as rugged. As an example, a transformer is energized but contains components that can be shown to remain linearly elastic and are inherently rugged. On the other hand, switch equipment that contains fragile components is similarly energized but not inherently rugged, and therefore cannot be certified solely by analysis. For complex components, testing or experience may therefore be the only practical way to ensure that the equipment will be operable following a design earthquake. Past earthquake experience has shown that most active equipment is inherently rugged. Therefore, evaluation of experience data together with analysis of anchorage is adequate to demonstrate compliance of active equipment such as pumps, compressors, and electric motors. In other cases, such as for motor control centers and switching equipment, shake table testing may be required.

With some exceptions (e.g., elevator motors), experience indicates that active mechanical and electrical components that contains electric motor than 10 hp or that have a thermal exchange capacity greater than 200 MBH are unlikely to merit the exemption from shake table testing on the basis of inherent ruggedness. Components with lesser motor hp and thermal exchange capacity are generally considered to be small active components and are deemed rugged. Exceptions to this rule may be appropriate for specific cases, such as elevator motors that have higher horsepower but have been shown by experience to be rugged. Analysis is still required to ensure the structural integrity of the non-active components. For example, a 15-ton condenser would require analysis of the load path between the condenser fan and coil to the building structure attachment.

C13.2.3 Consequential Damage

Although the components identified in Tables 13.5-1 and 13.6-1 are listed separately, significant interrelationships exist and must be considered. Consequential damage occurs due to interaction between components and systems. Even “braced” components displace and the displacement between lateral supports can be significant in the case of distributed systems such as piping systems, cable and conduit systems and other linear systems. It is the intent of the standard that the seismic displacements considered include both relative displacement between multiple points of

support (addressed in Section 13.3.2) and, for mechanical and electrical components, displacement within the component assemblies. Impact of components must be avoided unless the components are fabricated of ductile materials that have been shown to be capable of accommodating the expected impact loads. With protective coverings, ductile mechanical and electrical components and many more fragile components are expected to survive all but the most severe impact loads. Flexibility and ductility of the connections between distribution systems and the equipment to which they attach is essential to the seismic performance of the system.

The determination of the displacements that generate these interactions are not addressed explicitly in Section 13.3.2.1. That section concerns relative displacement of support points. Consequential damage may occur due to displacement of components and systems between support points. For example, in older suspended ceiling installations, excessive lateral displacement of a ceiling system may fracture sprinkler heads that project through the ceiling. A similar situation may arise if sprinkler heads projecting from a small diameter branch line pass through a rigid ceiling system. While the branch line may be properly restrained, it may still displace sufficiently between lateral support points, to impact other components or systems. Similar interactions occur where a relatively flexible distributed system connects to a braced or rigid component.

The potential for impact between components that are in contact with or in close proximity to other structural or nonstructural components must be considered. However, where considering these potential interactions, the designer must determine if the potential interaction is both credible and significant. For example, the fall of a ceiling panel located above a motor control center is a credible interaction because the falling panel in older suspended ceiling installations can reach and impact the motor control center. An interaction is significant if it can result in damage to the target. Impact of a ceiling panel on a motor control center may not be significant, due to the light weight of the ceiling panel. Special design consideration is appropriate where the failure of a nonstructural element could adversely influence the performance of an adjacent critical nonstructural component, such as an emergency generator.

C13.2.4 Flexibility

In many cases, flexibility is more important than strength in the performance of distributed systems, such as piping and ductwork. A good understanding of the displacement demand on the system as well as its displacement capacity is required. Components or their supports and attachments must be flexible enough to accommodate the full range of expected differential movements; some localized inelasticity is permitted in accommodating the movements. Relative movements in all directions must be considered. For example, even a braced branch line of a piping system will displace, so it needs to be connected to other braced or rigid components in a manner that will accommodate the displacements without failure (see Figure C13.2-1). A further example is provided by cladding units (such as precast concrete wall units). Often very rigid in-plane, cladding units require connections capable of accommodating story drift if attached at more than one level. (See Figure C13.3-3 for an illustration.)

If component analysis assumes rigid anchors or supports, the predicted loads and local stresses can be unrealistically large, so it may be necessary to consider anchor and/or support stiffness.

DRAFT

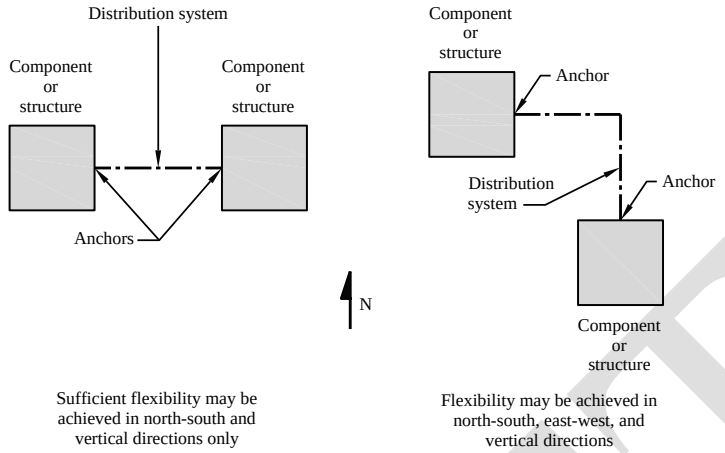

Figure C13.2- 1 Schematic plans illustrating branch line flexibility.

C13.2.5 Testing Alternative for Seismic Capacity Determination

Testing is a well-established alternative method of seismic qualification for small- to medium-size equipment. Several national reference documents have testing requirements adaptable for seismic qualification. One such reference document, ICC-ES AC156, is a shake-table testing protocol that has been adopted by the ICC Evaluation Service. It was developed specifically to be consistent with acceleration demands (that is, force requirements) of the standard.

The development or selection of testing and qualification protocols should at a minimum include the following:

1. Description of how the protocol meets the intent for the project-specific requirements and relevant interpretations of the standard.
2. Definition of a test input motion with a response spectrum that meets or exceeds the Design Earthquake spectrum for the site.
3. Accounting for dynamic amplification due to above-grade equipment installations. Consideration of the actual dynamic characteristics of the primary support structure is permitted, but not required.
4. Definition of how shake-table input demands were derived.
5. Definition and establishment of a verifiable pass/fail acceptance criterion for the seismic qualification based upon the equipment importance factor and consistent with the building code and project-specific design intent.
6. Development of criteria that can be used to rationalize test unit configuration requirements for highly variable equipment product lines.

To aid the design professional in assessing the adequacy of the manufacturer's certificate of compliance it is recommended that certificates of compliance include:

1. Product family or group covered
2. Building code(s) and standard(s) for which compliance was evaluated
3. Testing standard used
4. Performance objective and corresponding importance factor (I_p = 1.0 or I_p = 1.5)
5. Seismic demand for which the component is certified, including code and/or standard design parameters used to calculate seismic demand (such as values used for a_p, R_p, and site class)

DRAFT

6. Installation restrictions, if any (grade, floor, or roof level)

Without a test protocol recognized by the building code, qualification testing is inconsistent and difficult to verify. The use of ICC-ES AC156 simplifies the task of compliance verification since it was developed to address directly the testing alternative for nonstructural components, as specified in the standard. It also sets forth minimum test plan and report deliverables.

Use of other standards or ad-hoc protocols to verify compliance of nonstructural components with the requirement of the standard should be considered carefully and used only where project-specific requirements cannot be met otherwise.

Where other qualification test standards will be used, in whole or in part, it is necessary to verify compliance with this standard. For example, IEEE 693 indicates that it is to be used for the sole purpose of qualifying electrical equipment (specifically listed in the standard) for use in utility substations. Where equipment testing has been conducted to other standards (for instance, testing done in compliance with IEEE 693), a straightforward approach would be to permit evaluation, by the manufacturer, of the test plan and data to validate compliance with the requirements of ICC-ES AC156, because it was developed specifically to comply with the seismic demands of this standard.

The qualification of mechanical and electrical components for seismic loads alone may not be sufficient to achieve high performance objectives. Establishing a high confidence that performance goals will be met requires consideration of the performance of structures, systems (fluid, mechanical, electrical, instrumentation, etc.), and their interactions (for example interaction of seismic and other loads) as well as compliance with installation requirements.

C13.2.6 Experience Data Alternative for Seismic Capacity Determination

An established method of seismic qualification for certain types of nonstructural components is the assessment of data for the performance of similar components in past earthquakes. The seismic capacity of the component in question is extrapolated based on estimates of the demands (force, displacement) to which the components in the database were subjected. Procedures for such qualification have been developed for use in nuclear facility applications by the Seismic Qualification Utility Group (SQUG) of the Electric Power Research Institute.

The SQUG rules for implementing the use of experience data are described in a proprietary Generic Implementation Procedure (GIP) database. It is a collection of findings from detailed engineering studies by experts for equipment from a variety of utility and industrial facilities.

Valid use of experience data requires satisfaction of rules that address physical characteristics, manufacturer's classification and standards, and findings from testing, analysis, and expert consensus opinion.

Four criteria are used to establish seismic qualification by experience, as follows:

1. Seismic capacity versus demand (a comparison with a bounding spectrum)
2. Earthquake experience database cautions and inclusion rules
3. Evaluation of anchorage
4. Evaluation of seismic interaction

Experience data should be used with care, since the design and manufacture of components may have changed considerably in the intervening years. The use of this procedure is also limited by the relative rarity of strong motion instrument records associated with corresponding equipment experience data.

C13.2.7 Construction Documents

Where the standard requires seismic design of components or their supports and attachments, appropriate construction documents defining the required construction and installation must be prepared. This facilitates the special inspection and testing needed to provide a reasonable level of quality assurance. Of particular concern are large nonstructural components (such as rooftop chillers) whose manufacture and installation involves multiple trades and suppliers, and which impose significant loads on the supporting structure. In these cases, it is important that the construction documents used by the various trades and suppliers to satisfy the seismic design requirements are prepared by a registered design professional.

DRAFT

The information required to prepare construction documents for component installation includes the dimensions of the component, the locations of attachment points, the operating weight, and the location of the center of mass. For instance, if an anchorage angle will be attached to the side of a metal chassis, the gage and material of the chassis must be known so that the number and size of required fasteners can be determined. Or, when a piece of equipment has a base plate that will be anchored to a concrete slab with expansion anchors, the drawings must show the base plate's material and thickness, the diameter of the bolt holes in the plate, and the size and depth of embedment of the anchor bolts. If the plate will be elevated above the slab for leveling, the construction documents must also show the maximum gap permitted between the plate and the slab.

C13.3 SEISMIC DEMANDS ON NONSTRUCTURAL COMPONENTS

The seismic demands on nonstructural components, as defined in this section, are acceleration demands and relative displacement demands. Acceleration demands are represented by equivalent static forces. Relative displacement demands are provided directly and are based on either the actual displacements computed for the structure or the maximum allowable drifts that are permitted for the structure.

C13.3.1 Seismic Design Force

The seismic design force for a component depends on the weight of the component, the component importance factor, the component response modification factor, the component amplification factor, and the component acceleration at a point of attachment to the structure. The forces prescribed in this section of the standard reflect the dynamic and structural characteristics of nonstructural components. As a result of these characteristics, forces used for verification of component integrity and design of connections to the supporting structure typically are larger than those used for design of the overall seismic-force-resisting system.

Certain nonstructural components lack the desirable attributes of structures (such as ductility, toughness, and redundancy) that permit the use of greatly reduced lateral design forces. Thus values for the response modification factor, R_p, in Tables 13.5-1 and 13.6-1 generally are smaller than R values for structures. These R_p values, used to represent the energy absorption capability of a component and its attachments, depend on both overstrength and deformability. At present these potentially separate considerations are combined in a single factor. The tabulated values are based on the collective judgment of the responsible committee.

Beginning with the 2005 edition, significant adjustments to tabulated R_p values for certain mechanical and electrical systems. For example, the value of R_p for welded steel piping systems is increased from 3.5 to 9. The a_p value increased from 1.0 to 2.5, so while it might appear that forces on such piping systems have been reduced greatly, the net change is negligible, as R_p/a_p changes from 3.5 to 3.6. The minimum seismic design force of Equation 13.3-3, which governs in many cases, is unchanged.

The component amplification factor (a_p) represents the dynamic amplification of component responses as a function of the fundamental periods of the structure (T) and component (T_p). When components are designed or selected, the structural fundamental period is not always defined or readily available. The component fundamental period (T_p) is usually only accurately obtained by shake-table or pull-back tests and is not available for the majority of components. Tabulated a_p values are based on component behavior that is assumed to be either rigid or flexible. Where the fundamental period of the component is less than 0.06 seconds, dynamic amplification is not expected, and the component is considered rigid. The tabulation of assumed a_p values is not meant to preclude more precise determination of the component amplification factor where the fundamental periods of both structure and component are available. The NCEER formulation shown in Figure C13.3-1 may be used to compute a_p as a function of T_p/T.

Dynamic amplification occurs where the period of a nonstructural component closely matches that of any mode of the supporting structure, although this effect may not be significant depending on the ground motion. For most buildings, the primary mode of vibration in each direction will have the most influence on the dynamic amplification for nonstructural components. For long-period structures (such as tall buildings), where the period of vibration of the fundamental mode is greater than 3.5 times T_s, higher modes of vibration may have periods that more closely match the period of nonstructural components. For this case, it is recommended that amplification be considered using such higher mode periods in lieu of the higher fundamental period. This approach may be generalized by computing floor response spectra for various levels that reflect the dynamic characteristics of the supporting structure to determine how amplification will vary as a function of component period. Calculation of floor response

DRAFT

spectra can be complex, but simplified procedures are presented in Kehoe and Hachem (2003). Consideration of nonlinear behavior of the structure greatly complicates the analysis.

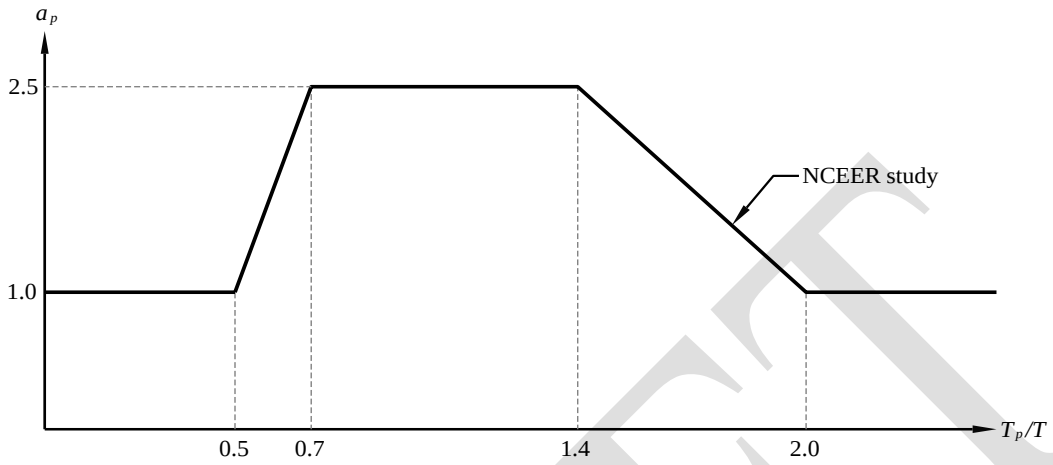

Figure C13.3- 1 NCEER formulation for a_p as function of structural and component periods.

Equation 13.3-1 represents a trapezoidal distribution of floor accelerations within a structure, varying linearly from the acceleration at the ground (taken as $0.4S_{DS}$) to the acceleration at the roof (taken as $1.2S_{DS}$). The ground acceleration ($0.4S_{DS}$) is intended to be the same acceleration used as design input for the structure itself, including site effects. The roof acceleration is established as three times the input ground acceleration based on examination of recorded in-structure acceleration data for short and moderate height structures in response to large California earthquakes. Work by Miranda and Singh (????) suggest that, for taller structures, the amplification with height may vary significantly due to higher mode effects. Where more information is available, Equation 13.3-4 permits an alternate determination of the component design forces based on the dynamic properties of the structure.

Equation 13.3-3 establishes a minimum seismic design force, F_p, that is consistent with current practice. Equation 13.3-2 provides a simple maximum value of F_p that prevents multiplication of the individual factors from producing a design force that would be unreasonably high, considering the expected nonlinear response of support and component. Figure C13.3-2 illustrates the distribution of the specified lateral design forces.

DRAFT

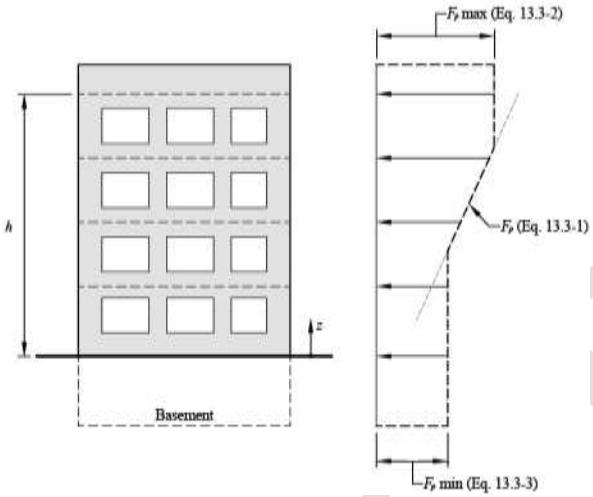

Figure C13.3- 2 Lateral force magnitude over height.

For elements with points of attachment at more than one height, it is recommended that design be based on the average of values of F_p determined individually at each point of attachment (but with the entire component weight, W_p) using Equations 13.3-1 through 13.3-3.

Alternatively, for each point of attachment a force F_p may be determined using Equations 13.3-1 through 13.3-3, with the portion of the component weight, W_p, tributary to the point of attachment. For design of the component, the attachment force F_p must be distributed relative to the component's mass distribution over the area used to establish the tributary weight. To illustrate these options, consider a solid exterior nonstructural wall panel, supported top and bottom, for a one-story building with a rigid diaphragm. The values of F_p computed, respectively, for the top and bottom attachments using Equations 13.3-1 through 13.3-3 are $0.48S_{DS}I_pW_p$ and $0.30S_{DS}I_pW_p$. In the recommended method, a uniform load is applied to the entire panel based on $0.39S_{DS}I_pW_p$. In the alternative method, a trapezoidal load varying from $0.48S_{DS}I_pW_p$ at the top to $0.30S_{DS}I_pW_p$ at the bottom is applied. Each anchorage force is then determined considering static equilibrium of the complete component subject to all the distributed loads.

Cantilever parapets that are part of a continuous element should be checked separately for parapet forces. The seismic force on any component must be applied at the center of gravity of the component and must be assumed to act in any horizontal direction. Vertical forces on nonstructural components equal to $\pm 0.2S_{DS}W_p$ are specified in Section 13.3.1 and are intended to be applied to all nonstructural components and not just cantilevered elements. Nonstructural concrete or masonry walls laterally supported by flexible diaphragms must be anchored out-of-plane in accordance with Section 12.11.2.

C13.3.2 Seismic Relative Displacements.

The equations of this section are for use in design of cladding, stairways, windows, piping systems, sprinkler components, and other components connected to one structure at multiple levels or to multiple structures. Two equations are given for each situation. Equations 13.3-6 and 13.3-8 produce structural displacements as determined by elastic analysis, unreduced by the structural response modification factor (R). Since the actual displacements may not be known when a component is designed or procured, Equations 13.3-7 and 13.3-9 provide upper-bound displacements based on structural drift limits. Use of upper-bound equations may facilitate timely design and procurement of components, but may also result in costly added conservatism.

The value of seismic relative displacements is taken as the calculated displacement D_p times the importance factor, I_e, since the elastic displacement calculated in accordance with Eq. (12.8-15) to establish δ_x (and thus D_p) is adjusted for I_e in keeping with the philosophy of displacement demand for the structure. For component design, the unreduced elastic displacement is appropriate.

DRAFT

The standard does not provide explicit acceptance criteria for the effects of seismic relative displacements, except for glazing. Damage to nonstructural components due to relative displacement is acceptable, provided the performance goals defined elsewhere in the chapter are achieved.

The design of some nonstructural components that span vertically in the structure can be complicated when supports for the element do not occur at horizontal diaphragms. The language in Section 13.3.2 was previously amended to clarify that story drift must be accommodated in the elements that will actually distort. For example, a glazing system supported by precast concrete spandrels must be designed to accommodate the full story drift, even though the height of the glazing system is only a fraction of the floor-to-floor height. This condition arises because the precast spandrels will behave as rigid bodies relative to the glazing system and therefore all the drift must be accommodated by anchorage of the glazing unit, the joint between the precast spandrel and the glazing unit, or some combination of the two.

C13.3.2.1 Displacements within Structures.

Seismic relative displacements can subject components or systems to unacceptable stresses. The potential for interaction resulting from component displacements (in particular for distributed systems) and the resulting impact effects should also be considered. See 13.2.3.

These interrelationships may govern the clearance requirements between components or between components and the surrounding structure. Where sufficient clearance cannot be provided, consideration should be given to the ductility and strength of the components and associated supports and attachments to accommodate the potential impact.

Where nonstructural components are supported between, rather than at, structural levels, as frequently occurs for glazing systems, partitions, stairs, veneers, and mechanical and electrical distributed systems, the height over which the displacement demand, D_p, must be accommodated may be less than the story height, h_{sx}, and should be considered carefully. For example, consider the glazing system supported by rigid precast concrete spandrels shown in Figure C13.3-3. The glazing system will be subjected to full story drift, D_p, although its height ($h_x - h_y$) is only a fraction of the story height. The design drift must be accommodated by anchorage of the glazing unit, the joint between the precast spandrel and the glazing unit, or some combination of the two. Similar displacement demands arise where pipes, ducts, or conduit that are braced to the floor or roof above are connected to the top of a tall, rigid, floor-mounted component.

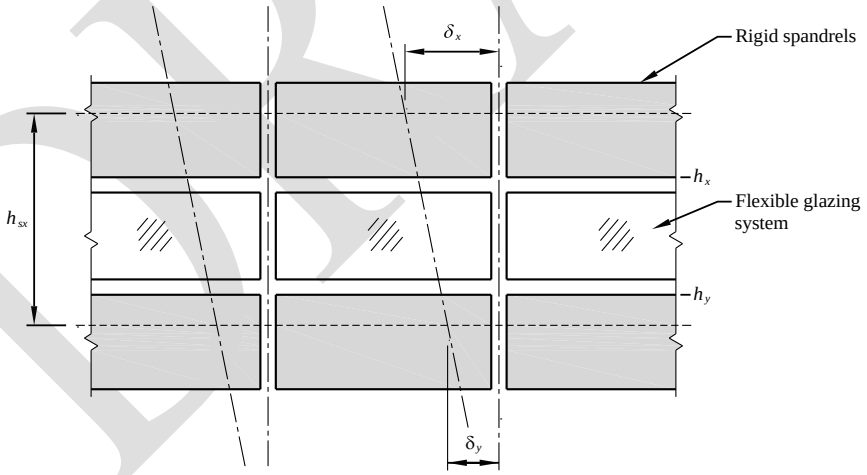

Figure C13.3- 3 Displacements over less than story height.

For ductile components, such as steel piping fabricated with welded connections, the relative seismic displacements between support points can be more significant than inertial forces. Ductile piping can accommodate relative displacements by local yielding with strain accumulations well below failure levels. However, for components

DRAFT

fabricated using less ductile materials, where local yielding must be avoided to prevent unacceptable failure consequences, relative displacements must be accommodated by flexible connections.

C13.3.2.2Displacements between Structures

A component or system connected to two structures must accommodate horizontal movements in any direction, as illustrated in Figure C13.3-4.

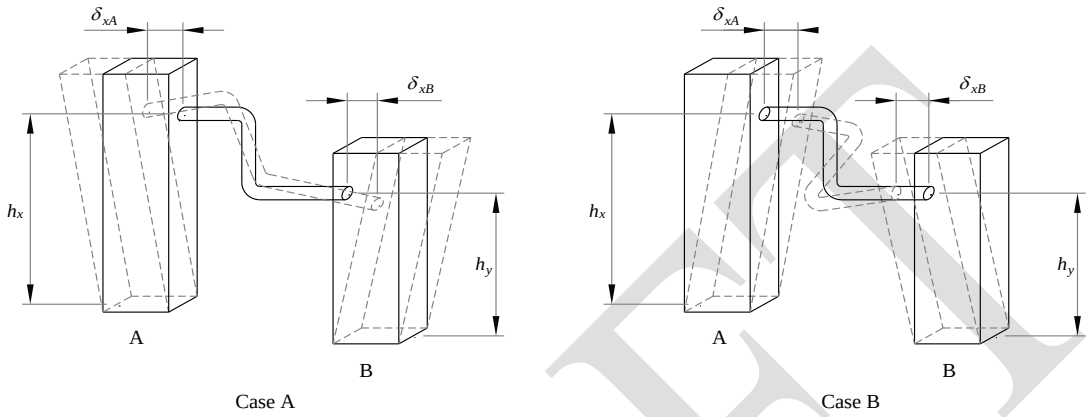

Figure C13.3- 4 Displacements between structures.

C13.4 NONSTRUCTURAL COMPONENT ANCHORAGE

Unless exempted in Section 13.1.4, components must be anchored to the structure, and all required supports and attachments must be detailed in the construction documents. To satisfy the load path requirement of this section, the detailed information described in Section C13.2.7 must be communicated during the design phase to the registered design professional responsible for the design of the supporting structure. The load path includes housekeeping slabs and curbs, which must be adequately reinforced and positively fastened to the supporting structure. Since the exact magnitude and location of the loads imposed on the structure may not be known until nonstructural components are ordered, the initial design of supporting structural elements should be based on conservative assumptions. The design of the supporting structural elements must be verified once the final magnitude and location of the design loads have been established.

Design documents should provide details with sufficient information so that compliance with these provisions can be verified. Parameters such as a_p, R_p, I_p, S_{DS}, W_p should be noted. Attachment details may include, as appropriate, dimensions and material properties of the connecting material, weld sizes, bolt sizes and material types for steel-to-steel connections, post-installed anchor types, diameters, embedments, and installation requirements, sheet metal screw diameters and material thicknesses of the connected parts, wood fastener types and minimum requirements for specific gravity of the base materials.

Seismic design forces are determined using the provisions of Section 13.3.1. Specific reference standards should be consulted for additional adjustments to loads or strengths. Refer, for example, to the anchor design provisions of ACI 318, Building Code Requirements for Structural Concrete and Commentary, Appendix D for specific provisions related to seismic design of anchors in concrete. Unanchored components often rock or slide when subjected to earthquake motions. Since this behavior may have serious consequences, is difficult to predict, and is exacerbated by vertical ground motions, positive restraint must be provided for each component.

The effective seismic weight used in design of the seismic force-resisting system must include the weight of supported components. To satisfy the load path requirements of this section, localized component demand must also be considered. This may be accomplished by checking the capacity of the first structural element in the load path (for example, a floor beam directly under a component) for combined dead, live, operating, and seismic loads, using the horizontal and vertical loads from Section 13.3.1 for the seismic demand, and repeating this procedure for each

DRAFT

structural element or connection in the load path until the load case including horizontal and vertical loads from Section 13.3.1 no longer governs design of the element. The load path includes housekeeping slabs and curbs, which must be adequately reinforced and positively fastened to the supporting structure.

Since the exact magnitude and location of loads imposed on the structure may not be known until nonstructural components are ordered, the initial design of supporting structural elements should be based on conservative assumptions. The design of the supporting structural elements may need to be verified once the final magnitude and location of the design loads have been established.

Tests have shown there are consistent shear ductility variations between bolts installed in drilled or punched plates with nuts and connections using welded shear studs. The need for reductions in allowable loads for particular anchor types to account for loss of stiffness and strength may be determined through appropriate dynamic testing. Although comprehensive design recommendations are not available at present, this issue should be considered for critical connections subject to dynamic or seismic loading.

C13.4.1 Design Force in the Attachment

Previous editions of ASCE/SEI 7 included provisions for the amplification of forces to design the component anchorage. These provisions were intended to ensure that either a) the anchorage would respond to overload in a ductile manner or b) would be designed so that the anchorage would not be the weakest link in the load path.

Due to the difficulties associated with the application of the anchorage provisions in Section 13.4 in conjunction with anchorage provisions in other reference standards, the provisions for anchorage in ASCE/SEI 7-10 are substantially simplified. Adjustments on the R_p value used for the anchorage calculation have been eliminated, with the exception of the upper limit on R_p of 6 which is intended primarily to address the anchorage of ductile piping systems that are assigned higher R_p values. These higher component response modification factors reflect the inherent ductility and overstrength of ductile piping, but may result in an under prediction of the forces on the anchorage.

C13.4.2 Anchors in Concrete or Masonry

Design capacity for anchors in concrete must be determined in accordance with ACI 318 Appendix D. Design capacity for anchors in masonry is determined in accordance with ACI 530. Anchors must be designed to have ductile behavior or to provide a specified degree of excess strength. Depending on the specifics of the design condition, ductile design of anchors in concrete may satisfy one or more of the following objectives:

1. Adequate load redistribution between anchors in a group
2. Allowance for anchor overload without brittle failure
3. Energy dissipation

Achieving deformable, energy-absorbing behavior in the anchor itself is often difficult. Unless the design specifically addresses the conditions influencing desirable hysteretic response (adequate gauge length, anchor spacing, edge distance, steel properties, etc.), anchors cannot be relied upon for energy dissipation. Simple geometric rules, such as restrictions on the ratio of anchor embedment length to depth, may not be adequate to produce reliable ductile behavior. For example, a single anchor with sufficient embedment to force ductile tension failure in the steel body of the anchor bolt may still experience concrete fracture (a non-ductile failure mode) if the edge distance is small, the anchor is placed in a group of tension-loaded anchors with reduced spacing, or the anchor is loaded in shear instead of tension. In the common case where anchors are subject primarily to shear, response governed by the steel element may be non-ductile if the deformation of the anchor is constrained by rigid elements on either side of the joint. Designing the attachment so that its response is governed by a deformable link in the load path to the anchor is encouraged. This approach provides ductility and overstrength in the connection while protecting the anchor from overload. Ductile bolts should only be relied upon as the primary ductile mechanism of a system if the bolts are designed to have adequate gauge length (unbonded strained length of the bolt) to accommodate the anticipated nonlinear displacements of the system at the design earthquake. Guidance for determining the gauge length can be found in Part 3 of the 2009 NEHRP *Provisions*.

Anchors used to support towers, masts, and equipment are often provided with double nuts for leveling during installation. Where baseplate grout is specified at anchors with double nuts, it should not be relied upon to carry loads since it can shrink and crack or be omitted altogether. The design should include the corresponding tension, compression, shear, and flexure loads.

Post-installed anchors in concrete and masonry should be qualified for seismic loading through appropriate testing. The requisite tests for expansion and undercut anchors in concrete are given in ACI 355.2-07, Qualification of Post-Installed Mechanical Anchors in Concrete and Commentary. Testing and assessment procedures based on the ACI standard that address expansion, undercut, screw, and adhesive anchors are incorporated in ICC-ES acceptance criteria AC193, Acceptance Criteria for Mechanical Anchors in Concrete Elements and AC308, Acceptance Criteria for Post-installed adhesive anchors provisions in concrete clements, refer to the new ACI document, ACI 355.4-11: Qualification of Post-Installed Adhesive Anchors in Concrete and Commentary. These criteria, which include specific provisions for screw anchors and adhesive anchors, also reference ACI qualification standards for anchors. For post-installed anchors in masonry, seismic prequalification procedures are contained in ICC-ES acceptance criteria AC01, Acceptance Criteria for Expansion Anchors in Masonry Elements, AC58, Acceptance Criteria for Adhesive Anchors in Masonry Elements, and AC106, Acceptance Criteria for Predrilled Fasteners (Screw Anchors) in Masonry Elements.

Other references to adhesives (such as in Section 13.5.7.2) apply not to adhesive anchors, but to steel plates and other structural elements bonded or glued to the surface of another structural component with adhesive; such connections are generally non-ductile.

C13.4.3 Installation Conditions.
Prying forces on anchors, which result from a lack of rotational stiffness in the connected part, can be critical for anchor design and must be considered explicitly.

For anchorage configurations that do not provide a direct mechanism to transfer compression loads (for example, a base plate that does not bear directly on a slab or deck but is supported on a threaded rod), the design for overturning must reflect the actual stiffness of baseplates, equipment, housing, and other elements in the load path when computing the location of the compression centroid and the distribution of uplift loads to the anchors.

C13.4.4 Multiple Attachments
While the standard does not prohibit the use of single anchor connections, it is good practice to use at least two anchors in any load-carrying connection whose failure might lead to collapse, partial collapse, or disruption of a critical load path.

C13.4.5 Power Actuated Fasteners
Restrictions on the use power actuated fasteners is based on observations of failures of sprinkler pipe runs in the 1994 Northridge earthquake. While it is unclear from the record as to what degree the failures occurred because of poor installation, product deficiency, overload, or consequential damage, the capacity of power actuated fasteners in concrete often varies more than that of drilled post-installed anchors. The shallow embedment, small diameter, and friction mechanism of these fasteners make them particularly susceptible to the effects of concrete cracking. The suitability of power actuated fasteners to resist tension in concrete should be demonstrated by simulated seismic testing in cracked concrete.

Where properly installed in steel, power actuated fasteners typically exhibit reliable cyclic performance. Nevertheless, they should not be used singly to support suspended elements. Where used to attach cladding and metal decking, subassembly testing may be used to establish design capacities since the interaction between the decking, the sub-frame, and the fastener can only be estimated crudely by currently available analysis methods.

The exception permits the use of power actuated fasteners for specific light-duty applications with upper limits on the load that can be resisted in these cases. All fasteners must have adequate capacity for the calculated loads, including prying forces.

The exception allows for the continued use of power actuated fasteners in concrete for the vertical support of suspended acoustical tile or lay-in panel ceilings and for other light distributed systems such as small diameter conduit held to the concrete surface with C-clips. Experience indicates that these applications have performed satisfactorily due to the high degree of redundancy and light loading. Other than ceilings, hung systems should not be included in this exception due to the potential for bending in the fasteners.

The exception for power actuated fasteners in steel provides a conservative limit on loading.

Currently, no accepted procedure exists for the qualification of power actuated fasteners to resist earthquake loads.

DRAFT

C13.4.6 Friction Clips

The term *friction clip* is defined in Section 11.2 in a general way to encompass C-type beam clamps, as well as cold-formed metal channel (strut) connections. Friction clips are suitable to resist seismic forces provided they are properly designed and installed, but under no circumstances should they be relied upon to resist sustained gravity loads. C-type clamps must be provided with restraining straps, as shown in Fig. C13.4-1.

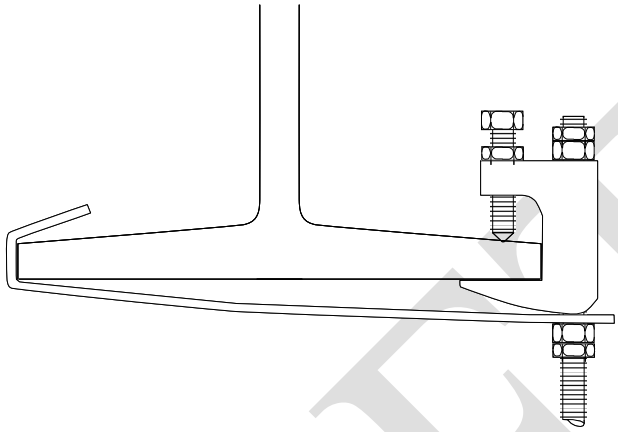

Figure C13.4- 1 C-type beam clamp equipped with a restraining strap

C13.5 ARCHITECTURAL COMPONENTS

For structures in Risk Category I through III, the requirements of Section 13.5 are intended to reduce property damage and life-safety hazards posed by architectural components due to loss of stability or integrity. When subjected to seismic motion, components may pose a direct falling hazard to building occupants or to people outside the building (as in the case of parapets, exterior cladding, and glazing). Failure or displacement of interior components (such as partitions and ceiling systems in exits and stairwells) may block egress.

For structures in Risk Category IV, the potential disruption of essential function due to component failure must also be considered.

Architectural component failures in earthquakes can be caused by deficient design or construction of the component, interrelationship with another component that fails, interaction with the structure, or inadequate attachment or anchorage. For architectural components, attachment and anchorage are typically the most critical concerns related to their seismic performance. Concerns regarding loss of function are most often associated with mechanical and electrical components. Architectural damage, unless very severe, can be accommodated temporarily. Very severe architectural damage is often accompanied by significant structural damage.

C13.5.1 General

Suspended architectural components are not required to satisfy the force and displacement requirements of Chapter 13, where prescriptive requirements are met. The requirements were relaxed in the 2005 edition of the standard to better reflect the consequences of the expected behavior. For example, impact of a suspended architectural ornament with a sheet metal duct may only dent the duct without causing a credible danger (assuming the ornament remains intact). The reference to Section 13.2.3 allows the designer to consider such consequences in establishing the design approach.

Nonstructural components supported by chains or otherwise suspended from the structure are exempt from lateral bracing requirements, provided they are designed not to inflict damage to themselves or any other component when subject to seismic motion. However, for the 2005 edition, it was determined that clarifications were needed on the type of nonstructural components allowed by these exceptions and the acceptable consequences of interaction between components. In ASCE/SEI 7-02, certain nonstructural components that could represent a fire hazard following an earthquake were exempted from meeting the Section 9.6.1 requirements. For example, gas-fired space heaters clearly pose a fire hazard following an earthquake, but were permitted to be exempted from the Section 9.6.1

DRAFT

requirements. The fire hazard following the seismic event must be given the same level of consideration as the structural failure hazard when considering components to be covered by this exception. In addition, the ASCE/SEI 7-02 language was sometimes overly restrictive because it did not distinguish between credible seismic interactions and incidental interactions. In ASCE/SEI 7-02, if a suspended lighting fixture could hit and dent a sheet metal duct, it would have to be braced, although no credible danger is created by the impact. The new reference in Section 13.2.3 of ASCE/SEI 7-05 allowed the designer to consider whether the failures of the component and/or the adjacent components are likely to occur if contact is made. These provisions have been brought into ASCE/SEI 7-10.

C13.5.2 Forces and Displacements

Partitions and interior and exterior glazing must accommodate story drift without failure that will cause a life-safety hazard. Design judgment must be used to assess potential life-safety hazards and the likelihood of life-threatening damage. Special detailing to accommodate drift for typical gypsum board or demountable partitions is unlikely to be cost-effective, and damage to these components poses a low hazard to life safety. Damage in these partitions occurs at low drift levels, but is inexpensive to repair.

If they must remain intact following strong ground motion, nonstructural fire-resistant enclosures and fire-rated partitions require special detailing that provides isolation from the adjacent or enclosing structure for deformation equivalent to the calculated drift (relative displacement). In-plane differential movement between structure and wall is permitted. Provision must be made for out-of-plane restraint. These requirements are particularly important in steel or concrete moment frame structures, which experience larger drifts. The problem is less likely to be encountered in stiff structures, such as those with shear walls.

Differential vertical movement between horizontal cantilevers in adjacent stories (such as cantilevered floor slabs) has occurred in past earthquakes. The possibility of such effects should be considered in the design of exterior walls.

C13.5.3 Exterior Nonstructural Wall Elements and Connections

Nonbearing wall panels that are attached to and enclose the structure must be designed to resist seismic (inertial) forces, wind forces, and gravity forces and to accommodate movements of the structure resulting from lateral forces and temperature change. The connections must allow wall panel movements due to thermal and moisture changes, and be designed so as to prevent the loss of load-carrying capacity in the event of significant yielding. Where wind loads govern, common practice is to design connectors and panels to allow for not less than two times the story drift caused by wind loads determined using a return period appropriate to the site location.

Design to accommodate seismic relative displacements often presents a greater challenge than design for strength. Story drifts can amount to 2 inches (50 mm) or more. Separations between adjacent panels are intended to limit contact and resulting panel misalignment or damage under all but extreme building response. Section 13.5.3(a) calls for a minimum separation of 1/2 inch (13 mm). For practical joint detailing and acceptable appearance, separations typically are limited to about 3/4 inch (19 mm). Manufacturing and construction tolerances for both wall elements and the supporting structure must be considered in establishing design joint dimensions and connection details.

Cladding elements, which are often very stiff in-plane, must be isolated so that they do not restrain and are not loaded by drift of the supporting structure. Slotted connections can provide isolation, but connections with long rods that flex achieve the desired behavior without requiring precise installation. Such rods must be designed to resist tension and compression in addition to induced flexural stresses, brittle, low-cycle fatigue failure.

Full-story wall panels are usually rigidly attached to and move with the floor structure nearest the panel bottom and isolated at the upper attachments. Panels also can be vertically supported at the top connections with isolation connections at the bottom. An advantage of this configuration is that failure of an isolation connection is less likely to result in complete detachment of the panel, since it will tend to rotate into the structure rather than away from it.

To minimize the effects of thermal movements and shrinkage on architectural cladding panels, connection systems are generally detailed to be statically determinate. Since the resulting support systems often lack redundancy, exacerbating the consequences of a single connection failure, fasteners must be designed for amplified forces and connecting members must be ductile. The intent is to keep inelastic behavior in the connecting members while the more brittle fasteners remain essentially elastic. To achieve this intent, the tabulated a_p and R_p values produce fastener design forces that are about 3 times those for the connecting members.

Limited deformability curtain walls, such as aluminum systems, are generally light and can undergo large deformations without separating from the structure. However, care must be taken in design of these elements so that

DRAFT

low deformability components (as defined in Section 11.2) that may be part of the system, such as glazing panels, are detailed to accommodate the expected deformations without failure.

In Table 13.5-1, veneers are classified as either limited or low deformability elements. Veneers with limited deformability, such as vinyl siding, pose little risk. Veneers with low deformability, such as brick and ceramic tile, are highly sensitive to the performance of the supporting substrate. Significant distortion of the substrate results in veneer damage, possibly including separation from the structure. The resulting risk depends on the size and weight of fragments likely to be dislodged and on the height from which the fragments would fall. Detachment of large portions of the veneer can pose a significant risk to life. Such damage can be reduced by isolating veneer from displacements of the supporting structure. For structures with flexible lateral force-resisting systems, such as moment frames and buckling-restrained braced frames, approaches used to design non-bearing wall panels to accommodate story drift should be applied to veneers.

C13.5.5 Out-of-Plane Bending

The effects of out-of-plane application of seismic forces (defined in Section 13.3.1) on nonstructural walls, including the resulting deformations, must be considered. Where weak or brittle materials are employed, conventional deflection limits are expressed as a proportion of the span. The intent is to preclude out-of-plane failure of heavy materials (such as brick or block) or applied finishes (such as stone or tile).

C13.5.6 Suspended Ceilings

Suspended ceiling systems are fabricated using a wide range of building materials with differing characteristics. Some systems (such as or gypsum board, screwed or nailed to suspended members) are fairly homogeneous and should be designed as light-frame diaphragm assemblies, using the forces of Section 13.3 and the applicable material-specific design provisions of Chapter 14. Others comprise discrete elements laid into a suspension system and are the subject of this section.

Seismic performance of ceiling systems with lay-in or acoustical panels depends on support of the grid and individual panels at walls and expansion joints, integrity of the grid/panel assembly, interaction with other systems (such as fire sprinklers), and support for other nonstructural components (such as light fixtures and HVAC systems). Observed performance problems include dislodgement of tiles due to impact with walls and water damage (sometimes leading to loss of occupancy) due to interaction with fire sprinklers.

Suspended lath and plaster ceilings are not exempted from the requirements of this section because of their more significant mass and the greater potential for harm associated with their failure. However, the prescriptive seismic provisions of Section 13.5.6.2 and ASTM E580 for acoustical tile and lay-in panel ceilings, including the use of compression posts, are not directly applicable to these systems primarily owing to their behavior as a continuous diaphragm and greater mass. As such they require more attention to design and detailing, in particular for the attachment of the hanger wires to the structure and main carriers, the attachment of the cross furring channels to main carriers, and the attachment of lath to cross furring channels. Attention should also be given to the attachment of light fixtures and diffusers to the ceiling structure. Bracing should consider both horizontal and vertical movement of the ceiling, as well as discontinuities and offsets. The seismic design and detailing of lath and plaster ceilings should utilize rational engineering methods to transfer seismic design ceiling forces to the building structural elements.

The performance of ceiling systems is affected by the placement of seismic bracing and the layout of light fixtures and other supported loads. Dynamic testing has demonstrated that splayed wires, even with vertical compression struts, may not adequately limit lateral motion of the ceiling system due to straightening of the end loops. Construction problems include slack installation or omission of bracing wires due to obstructions. Other testing has shown that unbraced systems may perform well where the system can accommodate the expected displacements, by providing both sufficient clearance at penetrations and wide closure members which are now required by the standard.

With reference to the exceptions in 13.5.6:

The first exemption is based on the presumption that lateral support is accomplished by the surrounding walls for areas equal to or less than 144 square ft (e.g., a 12-foot by 12-foot room). The 144 square-foot limit corresponds historically to an assumed connection strength of 180 lb and forces associated with requirements for suspended ceilings that first appeared in the 1976 Uniform Building Code.

DRAFT

The second exemption assumes that planar, horizontal drywall ceilings behave as diaphragms (i.e., develop in-plane strength). This is supported by the performance of drywall ceilings in past earthquakes.

C13.5.6.1 Seismic Forces

Where the weight of the ceiling system is distributed non-uniformly, that condition should be considered in the design, since the typical T-bar ceiling grid has limited ability to redistribute lateral loads.

C13.5.6.2 Industry Standard Construction for Acoustical Tile or Lay-in Panel Ceilings

The key to good seismic performance is sufficiently wide closure angles at the perimeter to accommodate relative ceiling motion and adequate clearance at penetrating components (such as columns and piping) to avoid concentrating restraining loads on the ceiling system.

Table C13.5.6.1 provides an overview of the combined requirements of ASCE/SEI 7 and ASTM E 580. Careful review of both documents is required to determine the actual requirements.

C13.5.6.2.1 Seismic Design Category C

The prescribed method for Seismic Design Category C is a floating ceiling. The design assumes a small displacement of the building structure caused by the earthquake at the ceiling and isolates the ceiling from the perimeter. The vertical hanger wires are not capable of transmitting significant movement or horizontal force into the ceiling system and therefore the ceiling will not experience significant force or displacement as long as the perimeter gap is not exceeded. All penetrations and services must be isolated from the building structure for this construction method to be effective. If this is impractical or undesirable, the prescribed construction for Seismic Design Categories D, E, and F may be used.

C13.5.6.2.2 Seismic Design Categories D through F

The industry standard construction addressed in this section relies on ceiling contact with the perimeter wall for restraint.

Typical splay wire lateral bracing allows for some movement before it effectively restrains the ceiling. The intent of the 2-in. perimeter closure wall angle is to permit back and forth motion of the ceiling during an earthquake without loss of support, and the width of the closure angle is key to good performance. This has been experimentally verified by large-scale testing conducted by ANCO Engineering in 1983.

Extensive shake table testing using the protocol contained in ICC-ES acceptance criteria AC156 by major manufacturers of suspended ceilings has shown that perimeter clips can provide equivalent performance if they are designed to accommodate the same degree of movement as the closure angle while supporting the tee ends.

The requirement for a 1-inch clearance around sprinkler drops found in 13.5.6.2.2 (e) of ASCE/SEI 7-05 is maintained and is contained in ASTM E580.

This seismic separation joint is intended to break the ceiling into isolated areas preventing large scale force transfer across the ceiling. The new requirement to accommodate 3/4-inch axial movement specifies the performance requirement for the separation joint.

The requirement for seismic separation joints to limit ceiling areas to 2,500 square ft is intended to prevent overload of the connections to the perimeter angle. Limiting the ratio of long to short dimensions to 4:1 prevents dividing the ceiling into very long and narrow sections, which could defeat the purpose of the separation.

Table C13.5.6.2 – Summary of Requirements for Acoustical Tile or Lay-in Panel Ceilings [1,2]

Item	Seismic Design Category C	Seismic Design Categories D, E, & F
Up to 144 sq. ft.		
NA	No requirements.	No requirements.

Table C13.5.6.2 – Summary of Requirements for Acoustical Tile or Lay-in Panel Ceilings [1,2]

Item	Seismic Design Category C	Seismic Design Categories D, E, & F
Greater than 144 sq. ft. but less than or equal to 1000 sq. ft.		
Duty Rating	Only Intermediate or Heavy Duty Load Rated grid as defined by ASTM C 635 may be used for commercial ceilings. (ASTM C635 sections 4.1.3.1, 4.1.3.2, & 4.1.3.3)	Heavy Duty Load Rating as defined in ASTM C 635 is required. (§5.1.1)
Grid Connections	Minimum main tee connection and cross tee intersection strength of 60 lb. (§4.1.2)	Minimum main tee connection and cross tee intersection strength of 180 lb. (§5.1.2)
Vertical Suspension Wires	Vertical hanger wires must be a minimum 12-gage. (§4.3.1) Vertical hanger wires maximum 4 ft on center. (§4.3.1) Vertical hanger wires must be sharply bent and wrapped with three turns in three inches or less. (§4.3.2) All vertical hanger wires may not be more than 1 in 6 out of plumb without having additional wires counter-splayed. (§4.3.3) Wires may not attach to or bend around interfering equipment without the use of trapezes. (§4.3.4)	Vertical hanger wire must be a minimum 12-gage. (§5.2.7.1) Vertical hanger wires maximum 4 ft on center. (§5.2.7.1) Vertical hanger wires must be sharply bent and wrapped with three turns in three inches or less. (§5.2.7.2) All vertical hanger wires may not be more than 1 in 6 out of plumb without having additional wires counter-splayed. (§5.2.7.3) Any connection device from the vertical hanger wire to the structure above must sustain a minimum load of 100 lb. (§5.2.7.2) Wires may not attach to or bend around interfering equipment without the use of trapezes. (§5.2.7.4)
Lateral Bracing	Lateral bracing is not permitted. Ceiling is intended to "float" relative to balance of structure. Tee connections may be insufficient to maintain integrity if braces were included. (§4.2.6, NOTE 1)	Not required under 1000 sq. ft. For ceiling areas under 1000 sq. ft., perimeter and tee connections are presumed to be sufficiently strong to maintain integrity whether bracing is installed or not. (§5.2.8)
Perimeter	Perimeter closure (molding) width must be a minimum 7/8-inch. (§4.2.2) Perimeter closures with a support ledge of less than 7/8-inch shall be supported by perimeter vertical hanger wires not more than 8 inches from the wall. (§4.2.3) A minimum clearance of 3/8-inch must be maintained on all four sides. (§4.2.4) Grid ends on all four walls must be free to move (§4.2.6)	Perimeter closure (molding) width must be a minimum of 2 inches (§5.2.2) Proprietary solutions using approved perimeter clips may utilize perimeter closures less than 2 inches (ASCE 7-10 para. 13.5.6.2.2 a) Two, adjacent sides must be connected to the wall or perimeter closure. (§5.2.3) A minimum clearance of 3/4 inch must be maintained on the other two, adjacent sides (§5.2.3)

DRAFT

Table C13.5.6.2 – Summary of Requirements for Acoustical Tile or Lay-in Panel Ceilings [1,2]

Item	Seismic Design Category C	Seismic Design Categories D, E, & F
	Proprietary solutions may utilize approved attachment devices on some walls and varying closure widths Perimeter tee ends must be tied together to prevent spreading (§4.2.5)	Perimeter tees must be supported by vertical hanger wires not more than 8 inches from the wall (§5.2.6) Perimeter tee ends must be tied together not more than 8 inches from the wall to prevent spreading (§5.2.4)
Light Fixtures	Light fixtures must be positively attached to the grid by at least two connections each capable of supporting the weight of the lighting fixture. (§4.4.1 and NEC) Surface mounted light fixtures shall be positively clamped to the grid. (§4.4.2) Clamping devices for surface mounted light fixtures shall have safety wires to the grid or the structure above. (§4.4.2) Light fixtures and attachments weighing 10 lb or less require number 12 gage (minimum) hanger wire connected to the housing (e.g. canister light fixture). This wire may be slack. (§4.4.3) Light fixtures weighing 10 to 56 lb require two number 12 gage (minimum) hanger wires at diagonal corners. These wires may be slack. (§4.4.4) Light fixtures greater than 56 lb require independent support from the structure. (§4.4.5) Pendent-hung light fixtures shall be supported by a minimum 9-gage wire or other approved alternate. (§4.4.6) Rigid conduit is not permitted for the attachment of fixtures. (§4.4.7)	Light fixtures must be positively attached to the grid by at least two connections each capable of supporting the weight of the lighting fixture. (NEC, para. 5.3.1) Surface mounted light fixtures shall be positively clamped to the grid. (§5.3.2) Clamping devices for surface mounted light fixtures shall have safety wires to the grid or the structure above. (§5.3.2) When cross tees with a load carrying capacity of less than 16 lb/foot are used, supplementary hanger wires are required. (§5.3.3) Light fixtures and attachments weighing 10 lb or less require one 12 gage minimum hanger wire connected to the housing (e.g. canister light fixture) and connected to the structure above. This wire may be slack. (§5.3.4) Light fixtures weighing 10 to 56 lb require two number 12 gage minimum hanger wires attached to the fixture housing and connected to the structure above. These wires may be slack. (§5.3.5) Light fixtures greater than 56 lb require independent support from the structure by approved hangers. (§5.3.6) Pendent-hung light fixtures shall be supported by a minimum 9-gage wire or other approved alternate. (§5.3.7) Rigid conduit is not permitted for the attachment of fixtures. (§5.3.8)
Mechanical Services	Flexibly mounted mechanical services weighing less than 20 lb must be positively attached to main runners or cross runners with the same load carrying capacity as the main runners (§4.5.1)	Flexibly mounted mechanical services weighing less than 20 lb must be positively attached to main runners or cross runners with the same load carrying capacity as the main runners. (§5.4.1)

DRAFT

Table C13.5.6.2 – Summary of Requirements for Acoustical Tile or Lay-in Panel Ceilings [1,2]

Item	Seismic Design Category C	Seismic Design Categories D, E, & F
	Flexibly mounted mechanical services weighing more than 20 lb but less than 56 lb or less require two 12 gauge (minimum) hanger wires. These wires may be slack. (§4.5.2) Flexibly mounted mechanical services greater than 56 lb require direct support from the structure. (§4.5.3)	Flexibly mounted mechanical services weighing more than 20 lb but less than or equal to 56 lb require two 12 gage (minimum) hanger wires. These wires may be slack. (§5.4.2) Flexibly mounted mechanical services greater than 56 lb require direct support from the structure. (§5.4.3)
Supplemental Requirements	All ceiling penetrations must have a minimum of 3/8 inch clearance on all sides. (§4.2.4)	Direct concealed systems must have stabilizer bars a maximum of 60 inches on center with stabilizer bars within 24 inches of the perimeter. (§5.2.5) Bracing is required for ceiling plane elevation changes. (§5.2.8.6) Cable trays and electrical conduits shall be supported independently of the ceiling. (§5.2.8.7) Seismic separation joints or full height partitions are required for ceiling areas greater than 2,500 sq. ft. (§5.2.9.1) All ceiling penetrations and independently supported fixtures or services must have closures which allow for a 1-inch movement. (§5.2.8.5) An integral ceiling sprinkler system may be designed by the licensed design professional to eliminate the required spacings of penetrations. (§5.2.8.8) A licensed design professional must review the interaction of non-essential ceiling components with essential ceiling components to prevent the failure of the essential components. (§5.7.1)
Partitions	The ceiling may not provide lateral support to partitions. (§4.6.1) Partitions attached to the ceiling must use flexible connections to avoid transferring force to the ceiling. (§4.6.1)	Partition bracing must be independent of the ceiling. (§5.5.1)

DRAFT

Table C13.5.6.2 – Summary of Requirements for Acoustical Tile or Lay-in Panel Ceilings [1,2]

Item	Seismic Design Category C	Seismic Design Categories D, E, & F
Exceptions	The ceiling weight must be less than 2.5 lb/sq. ft., otherwise the prescribed construction for Seismic Design Categories D, E, and F must be used. (§4.1.1)	None.
Greater than 1000 sq. ft. but less than or equal to 2500 sq. ft.		
Lateral Bracing	No additional requirements.	Lateral force bracing (splay wires or rigid bracing) is required within 2 inches of main tee / cross tee intersection and splayed 90 degrees apart in the plan view, at maximum 45 degree angle from the horizontal and located 12 ft. on center in both directions, starting 6 ft. from walls. (§5.2.8.1 & §5.2.8.2) Lateral force bracing must be spaced a minimum of 6 inches from unbraced horizontal piping or ductwork. (§5.2.8.3) Lateral force bracing connection strength must be a minimum of 250 lb. (§5.2.8.3) Unless rigid bracing is used or calculations have shown that lateral deflection is less than 1/4 inch, sprinkler heads and other penetrations shall have a minimum of 1 inch clear space in all directions. (§5.2.8.5)
Greater than 2500 sq. ft.		
Special Considerations	No additional requirements.	Seismic separation joints with a minimum or 3/4-inch axial movement or full height partitions with the usual 2-inch closure and other requirements. (§5.2.9.1)

[1] There are no requirements for suspended ceilings located in structures assigned to Seismic Design Categories A and B.

[2] Unless otherwise noted, all section references in parentheses (§) refer to ASTM E580 (2006).

C13.5.6.3 Integral Construction

Ceiling systems utilizing integral construction are constructed of modular pre-engineered components, which integrate lights, ventilation components, fire-sprinklers, and seismic bracing into a complete system. They may include aluminum, steel, and PVC components and may be designed using integral construction of ceiling and wall. They often use rigid grid and bracing systems, which provide lateral support for all the ceiling components, including sprinkler drops. This reduces the potential for adverse interactions between components, and eliminates the need to provide clearances for differential movement.

DRAFT

C13.5.7 Access Floors

C13.5.7.1 General

In past earthquakes and in cyclic load tests, some typical raised access floor systems behaved in a brittle manner and exhibited little reserve capacity beyond initial yielding or failure of critical connections. Testing shows that unrestrained individual floor panels may pop out of the supporting grid unless mechanically fastened to supporting pedestals or stringers. This may be a concern, particularly in egress pathways.

For systems with floor stringers, it is accepted practice to calculate the seismic force, F_p, for the entire access floor system within a partitioned space and then distribute the total force to the individual braces or pedestals. For stringerless systems, the seismic load path should be established explicitly.

Overturning effects subject individual pedestals to vertical loads well in excess of the weight, W_p, used in determining the seismic force, F_p. It is unconservative to use the design vertical load simultaneously with the design seismic force for design of anchor bolts, pedestal bending, and pedestal welds to base plates. "Slip on" heads that are not mechanically fastened to the pedestal shaft and thus cannot transfer tension are likely unable to transfer to the pedestal the overturning moments generated by equipment attached to adjacent floor panels.

To preclude brittle failure, each element in the seismic load path must have energy absorbing capacity. Buckling failure modes should be prevented. Lower seismic force demands are allowed for special access floors that are designed to preclude brittle and buckling failure modes.

C13.5.7.2 Special Access Floors

An access floor can be a "special access floor" if the registered design professional opts to comply with the requirements of Section 13.5.7.2. Special access floors include construction features that improve the performance and reliability of the floor system under seismic loading. The provisions focus on providing an engineered load path for seismic shear and overturning forces. Special access floors are designed for smaller lateral forces, and their use is encouraged at facilities with higher nonstructural performance objectives.

C13.5.8 Partitions

Partitions subject to these requirements must have independent lateral support bracing from the top of the partition to the building structure or to a substructure attached to the building structure. Some partitions are designed to span vertically from the floor to a suspended ceiling system. The ceiling system must be designed to provide lateral support for the top of the partition. An exception to this condition is provided to exempt bracing of light (gypsum board) partitions where the load does not exceed the minimum partition lateral load. Experience has shown that partitions subjected to the minimum load can be braced to the ceiling without failure.

C13.5.9 Glass in Glazed Curtain Walls, Glazed Storefronts, and Glazed Partitions

The performance of glass in earthquakes falls into one of four categories:

1. The glass remains unbroken in its frame or anchorage.
2. The glass cracks but remains in its frame or anchorage while continuing to provide a weather barrier, and to be otherwise serviceable.
3. The glass shatters but remains in its frame or anchorage in a precarious condition, likely to fall out at any time.
4. The glass falls out of its frame or anchorage, either in shards or as whole panels.

Categories 1 and 2 satisfy both immediate-occupancy and life-safety performance objectives. Although the glass is cracked in Category 2, immediate replacement is not required. Categories 3 and 4 cannot provide for immediate occupancy, and their provision of life safety depends on the post-breakage characteristics of the glass and the height from which it can fall. Tempered glass shatters into multiple, pebble-size fragments that fall from the frame or anchorage in clusters. These broken glass clusters are relatively harmless to humans when they fall from limited heights, but they could be harmful when they fall from greater heights.

C13.5.9.1 General

Equation 13.5-1 is derived from *Earthquake Safety Design of Windows*, published in November 1982 by the Sheet Glass Association of Japan and is similar to an equation in Bouwkamp and Meehan (1960) that permits calculation of the story drift required to cause glass-to-frame contact in a given rectangular window frame. Both calculations

DRAFT

are based on the principle that a rectangular window frame (specifically, one that is anchored mechanically to adjacent stories of a structure) becomes a parallelogram as a result of story drift, and that glass-to-frame contact occurs when the length of the shorter diagonal of the parallelogram is equal to the diagonal of the glass panel itself. The value $\Delta_{fallout}$ represents the displacement capacity of the system and D_p represents the displacement demand.

The 1.25 factor in the requirements described above reflect uncertainties associated with calculated inelastic seismic displacements of building structures. Wright (1989) states that "post-elastic deformations, calculated using the structural analysis process, may well underestimate the actual building deformation by up to 30 percent. It would therefore be reasonable to require the curtain wall glazing system to withstand 1.25 times the computed maximum interstory displacement to verify adequate performance."

The reason for Exception 2 to Equation 13.5-1 is that the tempered glass, if shattered, would not produce an overhead falling hazard to adjacent pedestrians, although some pieces of glass may fall out of the frame.

C13.5.9.2 Seismic Drift Limits for Glass Components

As an alternative to the prescriptive approach of Section 13.5.9.1, the deformation capacity of glazed curtain wall systems may be established by test.

C13.6 MECHANIAL AND ELECTRICAL COMPONENTS

These requirements, focused on design of supports and attachments, are intended to reduce the hazard to life posed by loss of component structural stability or integrity. The requirements increase the reliability of component operation but do not address functionality directly. For critical components where operability is vital, Section 13.2.2 provides methods for seismically qualifying the component.

Traditionally, mechanical components (such as tanks and heat exchangers) without rotating or reciprocating components are directly anchored to the structure. Mechanical and electrical ~~equipment~~ components with rotating or reciprocating elements are often isolated from the structure by vibration isolators (utilizing rubber acting in shear, springs, or air cushions). Heavy mechanical equipment (such as large boilers) may not be restrained at all, and electrical equipment other than generators, which are normally isolated to dampen vibrations, usually is rigidly anchored (for example, switchgear and motor control centers).

Two distinct levels of earthquake safety are considered in the design of mechanical and electrical components. At the usual safety level, failure of the mechanical or electrical component itself due to seismic effects poses no significant hazard. In this case, design of the supports and attachments to the structure is required to avoid a life-safety hazard. At the higher safety level, the component must continue to function acceptably following the design earthquake. Such components are defined as designated seismic systems in Section 11.2 and may be required to meet the special certification requirements of Section 13.2.2.

Not all equipment or parts of equipment need to be designed for seismic forces. Where I_p is specified to be 1.0, damage to, or even failure of, a piece or part of a component does not violate these requirements as long as a life-safety hazard is not created. The restraint or containment of a falling, breaking, or toppling component (or its parts) by means of bumpers, braces, guys, wedges, shims, tethers, or gapped restraints to satisfy these requirements often is acceptable, although the component itself may suffer damage.

Judgment is required to fulfill the intent of these requirements; the key consideration is the threat to life safety. For example, a nonessential air handler package unit that is less than 4 feet (1.2 meters) tall bolted to a mechanical room floor is not a threat to life as long as it is prevented from significant displacement by having adequate anchorage. In this case, seismic design of the air handler itself is unnecessary. On the other hand, a 10-foot (3.0 meters) tall tank on 6-foot (1.8 meters) long angles used as legs, mounted on a roof near a building exit does pose a hazard. The intent of these requirements is that the supports and attachments (tank legs, connections between the roof and the legs, and connections between the legs and the tank), and possibly even the tank itself be designed to resist seismic forces. Alternatively, restraint of the tank by guys or bracing could be acceptable.

It is not the intent of the standard to require the seismic design of shafts, buckets, cranks, pistons, plungers, impellers, rotors, stators, bearings, switches, gears, nonpressure retaining casings and castings, or similar items. Where the potential for a hazard to life exists, the design effort should focus on equipment supports including base plates, anchorages, support lugs, legs, feet, saddles, skirts, hangers, braces, or ties.

Many mechanical and electrical components consist of complex assemblies of parts that are manufactured in an industrial process that produces similar or identical items. Such equipment may include manufacturer's catalog

items and often are designed by empirical (trial-and-error) means for functional and transportation loadings. A characteristic of such equipment is that it may be inherently rugged. The term "rugged" refers to an ampleness of construction that provides such equipment with the ability to survive strong motions without significant loss of function. By examining such equipment, an experienced design professional usually should be able to confirm such ruggedness. The results of an assessment of equipment ruggedness may be used in determining an appropriate method and extent of seismic design or qualification effort.

The revisions to Table 13-3 in ASCE/SEI 07-10 are the result of work done in recent years to better understand the performance of mechanical and electrical components and their attachment to the structure. The primary concepts of flexible and rigid equipment and ductile and rugged behavior are drawn from SEAOC (1999), Commentary Section C107.1.7. Material on HVAC is based on ASHRAE (2000). Other material on industrial piping, boilers, and pressure vessels is based on the American Society of Mechanical Engineers codes and standards publications.

C13.6.1 General

The exception allowing unbraced suspended components has been clarified, addressing concerns about the type of nonstructural components allowed by these exceptions as well as the acceptable consequences of interaction between components. In previous editions of the standard, certain nonstructural components that could represent a fire hazard following an earthquake were exempt from lateral bracing requirements. In the revised exception, reference to Section 13.2.3 addresses such concerns while distinguishing between credible seismic interactions and incidental interactions.

The seismic demand requirements are based on component structural attributes of flexibility (or rigidity) and ruggedness. Table 13.6-1 provides seismic coefficients based on judgments of the component flexibility, expressed in the a_p term, and ruggedness expressed in the R_p term. It may also be necessary to consider the flexibility and ductility of the attachment system that provides seismic restraint.

Entries for components and systems in Table 13.6-1 are grouped and described to improve clarity of application. Components are divided into three broad groups, within which they are further classified depending on the type of construction or expected seismic behavior. For example, mechanical components include "air-side" components (such as fans and air handlers) that experience dynamic amplification but are light and deformable; "wet-side" components that generally contain liquids (such as boilers and chillers) that are more rigid and somewhat ductile; and very rugged components (such as engines, turbines, and pumps) that are of massive construction due to demanding operating loads, and generally perform well in earthquakes, if adequately anchored.

A distinction is made between components isolated using neoprene and those that are spring isolated. Spring isolated are assigned a lower R_p value since they tend to have less effective damping. Internally isolated components are classified explicitly to avoid confusion.

C13.6.2 Component Period

Component period is used to clarify components as rigid ($T \leq 0.06$s) or flexible ($T > 0.06$s). Determination of the fundamental period of a mechanical or electrical component using analytical or test methods can become very involved. If not properly performed, the fundamental period may be underestimated, producing unconservative results. The flexibility of the component's supports and attachments typically dominates response and thus fundamental component period. Therefore, analytical determinations of component period must consider those sources of flexibility. Where determined by testing, the dominant mode of vibration of concern for seismic evaluation must be excited and captured by the test setup. This dominant mode of vibration cannot be discovered through in-situ tests that measure only ambient vibrations. To excite the mode of vibration with the highest fundamental period by in-situ tests, relatively significant input levels of motion are required (that is, the flexibility of the base and attachment must be exercised). A resonant frequency search procedure, such as that given in ICC-ES AC156, may be used to identify the dominant modes of vibration of a component.

Many types of mechanical components have fundamental periods below 0.06 seconds and may be considered to be rigid. Examples include horizontal pumps, engine generators, motor generators, air compressors, and motor driven centrifugal blowers. Other types of mechanical equipment are very stiff, but may have fundamental periods up to about 0.125 seconds. Examples include vertical immersion and deep well pumps, belt driven and vane axial fans, heaters, air handlers, chillers, boilers, heat exchangers, filters, and evaporators. These fundamental period estimates do not apply where the equipment is mounted on vibration isolators.

DRAFT

Electrical equipment cabinets can have fundamental periods of about 0.06 to 0.3 seconds, depending upon the supported weight and its distribution, the stiffness of the enclosure assembly, the flexibility of the enclosure base, and the load path through to the attachment points. Tall, narrow motor control centers and switchboards lie at the upper end of this period range. Low- and medium-voltage switchgear, transformers, battery chargers, inverters, instrumentation cabinets, and instrumentation racks usually have fundamental periods ranging from 0.1 to 0.2 seconds. Braced battery racks, stiffened vertical control panels, benchboards, electrical cabinets with top bracing, and wall-mounted panelboards have fundamental periods ranging from 0.06 to 0.1 seconds.

C13.6.3 Mechanical Components and C13.6.4 Electrical Components

Most mechanical and electrical equipment is inherently rugged and, where properly attached to the structure, has performed well in past earthquakes. Since the operational and transportation loads for which the equipment is designed typically are larger than those due to earthquakes, these requirements focus primarily on equipment anchorage and attachments. However, Designated Seismic Systems, which are required to function following an earthquake or which must maintain containment of flammable or hazardous materials, must themselves be designed for seismic forces or be qualified for seismic loading in accordance with Section 13.2.2.

The likelihood of post-earthquake operability can be increased where the following measures are taken:

1. Internal assemblies, subassemblies, and electrical contacts are attached sufficiently to prevent their being subjected to differential movement or impact with other internal assemblies or the equipment enclosure.
2. Operators, motors, generators, and other such components that are functionally attached to mechanical equipment by means of an operating shaft or mechanism are structurally connected or commonly supported with sufficient rigidity such that binding of the operating shaft will be avoided.
3. Any ceramic or other nonductile components in the seismic load path are specifically evaluated.
4. Adjacent electrical cabinets are bolted together and cabinet lineups are prevented from impacting adjacent structural members.

Components that could be damaged, or could damage other components, and are fastened to multiple locations of a structure must be designed to accommodate seismic relative displacements. Such components include bus ducts, cable trays, conduit, elevator guide rails, and piping systems. As discussed in Section C13.3.2.1, special design consideration is required where full story drift demands are concentrated in a fraction of the story height.

C13.6.5 Component Supports

The intent of this section is to require seismic design of all mechanical and electrical component supports to prevent sliding, falling, toppling, or other movement that could imperil life. Component supports are differentiated here from component attachments to emphasize that the supports themselves, as enumerated in the text, require seismic design even if fabricated by the mechanical or electrical component manufacturer. This is regardless of whether the mechanical or electrical component itself is designed for seismic loads.

C13.6.5.1 Design Basis

Standard supports are those developed in accordance with a reference document (Section 13.1.6). Where standard supports are not used, the seismic design forces and displacement demands of Chapter 13 are used with applicable material-specific design procedures of Chapter 14.

C13.6.5.2 Design for Relative Displacement

For some items, such as piping, seismic relative displacements between support points are of more significance than inertial forces. Components made of high deformability materials such as steel or copper can accommodate relative displacements inelastically, provided the connections also provide high deformability. Threaded and soldered connections exhibit poor ductility under inelastic displacements, even for ductile materials. Components made of less ductile materials can accommodate relative displacement effects only if appropriate flexibility or flexible connections are provided.

Detailing distribution systems that connect separate structures with bends and elbows makes them less prone to damage and less likely to fracture and fall, provided the supports can accommodate the imposed loads.

C13.6.5.3 Support Attachment to Component

As used in this Section, "integral" relates to the manufacturing process, not the location of installation. For example, both the legs of a cooling tower and the attachment of the legs to the body of the cooling tower must be

DRAFT

designed, even if the legs are provided by the manufacturer and installed at the plant. Also, if the cooling tower has an I_p=1.5, the design must address not only the attachments (welds, bolts, etc.) of the legs to the component but also local stresses imposed on the body of the cooling tower by the support attachments.

C13.6.5.5 Additional Requirements

As reflected in this Section of the standard and in the footnote to Table 13.6-1, vibration isolated equipment with snubbers is subject to amplified loads as a result of dynamic impact.

Most sheet metal connection points for seismic anchorage do not exhibit the same mechanical properties as bolted connections with structural elements. The use of Belleville washers improves the seismic performance of connections to equipment enclosures fabricated from sheet metal 7 gauge (0.18 inches) or thinner by distributing the stress over a larger surface area of the sheet metal connection interface, allowing for bolted connections to be torqued to recommended values for proper preload while reducing the tendency for local sheet metal tearing or bending failures or loosening of the bolted connection. (See Figure C13.6-1). The intrinsic spring loading capacity of the Belleville washer assists with long-term preload retention to maintain integrity of the seismic anchorage.

Manufacturers test or design their equipment to handle seismic loads at the equipment "hard points" or anchor locations. The results of this design qualification effort are typically reflected in installation instructions provided by the manufacturer. It is imperative that the manufacturer's installation instructions be followed. Where such guidance does not exist, the registered design professional should design appropriate reinforcement.

Failure of sheet metal base anchored with standard washer (With permission)

Anchorage equipped with Belleville washer (With permission)

Fig. C13.6-1 Equipment anchorage with Belleville washers

C13.6.5.6 Conduit, Cable Tray, and Other Electrical Distribution Systems (Raceways)

The term raceway is defined in several standards with somewhat varying language. As used here, it is intended to describe all electrical distribution systems including conduit, cable trays, and open and closed raceways. Experience indicates that a size limit of 2.5 in. can be established for the provision of flexible connections to accommodate seismic relative displacements that might occur between pieces of connected equipment because smaller conduit normally possesses the required flexibility to accommodate such displacements. The bracing exemption for hangers less than 12 in (305 mm) in length presumes the hangars have negligible bending strength and sufficient resistance to lateral seismic loads is provided by the restoring force induced by pendulum displacement of the raceway. The short length of the hangars is also presumed to limit the amount of horizontal raceway displacement.

Short hangars fabricated from threaded rods will resist lateral force primarily through bending and are prone to failure through cyclic fatigue. Providing a swivel at the connection between the threaded rod hangar and the structure eliminates the bending stress in the threaded rod. Where this is not done and where braces are not provided, the rod hangers (and, where applicable, the anchors) must be designed for the resultant bending forces.

The exemption for short hangars is limited to the case where every hanger in the raceway run is less than 12 in (305 mm) because of the need to carefully consider the seismic loads and compatible displacement limits for the portions of raceways with longer hangar supports.

DRAFT

C13.6.6 Utility and Service Lines

For essential facilities (Risk Category IV), auxiliary on-site mechanical and electrical utility sources are recommended.

Where utility lines pass through the interface of adjacent, independent structures, they must be detailed to accommodate differential displacement computed in accordance with Section 13.3.2 and including the C_d factor of Section 12.2.1.

As specified in Section 13.1.3, nonessential piping whose failure could damage essential utilities in the event of pipe rupture may be considered as Designated Seismic Systems.

C13.6.7 Ductwork

Experience in past earthquakes has shown that HVAC duct systems are rugged and perform well in strong ground shaking. Bracing in accordance with the Sheet Metal and Air Conditioning Contractors National Association ANSI/SMACNA 001 has been effective in limiting damage to duct systems. Typical failures have affected only system function, and major damage or collapse has been uncommon. Therefore, industry standard practices should prove adequate for most installations. Expected earthquake damage is limited to opening of duct joints and tears in ducts. Connection details that are prone to brittle failures, especially hanger rods subject to large amplitude cycles of bending stress, should be avoided.

The amplification factor for ductwork has been increased from 1.0 to 2.5, because even braced duct systems are relatively flexible. The R_p values also have been increased so that the resulting seismic design forces are consistent with those determined previously.

Ductwork systems that carry hazardous materials or must remain operational during and after an earthquake, are assigned a value of I_p =1.5, and require a detailed engineering analysis addressing leak-tightness.

Lighter in-line components may be designed to resist the forces from Section 13.3 as part of the overall duct system design, whereby the duct attached to the in-line component is explicitly designed for the forces generated by the component. Where in-line components are more massive, the component must be supported and braced independently of the ductwork in order to avoid failure of the connections.

The requirements for flexible connections of unbraced piping to in-line components such as reheat coils applies regardless of the component weight.

C13.6.8 Piping Systems

Due to the typical redundancy of piping system supports, documented cases of total collapse of piping systems in earthquakes are rare; however, pipe leakage resulting from excessive displacement or overstress often results in significant consequential damage and in some cases loss of facility operability. Loss of fluid containment (leakage) normally occurs at discontinuities such as threads, grooves, bolted connectors, geometric discontinuities, or locations where incipient cracks exist, such as at the toe or root of a weld or braze. Numerous building and industrial national standards and guidelines address a wide variety of piping systems materials and applications. Construction in accordance with the national standards referenced in these provisions is usually effective in limiting damage to piping systems and avoiding loss of fluid containment under earthquake conditions.

ASHRAE (2000) and MSS (2001) are derived in large part from the predecessors of SMACNA (2008). These documents may be appropriate references for use in the seismic design of piping systems. As the SMACNA standard does not refer to pipe stresses in the determination of hanger and brace spacing, however, a supplementary check of pipe stresses may be necessary when this document is used. ASME piping rules as given in the ASME (2010) and ASME B31 parts B31.1, B31.3, B31.5, B31.9 and B31.12 are normally used for high pressure, high temperature piping, but can also conservatively be applied to other lower pressure, lower temperature piping systems. Code-compliant seismic design manuals prepared specifically for proprietary systems may also be appropriate references.

Table 13-3 entries for piping previously listed the amplification factor related to the response of piping systems as rigid (a_p = 1.0) and values for component response modification factors lower than in the current table. However, it was realized that most piping systems are flexible and that the amplification factor values should reflect this fact; thus, a_p was increased to 2.5 and the R_p values adjusted accordingly such that a_p / R_p remains roughly consistent with earlier provisions.

DRAFT

Although seismic design in accordance with Section 13.6.8 generally ensures that effective seismic forces will not fail piping, seismic displacements may be underestimated such that impact with nearby structural, mechanical, or electrical components could occur. In marginal cases it may be advisable to protect the pipe with wrapper plates where impacts could occur, including at gapped supports. Insulation may in some cases also serve to protect the pipe from impact damage. Piping systems are typically designed for pressure containment, and piping designed with a factor of safety of 3 or more against pressure failure (rupture) may be inherently robust enough to survive impact with nearby structures, equipment, and other piping, particularly if the piping is insulated. Piping having less than standard weight wall thickness may require the evaluation of the effects of impact locally on the pipe wall and may necessitate means to protect the pipe wall.

It is usually preferable for piping to be detailed to accommodate seismic relative displacements between the first seismic support upstream or downstream from connections and other seismically supported components or headers. This is preferably achieved by means of pipe flexibility or, where this is not possible, flexible supports. Piping not otherwise detailed to accommodate such seismic relative displacements must be provided with connections having sufficient flexibility in the connecting element or in the component or header to avoid failure of the piping. The option to use a flexible connecting element may be less desirable due to the need for greater maintenance efforts to ensure continued proper function of the flexible element.

Grooved couplings, ball joints, resilient gasket compression fittings, other articulating-type connections, bellows expansion joints, and flexible metal hose are used in many piping systems and can serve to increase the rotational and lateral deflection design capacity of the piping connections.

Grooved couplings are classified as either rigid or flexible. Flexible grooved couplings demonstrate limited free rotational capacity. The free rotational capacity is the maximum articulating angle where the connection behaves essentially as a pinned joint with limited or negligible stiffness. The remaining rotational capacity of the connection is associated with conventional joint behavior, and design force demands in the connection are determined by traditional means.

Rigid couplings are typically used for high pressure applications and usually are assumed to be stiffer than the pipe. Alternatively, rigid coupling may exhibit bi-linear rotational stiffness with the initial rotational stiffness affected by installation.

Coupling flexibilities vary significantly between manufacturers, particularly for rigid couplings. Manufacturer's data may be available. Industry-wide procedures for the determination of coupling flexibility are not currently available; however, some guidance for couplings may be found in the provisions for fire sprinkler piping, where grooved couplings are classified as either rigid or flexible on the basis of specific requirements on angular movement. In Section 3.5.4 of NFPA (2007), flexible couplings are defined as follows:

A listed coupling or fitting that allows axial displacement, rotation, and at least 1 degree of angular movement of the pipe without inducing harm on the pipe. For pipe diameters of 8-inch (203.2 mm) and larger, the angular movement shall be permitted to be less than 1 degree but not less than 0.5 degrees.

Couplings determined to be flexible on this basis are listed either with FM (2007) or UL (2004).

Piping component testing suggests that the ductility capacity of carbon steel threaded and flexible grooved piping component joints ranges between 1.4 and 3.0, implying an effective stress intensification of approximately 2.5. These types of connections have been classified as having limited deformability, and piping systems with these connections have R_p values lower than piping with welded or brazed joints.

The allowable stresses for piping constructed with ductile materials assumed to be materials with high deformability, and not designed in accordance with an applicable standard or recognized design basis are based on values consistent with industrial piping and structural steel standards for comparable piping materials.

The allowable stresses for piping constructed with low-deformability materials, and not designed in accordance with an applicable standard or recognized design basis are derived from values consistent with ASME standards for comparable piping materials.

For typical piping materials, pipe stresses may not be the governing parameter in determining the hanger and other support spacing. Other considerations, such as the capacity of the hanger and other support connections to the structure, limits on the lateral displacements between hangers and other supports to avoid impacts, the need to limit pipe sag between hangers in order to avoid the pooling of condensing gases, and the loads on connected equipment

DRAFT

may govern the design. Nevertheless, seismic span tables, based on limiting stresses and displacements in the pipe, can be a useful adjunct for establishing seismic support locations.

Piping systems' service loads of pressure and temperature need also be considered in conjunction with seismic inertia loads. The potential for low ambient and lower than ambient operating temperatures should be considered in the designation of the piping system materials as having high or low deformability. High deformability may often be assumed for steels, particularly ASME listed materials operating at high temperatures, copper and copper alloys, and aluminum. Low deformability should be assumed for any piping material that exhibits brittle behavior, such as glass, ceramics, and many plastics.

Piping should be designed to accommodate relative displacements between the first rigid piping support and connections to equipment or piping headers often assumed to be anchors. Barring such design, the equipment or header connection could be designed to have sufficient flexibility to avoid failure. The specification of such flexible connections should consider the necessity of connection maintenance.

Where appropriate, a walkdown of the finally installed piping system by an experienced design professional familiar with seismic design is recommended, particularly for piping greater than 6 in. (152.4 mm) nominal pipe size, high-pressure piping, piping operating at higher than ambient temperatures, and piping containing hazardous materials. The need for a walkdown may also be related to the scope, function, and complexity of the piping system as well as the expected performance of the facility. In addition to providing a review of seismic restraint location, orientation, and attachment to the structure, the walkdown verifies that the required separation exists between the piping and nearby structures, equipment, and other piping in the as-built condition.

C13.6.8.1 ASME Pressure Piping Systems

In Table 13-3, the increased R_p values listed for ASME B31-compliant piping systems are intended to reflect the more rigorous design, construction, and quality control requirements as well as the intensified stresses associated with ASME B31 designs.

Materials meeting ASME toughness requirements may be considered to be high-deformability materials.

C13.6.8.2 Fire Protection Sprinkler Piping Systems

The lateral design procedures of NFPA (2007) have been revised for consistency with the ASCE/SEI 7 design approach while retaining traditional sprinkler system design concepts. Using conservative upper-bound values of the various design parameters, a single lateral force coefficient, C_p, was developed. It is a function of the mapped short period response parameter S_s. Stresses in the pipe and connections are controlled by limiting the maximum reaction at bracing points, as a function of pipe diameter.

Other components of fire protection systems, e.g., pumps and control panels, are subject to the general requirements of ASCE/SEI 7.

C13.6.8.3 Exceptions

The conditions under which the force and displacement requirements of Section 13.3 may be waived are based on observed performance in past earthquakes. The 12-in. (305-mm) limit on the hanger or trapeze drop must be met by all the hangers or trapezes supporting the piping system.

C13.6.9 Boilers and Pressure Vessels

Experience in past earthquakes has shown that boilers and pressure vessels are rugged and perform well in strong ground motion. Construction in accordance with current requirements of the ASME *Boiler and Pressure Vessel Code* (ASME BPVC) has been shown to be effective in limiting damage to and avoiding loss of fluid containment in boilers and pressure vessels under earthquake conditions. It is, therefore, the intent of the standard that nationally recognized codes be used to design boilers and pressure vessels provided that the seismic force and displacement demands are equal to or exceed those outlined in Section 13.3. Where nationally recognized codes do not yet incorporate force and displacement requirements comparable to the requirements of Section 13.3, it is nonetheless the intent to use the design acceptance criteria and construction practices of those codes.

C13.6.10 Elevator and Escalator Design Requirements

The ASME *Safety Code for Elevators and Escalators* (ASME A17.1) has adopted many requirements to improve the seismic response of elevators; however, they do not apply to some regions covered by this chapter. These changes are to extend force requirements for elevators to be consistent with the standard.

DRAFT

C13.6.10.3 Seismic Controls for Elevators

ASME A17.1 Section 8.4.10.1.2 specifies the requirements for the location and sensitivity of seismic switches to achieve the following goals: a) safe shutdown in the event of an earthquake severe enough to impair elevator operations, b) rapid and safe reactivation of elevators following an earthquake, and c) avoidance of unintended elevator shutdowns. This is achieved by requiring the switches to be in or near the elevator equipment room, by using switches located on or near building columns that respond to vertical accelerations as would result from P and S waves, and by setting the sensitivity of the switches at a level that avoids false shutdowns due to non-seismic sources of vibration. The trigger levels for switches with horizontal sensitivity (for cases where the switch cannot be located near a column) are based on the experience with California hospitals in the Northridge earthquake of 1994.Elevators in which the seismic switch and counterweight derail device have triggered should not be put back into service without a complete inspection. However, in the case where the loss of use of the elevator creates a life-safety hazard, an attempt to put the elevator back into service may be attempted. Operating the elevator prior to inspection may cause severe damage to the elevator or its components.

The building owner should have detailed written procedures in place defining for the elevator operator/maintenance personnel which elevators in the facility are necessary from a post-earthquake life safety perspective. It is highly recommended that these procedures be in-place, with appropriate personnel training, prior to an event strong enough to trip the seismic switch.

C13.6.10.4 Retainer Plates

The use of retainer plates is a very low cost provision to improve the seismic response of elevators.

C13.6.11 Other Mechanical and Electrical Components

The material properties set forth in Item 2 of this Section are similar to those allowed in ASME BPVC and reflect the high factors of safety necessary for seismic, service, and environmental loads.

DRAFT

Chapter C14
MATERIAL SPECIFIC SEISMIC DESIGN AND DETAILING REQUIREMENTS

Because seismic loading is expected to cause nonlinear behavior in structures, seismic design criteria require not only provisions to govern loading, but also provisions to define the required configurations, connections, and detailing to produce material and system behavior consistent with the design assumptions. Thus, while ASCE/SEI 7-10 is primarily a loading standard, compliance with Chapter 14, which covers material specific seismic design and detailing, is required. In general, Chapter 14 adopts material design and detailing standards developed by industry material standards organizations. These materials standards organizations maintain complete commentaries covering their standards and such material is not duplicated here.

C14.0 SCOPE

The scoping statement in this section clarifies that foundation elements are subject to all of the structural design requirements of the standard.

C14.1 STEEL

C14.1.1 Reference Documents

This section lists a series of structural standards published by the American Institute of Steel Construction (AISC), American Iron and Steel Institute (AISI), American Society of Civil Engineers (ASCE/SEI), and Steel Joist Institute (SJI) that are to be applied in the seismic design of steel members and connections in conjunction with the requirements of ASCE/SEI 7. The AISC references are available free of charge in electronic format at www.aisc.org, and the SJI references are available as a free download at www.steeljoist.org.

C14.1.2 Structural Steel

C14.1.2.1 General

This section adopts AISC 360 by direct reference. The specification applies to the design of the structural steel system or systems with structural steel acting compositely with reinforced concrete. In particular, the document sets forth criteria for the design, fabrication and erection of structural steel buildings and other structures, where other structures are defined as structures designed, fabricated and erected in a manner similar to buildings, with building-like vertical and lateral load resisting-elements. The document includes extensive commentary.

C14.1.2.2 Seismic Requirements for Structural Steel Structures

C14.1.2.2.1 Seismic Design Categories B and C

For the lower Seismic Design Categories B and C, a range of options are available in the design of a structural steel lateral force resisting system. The first option is to design the structure to meet the design and detailing requirements in AISC 341 for structures assigned to higher Seismic Design Categories, with the corresponding seismic design parameters (R, Ω_0, and C_d). The second option, presented in the exception, is to use an R factor of 3 (resulting in an increased base shear), an Ω_0 of 3, and a C_d value of 3 but without the specific seismic design and detailing requirements required in AISC 341. The basic concept underlying this option is that design for a higher base shear force results in essentially elastic response that compensates for the limited ductility of the members and connections. The resulting performance considered comparable to that of more ductile systems.

C14.1.2.2.2 Seismic Design Categories D through F

For the higher Seismic Design Categories, the Engineer must follow the seismic design provisions of AISC 341 using the seismic design parameters specified for the chosen structural system except as permitted in Table 15.4-1. For systems other than those identified in Table 15.4-1, it is not considered appropriate to design structures without specific design and detailing for seismic response in these high Seismic Design Categories.

DRAFT

C14.1.3 Cold-Formed Steel

C14.1.3.1 General

This section adopts two standards by direct reference: AISI S100, North American Specification for the Design of Cold-Formed Steel Structural Members, and ASCE/SEI 8, Specification for the Design of Cold Formed Stainless Steel Structural Members.

Both of the adopted reference documents have specific limits of applicability. AISI S100(Section A1.1) applies to the design of structural members that are cold-formed to shape from carbon or low-alloy steel sheet, strip, plate, or bar not more than one-inch in thickness. ASCE/SEI 8 (Section 1.1.1) governs the design of structural members that are cold-formed to shape from annealed and cold-rolled sheet, strip, plate, or flat bar stainless steels. Both documents focus on load-carrying members in buildings; however, allowances are made for applications in nonbuilding structures, if dynamic effects are considered appropriately.

Within each document, there are requirements related to general provisions for the applicable types of steel; design of elements, members, structural assemblies, connections, and joints; and mandatory testing. In addition, AISI S100 contains a chapter on the design of cold-formed steel structural members and connections undergoing cyclic loading. Both standards contain extensive commentaries.

C14.1.3.2 Seismic Requirements for Cold-Formed Steel Structures

This section adopts three standards by direct reference – AISI S100, ASCE 8 and AISI S110. Cold-formed steel and stainless steel members that are part of a seismic force resisting system listed in Table 12.2-1 must be detailed in accordance with the appropriate standard – AISI S100 or ASCE 8.

In addition, the section adopts a reference to AISI S110, which provides design provisions for a specific seismic force resisting system entitled “Cold-formed Steel – Special Bolted Moment Frame” or CFS-SBMFs. Research(Sato and Uang, 2007) has shown that this system experiences inelastic deformation at the bolted connections due to slip and bearing during significant seismic events. In order to develop the designated mechanism, requirements based on capacity design principles are provided for the design of the beams, columns and associated connections. The document has specific requirements for the application of quality assurance and quality control procedures.

C14.1.4 Cold-Formed Steel Light-Frame Construction

C14.1.4.1 General

This subsection of cold-formed steel relates to light-framed construction, which is defined as a method of construction where the structural assemblies are formed primarily by a system of repetitive wood or cold-formed steel framing members or subassemblies of these members (ASCE/SEI 7-10 Section 11.2). It adopts AISI S100, Section D4, which directs the user to an additional suite of AISI standards, including AISI S200, AISI S210, AISI S211, AISI S212, AISI S213 and AISI S214.

In addition, all of these documents include commentaries to aid the user in the correct application of their requirements.

C14.1.4.2 Seismic Requirements for Cold-Formed Steel Light-Frame Construction

Per AISI S213, Sections C1.1 and D1.1, all cold-formed steel light-frame construction systems with R taken greater than 3 must be designed in accordance with AISI S213 inclusive of AISI S213, Sections C5 and D3. In particular, this includes all ASCE 7, Table 12-2.1 entries for "light framed walls sheathed with wood structural panels ...or steel sheets" and "light framed wall systems using flat strap bracing".

Per AISI S213 Sections C1.1 and D1.1, cold-formed steel light-frame construction systems with R less than or equal to 3 are permitted to be designed and constructed exclusive of AISI S213, Sections C5 and D3 only – they must meet the other applicable requirements of AISI S213. This includes ASCE 7, Table 12-2.1 entries for "light framed walls with shear panels of all other materials" and "steel systems not specifically detailed for seismic resistance, excluding cantilever column systems".

C14.1.4.3 Prescriptive Cold-Formed Steel Light-Frame Construction

This section adopts AISI S230, *Standard for Cold-Formed Steel Framing – Prescriptive Method for One and Two Family Dwellings*, which applies to the construction of detached one-and two-family dwellings, townhouses, and other attached single-family dwellings not more than two stories in height using repetitive in-line framing practices

DRAFT

(Section A1). This document adopts AISI S200 by direct reference and includes a commentary to aid the user in the correct application of its requirements.

C14.1.5 Steel Deck Diaphragms

Design of steel deck diaphragms is to be based upon recognized national standards or a specific testing program directed by a person experienced in testing procedures and steel deck. All fastener design values (welds, screws, power actuated fasteners, button punches) for attaching steel deck sheet to steel deck sheet or for attaching the steel deck to the building framing members must be per recognized national design standards or specific steel deck testing programs. All steel deck diaphragm and fastener design properties must be approved for use by the authorities in whose jurisdiction the construction project occurs. Steel deck diaphragm in-plane design forces (seismic, wind, or gravity) must be determined per ASCE/SEI 7 Section 12.10.1. Steel deck manufacturer test reports prepared in accordance with this provision can be used where adopted and approved by the authority having jurisdiction for the building project. The diaphragm design manual produced by the Steel Deck Institute (2004) is also a reference for design values.

Steel deck is assumed to have a corrugated profile consisting of alternating up and down flutes that are manufactured in various widths and heights. Use of flat sheet metal as the overall floor or roof diaphragm is permissible where designed by engineering principles, but is beyond the scope of this section. Flat or bent sheet metal may be used as closure pieces for small gaps or penetrations or for shear transfer over short distances in the steel deck diaphragm where diaphragm design forces are considered.

Steel deck diaphragm analysis must include design of chord members at the perimeter of the diaphragm and around interior openings in the diaphragm. Chord members may be steel beams attached to the underside of the steel deck designed for a combination of axial loads and bending moments due to acting gravity and lateral loads.

Where diaphragm design loads exceed the bare steel deck diaphragm design capacity, then either horizontal steel trusses or a structurally designed concrete topping slab placed over the steel deck must be provided to distribute lateral forces. Where horizontal steel trusses are used, the steel deck must be designed to transfer diaphragm forces to the steel trusses. Where a structural concrete topping over the steel deck is used as the diaphragm, the diaphragm chord members at the perimeter of the diaphragm and edges of interior openings must be either: (a) designed flexural reinforcing steel placed in the structural concrete topping or (b) steel beams located under the steel deck with connectors (that provide a positive connection) as required to transfer design shear forces between the concrete topping and steel beams.

C14.1.6 Steel Cables

These provisions reference ASCE/SEI 19-96, *Structural Applications of Steel Cables for Buildings*, for the determination of the design strength of steel cables.

C14.1.7 Additional Detailing Requirements for Steel Piles in Seismic Design Categories D through F

Steel piles used in higher Seismic Design Categories are expected to yield just under the pile cap or foundation due to combined bending and axial load. Design and detailing requirements of AISC 341 for H-piles are intended to produce stable plastic hinge formation in the piles. Since piles can be subjected to tension due to overturning moment, mechanical means to transfer such tension must be designed for the required tension force, but not less than 10 percent of the pile compression capacity.

C14.2 CONCRETE

The section adopts by reference ACI 318-11 for structural concrete design and construction. In addition, modifications to ACI 318-08 are made that are needed to coordinate the provisions of that material design standard with the provisions of ASCE/SEI 7. Work is ongoing to better coordinate the provisions of the two documents (ACI 318 and ASCE/SEI 7) such that the provisions in Section 14.2 will be significantly reduced in future editions of ASCE/SEI 7.

C14.2.2.1 Definitions

The first two definitions describe wall types for which definitions currently do not exist in ACI 318. These definitions are essential to the proper interpretation of the R and C_d factors for each wall type specified in Table 12.2-1.

C14.2.2.2 ACI 318 Section 7.10

Section 7.10.5.7 of ACI 318 prescribes reinforcement details for ties in compression members. This modification prescribes additional details for ties around anchor bolts in structures assigned to SDC C through F.

C14.2.2.3 Scope

This provision describes how the ACI 318 provisions should be interpreted for consistency with the ASCE 7 provisions.

C14.2.2.4 Intermediate Precast Structural Walls

Section 21.4 of ACI 318 imposes requirements on precast walls for moderate seismic risk applications. Ductile behavior is to be ensured by yielding of the steel elements or reinforcement between panels or between panels and foundations. This provision requires the designer to determine the deformation in the connection corresponding to the earthquake design displacement, and then to check from experimental data that the connection type used can accommodate that deformation without significant strength degradation.

Several steel element connections have been tested under simulated seismic loading, and the adequacy of their load-deformation characteristics and strain capacity have been demonstrated (Schultz and Magana 1996). One such connection was used in the five-story building test that was part of the PRESSS Phase 3 research. The connection was used to provide damping and energy dissipation, and it demonstrated a very large strain capacity (Nakaki et al. 2001). Since then, several other steel element connections have been developed that can achieve similar results (Banks and Stanton 2005, Nakaki et al. 2005). In view of these results, it is appropriate to allow yielding in steel elements that have been shown experimentally to have adequate strain capacity to maintain at least 80% of their yield force through the full design displacement of the structure.

C14.2.2.6Foundations

The intention is that there should be no conflicts between the provisions of Section 21.12 of ACI 318 and Sections 12.1.5, 12.13, or 14.2 of ASCE/SEI 7. However, the additional detailing requirements for concrete piles of Section 14.2.3 can result in conflicts with ACI 318 provisions if the pile is not fully embedded in the soil.

C14.2.2.7 Detailed Plain Concrete Shear Walls

Design requirements for plain masonry walls have existed for many years, and the corresponding type of concrete construction is the plain concrete wall. To allow the use of such walls as the lateral force-resisting system in SDC A and B, this provision requires such walls to contain at least the minimal reinforcement specified in Section 22.6.7.2.

C14.2.3 Additional Detailing Requirements for Concrete Piles

Chapter 20 of PCI (2004) Bridge Design Manual provides detailed information on the structural design of piles and on pile to cap connections for precast prestressed concrete piles. ACI 318 does not contain provisions governing the design and installation of portions of concrete piles, drilled piers, and caissons embedded in ground except for SDC D, E, and F structures.

C14.2.3.1.2 Reinforcement for Uncased Concrete Piles (SDC C)

The transverse reinforcing requirements in the potential plastic hinge zone of uncased concrete piles in Seismic Design Category C is a selective composite of two ACI 318 requirements. In the potential plastic hinge region of an intermediate moment-resisting concrete frame column, the transverse reinforcement spacing is restricted to the least of (1) eight times the diameter of the smallest longitudinal bar, (2) 24 times the diameter of the tie bar, (3) one-half the smallest cross-sectional dimension of the column, and (4) 12 in. Outside of the potential plastic hinge region of a special moment-resisting frame column, the transverse reinforcement spacing is restricted to the smaller of six times the diameter of the longitudinal column bars and 6 in.

C14.2.3.1.5 Reinforcement for Precast Nonprestressed Concrete Piles (SDC C)

Transverse reinforcement requirements in and outside of the plastic hinge zone of precast nonprestressed piles are clarified. The transverse reinforcement requirement in the potential plastic hinge zone is a composite of two ACI 318 requirements (see Section C14.2.3.1.2). Outside of the potential plastic hinge region, the transverse reinforcement spacing is restricted to sixteen (16) times the longitudinal bar diameter. This should permit the longitudinal bars to reach compression yield before buckling. The maximum 8-in. tie spacing comes from current building code provisions for precast concrete piles.

DRAFT

C14.2.3.1.6 Reinforcement for Precast Prestressed Piles (SDC C).
The transverse and longitudinal reinforcing requirements given in ACI 318, Chapter 21, were never intended for slender precast prestressed concrete elements and will result in unbuildable piles. These requirements are based on PCI Committee on Prestressed Concrete Piling (1993).

Equation 14-1, originally from ACI 318, has always been intended to be a lower-bound spiral reinforcement ratio for larger diameter columns. It is independent of the member section properties and can therefore be applied to large or small diameter piles. For cast-in-place concrete piles and precast prestressed concrete piles, the resulting spiral reinforcing ratios from this formula are considered to be sufficient to provide moderate ductility capacities (Fanous et al. 2007).

Full confinement per Eq. 14-1 is required for the upper 20 ft of the pile length where curvatures are large. The amount is relaxed by 50 percent outside of that length in view of lower curvatures and in consideration of confinement provided by the soil.

C14.2.3.2.3 Reinforcement for Uncased Concrete Piles (SDC D through F)
The reinforcement requirements for uncased concrete piles are taken from current building code requirements and are intended to provide ductility in the potential plastic hinge zones (Fanous et al. 2007).

C14.2.3.2.5 Reinforcement for Precast Concrete Piles (SDC D through F)
The transverse reinforcement requirements for precast nonprestressed concrete piles are taken from the IBC (2012) requirements and should be adequate to provide ductility in the potential plastic hinge zones (Fanous et al. 2007).

C14.2.3.2.6 Reinforcement for Precast Prestressed Piles (SDC D through F)
The reduced amounts of transverse reinforcement specified in this provision compared to those required for column members in ACI 318 are justified by the results of the study by Fanous et al. (2007). The last paragraph provides minimum transverse reinforcement outside of the zone of prescribed ductile reinforcing.

C14.3 COMPOSITE STEEL AND CONCRETE STRUCTURES

This section provides guidance on the design of composite and hybrid steel-concrete structures. Composite structures are defined as those incorporating structural elements made of steel and concrete portions connected integrally throughout the structural element by mechanical connectors, bond, or both. Hybrid structures are defined as consisting of steel and concrete structural elements connected together at discrete points. Composite and hybrid structural systems mimic many of the existing steel (moment and braced frame) and reinforced concrete (moment frame and wall) configurations, but are given their own design coefficients and factors in Table 12.2-1. Their design is based on ductility and energy dissipation concepts comparable to those used in conventional steel and reinforced concrete structures, but requires special attention to the interaction of the two materials as it affects the stiffness, strength, and inelastic behavior of the members, connections, and systems.

C14.3.1 Reference Documents
Seismic design for composite structures assigned to Seismic Design Category D, E, or F is governed primarily by ANSI/AISC 341. Composite design provisions in ANSI/AISC 341 are less prescriptive than those for structural steel and provide flexibility for designers to utilize analytical tools and results of research in their practice. Composite structures assigned to Seismic Design Category A, B, or C may be designed according to principles outlined in ANSI/AISC 360 and ACI 318. ANSI/AISC 360 and ACI 318 provide little guidance on connection design; therefore, designers are encouraged to review ANSI/AISC 341 for guidance on the design of joint areas. Differences between older AISC and ACI provisions for cross-sectional strength for composite beam-columns have been minimized by changes in the latest ANSI/AISC 360, and ANSI/AISC 360 refers to ACI 318 for much of the design of reinforced concrete components of composite structures. However, there is not uniform agreement between the provisions in ACI 318 and ANSI/AISC 360 regarding detailing, limits on material strengths, stability, and strength for composite beam-columns. The composite design provisions in ANSI/AISC 360 are considered to be current.

C14.3.4 Metal-Cased Concrete Piles
Design of metal-cased concrete piles, which are analogous to circular concrete filled tubes, is governed by ASCE/SEI 7Sections 14.2.3.1.3 and 14.2.3.2.4. The intent of these provisions is to require metal-cased concrete piles to have confinement and protection against long-term deterioration comparable to that for uncased concrete piles.

DRAFT

C14.4 MASONRY

This section adopts by reference and then makes modifications to TMS 402/ACI 530/ASCE 5 and TMS 602/ACI 530.1/ASCE 6, which are commonly referred to as the "MSJC Standards (Code and Specification)" after the Masonry Standards Joint Committee (MSJC), which is charged with development and maintenance of these standards. In past editions of ASCE/SEI 7, modifications to these referenced standards were made. During the development of the 2008 edition of the MSJC standards, each of these modifications were considered by the MSJC. Some were incorporated directly into the MSJC standards. These modifications have accordingly been removed from the modifications in ASCE/SEI 7-10. Work is ongoing to better coordinate the provisions of the two documents (MSJC and ASCE/SEI 7) such that the provisions in Section 14.4 will be significantly reduced or eliminated in future editions.

C14.5 WOOD

C14.5.1 Reference Documents

Two national consensus standards are adopted for seismic design of engineered wood structures: the *National Design Specification* (NDS), and the *Special Design Provisions for Wind and Seismic* (SDPWS). Both of these standards are presented in dual allowable stress design (ASD) and load and resistance factor design (LRFD) formats. Both standards reference a number of secondary standards for related items such as wood materials and fasteners. SDPWS addresses general principles and specific detailing requirements for shear wall and diaphragm design and provides tabulated nominal unit shear capacities for shear wall and diaphragm sheathing and fastening. The balance of member and connection design is to be in accordance with the NDS.

Chapter C15
SEISMIC DESIGN REQUIREMENTS FOR NONBUILDING STRUCTURES

C15.1 GENERAL

C15.1.1 Nonbuilding Structures

Building codes traditionally have been perceived as minimum standards for the design of nonbuilding structures, and building code compliance of these structures is required by building officials in many jurisdictions. However, requirements in the industry reference documents are often at odds with building code requirements. In some cases, the industry documents need to be altered while in other cases the building codes need to be modified. Registered design professionals are not always aware of the numerous accepted documents within an industry and may not know whether the accepted documents are adequate. One of the intents of Chapter 15 of the standard is to bridge the gap between building codes and existing industry reference documents.

Differences between the ASCE/SEI 7-10 design approaches for buildings and industry document requirements for steel multi-legged water towers (Figure C15.1-1) are representative of this inconsistency. Historically, such towers have performed well when properly designed in accordance with American Water Works Association (AWWA) standards and industry practices. Those standards and practices differ from the ASCE/SEI 7-10 treatment of buildings in that tension-only rods are allowed, upset rods are preloaded at the time of installation, and connection forces are not amplified.

Figure C15.1- 1 Steel multi-legged water tower.

Chapter 15 also provides an appropriate link so that the industry reference documents can be used with the seismic ground motions established in the standard. It should be noted that some nonbuilding structures are very similar to buildings and can be designed employing sections of the standard directly, whereas other nonbuilding structures require special analysis unique to the particular type of nonbuilding structure.

Note that building structures, vehicular bridges, electrical transmission towers, hydraulic structures (e.g., dams), buried utility lines and their appurtenances, and nuclear reactors are excluded from the scope of the nonbuilding structure requirements although industrial buildings are permitted per Chapter 11 to utilize the provisions in Chapter 15 for nonbuilding structures with structural systems similar to buildings provided specific conditions are met. The excluded structures are covered by other well established design criteria (e.g., electrical transmission towers and

DRAFT

vehicular bridges), are not under the jurisdiction of local building officials (e.g., nuclear reactors, and dams), or require technical considerations beyond the scope of the standard (e.g., buried utility lines and their appurtenances).

C15.1.2 Design

Nonbuilding structures and building structures have much in common with respect to design intent and expected performance, but there are also important differences. Chapter 15 relies on other portions of the standard where possible and provides special notes where necessary.

There are two types of nonbuilding structures: those with structural systems similar to buildings, and those with structural systems not similar to buildings. Specific requirements for these two cases appear in Sections 15.5 and 15.6.

C15.1.3 Structural Analysis Procedure Selection

Nonbuilding structures that are similar to buildings are subject to the same analysis procedure limitations as building structures. Nonbuilding structures that are not similar to buildings are subject to those limitations and are subject to procedure limitations prescribed in applicable specific reference documents.

For many nonbuilding structures supporting flexible system components, such as pipe racks (Figure C15.1-2), the supported piping and platforms generally are not regarded as rigid enough to redistribute seismic forces to the supporting frames.

Figure C15.1- 2 Steel pipe rack.

For nonbuilding structures supporting very stiff (i.e. rigid)system components, such as steam turbine generators (STGs) and heat recovery steam generators (HRSGs) (Figure C15.1-3), the supported equipment, ductwork, and other components (depending on how they are attached to the structure) may be rigid enough to redistribute seismic forces to the supporting frames. Torsional effects may need to be considered in such situations.

Section 12.6 presents seismic analysis procedures for building structures based on the Seismic Design Category; the fundamental period, *T*; and the presence of certain horizontal or vertical irregularities in the structural system.

Where the fundamental period is greater than or equal to $3.5T_s$ (where $T_s = S_{D1}/S_{DS}$), the use of the equivalent lateral force procedure is not permitted in Seismic Design Categories D, E, and F. This requirement is based on the fact that, unlike the dominance of the first mode response in case of buildings with lower first mode period, higher vibration modes do contribute more significantly in situations when the first mode period is larger than $3.5T_s$. For buildings that exhibit classic flexural deformation patterns (such as slender shear wall or braced frame systems), the second mode frequency is at least 3.5 times the first mode frequency, so where the fundamental period exceeds $3.5T_s$, the higher modes will have larger contributions to the total response as they occur near the peak of the design response spectrum

It follows that dynamic analysis (modal response spectrum analysis, or response-history analysis) may be necessary to properly evaluate building-like nonbuilding structures if the first mode period is larger than $3.5T_s$ and the equivalent lateral force analysis is sufficient for nonbuilding structures that respond as single-degree-of-freedom systems.

The recommendations for nonbuilding structures provided below are intended to supplement the designer's judgment and experience. The designer is given considerable latitude in selecting a suitable analysis method for nonbuilding structures.

Figure C15.1- 3 Heat recovery steam generators.

Building-like Nonbuilding Structures. Table 12.6-1 is used in selecting analysis methods for building-like nonbuilding structures, but, as illustrated in the following three conditions, the relevance of key behavior must be considered carefully:

1. Irregularities: Table 12.6-1 requires dynamic analysis for Seismic Design Category D, E, and F structures having certain horizontal or vertical irregularities. Some of these building irregularities (defined in Section 12.3.2) are relevant to nonbuilding structures. The weak-and soft-story vertical irregularities

(Types 1a, 1b, 5a, and 5b of Table 12.3-2) are pertinent to the behavior of building-like nonbuilding structures. Other vertical and horizontal irregularities may or may not be relevant as described below.

a. Horizontal irregularities: Horizontal irregularities of Type 1a and 1b affect the choice of analysis method, but these irregularities apply only where diaphragms are rigid or semirigid and some building-like nonbuilding structures have either no diaphragms or flexible diaphragms.

b. Vertical irregularities: Vertical irregularity Type 2 is relevant where the various levels actually support significant loads. Where a building-like nonbuilding structure supports significant mass at a single level, while other levels support small masses associated with stair landings, access platforms, and so forth, dynamic response will be dominated by the first mode, so the equivalent lateral force procedure may be applied. Vertical irregularity Type 3 addresses large differences in the horizontal dimension of the seismic force-resisting system in adjacent stories, since the resulting stiffness distribution can produce a fundamental mode shape unlike that assumed in the development of the equivalent lateral force procedure. Since the concern relates to stiffness distribution, it is the horizontal dimension of the seismic force-resisting system, not of the overall structure, that is important.

2. Arrangement of supported masses: Even where a nonbuilding structure has building-like appearance, it may not behave like a building, depending on how masses are attached. For example, the response of nonbuilding structures with suspended vessels and boilers cannot be determined reliably using the equivalent lateral force procedure because of the pendulum modes associated with the significant mass of the suspended components. The resulting pendulum modes, while potentially reducing story shears and base shear, may require large clearances to allow pendulum motion of the supported components and may produce excessive demands on attached piping. Dynamic analysis is highly recommended in such cases, with consideration for appropriate impact forces in the absence of adequate clearances.

3. Relative rigidity of beams: Even where a classic building model may seem appropriate, the equivalent lateral force procedure may underpredict the total response if the beams are flexible relative to the columns (of moment frames) or the braces (of braced frames). This is because higher modes associated with beam flexure may contribute more significantly to the total response (even if the first mode response is at a period less than 3.5Ts). This situation of flexible beams can be especially pronounced for nonbuilding structures since the "normal" floors common to buildings may be absent. Therefore, the dynamic analysis procedures are suggested for building-like nonbuilding structures with flexible beams.

Nonbuilding Structures Not Similar to Buildings. The (static) equivalent lateral force procedure is based on classic building dynamic behavior, which differs from the behavior of many nonbuilding structures not similar to buildings. As discussed below, several issues should be considered for selecting either an appropriate method of dynamic analysis or a suitable distribution of lateral forces for static analysis.

1. Structural geometry: The dynamic response of nonbuilding structures with a fixed base and a relatively uniform distribution of mass and stiffness, such as bottom-supported vertical vessels, stacks, and chimneys, can be represented adequately by a cantilever (shear building) model. For these structures the equivalent lateral force procedure provided in the standard is suitable. This procedure treats the dynamic response as being dominated by the first mode. In such cases, it is necessary to identify the first mode shape (using, for instance, the Rayleigh-Ritz method or other classical methods from the literature) for distribution of the dynamic forces. For some structures, such as tanks with low height-to-diameter ratios storing granular solids, it is conservative to assume a uniform distribution of forces. Dynamic analysis is recommended for structures that have neither a uniform distribution of mass and stiffness nor an easily determined first mode shape.

2. Number of lateral supports: Cantilever models are obviously unsuitable for structures with multiple supports. Figure C15.1-4 shows a nonbuilding braced frame structure that provides non-uniform horizontal support to a piece of equipment. In such cases, the analysis should include coupled model effects. For such structures an application of the equivalent lateral force method could be used depending on the number and locations of the supports. For example, most beam -type configurations lend themselves to application of the equivalent lateral force method.

DRAFT

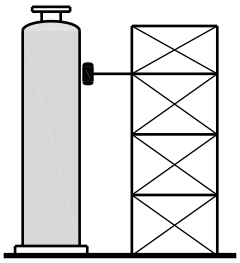

Figure C15.1- 4 Multiple lateral supports.

3. Method of supporting dead weight: Certain nonbuilding structures (such as power boilers) are supported from the top. They may be idealized as pendulums with uniform mass distribution. In contrast, a suspended platform may be idealized as a classic pendulum with concentrated mass. In either case, these types of nonbuilding structures can be analyzed adequately using the equivalent lateral force method by calculating the appropriate frequency and mode shape. Figure C15.1-5 shows a nonbuilding structure containing lug supported equipment with W_P greater than $0.25(W_S + W_P)$. In such cases, the analysis should include a coupled system with the mass of the equipment and the local flexibility of the supports considered in the model. Where the support is located near the nonbuilding structure's vertical location of the center of mass, a dynamic analysis is recommended.

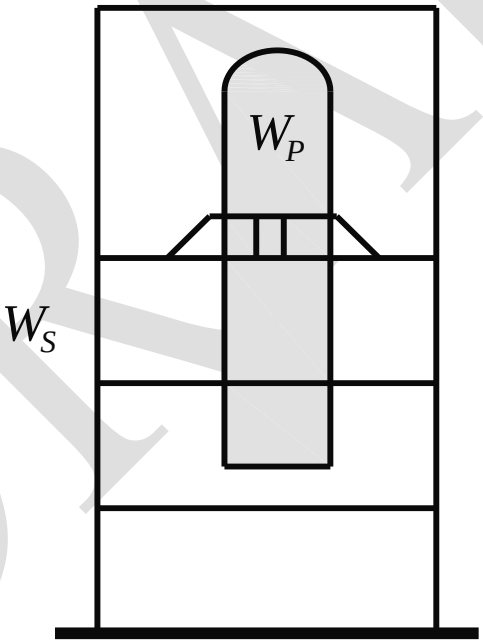

Figure C15.1- 5 Unusual support of dead weight.

4. Mass irregularities: Just as in the case of building-like nonbuilding structures, the presence of significantly uneven mass distribution is a situation where the equivalent lateral force method will likely not provide a very accurate and perhaps unconservative force distribution. The dynamic analysis methods are recommended in such situations. Figure C15.1-6 illustrates two such situations. In part (a), a mass irregularity exists if W_1 is greater than $1.5W_2$ or less than $0.67W_2$. In part (b), a mass irregularity exists if

DRAFT

W_3 is greater than either $1.5W_2$ or $1.5W_4$.

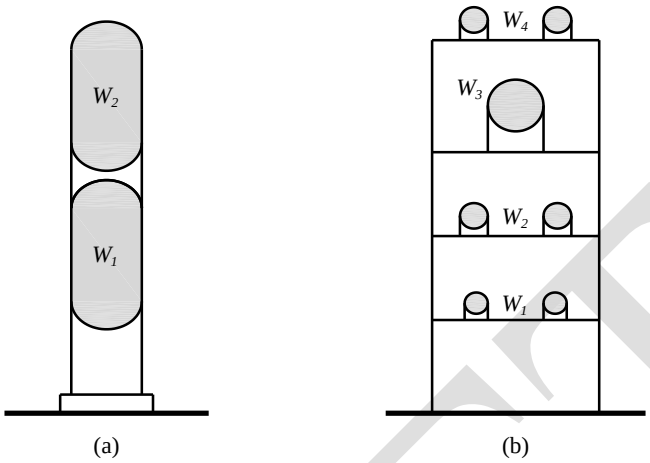

Figure C15.1- 6 Mass irregularities.

5. Torsional irregularities: Structures in which the fundamental mode of response is torsional or in which modes with significant mass participation exhibit a prominent torsional component may also have inertial force distributions that are significantly different from that predicted by the equivalent lateral force method. In such cases dynamic analyses should be considered. Figure C15.1-7 illustrates one such case where a vertical vessel is attached to a secondary vessel with W2 greater than about $0.25(W_1 + W_2)$.

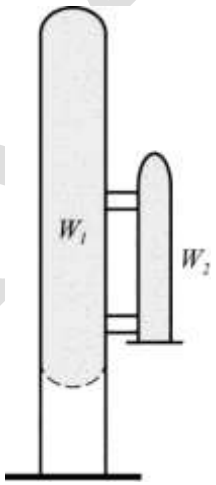

Figure C15.1- 7 Torsional irregularity.

6. Stiffness/strength irregularities: Just as for building-like nonbuilding structures, abrupt changes in the distribution of stiffness or strength in a nonbuilding structure not similar to buildings can result in substantially different inertial forces from those indicated by the equivalent lateral force method. Figure C15.1-8 represents one such case. For structures having such configurations, consideration should be given to use of dynamic analysis procedures. Even where dynamic analysis is required, the standard does not define in any detail the degree of modeling; an adequate model may have a few dynamic degrees of

DRAFT

freedom or tens of thousands of dynamic degrees of freedom. The important point is that the model captures the significant dynamic response features so that the resulting lateral force distribution is valid for design. The designer is responsible to determine whether dynamic analysis is warranted and, if so, the degree of detail required to address adequately the seismic performance.

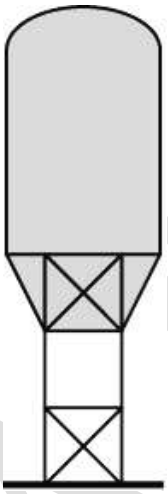

Figure C15.1- 8 Soft-story irregularity.

7. Coupled Response: Where the weight of the supported structure is large compared to the weight of the supporting structure, the combined response can be affected significantly by the flexibility of the supported nonbuilding structure. In that case, dynamic analysis of the coupled system is recommended. Examples of such structures are shown in Figure C15.1-9. Part (a) shows a flexible nonbuilding structure with W_p greater than $0.25(W_s + W_p)$, supported by a relatively flexible structure; the flexibility of the supports and attachments should be considered. Part (b) shows flexible equipment connected by a large-diameter, thick-walled pipe and supported by a flexible structure; the structures should be modeled as a coupled system including the pipe.

DRAFT

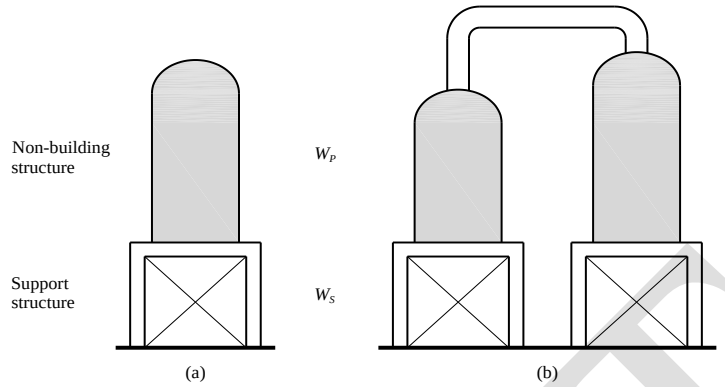

Figure C15.1- 9 Coupled system.

C15.2 REFERENCE DOCUMENTS

Chapter 15 of the standard makes extensive use of reference documents in the design of nonbuilding structures for seismic forces. The documents referenced in Chapter 15 are industry documents commonly used to design specific types of nonbuilding structures. The vast majority of these reference documents contain seismic provisions that are based on the seismic ground motions of the 1997 UBC or earlier editions of the UBC. In order to use these reference documents, Chapter 15 modifies the seismic force provisions of these reference documents through the use of "bridging equations." The standard only modifies industry documents that specify seismic demand and capacity. The bridging equations are intended to be used directly with the other provisions of the specific reference documents. Unlike the other provisions of the standard, if the reference documents are written terms of allowable stress design, then the bridging equations are shown in allowable stress design format. In addition, the detailing requirements referenced in Tables 15.4-1 and Table 15.4-2 are expected to be followed, as well as the general requirements found in Section 15.4.1. The usage of reference documents in conjunction with the requirements of Section 15.4.1 are summarized below in Table C15.2-1.

Table C15.2-1 Usage of Reference Documents in Conjunction with Section 15.4.1

Subject	Requirement
R, Ω_0, and C_d values, detailing requirements, and height limits	Use values and limits in Tables 12.2-1, 15.4-1, or 15.4-2 as appropriate. Values from the reference document are not to be used.
Minimum base shear	Use the appropriate value from Equation 15.4-1 or 15.4-2 for nonbuilding structures not similar to buildings. For structures containing liquids, gases, and granular solids supported at the base, the minimum seismic force cannot be less than that required by the reference document.
Importance factor	Use the value from Section 15.4.1.1 based on Risk Category. Importance factors from the reference document are not to be used unless they are greater than those provided in the standard.
Vertical distribution of lateral load	Use requirements of Section 12.8.3 or Section 12.9 or the applicable reference document.
Seismic provisions of reference documents	The seismic force provisions of reference documents may be used only if they have the same basis as Section 11.4 and the resulting values for total lateral force and total overturning moment are no less than 80 percent of the values obtained from the standard.
Load combinations	Load combinations specified in Section 2.3 (LRFD) or Section 15 (includes ASD load combinations of Section 2.4) must be used.

Currently, only four reference documents have been revised to meet the seismic requirements of the standard. AWWA D100-05, API 620 11th Edition Addendum 1 (2009), API 650 11th Edition Addendum 1 (2008), and

DRAFT

ANSI/MH 16.1 (2008) have been adopted by reference in the standard without modification except that height limits are imposed on "elevated tanks on symmetrically braced legs (not similar to buildings)" in AWWA D100-05 and the anchorage requirements of Section 15.4.9 are imposed on steel storage racks in ANSI/MH 16.1 (2008). Three of these reference documents apply to welded steel liquid storage tanks.

C15.3 NONBUILDING STRUCTURES SUPPORTED BY OTHER STRUCTURES

There are instances where nonbuilding structures not similar to buildings are supported by other structures or other nonbuilding structures. This section specifies how the seismic design loads for such structures are to be determined and the detailing requirements that are to be satisfied in the design.

C15.3.1 Less than 25 Percent of Combined Weight Condition

In many instances, the weight of the supported nonbuilding structure is relatively small compared to the weight of the supporting structure such that the supported nonbuilding structure will have a relatively small effect on the overall nonlinear earthquake response of the primary structure during design-level ground motions. It is permitted to treat such structures as nonstructural components and use the requirements of Chapter 13 for their design. The ratio of secondary component weight to total weight of 25 percent at which this treatment is permitted is based on judgment and was introduced into code provisions in the 1988 *Uniform Building Code* by the SEAOC Seismology Committee. Analytical studies, typically based on linear elastic primary and secondary structures, indicate that the ratio should be lower, but the SEAOC Seismology Committee judged that the 25 percent ratio is appropriate where primary and secondary structures exhibit non-linear behavior that tends to lessen the effects of resonance and interaction. In cases where a nonbuilding structures (or nonstructural component) is supported by another structure, it may be appropriate to analyze in a single model. In such cases it is intended that seismic design loads and detailing requirements be determined following the procedures of Section 15.3.2. Where there are multiple large nonbuilding structures, such as vessels supported on a primary nonbuilding structure, and the weight of an individual supported nonbuilding structure does not exceed the 25 percent limit but the combined weight of the supported nonbuilding structures does, it is recommended that the combined analysis and design approach of Section 15.3.2 be used. It is also suggested that dynamic analysis be performed in such cases, since the equivalent lateral force procedure may not capture some important response effects in some members of the supporting structure.

Where the weight of the supported nonbuilding structure does not exceed the 25 percent limit and a combined analysis is performed, the following procedure should be used to determine the F_p force of the supported nonbuilding structure based on Equation 13.3-4:

1. A modal analysis should be performed in accordance with Section 12.9. The base shear of the combined structure and nonbuilding structure should be taken as no less than 85 percent of the equivalent lateral force procedure base shear.
2. For a component supported at level i, the acceleration at that level should be taken as a_i, the total shear just below level i divided by the seismic weight at and above level i.
3. The elastic value of the component shear force coefficient should next be determined as the shear force from the modal analysis at the point of attachment of the component to the structure divided by the weight of the component. This value is preliminarily taken as $a_i a_p$. Since a_p cannot be taken as less than 1.0, the value of a_p is taken as $a_i a_p$ / a_i, except that the final value a_p need not be taken as greater than 2.5 and should not be taken as less than 1.0. The final value of $a_i a_p$ should be the final value of a_i determined in Step 2 multiplied by the final value of a_p determined earlier in this step.
4. The resulting value of ($a_i a_p$) should be used in Equation 13.3-4; the resulting value of F_p is subject to the maximum and minimum values of Equations 13.3-2 and 13.3-3, respectively.

C15.3.2 Greater Than or Equal to 25 Percent Combined Weight Condition

Where the weight of the supported structure is relatively large compared to the weight of the supporting structure, the overall response can be affected significantly. The standard sets forth two analysis approaches, depending on the rigidity of the nonbuilding structure. The determination of what is deemed rigid or flexible is based on the same criteria used for nonstructural components.

DRAFT

Where the supported nonbuilding structure is rigid, it is acceptable to treat the supporting structure as a nonbuilding structure similar to a building and to determine its design loads and detailing using the requirements of Section 15.5. The design of the rigid nonbuilding structure and its anchorage is determined using the requirements of Chapter 13 with the amplification factor, a_p, taken as 1.0. However, this is a relatively rare condition since the flexibility of any directly supporting members in the primary structure, such as floor beams, must be considered in determining the period of the component.

In the usual case, where the supported nonbuilding structure is flexible, a combined model of the supporting structure and the supported nonbuilding structure is used. The design loads and detailing are determined based on the lower *R* value of the supported nonbuilding structure or supporting structure.

Although not specifically mentioned in Section 15.3.2, another approach is permitted. A nonlinear response history analysis of the combined system can be performed in accordance with Section 16.2, and the results can be used for the design of both the supported and supporting nonbuilding structures. This option should be considered where standard static and dynamic elastic analysis approaches may be inadequate to evaluate the earthquake response (such as for suspended boilers). This option should be used with extreme caution since modeling and interpretation of results requires considerable judgment. Due to this sensitivity, Section 16.2 requires independent design review.

C15.4 STRUCTURAL DESIGN REQUIREMENTS

This section specifies the basic coefficients and minimum design forces to be used to determine seismic design loads for nonbuilding structures. It also specifies height limits and restrictions. As with building structures, it presumes that the first step in establishing the design forces is to determine the design base shear for the structure.

There are two types of nonbuilding structures: those with structural systems similar to buildings and those with structural systems not similar to buildings. Specific requirements for these two cases appear in Sections 15.5 and 15.6.

Table 15.4-1 contains response modification coefficient (*R*) for Nonbuilding Structures Similar to Buildings. Table 15.4-2 contains response modification coefficient for Nonbuilding Structures not Similar to Buildings. Every response modification coefficient has associated design and detailing requirements to ensure the required ductility associated with that response modification coefficient value (e.g., AISC 341, etc). Some structures, such as pipe racks, do not resemble a traditional building in that they do not house people, have walls, bathrooms, etc. These structures have lateral force resisting systems composed of braced frames and moment frames similar to a traditional building. Therefore, pipe racks are considered "Nonbuilding Structures Similar to Buildings". The response modification coefficient for a pipe rack should be taken from Table 15.4-1 for the appropriate lateral force resisting system used and the braced frames and/or moment frames used must meet all of the design and detailing requirements associated with the R value selected (see section 15.5.2, Pipe Racks).

Most major power distribution facility (power island) structures such as HRSG support structures, steam turbine pedestals, coal boiler support structures, pipe racks, air inlet structures, duct support structures, etc. also resist lateral forces predominantly by use of building-like framing systems such as moment frames braced frames, or cantilever column systems. Therefore, their response modification coefficient should be selected from Table 15.4-1 and they must meet all the design and detailing requirements associated with the response modification coefficient selected.

Many nonbuilding structures, such as flat bottom tanks, silos, and stacks, do not use braced frames or moment frames similar to those found in buildings to resist seismic loads. Therefore they have their own unique response modification coefficient which can be found in Table 15.4-2.

For nonbuilding structures with lateral systems composed predominantly of building-like framing systems such as moment frames braced frames, or cantilever column systems, it would be inappropriate to extrapolate the descriptions in Table 15.4-2 , resulting in inappropriately high response modification coefficient and the elimination of detailing requirements.

Once a response modification coefficient is selected from the tables, Section 15.4.1 provides additional guidance.

C15.4.1 Design Basis

Separate tables provided in this section identify the basic coefficients, associated detailing requirements, and height limits and restrictions for the two types of nonbuilding structures.

DRAFT

For nonbuilding structures similar to buildings, the design seismic loads are determined using the same procedures used for buildings as specified in Chapter 12 with two exceptions: fundamental periods are determined in accordance with Section 15.4.4, and Table 15.4-1 provides additional options for structural systems. Although only Section 12.8 (the equivalent lateral force procedure) is specifically mentioned in Section 15.4.1, Section 15.1.3 provides the analysis procedures that are permitted for nonbuilding structures.

In Table 15.4-1, seismic coefficients, system restrictions, and height limits are specified for a few nonbuilding structures similar to buildings. The values of R, Ω_o, and C_d, the detailing requirement references, and the structural system height limits are the same as those in Table 12.2-1 for the same systems, except for ordinary moment frames. In Chapter 12 increased height limits for ordinary moment frames structural systems apply to metal building systems, while in Chapter 15 they apply to pipe racks with end plate bolted moment connections. The seismic performance of pipe racks was judged to be similar to that of metal building structures with end plate bolted moment connections, so the height limits were made the same as those specified in previous editions.

Table 15.4-1 also provides lower R values with less restrictive height limits in Seismic Design Categories D, E, and F based on good performance in past earthquakes. For some options, no seismic detailing is required if very low values of R (and corresponding high seismic design forces) are used. The concept of extending this approach to other structural systems is the subject of future research using the methodology developed by the ATC 63 project.

For nonbuilding structures not similar to buildings, the seismic design loads are determined as in Chapter 12 with three exceptions: the fundamental periods are determined in accordance with Section 15.4.4, the minima are those specified in Section 15.4.1.2, and the seismic coefficients are those specified in Table 15.4-2.

Some entries in Table 15.4-2 may seem to be conflicting or confusing. For example, the first major entry is for elevated tanks, vessels, bins, or hoppers. A subset of this entry is for tanks on braced or unbraced legs. This subentry is intended for structures where the supporting columns are integral with the shell (such as an elevated water tank). Tension-only bracing is allowed for such a structure. Where the tank or vessel is supported by building-like frames, the frames are to be designed in accordance with all of the restrictions normally applied to building frames. The entry for tanks or vessels supported on structural towers similar to buildings assumes that the operating weight of the supported tank or vessel is less than 25 percent of the total weight; if the ratio is greater than 25 percent, the proper entry is that most closely related to the subject vessel or bin.

C15.4.1.1 Importance Factor

The importance factor for a nonbuilding structure is based on the risk category defined in Chapter 1 of the standard or the building code being used in conjunction with the standard. In some cases, reference standards provide a higher importance factor, in which case the higher importance factor is used.

If the importance factor is taken as 1.0 based on a Hazard and Operability (HAZOP) analysis performed in accordance with Chapter 1, the third paragraph of Section 1.5.3 requires careful consideration; worst-case scenarios (instantaneous release of a vessel or piping system) must be considered. HAZOP risk analysis consultants often do not make such assumptions, so the design professional should review the HAZOP analysis with the HAZOP consultant to confirm that such assumptions have been made in order to validate adjustment of the importance factor. Clients may not be aware that HAZOP consultants do not normally consider the worst-case scenario of instantaneous release but tend to focus on other more hypothetical limited-release scenarios, such as those associated with a 2-inch square hole in a tank or vessel.

C15.4.2 Rigid Nonbuilding Structures

The definition of rigid (having a natural period of less than 0.06 second) was selected judgmentally. Below that period, the energy content of seismic ground motion is generally believed to be very low, and therefore the building response is not likely to be excessively amplified. Also, it is unlikely that any building will have a first mode period as low as 0.06 second, and it is even unusual for a second mode period to be that low. Thus, the likelihood of either resonant behavior or excessive amplification becomes quite small for equipment having periods below 0.06 second.

The analysis to determine the period of the nonbuilding structure should include the flexibility of the soil subgrade.

C15.4.3 Loads

As for buildings, the seismic weight must include the range of design operating weight of permanent equipment.

DRAFT

C15.4.4 Fundamental Period

A significant difference between building structures and nonbuilding structures is that the approximate period formulas and limits of Section 12.8.2.1 may not be used for nonbuilding structures. In lieu of calculating a specific period for a nonbuilding structure for determining seismic lateral forces, it is of course conservative to assume a period of $T=T_s$ which results in the largest lateral design forces. Computing the fundamental period is not considered a significant burden, since most commonly used computer analysis programs can perform the required calculations.

C15.4.8 Site-Specific Response Spectra

Where site-specific response spectra are required, they should be developed in accordance with Chapter 21 of the standard. If determined for other recurrence intervals, Section 21.1 applies, but Sections 21.2 through 21.4 apply only to MCE determinations. Where other recurrence intervals are used, it should be demonstrated that the requirements of Chapter 15 also are satisfied.

C15.4.9 Anchors in Concrete or Masonry

Many nonbuilding structures rely on the ductile behavior of anchor bolts to justify the response modification factor, R, assigned to the structure. Nonbuilding structures typically rely more heavily on anchorage to provide system ductility. The additional requirements of Section 15.4.9 provide additional anchorage strength and ductility in order to support the Response Modification Factors assigned to these systems. The addition of Section 15.4.9 provides a consistent treatment of anchorage for nonbuilding structures.

C15.5 NONBUILDING STRUCTURES SIMILAR TO BUILDINGS

C15.5.1 General

Although certain nonbuilding structures exhibit behavior similar to that of building structures, their functions and occupancies are different. Section 15.5 of the standard addresses the differences.

C15.5.2 Pipe Racks

Free-standing pipe racks supported at or below grade with framing systems that are similar to building systems are designed in accordance with Section 12.8 or 12.9 and Section 15.4. Single-column pipe racks that resist lateral loads should be designed as inverted pendulums.

Based on good performance in past earthquakes, Table 15.4-1 sets forth the option of lower *R* values and less restrictive height limits for structural systems commonly used in pipe racks. The *R* value versus height limit trade-off recognizes that the size of some nonbuilding structures is determined by factors other than traditional loadings and results in structures that are much stronger than required for seismic loadings. Therefore, the ductility demand is generally much lower than that for a corresponding building. The intent is to obtain the same structural performance at the increased heights. This option will prove to be economical in most situations due to the relative cost of materials and construction labor. The lower *R* values and increased height limits of Table 15.4-1 apply to nonbuilding structures similar to buildings; they cannot be applied to building structures. Table C15.5-1 illustrates the *R* values and height limits for a 70-foot-high steel ordinary moment frame (OMF) pipe rack.

Table C15.5-1 *R* Value Selection Example for Steel OMF Pipe Racks

SDC	*R*	ASCE/SEI 7-10 Table	System	Seismic Detailing Requirements
C	3.5	12.2-1 or 15.4-1	Ordinary steel moment frame	AISC 341
C	3	12.2-1	Structural steel systems not specifically detailed for seismic resistance	None
D or E	2.5	15.4-1	Steel OMF with permitted height increase	AISC 341
D, E, or F	1	15.4-1	Steel OMF with unlimited height	AISC 360

C15.5.3 Steel Storage Racks

The two approaches to the design of steel storage racks set forth by the standard are intended to produce comparable results. The specific revisions to the RMI specification cited in earlier editions of this standard and the detailed

DRAFT

requirements of the new ANSI/RMI standard reflect the recommendations of FEMA 460, *Seismic Considerations for Steel Storage Racks Located in Areas Accessible to the Public*.

While the ANSI/RMI standard reflects the recommendations of FEMA 460, the anchorage provisions of the ANSI/RMI standard are not in conformance with ASCE/SEI 7. Therefore, specific anchorage requirements were added in Sections 15.5.3.2 and 15.5.3.3.

These recommendations address the concern that storage racks in warehousetype retail stores may pose a greater seismic risk to the general public than exists in low-occupancy warehouses or more conventional retail environments. Under normal conditions, retail stores have a far higher occupant load than an ordinary warehouse of a comparable size. Failure of a storage rack system in a retail environment is much more likely to cause personal injury than would a similar failure in a storage warehouse. To provide an appropriate level of additional safety in areas open to the public, an importance factor of 1.50 is specified. Storage rack contents, while beyond the scope of the standard, may pose a potentially serious threat to life should they fall from the shelves in an earthquake. It is recommended that restraints be provided, as shown in Figure C15.5-1, to prevent the contents of rack shelving open to the general public from falling during strong ground shaking.

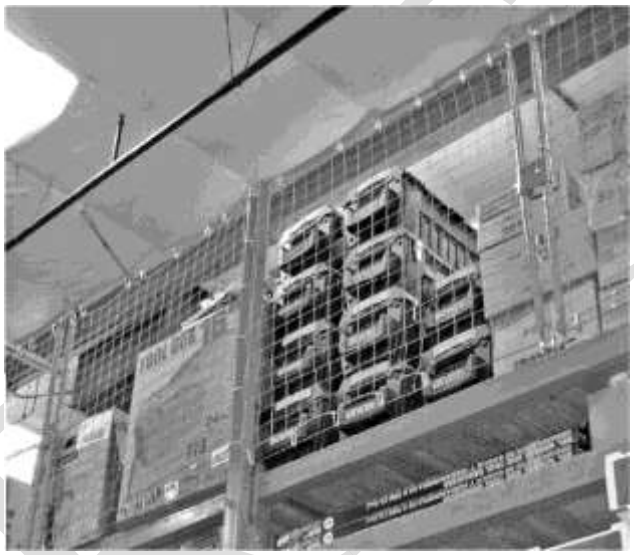

Figure C15.5- 1 Merchandise restrained by netting.

C15.5.4 Electrical Power Generating Facilities

Electrical power plants closely resemble building structures, and their performance in seismic events has been good. For reasons of mechanical performance, lateral drift of the structure must be limited. The lateral bracing system of choice has been the concentrically braced frame. In the past, the height limits on braced frames in particular have been an encumbrance to the design of large power generating facilities. Based on acceptable past performance, Table 15.4-1 permits the use of OCBFs with both lower *R* values and less restrictive height limits. This option is particularly effective for boiler buildings that generally are 300 feet or more in height. A peculiarity of large boiler buildings is the general practice of suspending the boiler from the roof structures; this results in an unusual mass distribution as discussed in Section C15.1.3.

C15.5.5 Structural Towers for Tanks and Vessels

The requirements of this section apply to structural towers that are not integral with the supported tank. Elevated water tanks designed in accordance with AWWA D100-05 are not subject to Section 15.5.5.

DRAFT

C15.5.6 Piers and Wharves

Current industry practice recognizes the distinct differences between the two categories of piers and wharves described in the standard. Piers and wharves with public occupancy, described in Section 15.5.6.2, are commonly treated as the "foundation" for buildings or building-like structures; design is performed using the standard, likely under the jurisdiction of the local building official. Piers and wharves without occupancy by the general public are often treated differently and are outside the scope of the standard; in many cases, these structures do not fall under the jurisdiction of building officials, and design is performed using other industry-accepted approaches.

Design decisions associated with these structures often reflect economic considerations by both owners and local, regional, or state jurisdictional entities with interest in commercial development. Where building officials have jurisdiction but lack experience analyzing pier and wharf structures, reliance on other industry-accepted design approaches is common.

Where occupancy by the general public is not a consideration, seismic design of structures at major ports and marine terminals often uses a performance-based approach, with criteria and methods that are very different from those used for buildings, as provided in the standard. Design approaches most commonly used are generally consistent with the practices and criteria described in the following documents:

1. *Seismic Design Guidelines for Port Structures*, Working Group No. 34 of the Maritime Navigation Commission (PIANC/MarCom/WG34), A. A. Balkema, Lisse, Netherlands, 2001.
2. *Seismic Criteria for California Marine Oil Terminals*, Vol. 1 and Vol. 2, Technical Report TR-2103-SHR, Naval Facilities Engineering Service Center, Ferritto, J., Dickenson, S., Priestley N., Werner, S., Taylor, C., Burke D., Seelig W., and Kelly, S., Port Hueneme, CA, 1999.
3. *Seismic Design and Retrofit of Bridges*, Priestley, N.J.N., Siebel, F., and Calvi, G.M., New York, 1996.
4. *Seismic Guidelines for Ports*, by the Ports Committee of the Technical Council on Lifeline Earthquake Engineering, ASCE/SEI, edited by Stuart D. Werner, Monograph No. 12, published by ASCE, Reston, Virginia, March 1998.
5. *MOTEMS, 2005, "Marine Oil Terminal Engineering and Maintenance Standards"*, 2001 Title 24, Part 2, California Building Code, Chapter 31F, January 31, 2005.

These alternative approaches have been developed over a period of many years by working groups within the industry, and they reflect the historical experience and performance characteristics of these structures, which are very different from those of building structures.

The main emphasis of the performance-based design approach is to provide criteria and methods that depend on the economic importance of a facility. Adherence to the performance criteria in the documents listed above does not seek to provide uniform margins of collapse for all structures; their application is expected to provide at least as much inherent life-safety as for buildings designed using the standard. The reasons for the higher inherent level of life-safety for these structures include the following:

1. These structures have relatively infrequent occupancy, with few working personnel and very low density of personnel. Most of these structures consist primarily of open area, with no enclosed structures that can collapse onto personnel. Small control buildings on marine oil terminals or similar secondary structures are commonly designed in accordance with the local building code.
2. These pier or wharf structures typically are constructed of reinforced concrete, prestressed concrete, or steel and are highly redundant due to the large number of piles supporting a single wharf deck unit. Tests done at the University of California at San Diego for the Port of Los Angeles have shown that very high ductilities (10 or more) can be achieved in the design of these structures using practices currently employed in California ports.
3. Container cranes, loading arms, and other major structures or equipment on piers or wharves are specifically designed not to collapse in an earthquake. Typically, additional piles and structural members are incorporated into the wharf or pier specifically to support such items.
4. Experience has shown that seismic "failure" of wharf structures in zones of strong seismicity is indicated not by collapse but by economically irreparable deformations of the piles. The wharf deck generally remains level or slightly tilting, but has shifted out of position. Earthquake loading on properly maintained marine structures has never induced complete failure that could endanger life-safety.

DRAFT

5. The performance-based criteria of the listed documents address reparability of the structure. These criteria are much more stringent than collapse prevention criteria and create a greater margin for life-safety.

Lateral load design of these structures in low, or even moderate, seismic regions often is governed by other marine conditions.

C15.6 GENERAL REQUIREMENTS FOR NONBUILDING STRUCTURES NOT SIMILAR TO BUILDINGS

Nonbuilding structures not similar to buildings exhibit behavior markedly different from that of building structures. Most of these types of structures have reference documents that address their unique structural performance and behavior. The ground motion in the standard requires appropriate translation to allow use with industry standards.

C15.6.1 Earth-Retaining Structures

Section C11.8.3 presents commonly used approaches for the design of nonyielding walls and yielding walls for bending, overturning, sliding, etc., taking into account the varying soil types, importance, and site seismicity.

C15.6.2 Stacks and Chimneys

The design of stacks and chimneys to resist natural hazards generally is governed by wind design considerations. The exceptions to this general rule involve locations with high seismicity, stacks and chimneys with large elevated masses, and stacks and chimneys with unusual geometries. It is prudent to evaluate the effect of seismic loads in all but those areas with the lowest seismicity. Although not specifically required, it is recommended that the special seismic details required elsewhere in the standard be considered for application to stacks and chimneys.

Concrete chimneys typically possess low ductility, and their performance is especially critical in the regions around large (breach) opening due to reductions in strength and loss of confinement for vertical reinforcement in the jamb regions around the openings. Earthquake-induced chimney failures have occurred in recent history (in Turkey in 1999) and have been attributed to strength/detailing problems (Kilic and Sozen, 2003). Therefore, the R value of 3 traditionally used in ASCE/SEI 7-05 for concrete stacks and chimneys is reduced to 2 and detailing requirements for breach openings are added in the 2010 edition of this standard.

Guyed steel stacks and chimneys generally are lightweight. As a result, the design loads due to natural hazards generally are governed by wind. On occasion, large flares or other elevated masses located near the top may require in-depth seismic analysis. Although it does not specifically address seismic loading, Chapter 6 of Troitsky (1990) provides a methodology appropriate for resolution of the seismic forces defined in the standard.

C15.6.4 Special Hydraulic Structures

The most common special hydraulic structures are baffle walls and weirs that are used in water treatment and waste water treatment plants. Because there are openings in the walls, during normal operations the fluid levels are equal on each side of the wall, exerting no net horizontal force. Sloshing during a seismic event can exert large forces on the wall, as illustrated in Figure C15.6-1. The walls can fail unless they are designed properly to resist the dynamic fluid forces.

C15.6.5 Secondary Containment Systems

This section reflects the judgment that designing all impoundment dikes for the MCE ground motion when full and sizing all impoundment dikes for the sloshing wave is too conservative. Designing an impoundment dike as full for the MCE assumes failure of the primary containment and occurrence of a significant aftershock. Such significant aftershocks (of the same magnitude as the MCE ground motion) are rare and do not occur in all locations. While explicit design for aftershocks is not a requirement of the standard, secondary containment must be designed full for an aftershock to protect the general public. The use of two-thirds of the MCE ground motion as the magnitude of the design aftershock is supported by Bath's Law, according to which the maximum expected aftershock magnitude may be estimated to be 1.2 scale units below the main shock magnitude.

The risk assessment and risk management plan described in Section 1.5.2 are used to determine where the secondary containment must be designed full for the MCE. The decision to design secondary containment for this more severe condition should be based on the likelihood of a significant aftershock occurring at the particular site, considering the risk posed to the general public by the release of hazardous material from the secondary containment.

DRAFT

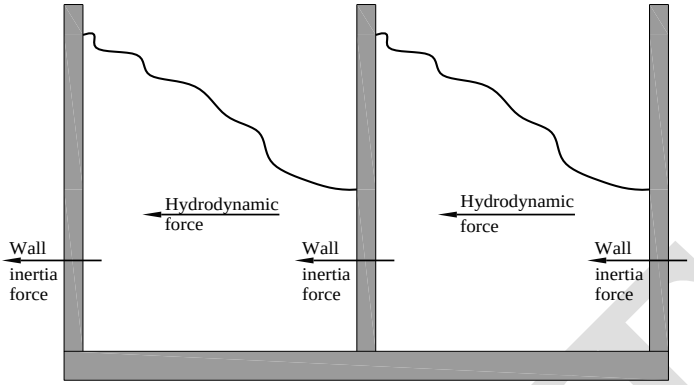

Figure C15.6- 11 Wall forces.

Secondary containment systems must be designed to contain the sloshing wave where the release of liquid would place the general public at risk by exposing them to hazardous materials, by scouring of foundations of adjacent structures, or by causing other damage to adjacent structures.

C15.6.5.1 Freeboard

Equation 15.6-1 was revised to return to the more exact theoretical formulation for sloshing wave height instead of the rounded value introduced in ASCE/SEI 7-05. The rounded value in part accounted for maximum direction of response effects. Since the ground motion definition in ASCE/SEI 7-10 is changed and the maximum direction of response is now directly accounted for, it is no longer necessary to account for these effects by rounding up the theoretical sloshing wave height factor in Equation 15.6-1.

C15.6.6 Telecommunication Towers

Telecommunication towers support small masses, and their design generally is governed by wind forces. Although telecommunication towers have a history of experiencing seismic events without failure or significant damage, seismic design in accordance with the standard is required.

Typically bracing elements bolt directly (without gusset plates) to the tower legs, which consist of pipes or bent plates in a triangular plan configuration.

C15.7 TANKS AND VESSELS

C15.7.1 General

Methods for seismic design of tanks, currently adopted by a number of reference documents, have evolved from earlier analytical work by Jacobsen, Housner, Veletsos, Haroun, and others. The procedures used to design flat-bottom storage tanks and liquid containers are based on the work of Housner, Wozniak, and Mitchell. The reference documents for tanks and vessels have specific requirements to safeguard against catastrophic failure of the primary structure based on observed behavior in seismic events since the 1930s. Other methods of analysis, using flexible shell models, have been proposed but at present are beyond the scope of the standard.

The industry-accepted design methods employ three basic steps:

1. Dynamic modeling of the structure and its contents. When a liquid-filled tank is subjected to ground acceleration, the lower portion of the contained liquid, identified as the impulsive component of mass, W_i, acts as if it were a solid mass rigidly attached to the tank wall. As this mass accelerates, it exerts a horizontal force, P_i, on the wall; this force is directly proportional to the maximum acceleration of the tank base. This force is superimposed on the inertia force of the accelerating wall itself, P_s. Under the influence of the same ground acceleration, the upper portion of the contained liquid responds as if it were a solid mass flexibly attached to the tank wall. This portion, which oscillates at its own natural frequency, is identified as the convective component, W_c, and exerts a horizontal force, P_c, on the wall. The convective component oscillations are

characterized by sloshing whereby the liquid surface rises above the static level on one side of the tank and drops below that level on the other side.

2. Determination of the period of vibration, T_i, of the tank structure and the impulsive component; and determination of the natural period of oscillation (sloshing), T_c, of the convective component.

3. Selection of the design response spectrum. The response spectrum may be site-specific or it may be constructed on the basis of seismic coefficients given in national codes and standards. Once the design response spectrum is constructed, the spectral accelerations corresponding to T_i and T_c are obtained and are used to calculate the dynamic forces P_i, P_s, and P_c.

Detailed guidelines for the seismic design of circular tanks, incorporating these concepts to varying degrees, have been the province of at least four industry reference documents: AWWA D100 for welded steel tanks (since 1964); API 650 for petroleum storage tanks; AWWA D110 for prestressed, wire-wrapped tanks (since 1986); and AWWA D115 for prestressed concrete tanks stressed with tendons (since 1995). In addition, API 650 and API 620 contain provisions for petroleum, petrochemical, and cryogenic storage tanks. The detail and rigor of analysis prescribed in these documents have evolved from a semi-static approach in the early editions to a more rigorous approach at present, reflecting the need to include the dynamic properties of these structures.

The requirements in Section 15.7 are intended to link the latest procedures for determining design-level seismic loads with the allowable stress design procedures based on the methods in the standard. These requirements, which in many cases identify specific substitutions to be made in the design equations of the reference documents, will assist users of the standard in making consistent interpretations.

ACI has published ACI 350.3-06, "*Seismic Design of Liquid-Containing Concrete Structures.*" This document, which addresses all types of concrete tanks (prestressed and non-prestressed, circular and rectilinear), has provisions that are unfortunately not consistent with the seismic criteria of ASCE/SEI 7-10. However, the document, when combined with the modifications required in Section 15.7.7.3, serves as both a practical "how-to" loading reference and a guide to supplement application of ACI 318 Chapter 21.

C15.7.2 Design Basis

In the case of the seismic design of nonbuilding structures, standardization requires adjustments to industry reference documents to minimize existing inconsistencies among them, while recognizing that structures designed and built over the years in accordance with these documents have performed well in earthquakes of varying severity. Of the inconsistencies among reference documents, the ones most important to seismic design relate to the base shear equation. The traditional base shear takes the following form:

$$V = \frac{ZIS}{R_w} CW \qquad \text{(C15.7-1)}$$

An examination of those terms as used in the different references reveals the following:

1. *ZS:* The seismic zone coefficient, *Z*, has been rather consistent among all the documents since it usually has been obtained from the seismic zone designations and maps in the model building codes. On the other hand, the soil profile coefficient, *S*, does vary from one document to another. In some documents these two terms are combined.

2. *I*: The importance factor, *I*, has varied from one document to another, but this variation is unavoidable and understandable owing to the multitude of uses and degrees of importance of tanks and vessels.

3. *C:* The coefficient *C* represents the dynamic amplification factor that defines the shape of the design response spectrum for any given ground acceleration. Since *C* is primarily a function of the frequency of vibration, inconsistencies in its derivation from one document to another stem from at least two sources: differences in the equations for the determination of the natural frequency of vibration, and differences in the equation for the coefficient itself. (For example, for the shell/impulsive liquid component of lateral force, the steel tank documents use a constant design spectral acceleration [constant *C*] that is independent of the "impulsive" period, *T*.) In addition, the value of *C* will vary depending on the damping ratio assumed for the vibrating structure (usually between 2 percent and 7 percent of critical).

4. Where a site-specific response spectrum is available, calculation of the coefficient *C* is not necessary except in the case of the convective component (coefficient C_c) which is assumed to oscillate with 0.5 percent of critical

DRAFT

damping and whose period of oscillation is usually long (greater than 2.5 seconds). Since site-specific spectra are usually constructed for high damping values (3 percent to 7 percent of critical) and since the site-specific spectral profile may not be well-defined in the long-period range, an equation for C_c applicable to a 0.5 percent damping ratio is necessary in order to calculate the convective component of the seismic force.

5. R_w: The response modification factor, R_w, is perhaps the most difficult to quantify, for a number of reasons. While R_w is a compound coefficient that is supposed to reflect the ductility, energy-dissipating capacity, and redundancy of the structure, it is also influenced by serviceability considerations, particularly in the case of liquid-containing structures.

In the standard the base shear equation for most structures has been reduced to $V = C_s W$, where the seismic response coefficient, C_s, replaces the product ZSC/R_w. C_s is determined from the design spectral response acceleration parameters S_{DS} and S_{D1} (at short periods and at a period of 1, respectively) which, in turn, are obtained from the mapped MCE spectral accelerations S_s and S_1. As in the case of the prevailing industry reference documents, where a site-specific response spectrum is available, C_s is replaced by the actual values of that spectrum.

The standard contains several bridging equations, each designed to allow proper application of the design criteria of a particular reference document in the context of the standard. These bridging equations associated with particular types of liquid-containing structures and the corresponding reference documents are discussed below. Calculation of the periods of vibration of the impulsive and convective components is in accordance with the reference documents, and the detailed resistance and allowable stresses for structural elements of each industry structure are unchanged, except where new information has led to additional requirements.

It is expected that the bridging equations of Sections 15.7.7.3 and 15.7.10.7 will be eliminated as the relevant reference documents are updated to conform to the standard. The bridging equations previously provided for AWWA D100 and API 650 already have been eliminated as a result of updates of these documents.

C15.7.3 Strength and Ductility

As is the case for building structures, ductility and redundancy in the lateral support systems for tanks and vessels are desirable and necessary for good seismic performance. Tanks and vessels are not highly redundant structural systems, and therefore ductile materials and well-designed connection details are needed to increase the capacity of the vessel to absorb more energy without failure. The critical performance of many tanks and vessels is governed by shell stability requirements rather than by yielding of the structural elements. For example, contrary to building structures, ductile stretching of anchor bolts is a desirable energy absorption component where tanks and vessels are anchored. The performance of cross-braced towers is highly dependent on the ability of the horizontal compression struts and connection details to develop fully the tension yielding in the rods. In such cases, it is also important to preclude both premature failure in the threaded portion of the connection and failure of the connection of the rod to the column prior to yielding of the rod.

The changes made to Section 15.7.3(a) are intended to ensure that anchors and anchor attachments are designed such that the anchor will yield (stretch) before the anchor attachment to the structure fails. The changes also clarify that the anchor rod embedment requirements are to be based on the requirements of Section 15.7.5 and not Section 15.7.3(a).

C15.7.4 Flexibility of Piping Attachments

Poor performance of piping connections (tank leakage and damage) due to seismic deformations is a primary weakness observed in seismic events. While commonly used piping connections can impart mechanical loads to the tank shell, proper design in seismic areas results in only negligible mechanical loads on tank connections subject to the displacements shown in Table 15.7-1. API 650 treats the values shown in Table 15.7-1 as allowable stress based values and therefore requires that these values be multiplied by 1.4 where strength-based capacity values are required for design.

The displacements shown in Table 15.7-1 are based on movements observed during past seismic events. The vertical tank movements listed are due to stretch of the mechanical anchors or steel tendons (in the case of a concrete tank) for mechanically anchored tanks or the deflection due to bending of the bottom of self anchored tanks. The horizontal movements listed are due to the deformation of the tank at the base.

DRAFT

In addition, interconnected equipment, walkways, and bridging between multiple tanks must be designed to resist the loads and accommodate the displacements imposed by seismic forces. Unless connected tanks and vessels are founded on a common rigid foundation, the calculated differential movements must be assumed to be out of phase.

C15.7.5 Anchorage

Many steel tanks can be designed without anchors by using annular plate detailing in accordance with reference documents. Where tanks must be anchored due to overturning potential, proper anchorage design will provide both a shell attachment and an embedment detail that will allow the bolt to yield without tearing the shell or pulling the bolt out of the foundation. Properly designed anchored tanks have greater reserve strength to resist seismic overload than do unanchored tanks.

To ensure that the bolt yields (stretches) before failure of the anchor embedment, the anchor embedment must be designed in accordance with ACI 318, Appendix D, Equation D-3 and be provided with a minimum gauge length of eight bolt diameters. Gauge length is the length of the bolt that is allowed to stretch. It may include part of the embedment length into the concrete that is not bonded to the bolt. A representation of gauge length is shown in Figure C15.7-1.

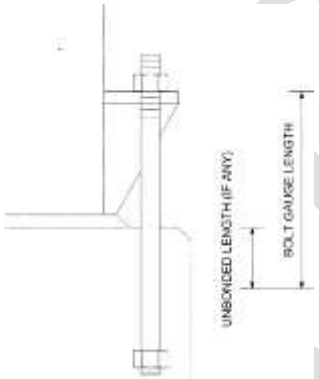

Figure C15.7- 1 Bolt Gauge Length.

It is also important that the bolt not be significantly oversized to ensure that the bolt stretches. The prohibition on using the load combinations with overstrength of Section 12.4.3 is intended to accomplish this goal.

Where anchor bolts and attachments are misaligned such that the anchor nut or washer does not bear evenly on the attachment, additional bending stresses in threaded areas may cause premature failure before anchor yielding.

C15.7.6 Ground-Supported Storage Tanks for Liquids

C15.7.6.1 General

The response of ground storage tanks to earthquakes is well documented by Housner, Mitchell and Wozniak, Veletsos, and others. Unlike building structures, the structural response of these tanks is influenced strongly by the fluid-structure interaction. Fluid-structure interaction forces are categorized as sloshing (convective) and rigid (impulsive) forces. The proportion of these forces depends on the geometry (height-to-diameter ratio) of the tank. API 650, API 620, AWWA D100, AWWA D110, AWWA D115, and ACI 350.3 provide the data necessary to determine the relative masses and moments for each of these contributions.

The standard requires that these structures be designed in accordance with the prevailing reference documents, except that the height of the sloshing wave, δ_s, must be calculated using Equations 15.7-13. Note that API 650 and AWWA D100 include this requirement in their latest editions.

Equations 15.7-10 and 15.7-11 provide the spectral acceleration of the sloshing liquid for the constant-velocity and constant-displacement regions of the response spectrum, respectively. The 1.5 factor in these equations is an adjustment for 0.5 percent damping. An exception in the use of Equation 15.7-11 was added for the 2010 edition of this standard. The mapped values of T_L were judged to be unnecessarily conservative by the ASCE 7 Seismic

DRAFT

Subcommittee in light of actual site-specific studies carried out since the introduction of the T_L requirements of ASCE/SEI 7-05. These studies indicate the mapped values of T_L appear to be very conservative based on observations during recent large earthquakes, especially the 2010 M_w 8.8 Chile earthquake, where the large amplifications at very long periods (6 - 10 seconds) were not evident either in the ground motion records or in the behavior of long period structures (particularly sloshing in tanks). Because a revision of the T_L maps is a time-consuming task that would not be possible during the 2010 update cycle, an exception was added to allow the use of site-specific values that are less than the mapped values with a floor of 4 seconds or one-half the mapped value of T_L. The exception was added under Section 15.7.6 because, for nonbuilding structures, the overly conservative values for T_L are primarily an issue for tanks and vessels. Discussion of the site-specific procedures can be found in the Commentary for Chapter 22.

Small-diameter tanks and vessels are more susceptible to overturning and vertical buckling. As a general rule, a greater ratio of *H*/*D* produces lower resistance to vertical buckling. Where *H*/*D* is greater than 2, overturning approaches "rigid mass" behavior (the sloshing mass is small). Large-diameter tanks may be governed by additional hydrodynamic hoop stresses in the middle regions of the shell.

The impulsive period (the natural period of the tank components and the impulsive component of the liquid) is typically in the 0.25 to 0.6 second range. Many methods are available for calculating the impulsive period. The Veletsos flexible-shell method is commonly used by many tank designers. For example, see Velestos (1974) and Malhotra, Wenk, and Wieland (2000).

C15.7.6.1.1 Distribution of Hydrodynamic and Inertia Forces

Most of the reference documents for tanks define reaction loads at the base of shell-foundation interface, without indicating the distribution of loads on the shell as a function of height. ACI 350.3 specifies the vertical and horizontal distribution of such loads.

The overturning moment at the base of the shell in the industry reference documents is only the portion of the moment that is transferred to the shell. The total overturning moment also includes the variation in bottom pressure, which is an important consideration for design of pile caps, slabs, or other support elements that must resist the total overturning moment. Wozniak and Mitchell (1978) and TID 7024 (1963) provide additional information.

C15.7.6.1.2 Sloshing

In past earthquakes, sloshing contents in ground storage tanks have caused both leakage and non-catastrophic damage to the roof and internal components. Even this limited damage, and the associated costs and inconvenience, can be significantly mitigated where the following items are considered:

1. Effective masses and hydrodynamic forces in the container.
2. Impulsive and pressure loads at
    a. The sloshing zone (that is, the upper shell and edge of the roof system),
    b. The internal supports (such as roof support columns and tray-supports), and
    c. The internal equipment (such as distribution rings, access tubes, pump wells, and risers).
3. Freeboard (which depends on the sloshing wave height).

When no freeboard is required, a minimum freeboard of $0.7\delta_s$ is recommended for economic considerations. Freeboard is always required for tanks assigned to Risk Category IV.

Tanks and vessels storing biologically or environmentally benign materials typically do not require freeboard to protect the public health and safety. However, providing freeboard in areas of frequent seismic occurrence for vessels normally operated at or near top capacity may lessen damage (and the cost of subsequent repairs) to the roof and upper container.

The sloshing wave height specified in Section 15.7.6.1.2 is based on the design earthquake defined in the standard. For economic reasons, freeboard for tanks assigned to Risk Category I, II, or III may be calculated using a fixed value of T_L equal to 4 seconds (as indicated in Section 15.7.6.1, Note d) but using the appropriate importance factor taken from Table 1.5-2. Due to life-safety concerns, freeboard for tanks assigned to Risk Category IV must be based on the mapped value of T_L. Because use of the mapped value of T_L results in the theoretical maximum value of freeboard, the calculation of freeboard in the case of Risk Category IV tanks is based on an importance factor equal to 1.0 (as indicated in Section 15.7.6.1, Note c).

DRAFT

If the freeboard provided is less than the computed sloshing height, δ_s, the sloshing liquid will impinge on the roof in the vicinity of the roof-to-wall joint, subjecting it to a hydrodynamic force. This force may be approximated by considering the sloshing wave as a hypothetical static liquid column having a height, δ_s. The pressure exerted at any point along the roof at a distance y_s above the at-rest surface of the stored liquid may be assumed equal to the hydrostatic pressure exerted by the hypothetical liquid column at a distance $\delta_s - y_s$ from the top of that column. A better approximation of the pressure exerted on the roof is found in Malhotra (2005 and 2006).

Another effect of a less-than-full freeboard is that the restricted convective (sloshing) mass "converts" into an impulsive mass thus increasing the impulsive forces. This effect should be taken into account in the tank design. A method for converting the restricted convective mass into an impulsive mass is found in Malhotra (2005 and 2006). It is recommended that sufficient freeboard to accommodate the full sloshing height be provided wherever possible.

Equation 15.7-13 was revised to use the theoretical formulation for sloshing wave height instead of the rounded value introduced in ASCE/SEI 7-05. The rounded value of Equation 15.6-1 increased the required freeboard by approximately 19 percent thereby significantly increasing the cost of both secondary containment and large diameter ground-supported storage tanks.

See C15.6.5.1 for additional commentary on freeboard.

C15.7.6.1.4 Internal Components

Wozniak and Mitchell (1978) provides a recognized analysis method for determining the lateral loads on internal components due to sloshing liquid.

C15.7.6.1.5 Sliding Resistance

Historically, steel ground-supported tanks full of product have not slid off foundations. A few unanchored, empty tanks or bulk storage tanks without steel bottoms have moved laterally during earthquake ground shaking. In most cases, these tanks may be returned to their proper locations. Resistance to sliding is obtained from the frictional resistance between the steel bottom and the sand cushion on which bottoms are placed. Because tank bottoms usually are crowned upward toward the tank center and are constructed of overlapping, fillet-welded, individual steel plates (resulting in a rough bottom), it is reasonably conservative to take the ultimate coefficient of friction on concrete as 0.70 (AISC, 1986), and therefore a value of tan 30^o (= 0.577) for sand is used in design. The value of 30^o represents the internal angle of friction of sand and is conservatively used in design. The vertical weight of the tank and contents, as reduced by the component of vertical acceleration, provides the net vertical load. An orthogonal combination of vertical and horizontal seismic forces, following the procedure in Section 12.5.3, may be used. In recent years, a significant issue has been the prevention of subsurface pollution caused by tank bottom corrosion and leakage. To prevent this, liners are often used with the tank foundation. Some of these liners are used, sliding of the tank and/or foundation caused by the seismic base shear may be an issue. If the liner is completely contained within a concrete ringwall foundation, the liner's surface is not the critical plane to check for sliding. If the liner is placed within an earthen foundation or is placed above or completely below a concrete foundation, it is imperative that sliding be evaluated. It is recommended that the sliding resistance factor of safety be at least 1.5.

C15.7.6.1.6 Local Shear Transfer

The transfer of seismic shear from the roof to the shell and from the shell to the base is accomplished by a combination of membrane shear and radial shear in the wall of the tank. For steel tanks, the radial (out-of-plane) seismic shear is very small and usually is neglected; thus, the shear is assumed to be resisted totally by membrane (in-plane) shear. For concrete walls and shells, which have a greater radial shear stiffness, the shear transfer may be shared. The ACI 350.3 commentary provides further discussion.

C15.7.6.1.7 Pressure Stability

Internal pressure may increase the critical buckling capacity of a shell. Provision to include pressure stability in determining the buckling resistance of the shell for overturning loads is included in AWWA D100. Recent testing on conical and cylindrical shells with internal pressure yielded a design methodology for resisting permanent loads in addition to temporary wind and seismic loads. See Miller, Meier, and Czaska (1997).

C15.7.6.1.8 Shell Support

Anchored steel tanks should be shimmed and grouted to provide proper support for the shell and to reduce impact on the anchor bolts under reversible loads. The high bearing pressures on the toe of the tank shell may cause inelastic deformations in compressible material (such as fiberboard), creating a gap between the anchor and the attachment. As the load reverses, the bolt is no longer snug and an impact of the attachment on the anchor can occur. Grout is a

DRAFT

structural element and should be installed and inspected as an important part of the vertical- and lateral-force-resisting system.

C15.7.6.1.9 Repair, Alteration, or Reconstruction

During their service life, storage tanks are frequently repaired, modified, or relocated. Repairs often are related to corrosion, improper operation, or overload from wind or seismic events. Modifications are made for changes in service, updates to safety equipment for changing regulations, or installation of additional process piping connections. It is imperative these repairs and modifications be designed and implemented properly to maintain the structural integrity of the tank or vessel for seismic loads as well as the design operating loads.

The petroleum steel tank industry has developed specific guidelines in API 653 that are statutory requirements in some states. It is recommended that the provisions of API 653 also be applied to other liquid storage tanks (water, wastewater, chemical, etc.) as it relates to repairs, modifications, or relocation that affects the pressure boundary or lateral force-resisting system of the tank or vessel.

C15.7.7 Water Storage and Water Treatment Tanks and Vessels

The AWWA design requirements for ground-supported steel water storage structures use allowable stress design procedures that conform to the requirements of the standard.

C15.7.7.3 Reinforced and Prestressed Concrete

A review of ACI 350.3-06, Seismic Design of Liquid-Containing Concrete Structures and Commentary, revealed that this document is not in general agreement with the seismic provisions of ASCE/SEI 7.

This section was clarified to note that the importance factor, I, and the response modification factor, R, are to be specified by ASCE/SEI 7 and not the reference document. The descriptions used in ACI 350.3 to determine the applicable values of the importance factor and response modification factor do not match those used in ASCE/SEI 7.

It was noted that the ground motions for determining the convective (sloshing) seismic forces specified in ACI 350.3 were not the same and are actually lower than those specified by ASCE/SEI 7. ACI 350.3 essentially redefines the long-period transition period, T_L. This alternate transition period allows large diameter tanks to have significantly lower convective forces and lower seismic freeboard than permitted by the provisions of ASCE/SEI 7. Therefore, Section 15.7.7.3 was revised to require that the convective acceleration be determined according to the procedure found in Section 15.7.6.1.

It was also noted that the vertical ground motions specified in ACI 350.3 were not the same as those specified by ASCE/SEI 7. Therefore, appropriate modifications to ACI 350.3 Section 9.4.3 were introduced.

C15.7.8 Petrochemical and Industrial Tanks and Vessels Storing Liquids

C15.7.8.1 Welded Steel

The American Petroleum Institute (API) uses an allowable stress design procedure that conforms to the requirements of the standard.

The most common damage to tanks observed during past earthquakes includes the following:

1. Buckling of the tank shell near the base due to excessive axial membrane forces. This buckling damage is usually evident as “elephant foot” buckles a short distance above the base or as diamond-shaped buckles in the lower ring. Buckling of the upper ring also has been observed.
2. Damage to the roof due to impingement on the underside of the roof of sloshing liquid with insufficient freeboard.
3. Failure of piping or other attachments that are overly restrained.
4. Foundation failures.

Other than the above damage, the seismic performance of floating roofs during earthquakes has generally been good, with damage usually confined to the rim seals, gage poles, and ladders. However, floating roofs have sunk in some earthquakes due to lack of adequate freeboard or the proper buoyancy and strength required by API 650. Similarly the performance of open top tanks with top wind girder stiffeners designed per API 650 has been generally good.

DRAFT

C15.7.8.2 Bolted Steel

Bolted steel tanks are often used for temporary functions. Where use is temporary, it may be acceptable to the jurisdictional authority to design bolted steel tanks for no seismic loads or for reduced seismic loads based on a reduced return period. For such reduced loads based on reduced exposure time, the owner should include a signed removal contract with the fixed removal date as part of the submittal to the authority having jurisdiction.

C15.7.9 Ground-Supported Storage Tanks for Granular Materials

C15.7.9.1 General

The response of a ground-supported storage tank storing granular materials to a seismic event is highly dependent on its height-to-diameter (*H*/*D*) ratio and the characteristics of the stored product. The effects of intergranular friction are described in more detail in C15.7.9.3.1 (increased lateral pressure), C15.7.9.3.2 (effective mass), and C15.7.9.3.3 (effective density).

Long-term increases in shell hoop tension due to temperature changes after the product has been compacted also must be included in the analysis of the shell; Anderson (1966) provides a suitable method.

C15.7.9.2 Lateral Force Determination

Seismic forces acting on ground-supported liquid storage tanks are divided between impulsive and convective (sloshing) components. However, in a ground-supported storage tank for granular materials, all seismic forces are of the impulsive type and relate to the period of the storage tank itself. Due to the relatively short period of a tank shell, the response is normally in the constant acceleration region of the response spectrum, which relates to S_{DS}. Therefore, the seismic base shear is calculated as follows:

$$V = \frac{S_{DS}}{\left(\frac{R}{I}\right)} W_{Effective} \qquad \text{(C15.7-2)}$$

where V, S_{DS}, I, and R have been previously defined, and $W_{Effective}$ is the gross weight of the stored product multiplied by an effective mass factor and an effective density factor, as described in Sections C15.7.9.3.2 and C15.7.9.3.3, plus the dead weight of the tank. Unless substantiated by testing, it is recommended that the product of the effective mass factor and the effective density factor be taken as no less than 0.5 due to the limited test data and the highly variable properties of the stored product.

C15.7.9.3 Force Distribution to Shell and Foundation

C15.7.9.3.1 Increased Lateral Pressure

In a ground-supported tank storing granular materials, increased lateral pressures develop as a result of rigid body forces that are proportional to ground acceleration. Information concerning design for such pressure is scarce. Trahair et al. (1983) describes both a very simple, conservative method and a very difficult, analytical method using failure wedges based on the Mononobe-Okabe modifications of the classical Coulomb method.

C15.7.9.3.2 Effective Mass

For ground-supported tanks storing granular materials, much of the lateral seismic load can be transferred directly into the foundation, via intergranular shear, before it can reach the tank shell. The effective mass that loads the tank shell is highly dependent on the *H*/*D* ratio of the tank and the characteristics of the stored product. Quantitative information concerning this effect is scarce, but Trahair et al. (1983) describes a very simple, conservative method to determine the effective mass. That method presents reductions in effective mass, which may be significant, for *H*/*D* ratios less than 2. This effect is absent for elevated tanks.

C15.7.9.3.3 Effective Density

Granular material stored in tanks (both ground-supported and elevated) does not behave as a solid mass. Energy loss through intergranular movement and grain-to-grain friction in the stored material effectively reduces the mass subject to horizontal acceleration. This effect may be quantified by an effective density factor less than 1.0.

Based on Chandrasekaran and Jain (1968) and on shake-table tests reported in Chandrasekaran et al. (1968), ACI 313 recommends an effective density factor of not less than 0.8 for most granular materials. According to Chandrasekaran and Jain (1968), an effective density factor of 0.9 is more appropriate for materials with high moduli of elasticity, such as aggregates and metal ores.

DRAFT

C15.7.9.3.4 Lateral Sliding

Most ground-supported steel storage tanks for granular materials rest on a base ring and do not have a steel bottom. To resist seismic base shear, a partial bottom or annular plate is used in combination with anchor bolts or a curb angle. An annular plate can be used alone to resist the seismic base shear through friction between the plate and the foundation, in which case the friction limits of Section 15.7.6.1.5 apply. The curb angle detail serves to keep the base of the shell round while allowing it to move and flex under seismic load. Various base details are shown in Figure 13 of Kaups and Lieb (1985).

C15.7.9.3.5 Combined Anchorage Systems

This section is intended to apply to combined anchorage systems that share loads based on their relative stiffnesses, and not to systems where sliding is resisted completely by one system (such as a steel annular plate) and overturning is resisted completely by another system (such as anchor bolts).

C15.7.10 Elevated Tanks and Vessels for Liquids and Granular Materials

C15.7.10.1 General

The three basic lateral load-resisting systems for elevated water tanks are defined by their support structure:

1. Multi-leg braced steel tanks (trussed towers, as shown in Figure C15.7-2),
2. Small-diameter single-pedestal steel tanks (cantilever columns, as shown in Figure C15.7-3), and
3. Large-diameter single-pedestal tanks of steel or concrete construction (load-bearing shear walls, as shown in Figure C15.7-4).

Unbraced multi-leg tanks are uncommon. These types of tanks differ in their behavior, redundancy, and resistance to overload. Multi-leg and small-diameter pedestal tanks have longer fundamental periods (typically greater than 2 seconds) than the shear wall type tanks (typically less than 2 seconds). The lateral load failure mechanisms usually are brace failure for multi-leg tanks, compression buckling for small-diameter steel tanks, compression or shear buckling for large-diameter steel tanks, and shear failure for large-diameter concrete tanks. Connection, welding, and reinforcement details require careful attention in order to mobilize the full strength of these structures. To provide a greater margin of safety, *R* factors used with elevated tanks typically are less than those for other comparable lateral load-resisting systems.

C15.7.10.4 Transfer of Lateral Forces into Support Tower

The vertical loads and shears transferred at the base of a tank or vessel supported by grillage or beams typically vary around the base due to the relative stiffness of the supports, settlements, and variations in construction. Such variations must be considered in the design for vertical and horizontal loads.

C15.7.10.5 Evaluation of Structures Sensitive to Buckling Failure

Nonbuilding structures that are designed with limited structural redundancy for lateral loads may be susceptible to total failure when loaded beyond the design loads. This is particularly true for shell type structures that exhibit unstable post-buckling behavior, such as tanks and vessels supported on shell skirts or pedestals. Evaluation for this critical condition assures stability of the nonbuilding structure for governing design loads.

The design spectral response acceleration, S_a, used in this evaluation includes site factors. The I/R coefficient is taken as 1.0 for this critical check. The structural capacity of the shell is taken as the critical buckling strength (that is, the factor of safety is 1.0). Vertical and orthogonal combinations need not be considered for this evaluation, since the probability of peak values occurring simultaneously is very low.

The intent of Sect. 15.7.10.5 and *T*able 15.4-2 is that skirt supported vessels be checked for seismic loads based on $I_{e/R}$ = 1.0 if the structure falls in Risk Category IV or if an R-value of 3.0 is used in the design of the vessel. For the purposes of this section, a skirt is a thin walled steel cylinder or cone used to support the vessel in compression. Skirt supported vessels fail in buckling, which is not a ductile failure mode. Therefore, a more conservative design approach is required. The $I_{e/R}$ = 1.0 check will typically govern the design of the skirt over using loads determined with an R-factor of 3 in a moderate to high area of seismic activity. The only benefit of using an R-factor of 3 in this case is in the design of the foundation. The foundation is not required to be designed for the $I_{e/R}$ = 1.0 load. Sect. 15.7.10.5 Item b states that resistance of the structure be defined as the critical buckling resistance of the element for the $I_{e/R}$ = 1.0 load. This means that the support skirt can be designed based on critical buckling (factor of safety of 1.0). The critical buckling strength of a skirt can be determined using a number of published sources. The two most common methods for determining the critical buckling strength of a skirt are the 2007 *ASME BVPC*

DRAFT

Section VIII, Division 2, 2008 Addenda, Paragraph 4.4 using a factor of safety of 1.0 and *AWWA D100-05* Sect. 13.4.3.4. To use these methods, the radius, length, and thickness of the skirt, modulus of elasticity of the steel, and yield strength of the steel are required. These methods take into account both local buckling and slenderness effects of the skirt. Under no circumstance should the theoretical buckling strength of a cylinder, found in many engineering mechanics texts, be used to determine the critical buckling strength of the skirt. The theoretical value, based on a perfect cylinder, does not take into account imperfections built into real skirts. The theoretical buckling value is several times greater than the actual value measured in tests. The buckling values found in the suggested references above are based on actual tests.

Examples of applying the 2007 *ASME BVPC* Section VIII, Division 2, 2008 Addenda, Paragraph 4.4 and *AWWA D100-05* Sect. 13.4.3.4 buckling rules are shown below.

Per ASCE/SEI 7-10 Section 12.8.3 for T = 0.591 seconds, k = 1.045

Centroid for a distributed mass cantilever structure = [(k+1) / (k+2)]H = 67.16 ft

Overturning Moment = 219.9(67.16) = 14768 ft-kips

Determine Stresses at Base of Skirt

Axial Stress = P/A = 300000 / (π(10)12(0.625) = 1274 psi

Bending Stress = M/S = 14768(1000)12 / [(0.625)π(10(12))^2/4] = 25072 psi

Input Data for ASME Section VIII, Div. 2 Buckling Checks (Paragraph 4.4)

Input Values		
COURSE =	Skirt	
t = thickness of vessel section =	0.625	in
H_T = top elevation of course =	120	in
H_B = bottom elevation of course =	0	in
D_o = outer diameter of vessel section =	120	in
E_y = material modulus of elasticity =	29000000	psi
S_y = material yield strength =	36000	psi
P_{act} = external pressure =	0.000	psi
f_a = axial comp membrane stress from axial load =	1274	psi
f_b = axial comp membrane stress from bending =	25072	psi
V = net section shear force =	219900	lbs
V_{plv} = applied shear force angle =	90	deg.
C_m = coefficient =	1	0.85, 1.0, or 0.6 - 0.4 (M_1 / M_2)
K_y = effective length factor =	2.1	Free-Fixed
L_u = maximum laterally unbraced length =	1200	in
L = design length vessel section for external pressure =	120	in
L = design length vessel section for axial compression =	120	in
FS = Input Factor of Safety =	1.0	
Calculated Values		
R_o = outter radius of shell section =	60	in
R = radius to centerline of shell =	59.6875	in
R_m = vessel mean radius =	59.6875	in
r = radius of gyration of cyl = (1/4)(D_o^2+D_i^2)$^{0.5}$ =	42.2	in
A = Cross sectional area of cylinder =	234.4	in^2
f_a = axial compressive membrane stress = P/πD$_i^2$/4A =	0.0	psi

4.4.12 Combined Loadings and Allowable Compressive Stresses

b) Axial Compressive Stress Acting Alone - The allowable axial compressive membrane stress of a cylinder subject to an axial compressive load acting alone, F_{xa}, is computed by following equations.

1) For $lamda_c \leq 0.15$ (Local Buckling)

$F_{xa} = \min [F_{xa1}, F_{xa2}]$ (4.4.61)

$F_{xa1} = S_y / FS$ for $D_o / t \leq 135$ (4.4.62)

$F_{xa1} = 466\ S_y / [(331 + D_o / t)\ FS]$ for $135 < D_o / t < 600$ (4.4.63)

$F_{xa1} = 0.5\ S_y / FS$ for $D_o / t \geq 600$ (4.4.64)

$F_{xa2} = F_{xe} / FS$ (4.4.65)

where: $F_{xe} = C_x\ E_y\ t / D_o$ (4.4.66)

$C_x = \min[409\ c / [389 + D_o / t], 0.9]$ for $D_o / t < 1247$ (4.4.67)

$C_x = 0.25\ c$ for $1247 \leq D_o / t \leq 2000$ (4.4.68)

$c = 2.64$ for $M_x \leq 1.5$ (4.4.69)

$c = 3.13 / M_x^{0.42}$ for $1.5 < M_x < 15$ (4.4.70)

$c = 1.0$ for $M_x \geq 15$ (4.4.71)

$M_x = L / (R_o\ t)^{1/2}$ (4.4.124)

where L is the design length of a vessel section between lines of support

$D_o / t =$ 192.00 $135 < Do / t < 600$

$M_x = L / (R_o\ t)^{1/2} =$ 19.60 > 15 $c =$ 1.0000

$Do / t < 1247$ $Cx = \min [409\ c / [389 + Do / t], 0.9] =$ 0.7039587 (4.4.67)

$F_{xe} = C_x\ E_y\ t / D_o =$ 106,327 psi (4.4.66)

Calculate Fxa_1			Calculate Fxa_2		
Flc = 466*Sy/(331+Do/t)	32076	psi	Flc =	106327	psi
Use Input FS =	1.00		Use Input FS =	1.0	
Fxa1 = 466*Sy/((331+Do/t)*FS)	32076	psi	$Fxa_2 = Fxe / FS =$	106327	psi (4.4.65)

Calculate Fxa

$Fxa = \min[F_{xa1}, F_{xa2}] =$ 32,076 psi (4.4.61)

$lambda_c = (K)\ (L_u) / [(pi)(r_g)]\ [(F_{xa})\ (FS) / E]^{0.6} =$ 0.6321 $0.15 < lamda < 1.147$

2) For $lamda_c > 0.15$ and $K_o L_o / r_g < 200$ (Column Buckling)

$F_{cx} = F_{xa}\ [1 - 0.74\ (lamda_c - 0.15)]^{0.3}$ for $0.15 < lamda_c \leq 1.147$ (4.4.72)

$F_{cx} = 0.88\ F_{xa} / (lamda_c)^2$ for $lamda_c \geq 1.147$ (4.4.73)

$K\ L_u / r_g =$ 59.7 < 200

lamda > 0.15 and K Lu / r < 200 therefore:

Fca = Fxa [1 - 0.74 (lamda - 0.15)]^0.3 = 28,100 psi

1

4.4.12 Combined Loadings and Allowable Compressive Stresses (continued)

c) Compressive Bending Stress - The allowable axial compressive membrane stress of a cylindrical shell subject to a bending moment acting across the full circular cross section F_{bx}, is computed using the following equations.

$F_{bx} = F_{xx}$ for $135 \le D_o / t \le 2000$ (4.4.74)

$F_{bx} = 466\ S_y / [(331 + D_o / t)\ FS]$ for $100 \le D_o / t < 135$ (4.4.75)

$F_{bx} = 1.081\ S_y / FS$ for $D_o / t < 100$ and $y \ge 0.11$ (4.4.76)

$F_{bx} = (1.4 - 2.9\ y)\ S_y / FS$ for $D_o / t < 100$ and $y < 0.11$ (4.4.77)

where: $y = S_y\ D_o / E_y\ t$ (4.4.78)

$D_o / t =$ 192

$y = S_y\ D_o / E_y\ t =$ 0.2383

Flc = Fxa

Flc = 32,076 psi

$D_o / t =$ 192.000 > 135 (see Sect. 3.1.1) Use Input FS = 1.0

Fba = Fxa = 32,076 psi

d) Shear Stress - The allowable shear stress of a cylindrical shell, F_{vx}, is computed using the following equations.

$F_{vx} = n_v\ F_{ve} / FS$ (4.4.79)

where: $F_{ve} = a_v\ C_v\ E\ t / D_o$ (4.4.80)

$C_v = 4.454$ for $M_x \le 1.5$ (4.4.81)

$C_v = (9.64 / M_x^2)\ (1 + 0.0239\ M_x^3)^{1/2}$ for $1.5 < M_x < 26$ (4.4.82)

$C_v = 1.492 / (M_x)^{1/2}$ for $26 \le M_x < 4.347\ D_o / t$ (4.4.83)

$C_v = 0.716\ (t / D_o)^{1/2}$ for $M_x \ge 4.347\ D_o / t$ (4.4.84)

$a_v = 0.6$ for $D_o / t \le 500$ (4.4.85)

$a_v = 1.389 - 0.218 \log_{10} (D_o / t)$ for $D_o / t > 500$ (4.4.86)

$n_v = 1.0$ for $Fve / Sy < 0.48$ (4.4.87)

$nv = 0.43\ Sy / Fve + 0.1$ for $0.48 < Fve / Sy < 1.7$ (4.4.88)

$nv = 0.6\ Sy / Fve$ for $Fve / Sy > 1.7$ (4.4.89)

$D_o / t =$ 192.000

$M_x = L / (R_o\ t)^{0.5} =$ 19.596

$1.5 < Mx < 26$ Cv = (9.64/Mx^2)*(1+0.0239*Mx^3)^0.5 = 0.3376

Do / t < 500 av = 0.6000

$F_{ve} = a_v\ C_v\ E\ t / D_o =$ 40,793 psi

Fve / Sy = 1.13 0.48 < Fve / Sy < 1.7

nv = 0.43 Sy / Fve + 0.1 = 0.4795

$F_{tc} =$ 19,559 psi

Use Input FS = 1.000

$F_{vx} = n_v\ F_{ve} / FS =$ 19,559 psi

1

4.4.12 Combined Loadings and Allowable Compressive Stresses (continued)

i) Axial Compressive Stress, Compressive Bending Stress, and Shear -
the allowable compressive stress for the combination of uniform axial compression, axial compression due to bending, and shear in the absence of hoop compression.

Let $K_s = 1 - (f_v / F_{va})^2$ (4.4.105)

For $0.15 < (lamda)_c < 1.2$

$lamda_c =$ 0.63 (Section 3.2) **$0.15 < lamda < 1.2$ OK**

$f_a /(K_s F_{ca}) + (8 / 9)\ (delta)\ f_b /(K_s F_{ba}) \leq 1.0$ $f_a /(K_s F_{ca}) \geq 0.2$ (4.4.112)

$f_a /(2\ K_s F_{ca}) + (delta)\ f_b /(K_s F_{ba}) \leq 1.0$ $f_a /(K_s F_{ca}) < 0.2$ (4.4.113)

$K_s = 1 - (f_v / F_{va})^2 =$ 0.9977

$F_e = (pi)^2\ E / [K\ L_u / r]^2 =$ 80,287 psi

$delta = C_m / [1 - f_a\ FS / F_e] =$ 1.0161

$f_a /(K_s F_{ca}) =$ 0.045443 < 0.2

fa /(2 Ks Fca) + (delta) fb /(Ks Fba) =	**0.82**	**< 1.0**	***OK!***

DRAFT

Example Problem 2 – AWWA D100-05 Sect. 13.4.3.4

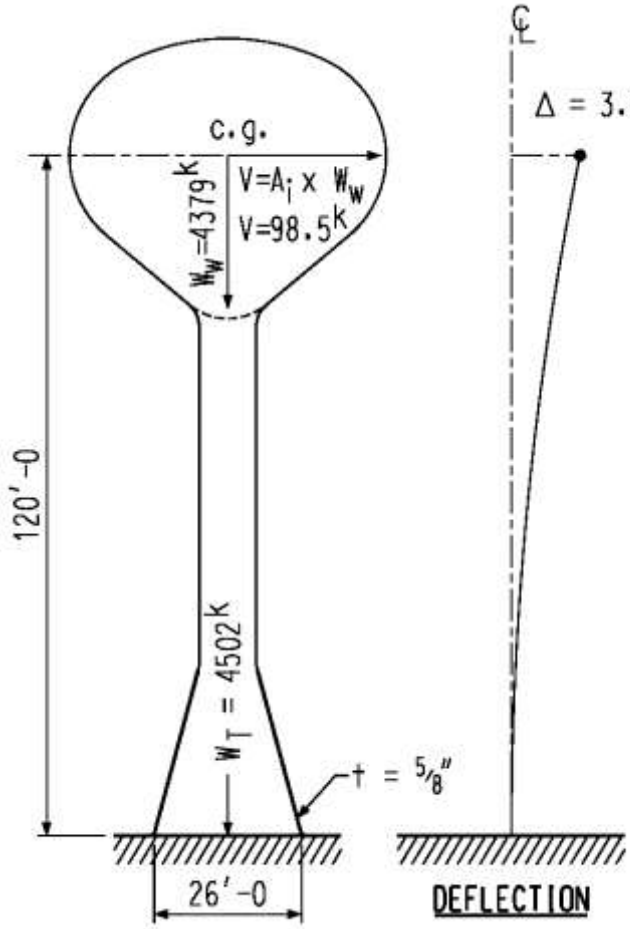

Figure Ex- 2 Single Pedestal Elevated Water Tank

Seismic Information	**Tank Information**
S_S = 0.162 S_1 = 0.077	Structure Period T_i = 3.88 seconds
Site Class C F_a = 1.2 F_v = 1.7	Class 2 Material: A36 (F_y = 36 ksi)
S_{DS} = 0.130 S_{D1} = 0.087 T_L = 12 seconds	Skirt Angle (from vertical) = 15 degrees
Risk Category IV	Weight of Tank & Water, W_W = 4379 kips
T_s = 0.674 seconds	Weight of Tank, Tower, & Water, W_T = 4502 kips
	KL/r = 50

Determine S_{ai} per AWWA D100-05 Section 13.2.7.2

$T_s < T_i \leq T_L$ ==> $S_{ai} = S_{D1}/T_i = 0.087/3.88 = 0.0225$

Determine Critical Buckling Acceleration ($I_e/1.4R_i = 1$)

Per Section 13.4.3.4, $A_i = S_{ai}$ for critical buckling check (A_i in AWWA D100-05 is the same as C_s in ASCE/SEI 7)

$A_i = 0.0225$

Lateral Displacement Due to S_{ai} (P-Δ)

The final deflected position of the water centroid is an iterative process and must account for the additional moment applied to the structure due to the P- Δ effect. The deflection from the critical buckling deflection is equal to 3.89 inches.

Check Skirt at Base of Tower

Seismic overturning moment at base of tower without P-Δ = 11,928 ft-kips (includes mass of tower).

Seismic overturning moment at base of tower with P-Δ = 11,928 ft-kips + 4379 kips x 3.89 in/12 in per ft

= 13,348 ft-kips

Area of Skirt = $\pi(26 \times 12)(0.625) = 612.6$ in^2 Section Modulus of Skirt = $\pi(26 \times 12)^2/4 \times 0.625 = 47{,}784$ in^3

Skirt Stress Due to Axial Load = 4502(1000)/(612.6 x cos 15) = 7608 psi

Skirt Stress Due to Moment = 13,348(12)(1000)/(47,784 x cos 15) = 3470 psi

Determine Critical Buckling Stress

R = 13 x 12/cos 15 = 161.5 inches t/R = 0.625/161.5 = 0.0039

For Class 2 Material, KL/r = 50, and t/R = 0.0039, determine allowable axial compressive stress Fa from Table 13 of AWWA D100-05.

$F_a = 9882$ psi Per AWWA D100-05 Section 13.4.3.4, Critical Buckling Stress = $2F_a = 19{,}764$ psi

For Class 2 Material and t/R = 0.0039, determine allowable bending compressive stress F_b from Table 11 of AWWA D100-05.

$F_b = F_L = 10{,}380$ psi Per AWWA D100-05 Section 13.4.3.4, Critical Bending Stress = $2F_b = 20.760$ psi

Check Unity per AWWA D100-05 Section 3.3.1

$7608/19{,}764 + 3470/20{,}760 = 0.552 \leq 1.0$ OK

C15.7.10.7 Concrete Pedestal (Composite) Tanks

A composite elevated water-storage tank is comprised of a welded steel tank for watertight containment, a single pedestal concrete support structure, a foundation, and accessories. The lateral load-resisting system is a load-bearing concrete shear wall. Since the seismic provisions in ACI 371R-98 are based on an older edition of ASCE/SEI 7, appropriate bridging equations are provided in Section 15.7.10.7.

C15.7.11 Boilers and Pressure Vessels

The support system for boilers and pressure vessels must be designed for the seismic forces and displacements presented in the standard. Such design must include consideration of the support, the attachment of the support to the vessel (even if "integral"), and the body of the vessel itself, which is subject to local stresses imposed by the support connection.

DRAFT

C15.7.12 Liquid and Gas Spheres

The commentary in Section C15.7.11 also applies to liquid and gas spheres.

C15.7.13 Refrigerated Gas Liquid Storage Tanks and Vessels

Even though some refrigerated storage tanks and vessels, such as those storing LNG, are required to be designed for ground motions and performance goals in excess of those found in the standard, all such structures must also meet the requirements of this standard as a minimum. All welded steel refrigerated storage tanks and vessels must be designed in accordance with the requirements of the standard and the requirements of API 620.

C15.7.14 Horizontal, Saddle Supported Vessels for Liquid or Vapor Storage

Past practice has been to assume that a horizontal, saddle supported vessel (including its contents) behaves as a rigid structure (with natural period, *T*, less than 0.06 seconds). For this situation, seismic forces would be determined using the requirements of Section 15.4.2. For large horizontal, saddle-supported vessels (length-to-diameter ratio of 6 or more), this assumption can be unconservative, so Section 15.7.14.3 requires that the natural period be determined assuming the vessel to be a simply supported beam.

Chapter C16
SEISMIC RESPONSE HISTORY PROCEDURES

C16.1 LINEAR RESPONSE HISTORY PROCEDURE

The standard does not require the use of linear response history analysis for design of a structure. The use of such analysis may be useful in validation of the results from the analysis methods presented in Chapter 12, or as a step in a series of analyses that culminate in a nonlinear response history analysis. While not commonly used in the past to design conventional structures, this technique is seeing increased use in the design of some structures that neither contain damping systems nor are base isolated.

The purpose of the linear response history procedure is to determine design forces for structural components and to compute displacements and story drifts, which must be within the limits specified by Table 12.12-1. In this sense, the linear response history procedure shares the same force-based philosophy of the Equivalent Lateral Force (ELF) procedure and the Modal Response Spectrum (MRS) analysis procedure (specified in Chapter 12). Response history analysis offers several advantages over modal response spectrum analysis: it is more accurate mathematically, signs of response quantities (such as tension or compression in a brace) are not lost as a result of the combination of modal responses, and story drifts are computed more accurately. The principal disadvantages of response history analysis are the need to select and scale an appropriate suite of ground motions, and the necessity to perform analysis for several (usually seven) such motions. See Section C16.1.3 and C16.1.4 for discussion of ground motion selection and scaling techniques.

C16.1.1 Analysis Requirements

In response history analysis, the seismic hazard is characterized by a number of ground acceleration records. Using these records and a detailed mathematical model of the structure, nodal displacements and component forces are computed, step-by-step, by solving the equations of motion. There are two basic approaches for solving these equations. In the first approach, called *direct analysis*, all the equilibrium equations for the entire system are solved simultaneously in each time step.

In the second approach, called modal analysis, the equilibrium equations are transformed, by change of coordinates, into a number of uncoupled single-degree-of-freedom (SDOF) systems, one for each mode

Where modal analysis uses the full set of mode shapes and the damping ratios in each mode are identical to those obtained from the equations of motion used in the direct analysis, the two approaches produce identical results. A distinct advantage of the modal analysis approach is that a limited number of modes may be used to produce reasonably accurate results. While some accuracy is sacrificed where fewer modes are used, the computer resources required to perform the analysis are significantly less than those required for direct analysis. The number of modes required for a "reasonably" accurate analysis is discussed in Section C12.9.1.

The damping matrix plays a very important role in the solution of the equations of motion. The classical modal analysis procedure, discussed above, is not applicable for structures consisting of subsystems with very different levels of damping (Chopra 2007); for example, base isolated structures, structure with energy-dissipating devices, and soil-structure interaction (when including both the structure and supporting soil in the analysis). This is a limitation of the uncoupled classical damping matrix. For nonclassical damping (coupled matrix) an alternative modal analysis approach, significantly more computationally demanding, is to include the damping term in the eigenvalue problem - see Veletsos and Ventura (1986). The direct analysis procedure has the advantage that the nonclassical damping matrix can be employed in the solution. The designer should be aware of the limitations of each solution method to represent the dynamic response of a structure.

C16.1.2 Modeling

The mathematical model used for linear response history analysis is usually identical to that used for modal response spectrum analysis, and it often reflects a preliminary design developed using the ELF procedure. The main modeling difference between response history analysis and modal response spectrum analysis is that the inherent damping (taken as 5 percent of critical) is included in the design response spectrum for modal response spectrum analysis, while it must be assigned explicitly for response history analysis.

DRAFT

In the modal analysis approach, damping is simply assigned to each mode that is included in the response (Wilson and Penzien, 1970). Although not specified in the standard, the damping used for each mode should be 5 percent of critical for consistency with the design response spectrum.

Linear response history analysis requires an explicit damping matrix. However, such a matrix cannot be formed from first principles; it is common to use a damping matrix that is proportional to the mass, the stiffness, or a linear combination of the two:

$$C = \alpha M + \beta K \qquad \text{(C16.1-1)}$$

where C is the damping matrix, M is the mass matrix, K is the stiffness matrix, and α and β are scalar constants of proportionality for each system forming the analytical model. Such damping is often referred to as Rayleigh damping.

The proportionality constants are determined as follows:

$$\begin{Bmatrix} \alpha \\ \beta \end{Bmatrix} = 2 \begin{bmatrix} 1/\omega_a & \omega_a \\ 1/\omega_b & \omega_b \end{bmatrix}^{-1} \begin{Bmatrix} \xi_a \\ \xi_b \end{Bmatrix} \qquad \text{(C16.1-2)}$$

where ξ_a and ξ_b are the desired damping ratios at any two system circular frequencies, ω_a and ω_b, where $\omega_b > \omega_a$. It is common, but not necessary, for the two specified frequencies to correspond to two of the system's lower natural frequencies (such as the first and third mode frequencies).

If both damping values are the same ($\xi = \xi_a = \xi_b$), which is usually the case, the mass and stiffness proportionality constants may be determined as follows:

$$\alpha = \xi \frac{2\omega_a \omega_b}{\omega_a + \omega_b}$$

$$\beta = \xi \frac{2}{\omega_a + \omega_b} \qquad \text{(C16.1-3)}$$

The advantage of Rayleigh damping is that it is simple to implement because all the analyst has to do is to specify the two proportionality constants α and β, and these can be established using Equation C16.1-2 given the two desired damping ratios and corresponding frequencies. The disadvantage is that the damping ratios increase with frequency and may cause the higher mode contributions to response to be over-damped. This effect is shown in Figure C16.1-1, where the damping ratios ξ have been set at 0.05 at frequencies of 4.2 and 12.5 radians per second. The damping at all other frequencies is given by the curve marked "Total". For frequencies above approximately 32 radians per second, the damping is greater than 10 percent of critical and may be excessive.

DRAFT

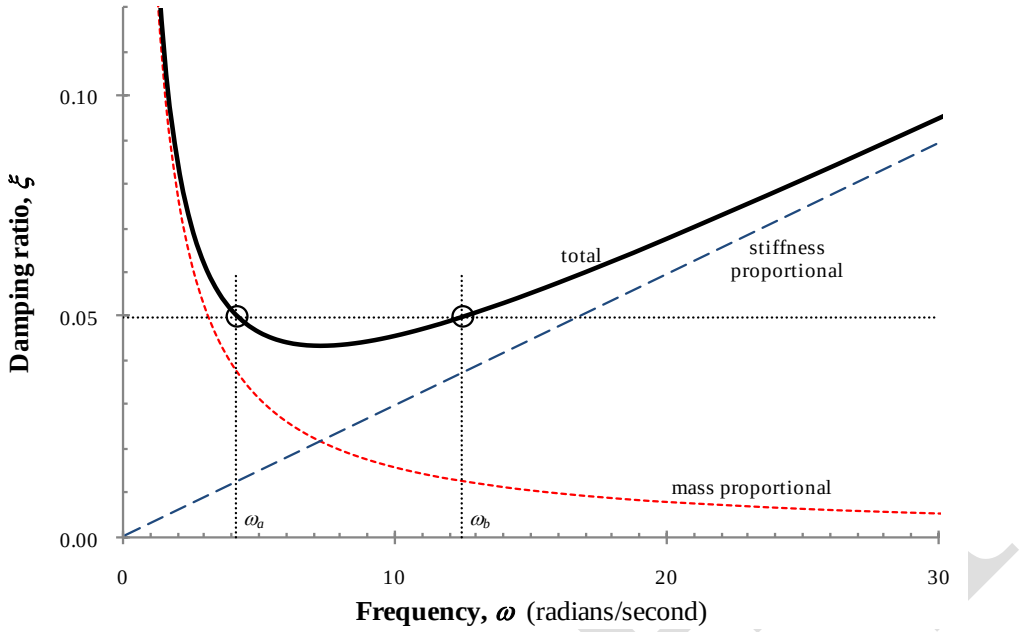

Figure C16.1-1 Example of Rayleigh damping.

C16.1.3 Ground Motion

One of the most demanding aspects of response history analysis is the selection and scaling of an appropriate suite of ground motions (Anderson and Bertero, 1987). It is considered appropriate to select records that have magnitudes, fault distances, source mechanisms, and soil conditions that are characteristic of the site. This poses quite a challenge even for sites in the western United States, where numerous records from large-magnitude earthquakes are available; it is virtually impossible in the central and eastern United States, where there are no recorded ground motions from large-magnitude events. (The web site for the Pacific Earthquake Engineering Research Center (PEER) provides a large number of ground motion acceleration records that may be used in response history analysis. In addition to the ground motions, the PEER site provides detailed background information on the source characteristics of the ground motions and on the instrument and site characteristics of the particular station that recorded the acceleration record.)

Because of the scarcity of available recorded motions, use of simulated ground motions is permitted. To this end, available records may be modified for site distance and soil conditions. Such modification is considered part of the ground motion selection.

The standard requires that at least three ground motions (or ground motion pairs, in the case of three-dimensional analysis) be used, and it provides an incentive for using at least seven motions (as discussed in Section C16.1.4).

The scaling technique specified in Sections 16.1.3.1 and 16.1.3.2 is one of several that have been proposed. See Shome and Cornell (1998), Shome et al. (1998), Somerville et al. (1998), Mehrain and Naeim (2003), and Iervolino and Cornell (2005) for background on ground motion selection and scaling.

C16.1.3.1 Two-Dimensional Analysis.

This scaling method begins with ground motions that have been selected (and modified as necessary) to have magnitude, distance, and site conditions compatible with the maximum considered earthquake. The 5 percent damped pseudo-acceleration response spectra for these records are scaled for consistency with the design ground motion spectrum shown in Figure 11.4-1. For two-dimensional analysis, the ground motion spectra must be scaled such that the average of the spectra is not less than the design spectrum in the period range from $0.2T$ to $1.5T$, where T is the fundamental period of vibration of the structure being designed. The short period of the range ($0.2T$) is set to capture higher mode response, and the long period of the range ($1.5T$) is set to allow for period lengthening that would be associated with inelastic response.

C16.1.3.2 Three-Dimensional Analysis

Approaches to scaling ground motions for three-dimensional analysis are similar to those for two-dimensional analysis. The two orthogonal components within each pair must have the same scale factor, but the individual pairs may have different scale factors. Within 3 miles (5 kilometers) of an active fault, ground motion components selected to represent fault-normal and fault-parallel directions are required to be included in the analysis. For certain structures, the response under both horizontal and vertical ground motions should be consideredVertical ground motion spectra are not readily available Section 12.4.2.2 provides procedures for estimating vertical seismic forces.

Given a set of appropriate ground motions, there are an infinite number of scaling factors that may be applied to the individual motions to meet the requirements of Sections 16.1.3.1 and 16.1.3.2. Thus, two analysts, working with the same set of ground motions, are likely to produce a different set of scale factors. While this difference in scaling would have little impact in linear analysis, it may lead to vastly different results in nonlinear analysis. For this reason, the process of selection and scaling of ground motions should be included in the design review (Section 16.2.5 of the standard) that is required wherever nonlinear response history analysis is used.

Both amplitude scaling and spectral matching procedures can be used to satisfy the scaling technique specified in Sections 16.1.3.1 and16.1.3.2. Both procedures provide reasonable estimates of mean response for the individual response parameters. Spectral matching can provide mean estimates with a smaller suite of motions, although seven suites are still required as outlined in Section 16.1.4. Neither scaling approach, however, is adequate to give an accurate estimate of the variability, although amplitude scaling gives a better understanding of the potential variability than spectral matching.

C16.1.4 Response Parameters

The responses derived from the response history analysis are multiplied by the Importance Factor, I_e, to provide enhanced strength and stiffness for more important facilities, and are divided by R to account for inelastic behavior. For consistency with the ELF and MRS analysis procedures, the displacements computed from the response histories that have been modified by I_e/R should be multiplied by C_d/I_e to obtain the displacement histories for computing the story drift histories.

The base shear typically is computed from component elastic forces. A slightly different shear would be computed from the total inertial forces, with the difference being due to damping. Note that while the results of MRS analysis must be scaled up such that the corresponding base shear is not less than 85 percent of the base shear that would be computed from an ELF analysis (see Section C12.9.4) for strength design forces, the scaling for linear response history analysis considers only 100 percent of the applicable minimum base shear coefficient. Similar but slightly different provisions (including the 85% multiplier) are prescribed for scaling of drifts.

If seven or more ground motions are used, the design values may be taken as the average of the scaled values from the response history analysis. This provides some difficulty for components for which the capacity depends on multiple values. For a column, for example, both the axial force and the concurrent bending moment are needed to compare demand and capacity. In that instance, if seven or more ground motions are used, the column is deemed suitable if the average of the seven peak demand-to-capacity ratios for the column is less than 1.0. Where fewer than seven ground motions are used, the column is deemed suitable if the maximum demand-to-capacity ratio is less than 1.0.

The direction of loading requirements of Section 12.5 and the modeling requirements of Section 12.7 apply to response history analysis.Accidental torsion, amplification of accidental torsion, or detailed consideration of P-delta effects should be included in a manner consistent with the requirements of Section 12.9 (see discussion in C12.9). Whether or not gravity loads should be applied simultaneously with the ground motion records will depend on whether the member stiffness is updated during each time step or initially set constant by a vertical load combination.

C16.2 NONLINEAR RESPONSE HISTORY PROCEDURE

Nonlinear response history analysis is not used as part of the normal design process for conventional structures. In some cases, however, nonlinear analysis is recommended, and in certain cases required, to obtain a more realistic assessment of structural response and verify the results of simpler methods of analysis. Such is the case for systems with friction-based passive energy dissipation devices, nonlinear viscous dampers, seismically isolated systems, self-centering systems, or systems that have components with highly irregular force-deformation relationships.

DRAFT

The principal aim of nonlinear response history analysis is to determine if the computed deformations of the structure are within appropriate limits. Strength requirements for the designated lateral load-resisting elements do not apply because element strengths are established prior to the analysis. These initial strengths typically are determined from a preliminary design using linear analysis.

The nonlinear response history analysis may also provide useful information on the strength requirements for nonstructural components, which are often assumed to remain elastic in the analysis.

Where displacements computed from the nonlinear response history analysis are excessive, a typical remedy is to increase the stiffness of the structure, which is likely to affect the computed strength.

Nonlinear response history analysis offers several advantages over linear response history analysis, including the ability to model a wide variety of nonlinear material behaviors, geometric nonlinearities (including large displacement effects), gap opening and contact behavior, and nonclassical damping, and to identify the likely spatial and temporal distributions of inelasticity. Nonlinear response history analysis has several disadvantages, including increased effort to develop the analytical model, increased time to perform the analysis (which is often complicated by difficulties in obtaining converged solutions), sensitivity of computed response to system parameters, and the inapplicability of superposition to combine live, dead, and seismic load effects.

C16.2.1 Analysis Requirements

Nonlinear response history analysis is highly sensitive to the modeling assumptions and solution procedures used. Seemingly minor changes in assumptions of elastic stiffness and strength, hysteretic behavior, solution time step and other parameters can significantly affect the indicated results. *NEHRP Technical Brief No. 4, Nonlinear Structural Analysis for Seismic Design*, (Deierlein *et al.*, 2010) provides guidance on the many decisions that must be made. Sensitivity analysis that explores the effect of modeling assumptions on predicted response is often a valuable tool to provide confidence in the analysis results. Other validation methods can include benchmarking analyses with alternative software and modeling structures with known behavior, such as laboratory tests, to confirm that reasonable solutions are obtained.

The mathematical model need only comply with the requirements of Section 12.7 which does not explicitly require accidental torsion be to modeled. It is generally accepted practice that when Three-Dimensional Dynamic Analysis is utilized in conjunction with the requirements of Nonlinear Response History Procedure, the effects of accidental torsion are not explicitly modeled, as they are assessed automatically. While consideration of accidental torsion (and amplification) is usually associated with the uncertainty regarding the center of mass and stiffness,, it also accounts for torsional ground motion and associated response effects and the increased torsional response associated with nonlinear behavior of the lateral force resisting system. Since the nonlinear behavior is being modeled and torsional ground motion effects are deemed to be small for conventional building structures with regular plans, it is considered unnecessarily conservative to additionally include accidental torsion effects especially using the the "dynamic" approach discussed in C12.9.5. Furthermore, for complex 3-D nonlinear response history analyses, it is often considered impractical to require multiple analyses to address all possibilities of eccentricity.

C16.2.2 Modeling

Nonlinear response history analysis requires a mathematical description of the hysteretic behavior of those portions of the structure that are expected to exhibit inelastic behavior during an earthquake. Such models must reflect the expected material properties of the components as well as account for the following behavioral effects as appropriate:

1. Material overstrength and strain hardening
2. Cyclic degradation of stiffness and strength
3. In-cycle degradation of stiffness and strength (Applied Technology Council, 2009)
4. Pinching
5. Buckling
6. Axial-flexural-shear interaction

Other effects inherent to a component (e.g., bolt slip, bond slip, gaps, sliding shear) represent inelastic actions as distinct elements (e.g., a nonlinear hinge/spring to model a plastic hinge) using concentrated phenomenological force-deformation relationships. More exact analysis may be performed using distributed plasticity models by subdividing inelastic portions into a number of slices or fibers. This more exact approach is preferable but is more

DRAFT

computationally demanding.

An inelastic three-dimensional analysis is particularly useful for buildings that are prone to torsional response in plan, even where the main seismic force-resisting systems resist loads predominantly in their own plane. If only two-dimensional software is available, a "pseudo" three-dimensional analysis may be performed (Mehrain and Naeim, 2003).

In moment resisting frames, the elastic and inelastic behavior of beam-column joint regions should be modeled explicitly. P-delta effects should be considered explicitly in the analysis with gravity loads applied simultaneously. Nonstructural components also should be included in the model if it is expected that their stiffness and strength have a significant effect on the response (e.g., infill walls).

Nonlinear response history analysis requires that inherent damping be set for the structure. As for linear response history procedure, analysis is typically performed assuming inherent damping of 5 percent of critical. However, the use of 5 percent of critical for inherent damping may be quite unconservative where the model includes significant hysteretic damping elements. Some analysts and designers advocate the use of lower levels of inherent damping (perhaps 2 percent of critical), especially for steel frames, but there is no widespread agreement on this point.

The mechanism used to include inherent damping in the analytical model is critically important to the accuracy of the computed response. Most nonlinear analysis programs use a form of Rayleigh damping, wherein the damping matrix (used for direct integration of the equations of motion) is represented as a linear combination of the mass and stiffness matrices (see Section C16.1.2). If the damping matrix is based on the initial stiffness (elastic) of the system, artificially high damping forces may be generated by system yielding. In some cases, these forces can completely skew the computed response (Chrisp, 1980; Carr, 2004; Charney, 2006; Hall, 2006). One method to counter this occurrence is to base the damping matrix on the mass and the instantaneous tangent stiffness. Where basing the damping on tangent stiffness, care must be taken so that the damping is not negative when the tangent stiffness is negative. Other approaches have been suggested, such as capped Rayleigh damping (Hall, 2006), hysteretic damping (Charney, 2006), or a combination of modal and Rayleigh damping (Powell, 2010).

Three-dimensional analysis must be used where certain horizontal structural irregularities are present. For structures composed of two-dimensional seismic force-resisting elements connected by floor and roof diaphragms, the diaphragms should be modeled as semi-rigid in-plane, particularly where the vertical elements of the seismic force-resisting system are of different types (such as moment frames and walls). Where structures are modeled in three dimensions, axial force-biaxial bending interaction should be considered for corner columns, nonrectangular walls, and other similar elements.

To properly capture the nonlinear dynamic response of structures where vertical dynamic response may have a significant influence on structural performance, it is at times necessary to include vertical mass in the mathematical model even though vertical ground motions are not included in the analysis. Typically the vertical mass is only provided at column nodes although it could be included at all vertical degrees of freedom provided the vertical stiffness of members has been modeled properly. Numerical convergence problems due to large oscillatory vertical accelerations have been noted (NEHRP2010) where base rotations due to wall cracking in fiber wall models is the primary source of vertical excitation. Sensitivity studies should be conducted as discussed in C16.2.1 when vertical mass is included in the mathematical model.

As mentioned above, P-delta effects should be included where significant. The significance of P-delta effects on the overall response may be assessed by performing analyses with and without P-delta effects, and comparing story drift response histories. Destabilizing effects of gravity loads are often manifested by accumulated residual deformations, and these deformations, if not controlled, can lead to dynamic instability of the structure.

C16.2.3 Ground Motion and Other Loading

Since linear superposition cannot be used with nonlinear analysis, each response history analysis must begin with an initial gravity load (sometimes called the initial ramping load), consisting of the expected dead load and live load. The live load may be as little as 25 percent of the unreduced design live load because multiple transient loads are unlikely to attain their maxima simultaneously. When determining behaviors such as uplift or column tension, the value of the 0.25LL should be taken as zero when it results in a larger response of concern, which is consistent with the requirements in Section 2.3.2.

DRAFT

C16.2.4 Response Parameters

As discussed above, the principal aim of nonlinear response history analysis is to determine deformation demands in structural and nonstructural components for comparison with accepted limits. Where at least seven ground motions are used, the member and connection deformations may be taken as the average of the values computed from the analyses. If fewer than seven motions are used, the maximum values among all analyses must be used. It is very important to note, however, that assessment of deformations in this manner should not be done without careful inspection of the story displacement histories of each analysis. It is possible that the maximum displacement or drift may be completely dominated by the response from one ground motion, and such dominance, when due to ratcheting (increasing deformations in one direction resulting in a high residual deformation), may be a sign of imminent dynamic instability. Where these kinds of dynamic instabilities are present, the analyst should attempt to determine the system characteristics that produce such effects. The ground motion that produces dynamic instability should not be replaced with one that does not.

C16.2.4.1 Member Strength

The seismic load effects including overstrength factor of Section 12.4.3 need not be assessed because linear combinations of load are not applicable in nonlinear analysis. Overstrength effects are evaluated directly since hysteretic force-deformation relationships are modeled explicitly and the material properties so used include overstrength and strain hardening (as required by Section 16.2.2).

C16.2.4.2 Member Deformation

This section requires that member and connection deformations be assessed on the basis of tests performed for similar configurations.

C16.2.4.3 Story Drift

The 25 percent increase in allowable story drift is provided because the nonlinear analysis is generally more accurate than linear analysis and because member deformations are assessed explicitly.

C16.2.5 Design Review

As discussed above, nonlinear response history analysis is quite complex, and the results may be strongly influenced by subtle changes in ground motion or system properties. Hence, such analysis must only be conducted by experienced professionals with training in engineering seismology, earthquake engineering, structural dynamics, stability, nonlinear analysis, and inelastic behavior of structures. Regardless of the level of expertise of the individual or individuals who perform the analysis and design, a design (peer) review of the structural system and the nonlinear analysis is required wherever the design is based on the nonlinear response history procedure.

Chapter C17
SEISMIC DESIGN REQUIREMENTS FOR SEISMICALLY ISOLATED STRUCTURES

C17.1 GENERAL

Seismic isolation, commonly referred to as base isolation, is a method used to substantially decouple the response of a structure from potentially damaging earthquake motions. This decoupling can result in response that is reduced significantly from that of a conventional, fixed-base building.

The potential advantages of seismic isolation and the recent advancements in isolation-system technology have led to the design and construction of a large number of seismically isolated buildings and bridges in the United States.

Design requirements for seismically isolated structures were first codified in the United States as an appendix to the 1991 *Uniform Building Code*, based on "General Requirements for the Design and Construction of Seismic-Isolated Structures" developed by the Structural Engineers Association of California State Seismology Committee. In the intervening years, those provisions have developed along two parallel tracks into the design requirements in Chapter 17 of the standard and the rehabilitation requirements in Section 9.2 of ASCE/SEI 41, *Seismic Rehabilitation of Existing Buildings*. The design and analysis methods of both standards are quite similar, but ASCE/SEI 41 permits more liberal design for the superstructure of rehabilitated buildings. The AASHTO (1999) *Guide Specification for Seismic Isolation Design* provides a systematic approach to determining bounding values of mechanical properties of isolators for analysis and design. Rather than addressing a specific method of seismic isolation, the standard provides general design requirements applicable to a wide range of possible seismic isolation systems. Because the design requirements are general, testing of isolation-system hardware is required to confirm the engineering parameters used in the design and to verify the overall adequacy of the isolation system. Use of isolation systems whose adequacy is not proved by testing is prohibited. In general, acceptable systems: (a) remain stable when subjected to design displacements, (b) provide increasing resistance with increasing displacement, (c) do not degrade under repeated cyclic load, and (d) have quantifiable engineering parameters (such as force-deflection characteristics and damping).

The force-deflection behavior of isolation systems falls into four categories, as shown in Figure C17.1-1, where each idealized curve has the same design displacement, D_D. A linear isolation system (Curve A) has an effective period independent of displacement, and the force generated in the superstructure is directly proportional to the displacement of the isolation system.

DRAFT

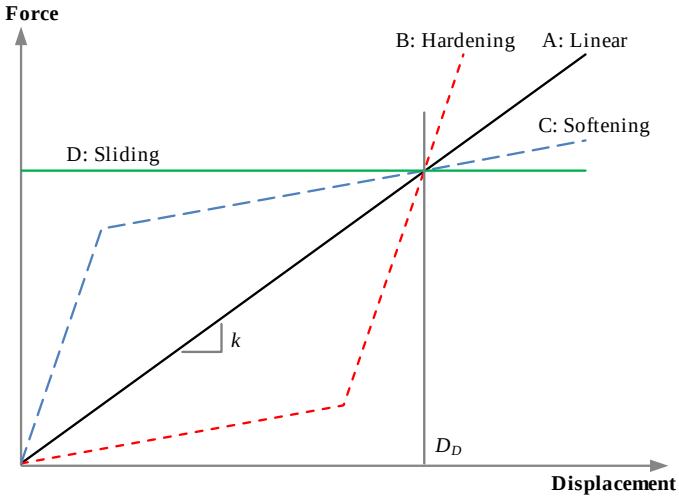

Figure C17.1- 1 Idealized force-deflection relationships for isolation systems(stiffness effects of sacrificial wind-restraint systems not shown for clarity).

A hardening isolation system (Curve B) is soft initially (long effective period) and then stiffens (effective period shortens) as displacement increases. Where displacements exceed the design displacement, the superstructure is subjected to larger forces and the isolation system to smaller displacements than for a comparable linear system.

A softening isolation system (Curve C) is stiff initially (short effective period) and then softens (effective period lengthens) as displacement increases. Where displacements exceed the design displacement, the superstructure is subjected to smaller forces and the isolation system to larger displacements than for a comparable linear system.

The response of a purely sliding isolation system (Curve D) is governed by the friction force at the sliding interface. For increasing displacement, the effective period lengthens, and loads on the superstructure remain constant. For isolation systems governed solely by friction forces, the total displacement due to repeated earthquake cycles is highly dependent on the characteristics of the ground motion and may exceed the design displacement, D_D. Since such systems do not have increasing resistance with increasing displacement, the procedures of the standard cannot be applied, and use of the system is prohibited.

Chapter 17 provides isolator design displacements, shear forces for structural design, and other specific requirements for seismically isolated structures. All other design requirements, including loads (other than seismic), load combinations, allowable forces and stresses, and horizontal shear distribution, are the same as those for conventional, fixed-base structures.

C17.1.1 Variations in Material Properties

For analysis, the mechanical properties of seismic isolators generally are based on values provided by isolator manufacturers. Values of these properties should be in the range that accounts for natural variability and uncertainty, and variability of properties among isolator of different manufacturers. Examples may be found in Constantinou et al. (2007). Prototype testing is used to confirm the values assumed for design. Unlike conventional materials whose properties do not vary substantially with time, the materials used in seismic isolators have properties that generally will vary with time. Because mechanical properties can vary over the life of a structure and the testing protocol of Section 17.8 cannot account for the effects of aging, contamination, scragging (temporary degradation of mechanical properties with repeated cycling), temperature, velocity effects, and wear, the designer must account for these effects by explicit analysis. One approach to accommodate these effects, introduced in Constantinou et al. (1999), is to use property modification factors. Information on variations in material properties of seismic isolators and dampers is reported in Constantinou et al. (2007).

DRAFT

C17.2 GENERAL DESIGN REQUIREMENTS

Ideally, most of the lateral displacement of an isolated structure will be accommodated by deformation of the isolation system rather than distortion of the structure above. Accordingly, the seismic-force-resisting system of the structure above the isolation system is designed to have sufficient stiffness and strength to avoid large, inelastic displacements. Therefore, the standard contains criteria that limit the inelastic response of the structure above the isolation system. Although damage control is not an explicit objective of the standard, design to limit inelastic response of the structural system also will reduce the level of damage that would otherwise occur during an earthquake. In general, isolated structures designed in accordance with the standard are expected:

1. To resist minor and moderate levels of earthquake ground motion without damage to structural elements, nonstructural components, or building contents and
2. To resist major levels of earthquake ground motion without failure of the isolation system, significant damage to structural elements, extensive damage to nonstructural components, or major disruption to facility function.

Isolated structures are expected to perform much better than fixed-base structures during moderate and major earthquakes. Table C17.2-1 compares the performance expected for isolated and fixed-base structures designed in accordance with the standard.

Table C17.2-1 Performance Expected for Minor, Moderate, and Major Earthquakes[a]

Performance Measure	Earthquake Ground Motion Level		
	Minor	Moderate	Major
Life safety: loss of life or serious injury is not expected	F, I	F, I	F, I
Structural damage: significant structural damage is not expected	F, I	F, I	I
Nonstructural damage: significant nonstructural or contents damage is not expected	F, I	I	I

[a] F indicates fixed base; I indicates isolated.

Loss of function is not included in Table C17.2-1. For certain fixed-base facilities, loss of function would not be expected unless there is significant structural damage causing closure or restricted access to the building. In other cases, a facility with only limited or no structural damage would not be functional as a result of damage to vital nonstructural components or contents. Isolation would be expected to mitigate structural and nonstructural damage and to protect the facility against loss of function.

C17.2.4 Isolation System

C17.2.4.1 Environmental Conditions

Environmental conditions that may adversely affect isolation system performance must be investigated thoroughly. Related research has been conducted since the 1970s in Europe, Japan, New Zealand, and the United States.

C17.2.4.2 Wind Forces

Lateral displacement over the depth of the isolator zone resulting from wind loads must be limited to a value similar to that required for other story heights.

C17.2.4.3 Fire Resistance

Where fire may adversely affect the lateral performance of the isolation system, the system must be protected so as to maintain the gravity-load resistance required for the other elements of the structure supported by the isolation system.

C17.2.4.4 Lateral Restoring Force

The restoring-force requirement is intended to limit residual displacement as a result of an earthquake, so that the isolated structure will survive aftershocks and future earthquakes.

DRAFT

C17.2.4.5 Displacement Restraint

The use of a displacement restraint is discouraged. Where a displacement restraint system is used, explicit analysis of the isolated structure for maximum considered earthquake response is required to account for the effects of engaging the displacement restraint.

C17.2.4.6 Vertical-load Stability

The vertical loads to be used in checking the stability of any given isolator should be calculated using bounding values of dead load and live load and the peak earthquake demand of the maximum considered earthquake. Since earthquake loads are reversible in nature, peak earthquake load should be combined with bounding values of dead and live load in a manner which produces both the maximum downward force and the maximum upward force on any isolator. Stability of each isolator should be verified for these two extreme values of vertical load at peak maximum considered earthquake displacement of the isolation system. In addition, all elements of the isolation system need testing or equivalent actions that demonstrate they are stable for the MCE_R ground motion levels. This stability can be demonstrated by performing a nonlinear static analysis for a MCE_R response displacement of the entire structural system, including the isolation system, and showing that stability is maintained. Alternatively, this stability can be demonstrated by performing a nonlinear dynamic analysis for the MCE_R motions using the same inelastic reductions for the Design Earthquake and acceptable capacities except that member and connection strengths can be taken as their nominal strengths with phi factors taken as 1.0.

C17.2.4.7 Overturning

The intent of this requirement is to prevent both global structural overturning and overstress of elements due to local uplift. Isolator uplift is acceptable so long as the isolation system does not disengage from its horizontal-resisting connection detail. The connection details used in some isolation systems are such that tension is not permitted on the system. Where the tension capacity of an isolator is used to resist uplift forces, design and testing in accordance with Sections 17.2.4.6 and 17.8.2.5 must be performed to demonstrate the adequacy of the system to resist tension forces at the total maximum displacement.

C17.2.4.8 Inspection and Replacement

Although most isolation systems will not need to be replaced after an earthquake, access for inspection and replacement must be provided, and periodic inspection is required. After an earthquake, the isolation system should be inspected and any damaged elements replaced or repaired.

C17.2.4.9 Quality Control

A testing and inspection program is necessary for both fabrication and installation of the isolator units. Because seismic isolation is a rapidly evolving technology, it may be difficult to reference standards for testing and inspection. Reference can be made to standards for some materials, such as elastomeric bearings (ASTM D 4014). Similar standards are yet to be developed for other isolation systems. Special inspection procedures and load testing to verify manufacturing quality must be developed for each project. The requirements will vary depending on the type of isolation system used.

C17.2.5 Structural System

C17.2.5.2 Building Separations

A minimum separation between the isolated structure and rigid obstructions is required to allow free movement of the superstructure in all lateral directions during an earthquake.

C17.2.6 Elements of Structures and Nonstructural Components

To accommodate the differential movement between the isolated building and the ground, flexible utility connections are required. In addition, stiff elements crossing the isolation interface (such as stairs, elevator shafts, and walls) must be detailed to accommodate the total maximum displacement without compromising life safety.

C17.3 GROUND MOTION FOR ISOLATED STRUCTURES

C17.3.1 Design Spectra

Seismically isolated structures located on Site Class F sites and on sites with $S_1 \geq 0.6$ must be analyzed using response history analysis. For those cases, the response spectra must be site-specific in order to account, in the analysis, for near-fault effects and for soft soil conditions, both of which are known to be important in the assessment of displacement demands in seismically isolated structures.

DRAFT

C17.3.2 Ground Motion Histories

The selection and scaling of ground motions for response history analysis requires fitting to the response spectra in the period range of $0.5T_D$ to $1.25T_M$, a range that is different from that for conventional structures $0.2T$ to $1.5T$. The following sections provide background on the two period ranges:

1. Period Range – Isolated Structures. The effective (fundamental) period of an isolated structure is based on amplitude-dependent, nonlinear (pushover) stiffness properties of the isolation system. The effective periods, T_D and T_M, correspond to design earthquake displacement and maximum considered earthquake displacement, respectively, in the direction under consideration. Values of effective (fundamental) periods, T_D and T_M, are typically in the range of 2 to 4 seconds, and the value of the effective period, T_D, typically is 15 to 25 percent less than the corresponding value of effective period, T_M.

   The response of an isolated structure is dominated by the fundamental mode in the direction of interest. The specified period range, $0.5T_D$ to $1.25T_M$, conservatively bounds amplitude-dependent values of the effective (fundamental) period of the isolated structure in the direction of interest, considering that individual earthquake records can affect response at effective periods somewhat longer than T_M, or significantly shorter than T_D.

2. Period Range – Conventional, Fixed-Base Structures. The fundamental period, T, of a conventional, fixed-base structure is based on amplitude-independent, linear-elastic stiffness properties of the structure. In general, response of conventional, fixed-base structures is influenced by both the fundamental mode and higher modes in the direction under consideration. The period range, $0.2T$ to $1.5T$, is intended to bound the fundamental period, considering some period lengthening due to nonlinear response of the structure (that is, inelastic periods up to $1.5T$) and periods corresponding to the more significant higher modes (that is, second and possibly third modes in the direction of interest).

C17.4 ANALYSIS PROCEDURE SELECTION

Three different analysis procedures are available for determining design-level seismic loads: the equivalent lateral force procedure, the response spectrum procedure, and the response history procedure. For the first procedure simple, lateral-force formulas (similar to those for conventional, fixed-base structures) are used to determine peak lateral displacement and design forces as a function of spectral acceleration and isolated-structure period and damping. For the second and third procedures, which are required for geometrically complex or especially flexible buildings, dynamic analysis (either the response spectrum procedure or the response history procedure) is used to determine peak response of the isolated structure.

The three procedures are based on the same level of seismic input and require a similar level of performance from the building. Where more complex analysis procedures are used, slightly lower design forces and displacements are permitted. The design requirements for the structural system are based on the design earthquake, taken as two-thirds of the maximum considered earthquake. The isolation system—including all connections, supporting structural elements, and the "gap"—is required to be designed (and tested) for 100 percent of maximum considered earthquake demand. Structural elements above the isolation system are not required to be designed for the full effects of the design earthquake but may be designed for slightly reduced loads (that is, loads reduced by a factor of up to 2) if the structural system is able to respond inelastically without sustaining significant damage. A similar fixed-base structure would be designed for loads reduced by a factor of 8 rather than 2.

This section delineates the requirements for the use of the equivalent lateral force procedure and dynamic methods of analysis. The limitations on the simplified lateral-force design procedure are quite restrictive. Limitations relate to the site location with respect to major, active faults; soil conditions of the site; the height, regularity, and stiffness characteristics of the building; and selected characteristics of the isolation system. Response-history analysis is required to determine the design displacement of the isolation system (and the structure above) for the following isolated structures:

1. Isolated structures with a "nonlinear" isolation system including, but not limited to, isolation systems with effective damping values greater than 30 percent of critical, isolation systems incapable of producing a significant restoring force, and isolation systems that restrain or limit extreme earthquake displacement; and

2. Isolated structures located on a Class E or Class F site (that is, a soft soil site that amplifies long-period ground motions).

DRAFT

Lower-bound limits on isolation system design displacements and structural-design forces are specified by the standard in Section 17.6 as a percentage of the values prescribed by the equivalent lateral force procedure, even where dynamic analysis is used as the basis for design. These lower-bound limits on key design parameters provide consistency in the design of isolated structures and serve as a "safety net" against gross underdesign. Table C17.4-1 provides a summary of the lower-bound limits on dynamic analysis specified by the standard.

C17.5 EQUIVALENT LATERAL FORCE PROCEDURE

C17.5.3 Minimum Lateral Displacements

The lateral displacement given by Equation 17.5-1 approximates peak design earthquake displacement of a single-degree-of-freedom, linear-elastic system of period, T_D, and effective damping, β_D. Similarly, the lateral displacement given by Equation 17.5-3 approximates peak maximum considered earthquake displacement of a single-degree-of-freedom, linear-elastic system of period, T_M, and effective damping, β_M.

Table C17.4-1 Lower-Bound Limits on Dynamic Procedures Specified in Relation to ELF Procedure Requirements

Design Parameter	ELF Procedure	Dynamic Procedure	
		Response Spectrum	Response History
Design displacement – D_D	$D_D = (g/4\pi^2)(S_{D1}T_D/B_D)$	—	—
Total design displacement - D_{TD}	$D_{TD} \geq 1.1D_D$	$\geq 0.9D_{TD}$	$\geq 0.9D_{TD}$
Maximum displacement – D_M	$D_M = (g/4\pi^2)(S_{M1}T_M/B_M)$	—	—
Total maximum displacement - D_{TM}	$D_{TM} \geq 1.1D_M$	$\geq 0.8D_{TM}$	$\geq 0.8D_{TM}$
Design shear – V_b (at or below the isolation system)	$V_b = k_{Dmax}D_D$	$\geq 0.9V_b$	$\geq 0.9V_b$
Design shear – V_s ("regular" superstructure)	$V_s = k_{Dmax}D_D/R_I$	$\geq 0.8V_s$	$\geq 0.6V_s$
Design shear – V_s ("irregular" superstructure)	$V_s = k_{Dmax}D_D/R_I$	$\geq 1.0V_s$	$\geq 0.8V_s$
Drift (calculated using R_I for C_d)	$0.015h_{sx}$	$0.015h_{sx}$	$0.020h_{sx}$

Equation 17.5-1 is an estimate of peak displacement in the isolation system for the design earthquake. In this equation, the spectral acceleration term, S_{D1}, is the same as that required for design of a conventional, fixed-base structure of period, T_D. A damping term, B_D, is used to decrease (or increase) the computed displacement where the effective damping coefficient of the isolation system is greater (or smaller) than 5 percent of critical damping. Values of coefficient B_D (or B_M for the maximum considered earthquake) are given in Table 17.5-1 for different values of isolation system damping, β_D (or β_M).

A comparison of values obtained from Equation 17.5-1 and those obtained from nonlinear time-history analyses are given in Kircher et al. (1988) and Constantinou et al. (1993).

Consideration should be given to possible differences in the properties used for design of the isolation system and those of the isolation system as installed in the structure. Similarly, consideration should be given to possible changes in isolation system properties due to different design conditions or load combinations. If the true deformational characteristics of the isolation system are not stable or if they vary with the nature of the load (being rate-, amplitude-, or time-dependent), the design displacements should be based on deformational characteristics of

DRAFT

the isolation system that give the largest possible deflection (k_{Dmin}), the design forces should be based on deformational characteristics of the isolation system that give the largest possible force (k_{Dmax}), and the damping level used to determine design displacements and forces should be based on deformational characteristics of the isolation system that represent the minimum amount of energy dissipated during cyclic response at the design level.

The isolation system for a seismically isolated structure should be configured to minimize eccentricity between the center of mass of the superstructure and the center of rigidity of the isolation system. In this way, the effect of torsion on the displacement of isolation elements will be reduced. As for conventional structures, allowance must be made for accidental eccentricity in both horizontal directions. Figure C17.5-1 illustrates the terminology used in the standard. Equation 17.5-5 (or Equation 17.5-6 for the maximum considered earthquake) provides a simplified formula for estimating the response due to torsion in lieu of a more refined analysis. The additional component of displacement due to torsion increases the design displacement at the corner of a structure by about 15 percent (for one perfectly square in plan) to about 30 percent (for one very long and rectangular in plan) if the eccentricity is 5 percent of the maximum plan dimension. These calculated torsional displacements are for structures with an isolation system whose stiffness is uniformly distributed in plan. Isolation systems that have stiffness concentrated toward the perimeter of the structure, or certain sliding systems that minimize the effects of mass eccentricity, will have smaller torsional displacements. The standard permits values of D_{TD} as small as $1.1D_D$, with proper justification.

DRAFT

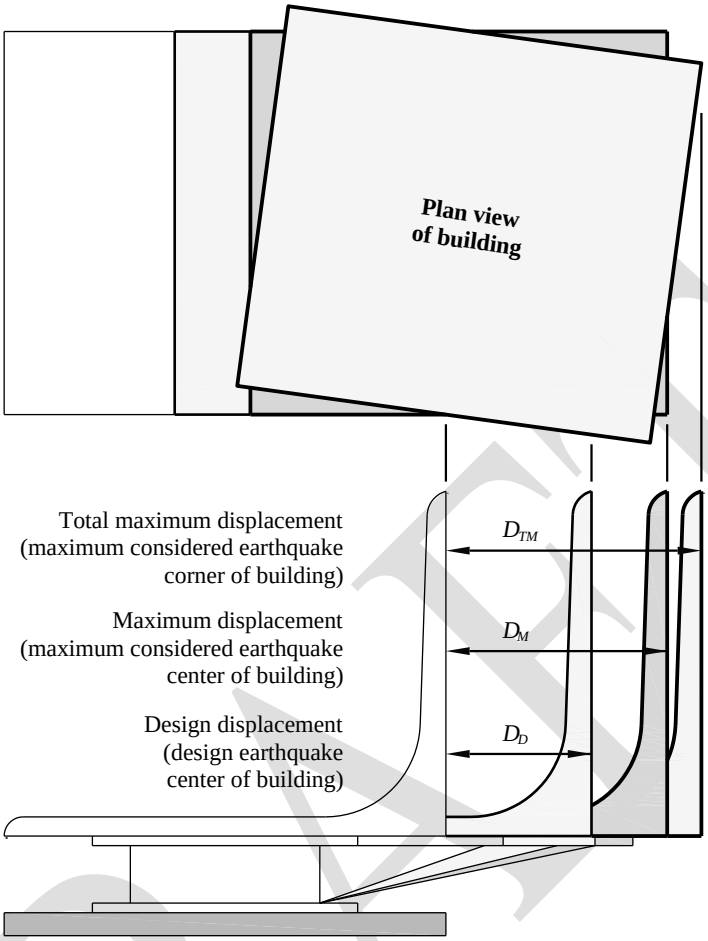

Figure C17.5- 1 Displacement terminology.

C17.5.4 Minimum Lateral Forces

Figure C17.5-2 illustrates the terminology for elements at, below, and above the isolation system. Equation 17.5-7 specifies the peak seismic shear for design of all structural elements at or below the isolation system (without reduction for ductile response). Equation 17.5-8 specifies the peak seismic shear for design of structural elements above the isolation system. For structures that have appreciable inelastic-deformation capability, this equation includes an effective reduction factor of up to 2 for response beyond the strength-design level.

The reduction factor is based on use of strength-design procedures. A factor of at least 2 is assumed to exist between the design-force level and the true-yield level of the structural system. An investigation of 10 specific buildings indicated that this factor varied between 2 and 5 (ATC, 1982). Thus, a reduction factor of 2 is appropriate to produce a structural system that remains essentially elastic for the design earthquake.

In Section 17.5.4.3, the limits given on V_S provide at least a factor of 1.5 between the nominal yield level of the superstructure and (a) the yield level of the isolation system, (b) the ultimate capacity of a sacrificial wind-restraint system that is intended to fail and release the superstructure during significant lateral load, or (c) the break-away friction level of a sliding system.

These limits are needed so that the superstructure will not yield prematurely before the isolation system has been activated and significantly displaced.

DRAFT

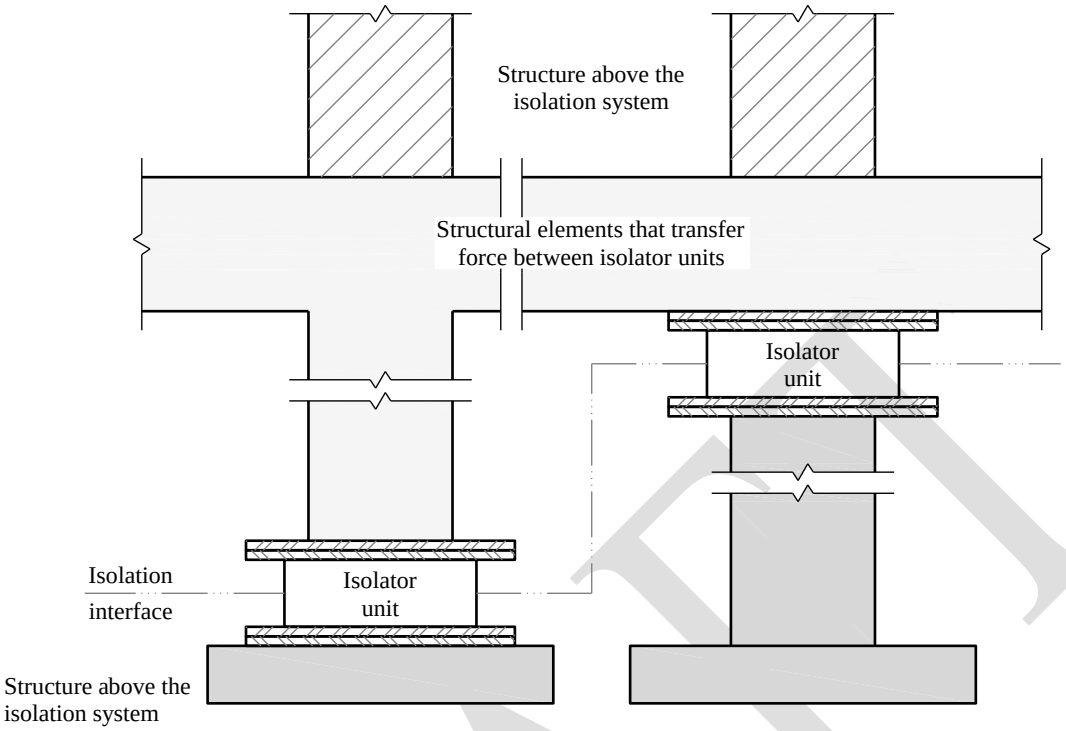

Figure C17.5- 2 Isolation system terminology.

The design shear force, V_S, specified in this section results in an isolated structural system being subjected to significantly lower inelastic demands than a conventionally designed structural system. Further reduction in V_S, such that the inelastic demand on a seismically isolated structure would be the same as the inelastic demand on a conventionally designed structure, was not considered during development of these requirements but may be considered in the future.

Using a smaller value of R_I in Equation 17.5-8 will reduce or eliminate inelastic response of the superstructure for the design-basis event, thus further improving the structural performance.

C17.5.5 Vertical Distribution of Forces

Equation 17.5-9 produces a vertical distribution of lateral forces consistent with a triangular profile of seismic acceleration over the height of the structure above the isolation interface. Kircher et al. (1988) and Constantinou et al. (1993) show that Equation 17.5-9 provides a conservative estimate of the distributions obtained from more detailed, nonlinear analysis studies for the type of structures for which use of Equation 17.5-9 is allowed.

C17.5.6 Drift Limits

The maximum story drift permitted for design of isolated structures is constant for all Risk Categories, as shown in Table C17.5-1. For comparison, the drift limits prescribed by the standard for fixed-base structures also are summarized in that table.

DRAFT

Table C17.5-1 Comparison of Drift Limits for Fixed-Base and Isolated Structures

Structure	Risk Category	Fixed-Base	Isolated
Buildings (other than masonry) four stories or less in height with component drift design	I or II	$0.025h_{sx}/(C_d/R)$	$0.015h_{sx}$
	III	$0.020h_{sx}/(C_d/R)$	$0.015h_{sx}$
	IV	$0.015h_{sx}/(C_d/R)$	$0.015h_{sx}$
Other (non-masonry) buildings	I or II	$0.020h_{sx}/(C_d/R)$	$0.015h_{sx}$
	III	$0.015h_{sx}/(C_d/R)$	$0.015h_{sx}$
	IV	$0.010h_{sx}/(C_d/R)$	$0.015h_{sx}$

Drift limits in Table C17.5-1 are divided by C_d/R for fixed-base structures since displacements calculated for lateral loads reduced by R are multiplied by C_d before checking drift. The C_d term is used throughout the standard for fixed-base structures to approximate the ratio of actual earthquake response to response calculated for "reduced" forces. Generally, C_d is 1/2 to 4/5 the value of R. For isolated structures, the R_I factor is used both to reduce lateral loads and to increase displacements (calculated for reduced lateral loads) before checking drift. Equivalency would be obtained if the drift limits for both fixed-base and isolated structures were based on their respective R factors. It may be noted that the drift limits for isolated structures generally are more conservative than those for conventional, fixed-base structures, even where fixed-base structures are assigned to Risk Category IV.

C17.6 DYNAMIC ANALYSIS PROCEDURES

This section specifies the requirements and limits for dynamic procedures. The design displacement and force limits on response spectrum and response history procedures are shown in Table C17.4-1.

A more detailed or refined study can be performed in accordance with the analysis procedures described in this section. The intent of this section is to provide procedures that are compatible with the minimum requirements of Section 17.5. Reasons for performing a more refined study include:

1. The importance of the building.
2. The need to analyze possible structure/isolation-system interaction where the fixed-base period of the building is greater than one-third of the isolated period.
3. The need to explicitly model the deformational characteristics of the lateral-force-resisting system where the structure above the isolation system is irregular.
4. The desirability of using site-specific ground-motion data, especially for very soft or liquefiable soils (Site Class F) or for structures located where S_1 is greater than 0.60.
5. The desirability of explicitly modeling the deformational characteristics of the isolation system. This is especially important for systems that have damping characteristics that are amplitude-dependent, rather than velocity-dependent, since it is difficult to determine an appropriate value of equivalent viscous damping for these systems.

Section C17.4 discusses other conditions that require use of the response history procedure. As shown in Table C17.4-1, the drift limit for isolated structures is relaxed where story drifts are computed using nonlinear response history analysis.

Where response history analysis is used as the basis for design, the design displacement of the isolation system and design forces in elements of the structure above are computed from not fewer than three separate analyses, each using a different ground motion selected and scaled in accordance with Section 17.3.2. Where the configuration of the isolation system or of the superstructure is not symmetric, additional analyses are required to satisfy the requirement of Section 17.6.3.4 to consider the most disadvantageous location of eccentric mass. As appropriate, near-field phenomena may also be incorporated. As in the nuclear industry, where at least seven ground motions are

DRAFT

used for nonlinear response history analysis, it is considered appropriate to base design of seismically isolated structures on the average value of the response parameters of interest.

C17.7 DESIGN REVIEW

Review of the design and analysis of the isolation system and design review of the isolator testing program is mandated by the standard for two key reasons:

1. The consequences of isolator failure could be catastrophic.
2. Isolator design and fabrication technology is evolving rapidly and may be based on technologies unfamiliar to many design professionals.

The standard requires review to be performed by registered design professionals who are independent of the design team and other project contractors. The review team should include individuals with special expertise in one or more aspects of the design, analysis, and implementation of seismic isolation systems.

The review team should be formed prior to the development of design criteria (including site-specific ground shaking criteria) and isolation system design options. Further, the review team should have full access to all pertinent information and the cooperation of the design team and regulatory agencies involved with the project.

C17.8 TESTING

The design displacements and forces determined using the standard assume that the deformational characteristics of the isolation system have been defined previously by comprehensive testing. If comprehensive test data are not available for a system, major design alterations in the structure may be necessary after the tests are complete. This would result from variations in the isolation-system properties assumed for design and those obtained by test. Therefore, it is advisable that prototype systems be tested during the early phases of design, if sufficient test data are not available on an isolation system.

Typical force-deflection (or hysteresis) loops are shown in Figure C17.8-1; also illustrated are the values defined in Section 17.8.5.1.

DRAFT

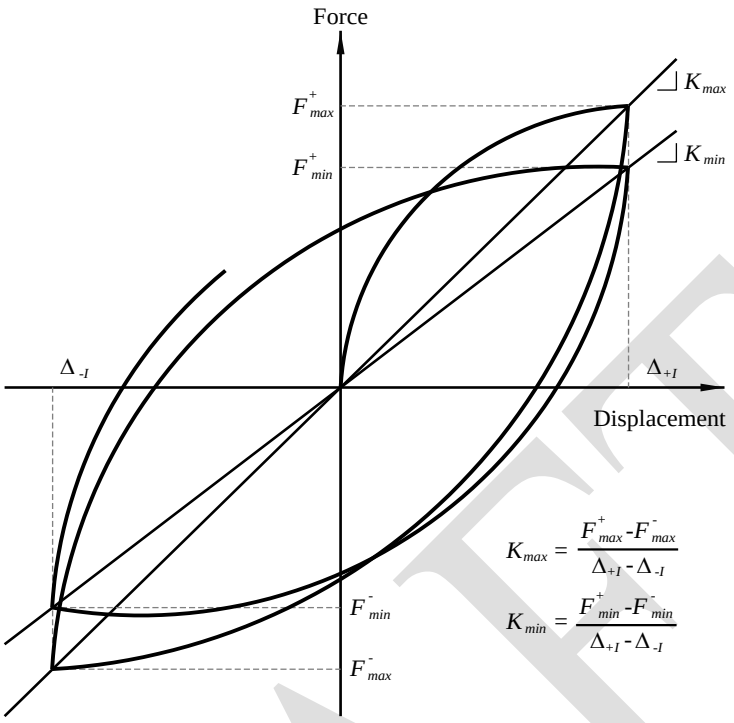

Figure C17.8- 1 The effect of stiffness on an isolation bearing.

The required sequence of tests will verify experimentally the following:

1. The assumed stiffness and capacity of the wind-restraining mechanism;
2. The variation of the isolator's deformational characteristics with amplitude (and with vertical load, if it is a vertical load-carrying member);
3. The variation of the isolator's deformational characteristics for a realistic number of cycles of loading at the design displacement; and
4. The ability of the system to carry its maximum and minimum vertical loads at the maximum displacement.

Force-deflection tests are not required if similarly sized components have been tested previously using the specified sequence of tests.

The variations in the vertical loads required for tests of isolators which carry vertical, as well as lateral, load are necessary to determine possible variations in the system properties with variations in overturning force.

C17.8.5 Design Properties of the Isolation System

C17.8.5.1 Maximum and Minimum Effective Stiffness

The effective stiffness is determined from the hysteresis loops as shown in Figure C17.8-1. Stiffness may vary considerably as the test amplitude increases but should be reasonably stable (within 15 percent) for more than three cycles at a given amplitude.

The intent of these requirements is that the deformational properties used in design result in the maximum design forces and displacements. For determining design displacement, this means using the smallest damping and effective stiffness values. For determining design forces, this means using the smallest damping value and the largest stiffness value.

DRAFT

C17.8.5.2 Effective Damping

The determination of effective damping is reasonably reliable for systems whose damping characteristics are velocity dependent. For systems that have amplitude-dependent energy-dissipating mechanisms, significant problems arise in determining an effective damping value. Since it is difficult to relate velocity- and amplitude-dependent phenomena, it is recommended that where the effective damping assumed for the design of amplitude-dependent energy-dissipating mechanisms (such as pure-sliding systems) is greater than 30 percent, the design-basis force and displacement be determined using the response history procedure, as discussed in Section C17.4.

DRAFT

Chapter C18
SEISMIC DESIGN REQUIREMENTS FOR STRUCTURES WITH DAMPING SYSTEMS

C18.1 GENERAL

The requirements of this chapter apply to all types of damping systems including both displacement-dependent damping devices of hysteretic or friction systems and velocity-dependent damping devices of viscous or visco-elastic systems (Soong and Dargush, 1997; Constantinou et al., 1998; Hanson and Soong, 2001). Compliance with these requirements is intended to produce performance comparable to that for a structure with a conventional seismic-force-resisting system, but the same methods can be used to achieve higher performance.

The damping system (DS) is defined separately from the seismic-force-resisting system (SFRS), although the two systems may have common elements. As illustrated in Figure C18.1-1, the damping system may be external or internal to the structure and may have no shared elements, some shared elements, or all elements in common with the seismic-force-resisting system. Elements common to the damping system and the seismic-force-resisting system must be designed for a combination of the two loads of the two systems. When the DS and SFRS have no common elements, the damper forces must be collected and transferred to members of the SFRS.

C18.2 GENERAL DESIGN REQUIREMENTS

C18.2.2 System Requirements

Structures with a damping system must have a seismic-force-resisting system that provides a complete load path. The seismic-force-resisting system must comply with all of the height, Seismic Design Category, and redundancy limitations and with the detailing requirements specified in this standard for the specific seismic-force-resisting system. The seismic-force-resisting system without the damping system (as if damping devices were disconnected) must be designed to have not less than 75 percent of the strength required for undamped structures having that type of seismic-force-resisting system (and not less than 100 percent if the structure is horizontally or vertically irregular). The damping systems, however, may be used to meet the drift limits (whether the structure is regular or irregular). Having the SFRS designed for a minimum of 75 percent of the strength required for undamped structures provides safety in the event of damping system malfunction and produces a composite system with sufficient stiffness and strength to have controlled lateral displacement response.

The damping system must be designed for the actual (unreduced) earthquake forces (such as, peak force occurring in damping devices) and deflections. For certain elements of the damping system (such as the connections or the members into which the damping devices frame), other than damping devices, limited yielding is permitted provided such behavior does not affect damping system function or exceed the amount permitted for elements of conventional structures by the standard.

C18.2.4 Procedure Selection

Linear static and response spectrum analysis methods can be used for design of structures with damping systems that meet certain configuration and other limiting criteria (for example, at least two damping devices at each story configured to resist torsion). In such cases, additional nonlinear response history analysis shall be used to confirm peak responses when the structure is located at a site with S_1 greater than or equal to 0.6. The analysis methods damperd structures are based on nonlinear static "pushover" characterization of the structure and calculation of peak response using effective (secant) stiffness and effective damping properties of the first (pushover) mode in the direction of interest. These are the concepts used in Chapter 17 to characterize the force-deflection properties of isolation systems, modified to incorporate explicitly the effects of ductility demand (post-yield response) and higher-mode response of structures with dampers. Like conventional structures, damped structures generally yield during strong ground shaking, and their performance can be influenced strongly by response of higher modes.

The response spectrum and equivalent lateral force procedures presented in the standard have several simplifications and limits, as outlined below:

1. A multi-degree-of-freedom (MDOF) structure with a damping system can be transformed into equivalent single-degree-of-freedom (SDOF) systems using modal decomposition procedures. This assumes that the

collapse mechanism for the structure is a single-degree-of-freedom mechanism so that the drift distribution over height can be estimated reasonably using either the first mode shape or another profile, such as an inverted triangle. Such procedures do not strictly apply to either yielding buildings or buildings that are non-proportionally damped.

2. The response of an inelastic single-degree-of-freedom system can be estimated using equivalent linear properties and a 5-percent-damped response spectrum. Spectra for damping greater than 5 percent can be established using damping coefficients, and velocity-dependent forces can be established either by using the pseudo-velocity and modal information or by applying correction factors to the pseudo-velocity.
3. The nonlinear response of the structure can be represented by a bilinear hysteretic relationship with zero post-elastic stiffness (elasto-plastic behavior).
4. The yield strength of the structure can be estimated either by performing simple plastic analysis or by using the specified minimum seismic base shear and values of R, Ω_0, and C_d.
5. Higher modes need to be considered in the equivalent lateral force procedure in order to capture their effects on velocity-dependent forces. This is reflected in the residual mode procedure.

DRAFT

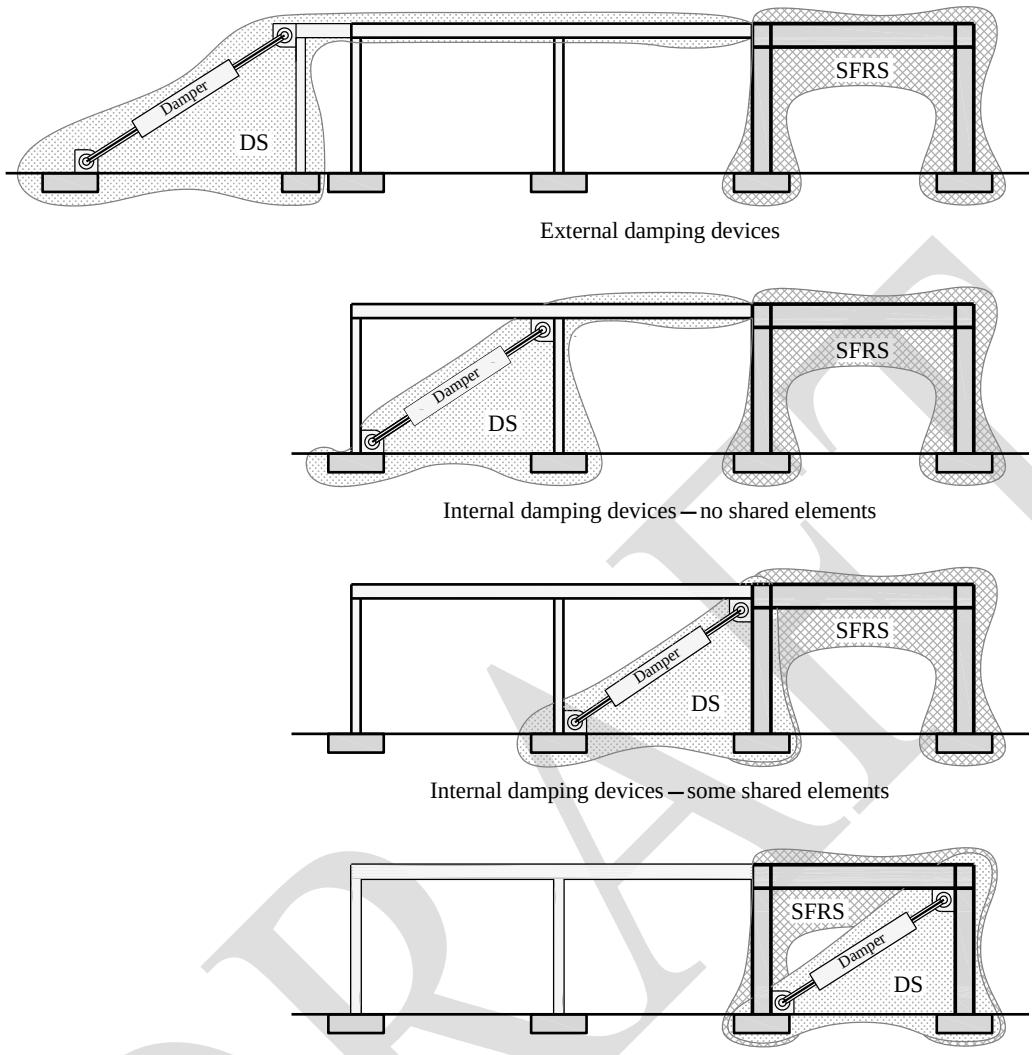

Figure C18.1- 1 Damping system (DS) and seismic-force-resisting system (SFRS) configurations.

FEMA 440 (Applied Technology Council, 2005) presents a review of simplified procedures for the analysis of yielding structures. The combined effects of the simplifications mentioned above are reported by Ramirez et al. (2001) and Pavlou and Constantinou (2004) based on studies of 3-story and 6-story buildings with damping systems designed by the procedures of the standard. The response spectrum and equivalent lateral force procedures of the standard are found to provide conservative predictions of drift and predictions of damper forces and member actions that are of acceptable accuracy when compared to results of nonlinear dynamic response history analysis. When designed in accordance with the standard, structures with damping systems are expected to have structural performance at least as good as that of structures without damping systems. Pavlou and Constantinou (2006) report that structures with damping systems designed in accordance with the standard provide the benefit of reduced secondary system response, although this benefit is restricted to systems with added viscous damping.

C18.3 NONLINEAR PROCEDURES

For designs in which the seismic-force-resisting-system is essentially elastic (assuming an overstrength of 50 percent), the only nonlinear characteristics that must be modeled in the analysis are those of the damping devices.

For designs in which the seismic-force-resisting system will yield, the post-yield behavior of the structural elements must be modeled explicitly.

C18.4 RESPONSE SPECTRUM PROCEDURES and C18.5 EQUIVALENT LATERAL FORCE PROCEDURE

Effective Damping

In the standard the reduced response of a structure with a damping system is characterized by the damping coefficient, B, based on the effective damping, β, of the mode of interest. This is the same approach as that used for isolated structures. Like isolation, effective damping of the fundamental-mode of a damped structure is based on the nonlinear force-deflection properties of the structure. For use with linear analysis methods, nonlinear properties of the structure are inferred from the overstrength factor, Ω_0, and other terms.

Figure C18.4-1 illustrates reduction in design earthquake response of the fundamental mode due to increased effective damping (represented by coefficient, B_{1D}). The capacity curve is a plot of the nonlinear behavior of the fundamental mode in spectral acceleration-displacement coordinates. The reduction due to damping is applied at the effective period of the fundamental mode of vibration (based on the secant stiffness).

In general, effective damping is a combination of three components:

1. Inherent Damping (β_I)—Inherent damping of the structure at or just below yield, excluding added viscous damping (typically assumed to be 5 percent of critical for structural systems without dampers).
2. Hysteretic Damping (β_H)—Post-yield hysteretic damping of the seismic-force-resisting system and elements of the damping system at the amplitude of interest (taken as 0 percent of critical at or below yield).
3. Added Viscous Damping (β_V)—Viscous component of the damping system (taken as 0 percent for hysteretic or friction-based damping systems).

Both hysteretic damping and added viscous damping are amplitude-dependent, and the relative contributions to total effective damping change with the amount of post-yield response of the structure. For example, adding dampers to a structure decreases post-yield displacement of the structure and, hence, decreases the amount of hysteretic damping provided by the seismic-force-resisting system. If the displacements are reduced to the point of yield, the hysteretic component of effective damping is zero, and the effective damping is equal to inherent damping plus added viscous damping. If there is no damping system (as in a conventional structure), effective damping simply equals inherent damping (typically assumed to be 5 percent of critical for most conventional structures).

Linear Analysis Methods

The section specifies design earthquake displacements, velocities, and forces in terms of design earthquake spectral acceleration and modal properties. For equivalent lateral force (ELF) analysis, response is defined by two modes: the fundamental mode and the residual mode. The residual mode is a new concept used to approximate the combined effects of higher modes. While typically of secondary importance to story drift, higher modes can be a significant contributor to story velocity and, hence, are important for design of velocity-dependent damping devices. For response spectrum analysis, higher modes are explicitly evaluated.

For both the ELF and the response spectrum analysis procedures, response in the fundamental mode in the direction of interest is based on assumed nonlinear (pushover) properties of the structure. Nonlinear (pushover) properties, expressed in terms of base shear and roof displacement, are related to building capacity, expressed in terms of spectral coordinates, using mass participation and other fundamental-mode factors shown in Figure C18.4-2. The conversion concepts and factors shown in Figure C18.4-2 are the same as those defined in Chapter 9 of *Seismic Rehabilitation of Existing Buildings* (ASCE 41), which addresses seismic rehabilitation of a structure with damping devices.

DRAFT

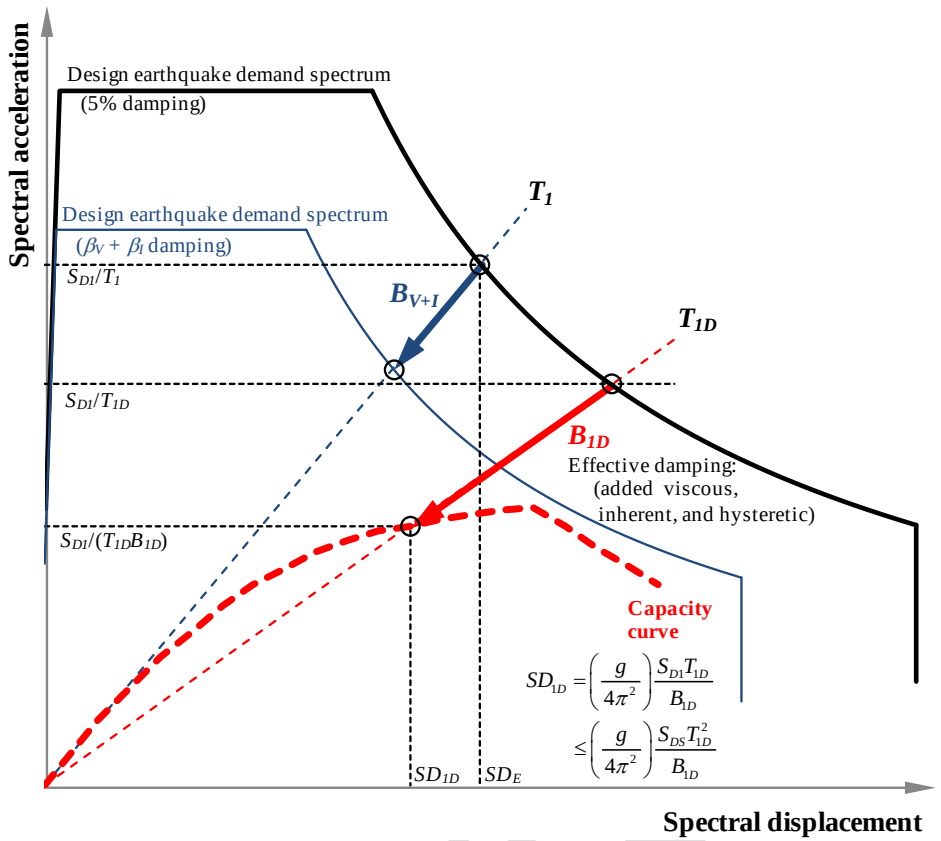

Figure C18.4- 1 Effective damping reduction of design demand.

DRAFT

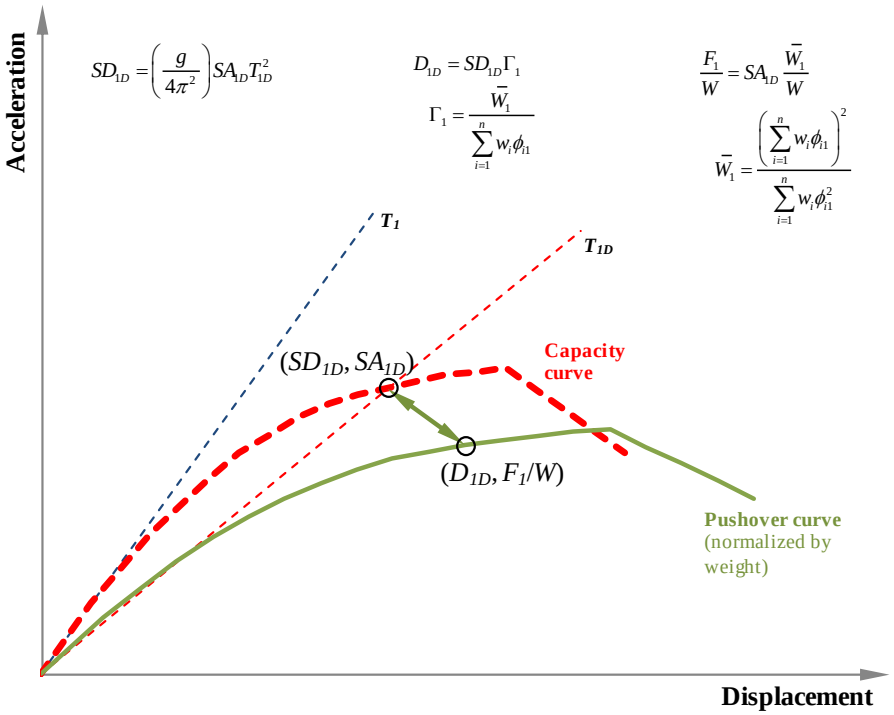

Figure C18.4- 2 Pushover and capacity curves.

Where using linear analysis methods, the shape of the fundamental-mode pushover curve is not known, so an idealized elasto-plastic shape is assumed, as shown in Figure C18.4-3. The idealized pushover curve is intended to share a common point with the actual pushover curve at the design earthquake displacement, D_{1D}. The idealized curve permits definition of the global ductility demand due to the design earthquake, μ_D, as the ratio of design displacement, D_{1D}, to yield displacement, D_Y. This ductility factor is used to calculate various design factors; it must not exceed the ductility capacity of the seismic-force-resisting system, μ_{max}, which is calculated using factors for conventional structural response. Design examples using linear analysis methods have been developed and found to compare well with the results of nonlinear time history analysis (Ramirez et al., 2001).

Elements of the damping system are designed for fundamental-mode design earthquake forces corresponding to a base shear value of V_Y (except that damping devices are designed and prototypes tested for maximum considered earthquake response). Elements of the seismic-force-resisting system are designed for reduced fundamental-mode base shear, V_1, where force reduction is based on system overstrength (represented by Ω_0), multiplied by C_d/R for elastic analysis (where actual pushover strength is not known). Reduction using the ratio C_d/R is necessary because the standard provides values of C_d that are less than those for R. Where the two parameters have equal value and the structure is 5 percent damped under elastic conditions, no adjustment is necessary. Because the analysis methodology is based on calculating the actual story drifts and damping device displacements (rather than the displacements calculated for elastic conditions at the reduced base shear and then multiplied by C_d), an adjustment is needed. Since actual story drifts are calculated, the allowable story drift limits of Table 12.12-1 are multiplied by R/C_d before use.

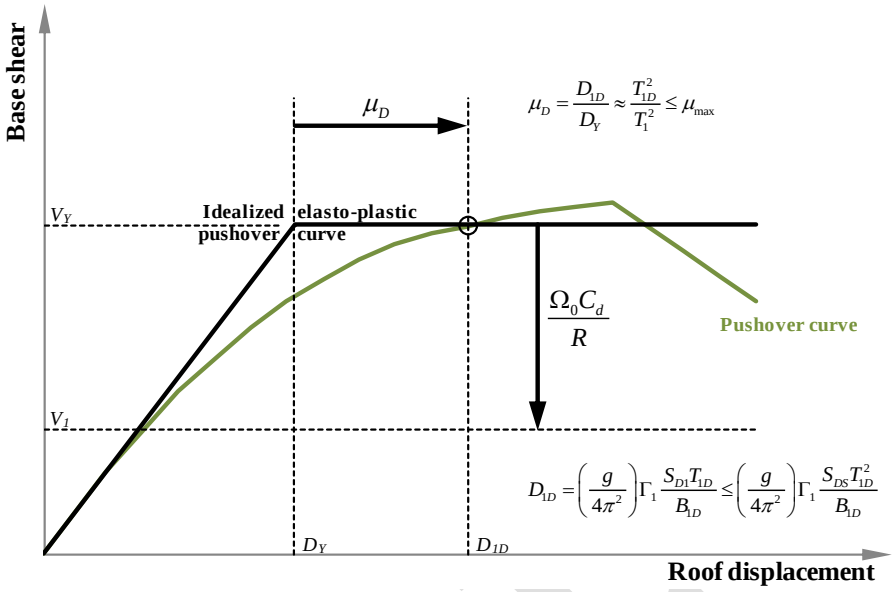

Figure C18.4- 3 Pushover and capacity curves.

C18.6 DAMPED RESPONSE MODIFICATION

C18.6.1 Damping Coefficient

Values of the damping coefficient, *B*, in Table 18.6-1 for design of damped structures are the same as those in Table 17.5-1 for isolated structures at damping levels up to 20 percent, but extend to higher damping levels based on results presented in Ramirez et al. (2001). Table C18.6-1 compares values of the damping coefficient as found in the standard and various resource documents and codes. FEMA 440 and the draft of Eurocode 8 present equations for the damping coefficient, *B*, whereas the other documents present values of *B* in tabular format.

The equation in FEMA 440 is

$$B = \frac{4}{5.6 - \ln(100\beta)}$$

The equation in Eurocode 8 is

$$B = \sqrt{\frac{0.05 + \beta}{0.10}}$$

C18.6.2 Effective Damping

The effective damping is calculated assuming the structural system exhibits perfectly bi-linear hysteretic behavior characterized by the effective ductility demand, μ, as described in Ramirez et al. (2001). Effective damping is adjusted using the hysteresis loop adjustment factor, q_H, which is the actual area of the hysteresis loop divided by the area of the assumed perfectly bi-linear hysteretic loop. In general, values of this factor are less than unity. In Ramirez et al. (2001) expressions for this factor (which they call Quality Factor) are too complex to serve as a simple rule. Equation 18.6-5 provides a simple estimate of this factor. The equation predicts correctly the trend in the constant acceleration domain of the response spectrum, and it is believed to be conservative for flexible structures.

C18.7 SEISMIC LOAD CONDITIONS AND ACCEPTANCE CRITERIA

C18.7.2.5 Seismic Load Conditions and Combination of Modal Responses

Seismic design forces in elements of the damping system are calculated at three distinct stages: maximum displacement, maximum velocity, and maximum acceleration. All three stages need to be checked for structures with velocity-dependent damping systems. For displacement-dependent damping systems, the first and third stages are identical, whereas the second stage is inconsequential.

Force coefficients C_{mFD} and C_{mFV} are used to combine the effects of forces calculated at the stages of maximum displacement and maximum velocity to obtain the forces at maximum acceleration. The coefficients are presented in tabular form based on analytic expressions presented in Ramirez et al. (2001) and account for nonlinear viscous behavior and inelastic structural system behavior.

DRAFT

Chapter C19
SOIL STRUCTURE INTERACTION FOR SEISMIC DESIGN

C19.1 GENERAL

The response of a structure to earthquake shaking is affected by interactions between three linked systems: the structure, the foundation, and the geologic media underlying and surrounding the foundation. A seismic Soil-Structure Interaction (SSI) analysis evaluates the collective response of these systems to a specified free-field ground motion. The term "free-field" refers to motions not affected by structural vibrations and represents the condition for which the design spectrum is derived using the procedures given in Chapter 11.

SSI effects are absent for the theoretical condition of rigid foundation and soil conditions. Accordingly, SSI effects reflect the differences between the actual response of the structure and the response for the theoretical, rigid base condition. Visualized within this context, three SSI effects can significantly affect the response of building structures:

1. Foundation stiffness and damping. Inertia developed in a vibrating structure gives rise to base shear, moment, and torsional excitation, and these loads in turn cause displacements and rotations of the foundation relative to the free field. These relative displacements and rotations are only possible because of compliance in the soil-foundation system, which can significantly contribute to the overall structural flexibility in some cases. Moreover, the relative foundation-free field motions give rise to energy dissipation via radiation damping (i.e., damping associated with wave propagation into the ground away from the foundation, which acts as the wave source) and hysteretic soil damping, and this energy dissipation can significantly affect the overall damping of the soil-foundation-structure system. Since these effects are rooted in the structural inertia, they are referred to as inertial interaction effects.

2. Variations between free-field and foundation-level ground motions. The differences between foundation and free-field motions result from two processes. The first is known as kinematic interaction and results from the presence of stiff foundation elements on or in soil, which cause foundation motions to deviate from free-field motion as a result of base slab averaging, wave scattering, and embedment effects. Procedures for modifying design spectra to account for these effects are given in FEMA 440 and ASCE/SEI 41. The second process is related to the structure and foundation inertia and consists of the relative foundation-free field displacements and rotations described above.

3. Foundation deformations. Flexural, axial, and shear deformations of foundation elements occur as a result of loads applied by the superstructure and the supporting soil medium. Such deformations represent the seismic demand for which foundation components should be designed. These deformations can also significantly affect the overall system behavior, especially with respect to damping.

Chapter 19 treats only the inertial interaction effects (the first item above). Inertial interaction in buildings tends to be important for stiff structural systems (such as shear walls and braced frames), particularly where the foundation soil is relatively soft (i.e., Site Classes C to E). Kinematic interaction effects are neglected in these provisions. Foundation design is covered in Section 12.13.

The procedures in Chapter 19 are used to modify the fixed-base properties (period and damping) of a structural system. If fixed-base properties are obtained from an analytical model of the structure, the fixed-base properties correspond to a condition without soil springs. If soil springs are included in the analytical model of the structure, then the procedures given in Chapter 19 should not be used to modify the building period. The damping procedures in Chapter 19 could still be used in this case if the foundation springs are linear (thus introducing no damping) and there are no dashpots in parallel with the springs. In the remainder of this commentary, it is assumed that the structural period and damping ratio that are being modified for SSI effects correspond to a fixed-base condition.

In design procedures that utilize response spectra to establish design values of base shear (i.e., force-based methods such as those given in Chapter 12), the effects of inertial SSI on the seismic response of buildings is represented as a function of the ratio of flexible- to fixed-base first-mode natural period, $\tilde{T}_1/T_1$, and system damping, β_0,

attributable to foundation-soil interaction. The flexible-base first-mode damping ratio, $\tilde{\beta}$, is calculated using Equation 19.2-9. Figure C19.1-1 illustrates two possible effects of inertial SSI on the peak base shear, which is commonly computed from spectral acceleration at the first-mode. The spectral acceleration for a flexible-based structure ($\tilde{S}_a = \tilde{C}_s / g$) is obtained by entering the spectrum drawn for effective damping ratio, $\tilde{\beta}$, at the corresponding elongated period, $\tilde{T}$. For buildings with periods greater than about 0.5 s, using $\tilde{S}_a$ in lieu of S_a (=C_s/g) typically reduces base shear demand, whereas in very stiff structures SSI can increase the base shear. Most equivalent lateral force methods feature a flat spectral shape at low periods that, when coupled with the requirement that $\tilde{\beta} > \beta$, results in modeling of inertial SSI that can only decrease the base shear demand.

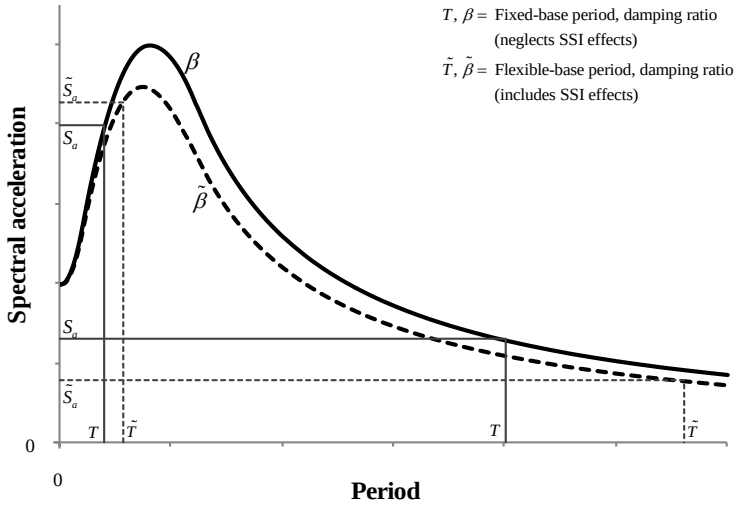

Figure C19.1- 1 Schematic showing effects of period lengthening and foundation damping on design spectral accelerations.

The method given in Chapter 19 for evaluating inertial SSI effects is optional and has rarely been used in practice. There are several reasons for this. First, because the guidelines were written such that base shear demand can only decrease through consideration of SSI, SSI effects are ignored in order to be conservative. Second, many design engineers who have attempted to apply the method on projects have done so for major, high-rise buildings for which they felt evaluating SSI effects could provide cost savings. Unfortunately, inertial interaction effects are negligible for these tall, flexible structures, and hence the design engineers realized no benefit for their efforts and thereafter discontinued use of the procedures. The use of the procedures actually yield the most benefit for short-period (T < 1 sec), stiff structures with stiff, interconnected foundation systems (i.e., mats or interconnected footings) founded on soil.

C19.2 EQUIVALENT LATERAL FORCE PROCEDURE

This procedure considers the response of the structure in its fundamental modEe of vibration and accounts for the contributions of the higher modes to story shears implicitly through the choice of the effective weight of the structure and the vertical distribution of the lateral forces. The effects of soil-structure interaction are accounted for on the assumption that they influence only the contribution of the fundamental mode of vibration.

C19.2.1 Base Shear

Base shear is reduced for the effects of SSI as indicated in Equation 19.2-1 and 19.2-2. As indicated in Equation 19.2-2, the change in base shear is related to the change in seismic coefficient (or spectral acceleration, as shown in

Figure C19-1). The term $(0.05/\tilde{\beta})^{0.4}$ in Equation 19.2-2 represents the reduction in spectral ordinate associated with a change of damping from the fixed base value of $\beta = 0.05$ to the flexible base value of $\tilde{\beta}$.

C19.2.1.1 Effective Building Period

The fixed base period, T, is lengthened to the flexible-base period, $\tilde{T}$, using Equation 19.2-3, which was derived by Veletsos and Meek (1974). Terms K_y and K_θ represent the translational and rocking stiffnesses of the foundation, respectively. The standard does not provide guidance on the evaluation of these stiffness terms. Equations for K_y and K_θ are given by Gazetas (1991), and a number of practical considerations associated with the analysis of these terms are reviewed in FEMA 440 (2005). For convenience, simplified guidelines are presented below for these stiffness terms for use with the standard.

For building foundation systems having lateral continuity, such as mats or footings interconnected with grade beams, stiffnesses K_y and K_θ can often be approximated as:

$$K_y = \frac{8}{2-\nu} G r_a \qquad \text{(C19.2-1)}$$

$$K_\theta = \frac{8}{3(1-\nu)} G r_m^3 \alpha_\theta \qquad \text{(C19.2-2)}$$

where: r_a = an equivalent foundation radius that matches the area of the foundation, A_0 (i.e., $r_a = \sqrt{(A_0/\pi)}$); r_m = an equivalent foundation radius that matches the moment of inertia of the foundation in the direction of shaking (i.e., $r_m = \sqrt[4]{4I_0/\pi}$); G = the strain-dependent shear modulus, as defined in the standard; ν = the soil Poisson's ratio (generally taken as 0.3 for sands and 0.45 for clays); and α_θ = a dimensionless coefficient that depends on the period of excitation, the dimensions of the foundation, and the properties of the supporting medium (Luco, 1974; Veletsos and Verbic, 1973; Veletsos and Wei, 1971). A similar coefficient exists for translation (α_y), but can be taken as 1.0 without introducing significant error, and hence is not shown in Equation C19-2.

As noted in the standard, shear modulus G is evaluated from small-strain shear wave velocity as $G = (G/G_o)G_o = (G/G_o)\gamma v_{so}^2/g$ (all terms defined in the standard). Shear wave velocity, v_{s0}, should be evaluated as the average small-strain shear wave velocity within the effective depth of influence below the foundation. The effective depth should be taken as $0.75r_a$ for horizontal vibrations of the foundation and $0.75r_m$ for rocking vibrations (Stewart et al., 2003). Methods for measuring v_{s0} (preferred) or estimating it from other soil properties are summarized elsewhere (e.g., Kramer, 1996).

The dynamic modifier for rocking, α_θ, can significantly affect the computed response of some building structures. In the absence of more detailed analyses, for ordinary building structures with an embedment ratio $d/r_m < 0.5$ (where d = depth of embedment, measured from ground surface to base of foundation), the factor α_θ can be estimated as follows (Stewart et al., 2003):

$r_m/(v_{s0}T)$	α_θ
< 0.05	1.0
0.15	0.85
0.35	0.7
0.5	0.6

Foundation embedment has the effect of increasing the stiffnesses K_y and K_θ. For embedded foundations for which there is positive contact between the side walls and the surrounding soil, K_y and K_θ may be determined from the following approximate formulas (Kausel, 1974):

$$K_y = \frac{8Gr_a}{2-\nu}\left[1+\left(\frac{2}{3}\right)\left(\frac{d}{r_a}\right)\right] \qquad \text{(C19-4)}$$

$$K_\theta = \frac{8Gr_m^3}{3(1-\nu)}\left[1+2\left(\frac{d}{r_m}\right)\right] \qquad \text{(C19-5)}$$

Experimental studies and field performance data (Stokoe and Erden, 1975; Stewart et al., 1999) indicate that the effects of foundation embedment are sensitive to the condition of the backfill and that judgment must be exercised in using Equations C19-4 and C19-5. For example, if contact is lost between the soil and basement walls, stiffnesses K_y and K_θ should be determined from the formulas for surface-supported foundations. More generally, the quantity d above should be interpreted as the effective depth of foundation embedment for the conditions that would prevail during the design earthquake ground motion.

The formulas for K_y and K_θ presented above can be applied to most soil profiles in which soil shear wave velocity, v_{s0}, changes with depth. However, if the soil profile consists of a surface stratum of soil underlain by a much stiffer deposit with a shear wave velocity more than twice that of the surface layer, K_y and K_θ may be determined from the following two generalized formulas in which G is the shear modulus of the surface soil and D_s is the total depth of the stratum:

$$K_y = \frac{8Gr_a}{2-\nu}\left[1+\left(\frac{2}{3}\right)\left(\frac{d}{r_a}\right)\right]\left[1+\left(\frac{1}{2}\right)\left(\frac{r_a}{D_s}\right)\right]\left[1+\left(\frac{5}{4}\right)\left(\frac{d}{D_s}\right)\right] \quad \text{(C19-6)}$$

$$K_\theta = \frac{8Gr_m^3}{3(1-\nu)}\left[1+2\left(\frac{d}{r_m}\right)\right]\left[1+\left(\frac{1}{6}\right)\left(\frac{r_m}{D_s}\right)\right]\left[1+0.7\left(\frac{d}{D_s}\right)\right] \quad \text{(C19-7)}$$

The above formulas are based on analyses of a stratum supported on a rigid base (Elsabee et al., 1977; Kausel and Roesset, 1975) and apply for $r/D_s < 0.5$ and $d/r < 1$ (r taken as either r_a or r_m). The applicability of those rigid base solutions to practical situations (non-rigid geologic media) was evaluated by Stewart et al. (2003), resulting in the recommendations provided above.

For buildings supported on footing foundations, the above formulas can generally be used with r_a and r_m calculated using the full building footprint dimensions, provided that the footings are interconnected with grade beams. An exception can occur for buildings with both shear walls and frames, for which the rotation of the foundation beneath the wall may be independent of that for the foundation beneath the column (this is referred to as weak rotational coupling). In such cases, r_m is often best calculated using the dimensions of the wall footing. Very stiff foundations, which provide strong rotational coupling, are best described using an r_m value that reflects the full foundation dimension. Regardless of the degree of rotational coupling, r_a should be calculated using the full foundation dimension if foundation elements are interconnected or continuous. Further discussion can be found in FEMA (2005). The use of discrete (non-interconnected) spread footing foundations in seismic regions is not recommended.

For buildings supported on pile foundations, lateral stiffness, K_y, can be taken as the sum of the lateral head stiffnesses of the supporting piles. These stiffness values are generally calculated using a beam on Winkler foundation model, which is discussed in detail elsewhere (e.g., Salgado, 2006). Rotational stiffness, K_θ, can be calculated from the vertical stiffness of the individual piles, k_{zi}, as follows:

$$K_\theta \approx \sum_i k_{zi} y_i^2 \quad \text{(C19-8)}$$

where y_i = horizontal distance from the foundation centroidal axis to pile i measured in the direction of shaking. The approximation in Equation C19-8 assumes an infinitely rigid pile cap and neglects the rotational stiffness of individual piles, which is typically a small contribution. Quantity k_{zi} can be calculated for an individual pile using well-established methods, such as discrete element modeling with t-z curves (e.g., Salgado, 2006).

The alternate approach in the standard, represented by Equation 19.2-5, was derived using Poisson's ratio $\nu = 0.4$, and is generally sufficient for non-embedded foundations that are laterally continuous across the building footprint and for which there is no "rigid" layer at depth in the profile (which would require the use of Equations C19-6 and C19-7 to calculate foundation stiffness). The value of relative weight parameter, α (defined in the standard), can be taken as approximately 0.15 for typical buildings.

C19.2.1.2 Effective Damping

Bielak (1975, 1976) and Veletsos and Nair (1975) expressed the flexible-base first-mode damping ratio, $\tilde{\beta}$, as indicated in Equation 19.2-9. This equation is based on analyses of the harmonic response of single-degree-of-freedom oscillators supported on a visco-elastic medium with hysteretic damping. Foundation damping factor β_0

DRAFT

incorporates the effects of energy dissipation into the soil due to radiation damping and hysteretic damping in the soil.

Figure 19.2-1 shows β_0 as a function of period lengthening ratio and was derived from the analytical solution presented in Veletesos and Nair (1975) for the condition of zero foundation embedment. Additional damping can be realized for embedded foundations, and the use of damping values from Figure 19.2-1 is conservative for such conditions. More exact solutions can be obtained using procedures given in FEMA (2005).

Equation 19.2-9, in combination with the information presented in Figure 19.2-1, may lead to damping factors for the soil-foundation-structure system, $\tilde{\beta}$, that are smaller than the fixed base structural damping, β (assumed to be 0.05). However, it is recommended that $\tilde{\beta}$ never be taken as less than 0.05 for design applications. The use of values of $\tilde{\beta} > \beta$ is well-justified from field case-history data (Stewart et al., 1999, 2003).

The presence of a stiff layer at depth in the soil profile can impede radiation damping, rendering the values in Figure 19.2-1 too high. If a site consists of a relatively uniform layer of depth, D_s, overlying a very stiff layer with a shear wave velocity more than twice that of the surface layer, damping values should be reduced as indicated by Equation 19.2-12.

C19.2.2 Vertical Distribution of Seismic Forces

The vertical distributions of the equivalent lateral forces for flexibly and rigidly supported structures are similar, and it is recommended that the same distribution be used in both cases, changing only the magnitude of the forces to correspond to the appropriate base shear. A greater degree of refinement in this step would be inconsistent with the approximations embodied in the requirements for rigidly supported structures.

With the vertical distribution of the lateral forces established, the overturning moments and the torsional effects about a vertical axis are computed as for rigidly supported structures. The above procedure is applicable to planar structures and, with some extension, to three-dimensional structures.

C19.2.3 Other Effects

In addition to its effect on base shear, inertial SSI also can increase the horizontal displacements of the structure relative to its base (because of rocking). This can increase the required spacing between structures and secondary design forces associated with *P*-delta effects. Such effects can be significant for stiff structural systems (e.g., walls and braced frames).

C19.3 MODAL ANALYSIS PROCEDURE

The procedure outlined above in Section C19.2 is applicable to a modal analysis by adjusting the modal period and damping ratio of the fundamental mode only. Higher modes are relatively unaffected by SSI (e.g., Bielak, 1976; Chopra and Gutierrez, 1974; Veletsos, 1977). Hence, the contributions of higher modes are computed as if the structure were fixed at the base, and the maximum value of a response quantity is determined as for fixed-base structures but with the adjusted first-mode responses.

DRAFT

Chapter C20
SITE CLASSIFICATION PROCEDURE FOR SEISMIC DESIGN

C20.1 SITE CLASSIFICATION

Site classification procedures are given in Chapter 20 for the purpose of classifying the site and determining site coefficients and site-adjusted maximum considered earthquake ground motions in accordance with Section 11.4.3. Site classification procedures are also used to define the site conditions for which site-specific site response analyses are required to obtain site ground motions in accordance with Section 11.4.7 and Chapter 21.

C20.3 SITE CLASS DEFINITIONS

C20.3.1 Site Class F

Site conditions for which the site coefficients F_a and F_v in Tables 11.4-1 and 11.4-2 may not be applicable for site-response analyses required by Section 11.4.7. For short-period structures it is permissible to determine values of F_a and F_v assuming that liquefaction does not occur, because ground motion data obtained in liquefied soil areas during earthquakes indicate that short-period ground motions generally are attenuated due to liquefaction whereas long-period ground motions may be amplified. This exception does not affect the requirements in Section 11.8 to assess liquefaction potential as a geologic hazard and to develop hazard mitigation measures as required.

Sections C20.3.2 through Sections C20.3.5

These sections and Table 20.3-1 provide definitions for Site Classes A through E. Except for the additional definitions for Site Class E in Section 20.3.2, the site classes are defined fundamentally in terms of the average small-strain shear wave velocity in the top 100 feet (30 meters) of the soil or rock profile. If shear wave velocities are available for the site, they should be used to classify the site. However, recognizing that in many cases shear wave velocities are not available for the site, alternative definitions of the site classes also are included. These definitions are based on geotechnical parameters: standard penetration resistance for cohesionless soils and rock, and standard penetration resistance and undrained shear strength for cohesive soils. The alternative definitions are intended to be conservative since the correlation between site coefficients and these geotechnical parameters is more uncertain than the correlation with shear wave velocity. That is, values of F_a and F_v will tend to be smaller if the site class is based on shear wave velocity rather than on the geotechnical parameters. Also, the site class definitions should not be interpreted as implying any specific numerical correlation between shear-wave velocity and standard penetration resistance or undrained shear strength.

Although the site class definitions in Sections 20.3.2 through 20.3.5 are straightforward, there are aspects of these assessments that may require additional judgment and interpretation. Highly variable subsurface conditions beneath a building footprint could result in overly conservative or unconservative site classification. Isolated soft soil layers within an otherwise firm soil site may not affect the overall site response if the predominant soil conditions do not include such strata. Conversely, site response studies have shown that continuous, thin, soft clay strata may affect the site amplification.

The site class should reflect the soil conditions that will affect the ground motion input to the structure or a significant portion of the structure. For structures receiving substantial ground motion input from shallow soils (for example, structures with shallow spread footings, with laterally flexible piles, or with basements where substantial ground motion input to the structure may come through the side walls), it is reasonable to classify the site on the basis of the top 100 feet (30 meters) of soils below the ground surface. Conversely, for structures with basements supported on firm soils or rock below soft soils, it may be reasonable to classify the site on the basis of the soils or rock below the mat, if it can be justified that the soft soils contribute very little to the response of the structure.

Buildings on sites with sloping bedrock or having highly variable soil deposits across the building area require careful study since the input motion may vary across the building (for example, if a portion of the building is on rock and the rest is over weak soils). Site-specific studies including two- or three-dimensional modeling may be used in such cases to evaluate the subsurface conditions and site and superstructure response. Other conditions that may warrant site-specific evaluation include the presence of low shear wave velocity soils below a depth of 100 feet (30 meters), location of the site in a sedimentary basin, or subsurface or topographic conditions with strong two- and

three-dimensional site-response effects. Individuals with appropriate expertise in seismic ground motions should participate in evaluations of the need for and nature of such site-specific studies.

C20.4 DEFINITION OF SITE CLASS PARAMETERS

Section 20.4 provides formulas for defining Site Classes in accordance with definitions in Section 20.3 and Table 20.3-1. Equation 20.4-1 is for determining the effective average small-strain shear-wave velocity, $\overline{v}_s$, to a depth of 100 feet (30 meters) at a site. This equation defines $\overline{v}_s$ as 100 feet (30 meters) divided by the sum of the times for a shear wave to travel through each layer within the upper 100 feet (30 meters), where travel time for each layer is calculated as the layer thickness divided by the small-strain shear wave velocity for the layer. It is important that this method of averaging be used as it may result in a significantly lower effective average shear wave velocity than the velocity that would be obtained by directly averaging the velocities of the individual layers.

For example, consider a soil profile having four 25-foot-thick layers with shear wave velocities of 500, 1,000, 1,500, and 2,000 ft/s. The arithmetic average of the shear wave velocities is 1250 ft/s (corresponding to Site Class C), but Equation 20.4-1 produces a value of 960 ft/s (corresponding to Site Class D). The Equation 20.4-1 value is appropriate as the four layers are being represented by one layer with the same wave passage time.

Equation 20.4-2 is for classifying the site using the average standard penetration resistance blow count, $\overline{N}$, for cohesionless soils, cohesive soils, and rock in the upper 100 feet (30 meters). A method of averaging analogous to the method of Equation 20.4-1 for shear wave velocity is used. The maximum value of N that may be used for any depth of measurement in soil or rock is 100 blows/foot. For the common situation where rock is encountered, the standard penetration resistance, N, for rock layers is taken as 100.

Equations 20.4-3 and 20.4-4 are for classifying the site using the standard penetration resistance of cohesionless soil layers, N_{ch}, and the undrained shear strength of cohesive soil layers, s_u, within the top 100 feet (30 meters). These equations are provided as an alternative to using Equation 20.4-2 for which N-values in all geologic materials in the top 100 feet (30 meters) are used. Where using Equations 20.4-3 and 20.4-4, only the respective thicknesses of cohesionless soils and cohesive soils within the top 100 feet (30 meters) are used.

DRAFT

Chapter C21
SITE-SPECIFIC GROUND MOTION PROCEDURES FOR SEISMIC DESIGN

C21.0 GENERAL

Site-specific procedures for computing earthquake ground motions include dynamic site response analyses and probabilistic and deterministic seismic hazard analyses (PSHA and DSHA), which may include dynamic site response analysis as part of the calculation. Use of site-specific procedures may be required in lieu of the general procedure in Sections 11.4.1 through 11.4.6; Section C11.4.7 explains the conditions under which the use of these procedures is required. Such studies must be comprehensive and incorporate current scientific interpretations. Because there is typically more than one scientifically credible alternative for models and parameter values used to characterize seismic sources and ground motions, it is important to formally incorporate these uncertainties in a site-specific analysis. For example, uncertainties may exist in seismic source location, extent and geometry; maximum earthquake magnitude; earthquake recurrence rate; ground-motion attenuation; local site conditions, including soil layering and dynamic soil properties; and possible two- or three-dimensional wave-propagation effects. The use of peer review for a site-specific ground-motion analysis is encouraged.

Site-specific ground-motion analysis can consist of one of the following approaches: (a) PSHA and possibly DSHA if the site is near an active fault, (b) PSHA/DSHA followed by dynamic site-response analysis, and (c) dynamic site response analysis only. The first approach is used to compute ground motions for bedrock or stiff soil conditions (not softer than Site Class D). In this approach, if the site consists of stiff soil overlying bedrock, for example, the analyst has the option of either (a) computing the bedrock motion from the PSHA/DSHA and then using the site-coefficient (F_a and F_v) tables in Section 11.4.3 to adjust for the stiff soil overburden or (b) computing the response spectrum at the ground surface directly from the PSHA/DSHA. The latter requires the use of attenuation equations for computing stiff soil-site response spectra (instead of bedrock response spectra).

The second approach is used where softer soils overlie the bedrock or stiff soils. The third approach assumes that a site-specific PSHA/DSHA is not necessary, but that a dynamic site response analysis should or must be performed. This analysis requires the definition of an outcrop ground motion, which can be based on the 5 percent damped response spectrum computed from the PSHA/DSHA or obtained from the general procedure in Section 11.4. A representative set of acceleration time histories are selected and scaled to be compatible with this outcrop spectrum. Dynamic site response analyses using these acceleration histories as input are used to compute motions at the ground surface. The response spectra of these surface motions are used to define a maximum considered earthquake (MCE) ground motion response spectrum.

The approaches described above have advantages and disadvantages. In many cases, user preference governs the selection, but geotechnical conditions at the site may dictate the use of one approach over the other. On the one hand, if bedrock is at a depth much greater than the extent of the site geotechnical investigations, the direct approach of computing the ground-surface motion in the PSHA/DSHA may be more reasonable. On the other hand, if bedrock is shallow and a large impedance contrast exists between it and the overlying soil (i.e., density times shear-wave velocity of bedrock is much greater than that of the soil), the two-step approach might be more appropriate.

Use of peak ground acceleration as the anchor for a generalized site-dependent response spectrum is discouraged because sufficiently robust ground-motion attenuation relations are available for computing response spectra in western United States and eastern United States tectonic environments.

C21.1 SITE RESPONSE ANALYSIS

C21.1.1 Base Ground Motions

Ground motion acceleration histories that are representative of horizontal rock motions at the site are required as input to the soil model. Where a site-specific ground motion hazard analysis is not performed, the MCE response spectrum for Site Class B (rock) is defined using the general procedure described in Section 11.4.1. If the model is terminated in material of Site Class A, C, or D, the input MCE response spectrum is adjusted in accordance with Section 11.4.3. The United States Geological Survey national seismic hazard mapping project website (http://earthquake.cr.usgs.gov/research/hazmaps/) includes hazard deaggregation options that can be used to evaluate

the predominant types of earthquake sources, magnitudes, and distances contributing to the probabilistic ground-motion hazard. Sources of recorded acceleration time histories include the databases of the Consortium of Organizations for Strong Motion Observation Systems (COSMOS) Virtual Data Center website (db.cosmos-eq.org) and the Pacific Earthquake Engineering Research Center (PEER) Strong Motion Data Base website (http://peer.berkeley.edu/products/strong_ground_motion_db.html/), and the United States National Center for Engineering Strong Motion Data (NCESMD) website (http://www.strongmotioncenter.org). Ground motion acceleration histories at these sites generally were recorded at the ground surface and hence apply for an outcropping condition and should be specified as such in the input to the site response analysis code (see Kwok et al., 2007, for additional details).

C21.1.2 Site Condition Modeling

Modeling criteria are established by site-specific geotechnical investigations that should include: (a) borings with sampling, (b) standard penetration tests (SPTs), cone penetrometer tests (CPTs), and/or other subsurface investigative techniques, and (c) laboratory testing to establish the soil types, properties, and layering. The depth to rock or stiff soil material should be established from these investigations. Investigation should extend to bedrock or, for very deep soil profiles, to material in which the model will be terminated. While it is preferable to measure shear wave velocities in all soil layers, it is also possible to estimate shear wave velocities based on measurements available for similar soils in the local area or through correlations with soil types and properties. A number of such correlations are summarized by Kramer (1996).

Typically, a one-dimensional soil column extending from the ground surface to bedrock is adequate to capture first-order site response characteristics. For very deep soils, the model of the soil columns may extend to very stiff or very dense soils at depth in the column. Two- or three-dimensional models should be considered for critical projects when two- or three-dimensional wave propagation effects may be significant (for example, sloping ground sites). The soil layers in a one-dimensional model are characterized by their total unit weights and shear wave velocities from which low-strain (maximum) shear moduli may be obtained, and by relationships defining the nonlinear shear stress-strain behavior of the soils. The required relationships for analysis are often in the form of curves that describe the variation of soil shear modulus with shear strain (modulus reduction curves) and by curves that describe the variation of soil damping with shear strain (damping curves). In a two- or three-dimensional model, compression wave velocities or moduli or Poisson ratios also are required. In an analysis to estimate the effects of liquefaction on soil site response, the nonlinear soil model also must incorporate the buildup of soil pore water pressures and the consequent reductions of soil stiffness and strength. Typically, modulus reduction curves and damping curves are selected on the basis of published relationships for similar soils (for example, Vucetic and Dobry, 1991; Electric Power Research Institute, 1993; Darendeli, 2001; Menq, 2003; Zhang et al., 2005). Site-specific laboratory dynamic tests on soil samples to establish nonlinear soil characteristics can be considered where published relationships are judged to be inadequate for the types of soils present at the site. Shear and compression wave velocities and associated maximum moduli should be selected based on field tests to determine these parameters or, if such tests are not possible, on published relationships and experience for similar soils in the local area. The uncertainty in the selected maximum shear moduli, modulus reduction and damping curves, and other soil properties should be estimated (see Darendeli, 2001; and Zhang et al., 2008). Consideration of the range of stiffnesses prescribed in Section 12.13.3 (increasing and decreasing by 50 percent) is recommended.

C21.1.3 Site Response Analysis and Computed Results

Analytical methods may be equivalent linear or nonlinear. Frequently used computer programs for one-dimensional analysis include the equivalent linear program SHAKE (Schnabel et al., 1972; Idriss and Sun, 1992) and the nonlinear programs FLAC (Itasca, 2005), DESRA-2 (Lee and Finn, 1978), MARDES (Chang et al., 1991), SUMDES (Li et al., 1992), DMOD_2 (Matasovic, 2006), DEEPSOIL (Hashash and Park, 2001), TESS (Pyke, 2000), and OpenSees (Ragheb, 1994; Parra, 1996; Yang, 2000). If the soil response induces large strains in the soil (such as for high acceleration levels and soft soils), nonlinear programs may be preferable to equivalent linear programs. For analysis of liquefaction effects on site response, computer programs incorporating pore water pressure development (effective stress analyses) should be used (for example, FLAC, DESRA-2, SUMDES, D-MOD, TESS, DEEPSOIL, and OpenSees). Response spectra of output motions at the ground surface are calculated as the ratios of response spectra of ground-surface motions to input outcropping rock motions. Typically, an average of the response spectral ratio curves is obtained and multiplied by the input MCE response spectrum to obtain the MCE ground-surface response spectrum. Alternatively, the results of site-response analyses can be used as part of the PSHA using procedures described by Goulet et al. (2007) and programmed for use in OpenSHA

DRAFT

(www.opensha.org; Field et al., 2005). Sensitivity analyses to evaluate effects of soil-property uncertainties should be conducted and considered in developing the final MCE response spectrum.

C21.2 RISK-TARGETED MAXIMUM CONSIDERED EARTHQUAKE (MCE_R) GROUND MOTION HAZARD ANALYSIS

Site-specific risk-targeted maximum considered earthquake (MCE_R) ground motions are based on separate calculations of site-specific probabilistic and site-specific deterministic ground motions.

Both the probabilistic and deterministic ground motions are defined in terms of 5 percent damped spectral response in the maximum direction of horizontal response. The maximum direction in the horizontal plane is considered the appropriate ground motion intensity parameter for seismic design using the equivalent lateral force (ELF) procedure of Section 12.8 with the primary intent of avoiding collapse of the structural system.

Most ground motion relations are defined in terms of average (geometric mean) horizontal response. Maximum response in the horizontal plane is greater than average response by an amount that varies with period. Maximum response may be reasonably estimated by factoring average response by period-dependent factors, such as 1.1 at short-periods and 1.3 at a period of 1.0 seconds (Huang et al., 2008). The maximum direction was adopted as the ground motion intensity parameter for use in seismic design in lieu of explicit consideration of directional effects.

C21.2.1 Probabilistic MCE

Probabilistic Seismic Hazard Analysis (PSHA) methods and subsequent computations of risk-targeted probabilistic ground motions based on the output of PSHA are sufficient to define MCE_R ground motion at all locations except those near highly active faults. Descriptions of current PSHA methods can be found in McGuire (2004). The primary output of PSHA methods is a so-called hazard curve which provides mean annual frequencies of exceeding various user-specified ground motion amplitudes. Risk-targeted probabilistic ground motions are derived from hazard curves using one (or both for comparison purposes) of the methods described in the following two subsections.

C21.2.1.1 Method 1

The simpler but more approximate method of computing a risk-targeted probabilistic ground motion for each spectral period in a response spectrum is to first interpolate from a site-specific hazard curve the ground motion for a mean annual frequency corresponding to 2% probability of exceedance in 50 years (namely 1/2475 per year). Then this "uniform-hazard" ground motion is factored by a so-called risk coefficient for the site location that is based on those mapped in Figures 22-17 and 22-18. Via the method explained in the next subsection, the mapped risk coefficients have been computed from the USGS hazard curves for Site Class B and spectral periods of 0.2 and 1.0 seconds.

C21.2.1.2 Method 2

The direct method of computing risk-targeted probabilistic ground motions uses the entire site-specific hazard curve that results from PSHA. The computation is detailed in Luco et al. (2007). Summarizing, the hazard curve is combined with a collapse fragility (or probability distribution of the ground motion amplitude that causes collapse) that depends on the risk-targeted probabilistic ground motion itself. The combination quantifies the risk of collapse. Iteratively, the risk-targeted probabilistic ground motion is modified until combination of the corresponding collapse fragility with the hazard curve results in a risk of collapse of 1% in 50 years. This target is based on the average collapse risk across the Western U.S. that is expected to result from design for the probabilistic MCE ground motions in ASCE 7-10.

C21.2.2 Deterministic MCE

Deterministic ground motions are to be based on characteristic earthquakes on all known active faults in a region. The magnitude of a characteristic earthquake on a given fault should be a best estimate of the maximum magnitude capable for that fault but not less than the largest magnitude that has occurred historically on the fault. The maximum magnitude should be estimated considering all seismic-geologic evidence for the fault, including fault length and paleoseismic observations. For faults characterized as having more than a single segment, the potential for rupture of multiple segments in a single earthquake should be considered in assessing the characteristic maximum magnitude for the fault.

For consistency, the same attenuation equations and ground motion variability used in the PSHA should be used in the Deterministic Seismic Hazard Analysis (DSHA). Adjustments for directivity/directional effects should also be

DRAFT

made, when appropriate. In some cases, ground-motion simulation methods may be appropriate for the estimation of long-period motions at sites in deep sedimentary basins or from great ($M \geq 8$) or giant ($M \geq 9$) earthquakes, for which recorded ground-motion data are lacking.

C21.2.3 Site-Specific MCE_R

Due to the deterministic lower limit on the MCE_R spectrum (Figure 21.2-1), the site-specific MCE_R ground motion is equal to the corresponding risk-targeted probabilistic ground motion wherever it is less than the deterministic limit (e.g., 1.5g and 0.6g for 0.2 and 1.0 seconds, respectively, and Site Class B). Where the probabilistic ground motions are greater than the lower limits, the deterministic ground motions sometimes govern, but only if they are less than their probabilistic counterparts. On the MCE_R ground motion maps in ASCE/SEI 7-10, the deterministic ground motions govern mainly near major faults in California (like the San Andreas) and Nevada. The deterministic ground motions that govern are as small as 40% of their probabilistic counterparts.

C21.3 DESIGN RESPONSE SPECTRUM

Eighty percent of the design response spectrum determined in accordance with Section 11.4.5 was established as the lower limit to prevent the possibility of site-specific studies generating unreasonably low ground motions from potential misapplication of site-specific procedures or misinterpretation or mistakes in the quantification of the basic inputs to these procedures. Even if site-specific studies were correctly performed and resulted in ground-motion response spectra less than the 80 percent lower limit, the uncertainty in the seismic potential and ground-motion attenuation across the United States was recognized in setting this limit. Under these circumstances, the allowance of up to a 20 percent reduction in the design response spectrum based on site-specific studies was considered reasonable.

C21.4 DESIGN ACCELERATION PARAMETERS

The 90 percent lower limit rule, which can affect the determination of S_{DS}, was inserted because it was recognized that site-specific studies could produce response spectra with ordinates at periods greater than 0.2 second that were significantly greater than those at 0.2 second. Similarly, the rule that requires that S_{D1} be taken as the larger of the spectral acceleration at a period of 1 second and two times the spectral acceleration at a period of 2 seconds accounts for the possibility that the assumed $1/T$ proportionality for the constant velocity portion of the design response spectrum begins at periods greater than 1 second or is actually $1/T^n$ (where $n < 1$). Thus, this rule leads to more accurate spectral ordinates at periods around 2 seconds and conservative estimates at shorter periods. However, the conservatism is unlikely to be excessive.

C21.5 MAXIMUM CONSIDERED EARTHQUAKE GEOMETRIC MEAN (MCE_G) PEAK GROUND ACCELERATION

Site-specific requirements for determination of PGA are provided in a new Section 21.5 that is parallel to the procedures for developing site-specific response spectra in Section 21.2. The site-specific MCE peak ground acceleration, PGA_M, is taken as the lesser of the probabilistic geometric mean peak ground acceleration of Section 21.5.1 and the deterministic geometric mean peak ground acceleration of Section 21.5.2. Similar to the provisions for site-specific spectra, a deterministic lower limit is prescribed for PGA_M with the intent to limit application of deterministic ground motions to the site regions containing active faults where probabilistic ground motions are unreasonably high. However, the deterministic lower limit for PGA_M (in g unit) is set at a lower value, 0.5 F_{PGA}, than the value set for the zero-period response spectral acceleration, 0.6 F_a. The rationale for the value of the lower deterministic limit for spectra is based on the desire to limit minimum spectral values, for structural design purposes, to the values given by the 1997 Uniform Building Code (UBC) for Zone 4 (multiplied by a factor of 1.5 to adjust to the MCE level). This rationale is not applicable to PGA_M for geotechnical applications, and therefore a lower value of 0.5 F_{PGA} was selected. Section 21.5.3 of ASCE 7-10 states that the site-specific MCE peak ground acceleration cannot be less than 80 percent of PGA_M derived from the PGA maps. The 80 percent limit is a long standing base for site-specific analyses in recognition of the uncertainties and limitations associated with the various components of a site-specific evaluation.

Chapter C22
SEISMIC GROUND MOTION, LONG-PERIOD TRANSITION AND RISK COEFFICIENT MAPS

RISK-ADJUSTED MAXIMUM CONSIDERED EARTHQUAKE (MCE_R) GROUND MOTIONS MAPS

ASCE/SEI 7-10 continues to use contour maps of 0.2 s and 1 s spectral response accelerations to describe maximum considered earthquake (MCE_R) ground motions (Figures 22-1 through 22-6). However, consistent with changes to the site-specific procedures of Section 21.2, the basis for the mapped values of the MCE_R ground motions in ASCE/SEI 7-10 is significantly different from that of the mapped values of MCE ground motions in previous editions of ASCE/SEI 7. These differences include use of (1) probabilistic ground motions that are risk-targeted (based on a uniform risk of collapse), rather than uniform-hazard (uniform hazard exceedance probability), (2) deterministic ground motions that are based on the 84th percentile (approximately 1.8 times median), rather than 1.5 times median response spectral acceleration for sites near active faults, and (3) ground motion intensity that is based on maximum, rather than the average (geometrical mean), response spectra acceleration in the horizontal plane. Except for determining the MCE_G PGA, the mapped values are given as MCE_R spectral values.

The MCE_R ground maps incorporate new seismic hazard data developed by the United States Geological Survey (USGS) for the 2008 version of United States National Seismic Hazard Maps including new seismic, geologic, and geodetic information on earthquake rates and associated ground shaking (Petersen et al., 2008a, 2008b). These 2008 maps supersede versions released in 1996 and 2002.

The most significant changes to the 2008 maps fall into two categories, as follows:

1. Changes to earthquake source and occurrence rate models:
    - In California, the source model was updated to account for new information on faults. For example, models for the southern San Andreas Fault System were modified to incorporate new geologic data. The source model was also modified to better match the historical rate of magnitude 6.5 to 7 earthquakes.
    - The Cascadia Subduction Zone lying offshore of northern California, Oregon, and Washington was modeled using a distribution of large earthquakes between magnitude 8 and 9. Additional weight was given to the possibility for a catastrophic magnitude-9 earthquake that occurs, on average, every 500 years and results in fault rupture from northern California to Washington, compared to a model that allows for smaller ruptures.
    - The Wasatch fault in Utah was modeled to include the possibility of rupture from magnitude 7.4 earthquakes on the fault.
    - Fault steepness estimates were modified based on global observations of normal faults.
    - Several new faults were included or revised in the Pacific Northwest, California, and the Intermountain West regions.
    - The New Madrid Seismic Zone in the Central U.S. was revised to include updated fault geometry and earthquake information. In addition, the model was adjusted to include the possibility of several large earthquakes taking place within a few years or less, similar to the earthquake sequence of 1811–1812.
    - Source models for the region near Charleston, S.C., have been modified to include offshore faults that are thought to be capable of generating earthquakes.
    - A broader range of earthquake magnitudes was used for the Central and Eastern U.S.
    - Earthquake catalogs and seismicity parameters were updated.
2. Changes to models of ground shaking (that show how ground motion decays with distance from an earthquake's source) for different parts of the U.S., based on new published studies:

DRAFT

- New NGA ground-motion prediction models developed by the Pacific Earthquake Engineering Research Center were adopted for crustal earthquakes beneath the Western U.S. These new models use shaking records from 173 global shallow crustal earthquakes to better constrain ground motion in western States.
- Several new and updated ground-shaking models for earthquakes in the Central and Eastern U.S. were implemented in the maps. One of the new ground-shaking models accounts for the possibility that ground motion decays more rapidly from the earthquake source than was previously considered.
- New ground-motion models were applied for earthquake sources along the Cascadia Subduction Zone.

The new National Seismic Hazard Maps show, with some exceptions, similar or lower ground motion compared with the 2002 edition. For example, ground motion in the Central and Eastern U.S. has been generally lowered by about 10–25 percent due to the modifications of the ground-motion models. Ground motion in the Western U.S. is as much as 30 percent lower for shaking caused by long-period (1-second) seismic waves, and ground motion is similar (within 10–20 percent) for shaking caused by short-period (0.2-second) waves. Note, however, that the MCE_R ground motion maps derived from these USGS National Seismic Hazard Maps do not necessarily exhibit the same trends from ASCE/SEI 7-05 to ASCE/SEI 7-10, due to the aforementioned differences in the basis of the new MCE_R ground motion maps.

MAXIMUM CONSIDERED EARTHQUAKE GEOMETRIC MEAN (MCE_G) PGA MAPS

ASCE/SEI 7-10 now includes contour maps of maximum considered earthquake geometric mean (PGA_G) peak ground acceleration (Figures 22-7 through 22-11) for use in geotechnical investigations (Section 11.8.3). In contrast to MCE_R ground motions, the maps of MCE_G PGA are defined in terms of geometric mean (rather than maximum direction) intensity and a 2 percent in 50-year hazard level (rather than 1 percent in 50-year risk). Like the MCE_R ground motions, the maps of MCE_G PGA are governed near major active faults by deterministic values defined as 84^{th}-percentile ground motions.

LONG-PERIOD TRANSITION MAPS

The maps of the long-period transition period, T_L, (Figures 22-12 through 22-16) were introduced in ASCE/SEI 7-05. They were prepared by the USGS in response to BSSC recommendations and subsequently included in the 2003 edition of the *Provisions*. See Section C11.4.5 for a discussion of the technical basis of these maps. The value of T_L obtained from these maps is used in Equation 11.4-7 to determine values of S_a for periods greater than T_L.

The exception in Section 15.7.6.1, regarding the calculation of S_{ac}, the convective response spectral acceleration for tank response, is intended to provide the user the option of computing this acceleration with three different types of site-specific procedures: (a) the procedures in Chapter 21, provided they cover the natural period band containing T_c, the fundamental convective period of the tank-fluid system, (b) ground-motion simulation methods using seismological models, and (c) analysis of representative accelerogram data. Elaboration of these procedures is provided below.

With regard to the first procedure, attenuation equations have been developed for the western United States (Next Generation Attenuation, e.g., Power et al., 2008) and for the central and eastern United States (e.g., Somerville et al., 2001) that cover the period band, 0 to 10 seconds. Thus, for $T_c \leq 10$ seconds, the fundamental convective period range for nearly all storage tanks, these attenuation equations can be used in the same PSHA/DSHA procedures described in Chapter 21 to compute S_a (T_c). The 1.5 factor in Equation 15.7-11, which converts a 5 percent damped spectral acceleration to a 0.5 percent damped value, could then be applied to obtain S_{ac}. Alternatively, this factor could be established by statistical analysis of 0.5 percent damped and 5 percent damped response spectra of accelerograms representative of the ground motion expected at the site.

In some regions of the United States, such as Pacific Northwest and southern Alaska, where subduction-zone earthquakes dominate the ground-motion hazard, attenuation equations for these events only extend to periods between 3 and 5 s, depending on the equation. Thus, for tanks with T_c greater than these periods, other site-specific methods are required.

The second site-specific method to obtain S_a at long periods is simulation through the use of seismological models of fault rupture and wave propagation (e.g., Graves and Pitarka, 2004; Hartzell and Heaton, 1983; Hartzell et al., 1999; Liu et al., 2006; Zeng et al., 1994). These models could range from simple seismic source-theory and wave-

DRAFT

propagation models, which currently form the basis for many of the attenuation equations used in the central and eastern United States for example, to more complex numerical models that incorporate finite fault rupture for scenario earthquakes and seismic wave propagation through 2-D or 3-D models of the regional geology, which may include basins. These models are particularly attractive for computing long-period ground motions from great earthquakes ($M_w \geq \sim 8$) because ground-motion data are limited for these events. Furthermore, the models are more accurate for predicting longer-period ground motions because: (a) seismographic recordings may be used to calibrate these models and (b) the general nature of the 2-D or 3-D regional geology is typically fairly well resolved at these periods and can be much simpler than would be required for accurate prediction of shorter period motions.

A third site-specific method is the analysis of the response spectra of representative accelerograms that have accurately recorded long-period motions to periods greater than T_C. As T_c increases, the number of qualified records decreases. However, as digital accelerographs continue to replace analog accelerographs, more recordings with accurate long-period motions will become available. Nevertheless, a number of analog and digital recordings of large and great earthquakes are available that have accurate long-period motions to 8 seconds and beyond. Subsets of these records, representative of the earthquake(s) controlling the ground-motion hazard at a site, can be selected. The 0.5 percent damped response spectra of the records can be scaled using seismic source theory to adjust them to the magnitude and distance of the controlling earthquake. The levels of the scaled response spectra at periods around T_c can be used to determine S_{ac}. If the subset of representative records is limited, then this method should be used in conjunction with the aforementioned simulation methods.

RISK COEFFICIENT MAPS

The risk coefficient maps in ASCE/SEI 7-10 (Figures 22-17 through 22-18) provide factors, C_{RS} and C_{R1}, that are used in the site-specific procedures of Chapter 21 (Section 21.2.1.1 Method 1). These factors are implicit in the MCE_R ground motion maps.

The mapped risk coefficients are the ratios of risk-targeted probabilistic ground motions (for 1%-in-50-years collapse risk) derived from the 2008 USGS National Seismic Hazard Maps to corresponding uniform-hazard (2%-in-50-years ground motion exceedance probability) ground motions. The computation of risk-targeted probabilistic ground motions is very briefly explained in Method 2 (Section 21.2.1.2) of the site-specific procedures of Chapter 21 and its commentary. Please see (Luco et al., 2007) for more information on the development of risk-targeted probabilistic ground motions and resultant risk coefficients.

GROUND MOTIONS SOFTWARE TOOL

The USGS has developed a companion software program that calculates location-specific spectral values based on latitude and longitude, address, or zip code; use of zip codes is discouraged in regions where ground-motion values vary substantially over a short distance. The calculated values are based on the data used to prepare the maps. The spectral values can be adjusted for Site Class effects within the program using the Site Classification Procedure in Section 20 and the site coefficients in Section 11.4. The companion software program may be accessed at the USGS website (http://earthquake.usgs.gov/designmaps) or through the SEI website at http://content.seinstitute.org. The software program should be used to establish spectral values for design because the maps found in ASCE/SEI 7-10 are too small to provide accurate spectral values for many sites.

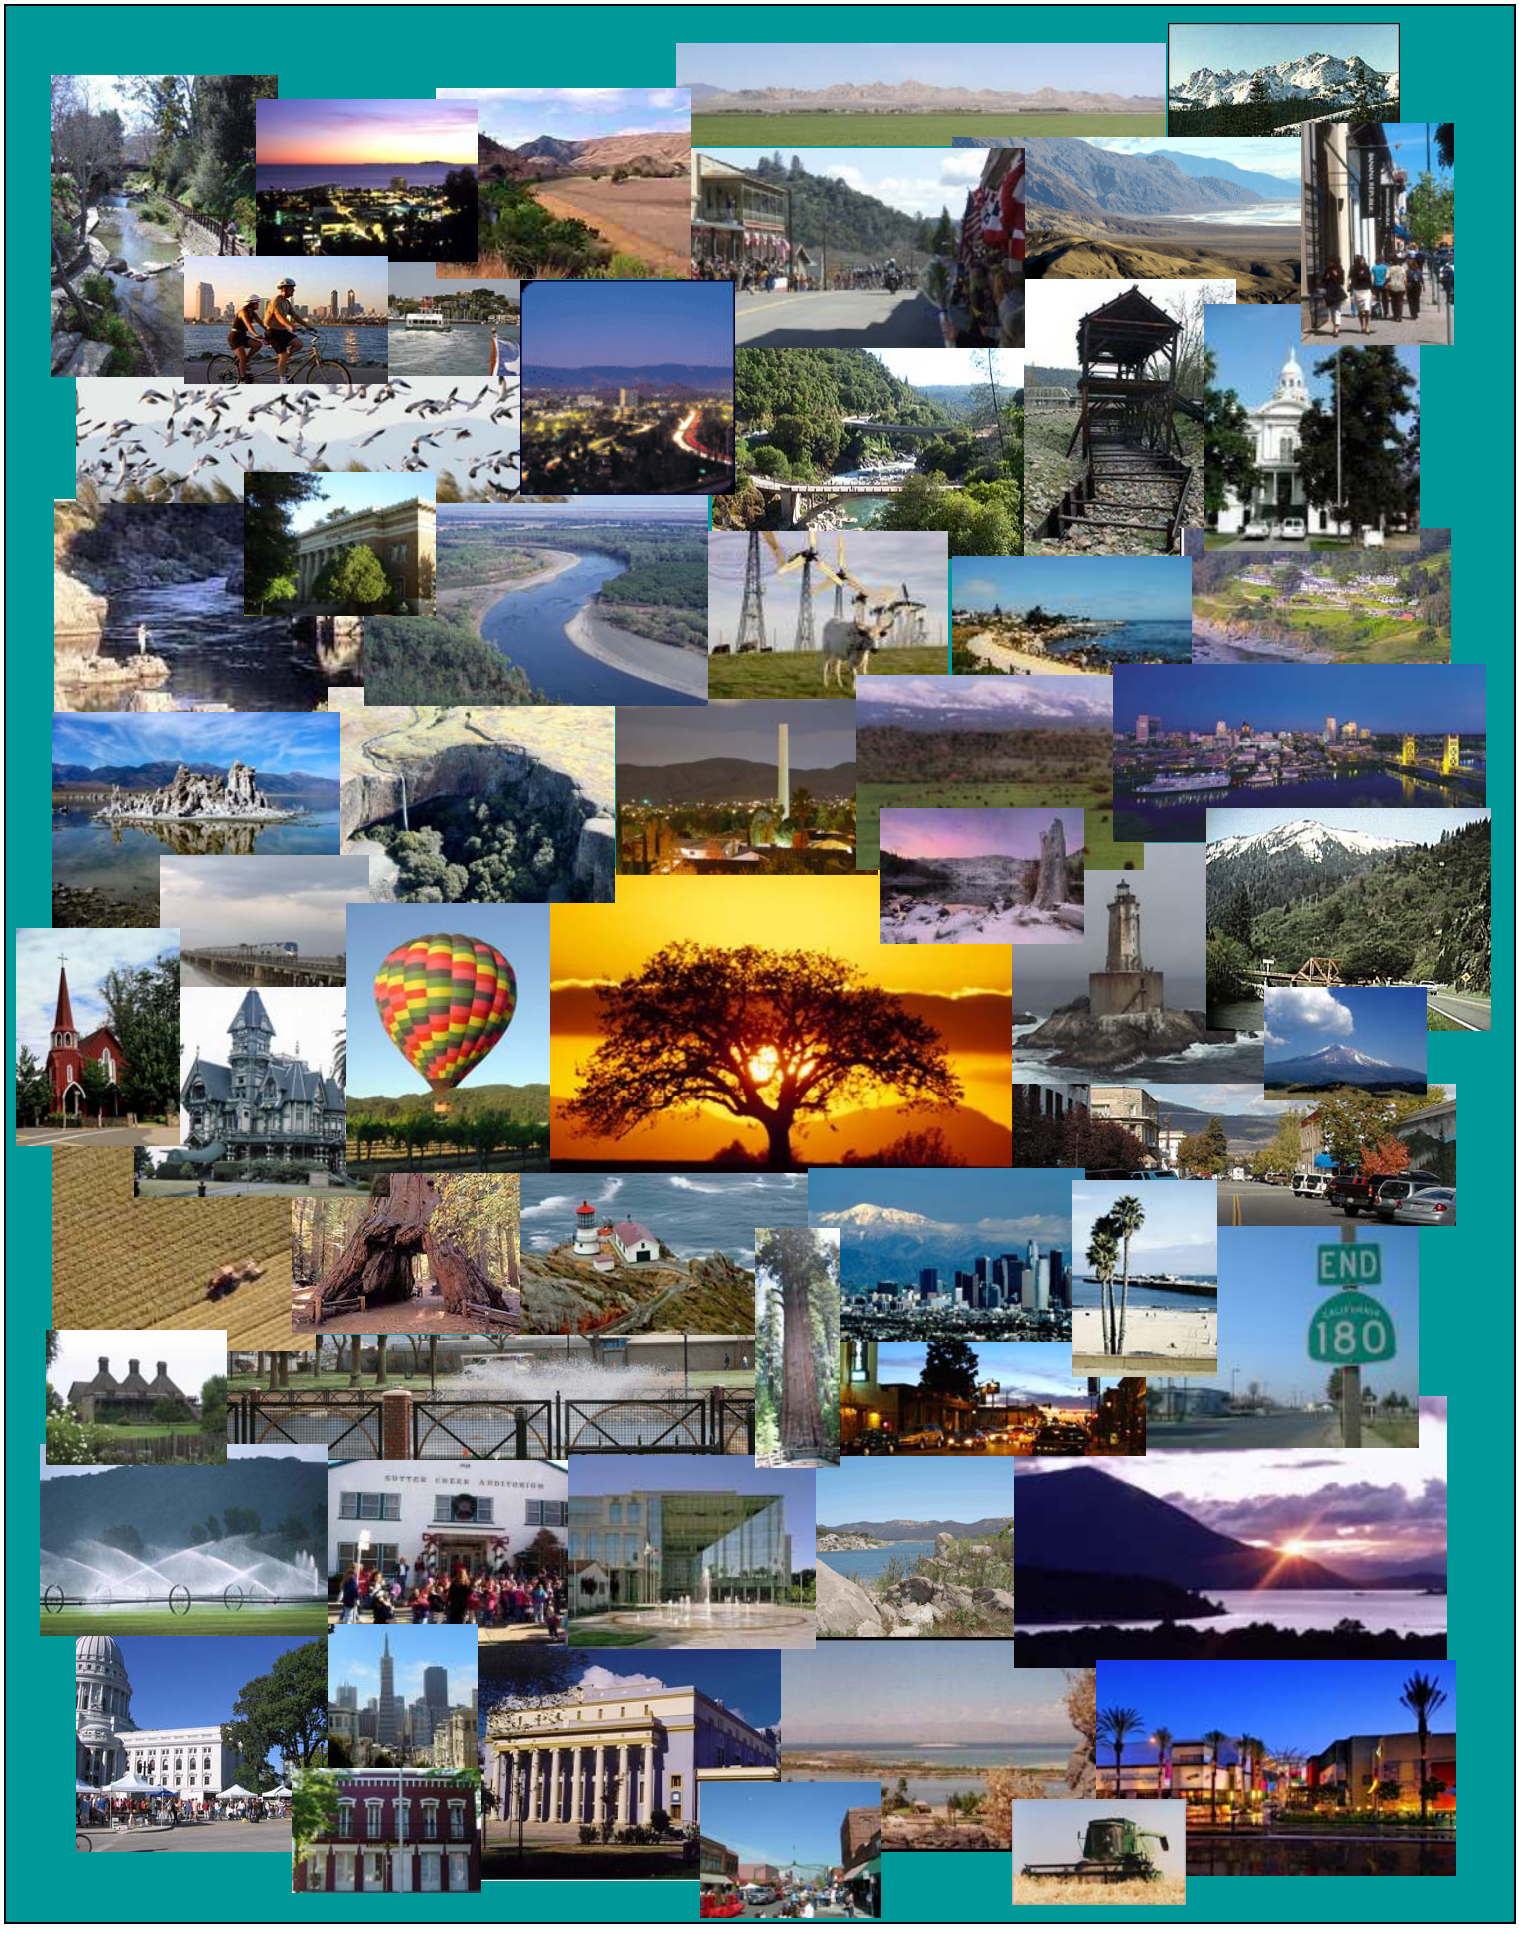
Model Policies for Greenhouse Gases in General Plans

A Resource for Local Government to Incorporate General Plan Policies to Reduce Greenhouse Gas Emissions

June 2009



SUTTER CREEK AUDITORIUM
END
CALIFORNIA
180

Disclaimer

The California Air Pollution Control Officers Association (CAPCOA) has prepared this white paper consideration of model policies for addressing greenhouse gas emissions in General Plans to provide a common platform of information and tools to support local governments.

This paper is intended as a resource, not a guidance document. It is not intended, and should not be interpreted, to dictate the manner in which a city or county chooses to address greenhouse gas emissions in the context of its General Plan.

This paper has been prepared at a time of flux in California law and regulation, as well as accepted practice, regarding how climate change should be addressed in government programs. There is pending litigation that may have bearing on these decisions, as well as active legislation at the federal level. And finally, our understanding of the science of climate change continues to evolve, too. In the face of this uncertainty, local governments are working to understand the new expectations, and how best to meet them. This paper is provided as a resource to local policy and decision makers to enable them to make the best decisions they can during this period of uncertainty.

Finally, this white paper reviews requirements, discusses policy options, and highlights methods, tools, and resources available, but it is not intended to provide legal advice and should not be construed as such. Questions of legal interpretation, or requests for legal advice, should be directed to the jurisdiction's counsel.

Acknowledgements

This paper on Model Policies for Addressing Greenhouse Gas Emissions in General Plans benefited from the hard work and creative insights of many people. CAPCOA appreciates the efforts of all who contributed their time and energy to the project. In particular, the Association thanks the following individuals:

Executive Summary

Global climate change has been clearly documented and is predicted to have substantial effects on the world we live in, not only in parts of the world that are far away, but here in California. Emissions of greenhouse gases (GHGs) must be curtailed if we hope to minimize the extent and impact of climate change. The majority of GHG emissions come from combustion of fossil fuels for energy and transportation. While renewable energy sources, cleaner fuels, and green technology will help to reduce GHG emissions, we also need significant changes in how we design and construct our "built environment" to meet our climate protection goals.

The General Plans developed and implemented by cities and counties must be at the heart of any effort to change our built environment, and many of these local governments have stepped up to the challenge. In order to support their important efforts, the California Air Pollution Control Officers Association (CAPCOA) has prepared this report of Model Policies for Greenhouse Gases in General Plans. The report is intended to serve as a resource for cities and counties. It discusses General Plan structure and options for including GHG policies in existing General Plan Elements, or by creating a separate GHG Element and/or GHG Reduction Plan. The Model Policies Report contains a menu of model language for inclusion in the General Plan Element(s). The report does not dictate policy decisions, rather, it provides cities and counties with an array of options to help them address GHGs in their General Plans.

The statutory and regulatory landscape affecting GHG emissions and climate planning in California has evolved considerably over the last several years. The Governor's Executive Order 2-3-05, and the Global Warming Solutions Act of 2006 (AB 32) establish the broad policy goals for the state for 2020 and 2050. To meet these goals, the Air Resources Board (ARB) has identified discrete Early Action Measures that will be adopted and enforceable by 2010, and approved a Scoping Plan that lays out the longer term strategy for rulemaking and market mechanisms to reduce GHG emissions. The Scoping Plan specifically includes reductions from local government operations and land use decisions. In addition to this core framework, there are a number of other important statutes and regulations affecting GHGs from motor vehicles, fuels, energy production and use, and land use planning, among others. In particular, SB 375 (Steinberg) was signed by the Governor in 2008, and puts in place the framework for regional targets for GHG reductions, and improved regional planning to meet them. There are also new sources for incentive funding to support clean energy and transportation, and reductions of GHG emissions. And the implementation of some programs that have been in place for a long time, such as the building standards in Title 24 and the California Environmental Quality Act (CEQA), is evolving in response to our heightened concern about climate change.

The role of local governments is increasingly in the spot light as we choose our path to a greener and more sustainable future. There are a number of ways cities and counties can reduce GHG emissions. Reductions need to be made in GHG emissions from local government operations, including energy use, waste and recycling, water delivery and wastewater treatment, transportation, and the built environment. Local governments also have a key role to play in educating local businesses and communities, and supporting

their efforts to reduce GHG emissions. Cities and counties can also ensure the impacts of GHG emissions are mitigated when projects are reviewed under CEQA. And, of course, GHG reduction polices can be incorporated into the regional and local planning efforts, including the General Plan.

Integrated regional planning (as supported by Steinberg's SB 375) can provide a framework for cities and counties to contribute to GHG reductions needed for the region to meet the target set by ARB. Cities and counties can also make explicit local commitments to reduce GHG emissions, and adopt Climate Action Plans to make those reductions happen. Policies can be incorporated into existing General Plan Elements. Alternatively a separate element can be created specifically to address GHGs and climate change. In order to be effective, local planning efforts alternatives must be evaluated for consistency with regional plans, including Blueprint Plans, Air Quality Management Plans, and Regional Transportation Plans. The robust and coordinated planning effort envisioned here provides important opportunities to streamline the CEQA review process while ensuring the environment is protected.

As we plan for and implement GHG reduction strategies, it is critical that we review our progress, not only to ensure that we are reaching our goals, but also to ensure that we are not creating unintended and potentially adverse outcomes. Air quality and public health must still be protected, and we must ensure equal protection for all Californians regardless of their income status or ethnic background.

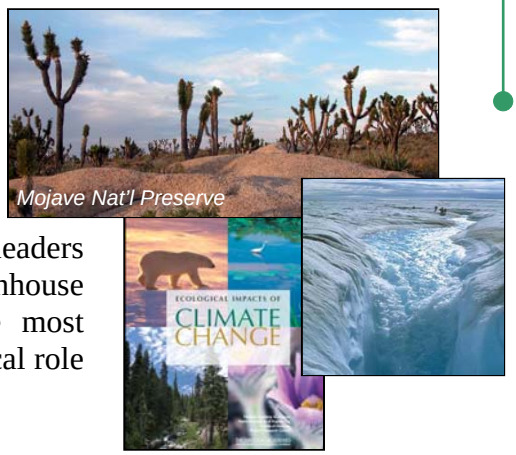
General Plans are, in a broad sense, comprised of goals, objectives, policies, standards, and/or implementation measures, as well as a set of maps and diagrams that describe a vision for the community's future development. The law requires that the General Plan be internally consistent, and there are specific measures of that consistency. Because of this, new policies for GHG need to be considered in the context of the existing elements. These include the mandatory elements, including land use, conservation, circulation, open space, housing, noise, safety, and, in certain circumstances, air quality, as well as non-mandatory elements, such as energy, economic development, capital improvements and public facilities, community design, water, and agriculture. The way the different elements interrelate is an important consideration when incorporating policies for GHGs in the General Plan, and ensuring that those policies are internally consistent throughout the Plan.

The majority of this report is comprised of model policies for GHG reduction that can be incorporated into a jurisdiction's General Plan. Model language is provided in nine major categories: GHG Reduction Planning (overall); Land Use and Urban Design; Transportation; Energy Efficiency; Alternative Energy; Municipal Operations; Waste Reduction and Diversion; Conservation and Open Space; and Education. In addition to the model language, the report provides a worksheet in the form of a table to facilitate the evaluation of the policies for local use, considering specific local factors and criteria. The table also has links to examples of plans that have incorporated the model policy, or a similar policy, to provide a more in-depth understanding of what has been done, under what circumstances, and how.

Finally the report contains technical appendices that provide more detailed information about greenhouse gases, programs that address them, the projected impacts of climate change, climate science, the top ten actions local governments should take, the roles of different agencies on climate and GHG, and examples of plans and policies that have been adopted in California as well as other resources.

(page intentionally left blank)

Chapter 1: Introduction



NAS Brochure

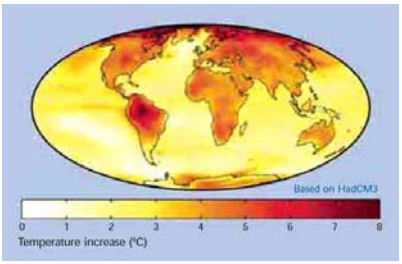
Climate change has already begun to have real and significant impacts on our world and our lives. Some of the changes seem trivial, while others are alarming. As the climate changes more over the next decades, the impacts we see will affect us in increasingly dramatic ways. Recognizing this, the public and government leaders have called for action to reduce emissions of greenhouse gases in the hope that we can stave off the most catastrophic effects. Local government has a critical role to play in this effort.

Because the vast majority of greenhouse gas emissions come from burning fossil fuels, there is tremendous interest in alternative fuels, renewable energy, green technology, and energy conservation as means to cut emissions. There is great promise in these solutions, however alone they are not enough. Studies show that in order to cut emissions to the levels needed, in time to make a difference, we will have to make significant changes in how we live our daily lives, and specifically in how we organize our communities and infrastructure. The key to this organization, and to changing it, is the General Plan that cities and counties develop and implement.

Addressing climate change in a General Plan is no small task. Historically, local air districts have assisted cities and counties in developing the Air Quality Element of their General Plans. In the last few years, air districts across California have been asked by cities and counties for help integrating greenhouse gas emission reduction strategies into their General Plans as they update them. In response, the air districts have pooled their resources through the California Air Pollution Control Officers Association (CAPCOA) to develop a series of Model Policies for Greenhouse Gases in General Plans, and supporting material. CAPCOA would like to acknowledge the Climate Focus Group at ICF Jones & Stokes, and Rimpo and Associates, for their assistance in collecting and compiling information on policies that have been adopted to address GHG emissions.

General Information on Climate Change

An understanding of climate change, and its current and potential future effects on our communities and resources, is essential to good decision making. A detailed description of the science and implications of climate change is provided in the technical appendices at the end of this document. The following provides a basic summary of the issue.



Source: www.scienceschools.org

Climate change is a shift in the "average weather" that a given region experiences. This is measured by changes in the features that we associate with weather, such as temperature, wind patterns, precipitation, and storms. Global climate change means change in the

climate of the Earth as a whole. The Earth's natural climate has always been, and still is, constantly changing. The climate change we are seeing today, however, differs from previous climate change in both its rate and its magnitude.

Human activities are exerting a major influence on some of the key factors that govern climate by changing the composition of the atmosphere and by modifying the land surface. The concentration of carbon dioxide (CO2) in the atmosphere has risen about 30 percent since the late 1800s (National Assessment Synthesis Team [NAST], 2001). This increase has resulted from the burning of coal, oil, and natural gas, and the destruction of forests around the world to provide space for agriculture and other human activities. Concentrations of other greenhouse gases caused by human activities have also increased significantly: for example methane has risen nearly 20% and nitrous oxides over 150% during the same period. Average global surface temperatures have shown a corresponding increase of more than 1° F over the past 100 years, with an average increase of 9° F in the polar regions. The nine warmest years on record have all occurred in the last decade. Figure 1 (right) shows the change in temperature over the last one thousand years. Figure 2 (below) provides thermal maps representing the high and the low in the range of predicted changes in temperature.

Figure 1: Temperature History

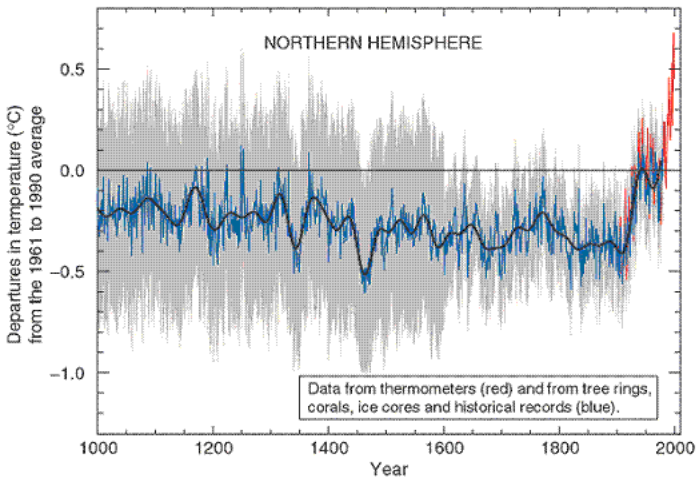


Figure 2:
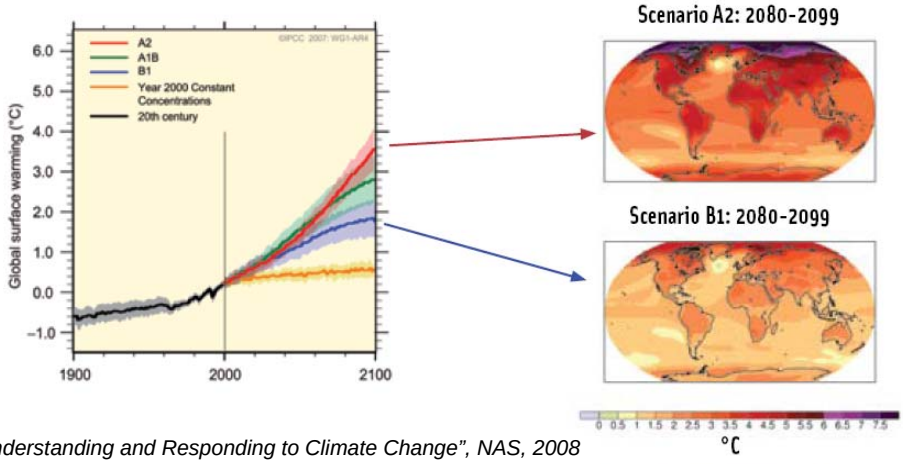
Temperature Projection Scenarios

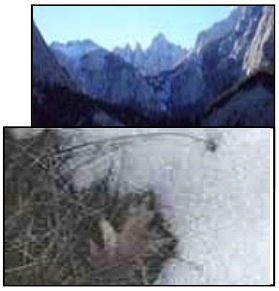


Source: "Understanding and Responding to Climate Change", NAS, 2008

Global projections of population growth and assumptions about energy use indicate that the CO2 concentration will continue to rise, likely reaching between two and three times its late-19th-century level of 280 ppm (parts per million) by 2100, depending on the level and timeliness of preventative actions taken by California and the rest of the world. Such increases in CO2 and other GHGs in the atmosphere and the resulting increase in average global temperatures are predicted to have significant consequences worldwide that will vary in nature and severity depending on location. Impacts predicted for California are summarized below.

Projected Climate Change Impacts in California

In California and throughout western North America, signs of a changing climate are evident. During the last 50 years, winter and spring temperatures have been warmer, spring snow levels in lower- and mid-elevation mountains have dropped, snowpack has been melting one to four weeks earlier, and flowers are blooming one to two weeks earlier. These regional changes are consistent with global trends. If left unchecked, by the end of the century CO2 concentrations could reach levels at which climate change impacts would severely impact our public health, economy, and environment.



State of the art climate modeling was performed for the California Energy Commission (CEC) to determine potential future impacts of climate change in California under three different scenarios: a low emissions scenario that assumes aggressive action is taken to reduce GHG emissions, a medium emissions scenario assuming a moderate level of GHG reductions, and a high emissions scenario that assumes little action is taken to reduce emissions. The range of potential impacts modeled was summarized in a 2006 CEC document called: *"Our Changing Climate: Assessing the Risks to California."* This document outlines the growing severity of consequences predicted statewide as temperature rises, and also identifies those impacts that may be unavoidable and for which we will need to develop coping and adaptation strategies. The report contains significant existing climate change scientific evidence to support the need for regulating GHG emissions. The CEC prepared a biennial update on the risks to California from climate change, and has summarized key points in the brochure: *"The Future is Now."*

As the atmospheric concentration of GHGs increases, California can anticipate increased average temperatures of 1 to 2 degrees F in the next few decades, and perhaps as much as 10°F by the end of the century. Figure 3 (right) shows results of thermal modeling performed for the CEC, including grid scales for the western region of the U.S., downscaled to California and Nevada. The higher temperatures will increase the formation of smog during summer months with the number of days with unhealthy air more than doubling under the worst-case scenario. In addition, there will be as many as 100 more days each year where temperatures exceed 90°F, and a corresponding rise in illness and death from extreme heat. While total annual precipitation in the state is not expected to change substantially, a much greater percentage will fall as rain instead of snow, with a corresponding decrease in snowpack and the spring runoff that supplies water to the state's agriculture and major urban centers. Reduced water supplies and increased temperatures will directly impact which crops can be grown in California, and this may lead to a greater incidence of disease and pest damage. This damage will also affect the state's forests which will likely sustain a sharp increase in catastrophic wildfires. Finally, as shown in Figure 4, the predicted rise in sea level from 1 to 3 meters by the end of the century will drastically alter California's extensive coast, as well as low-lying inland areas, and land along tributaries, inlets, and bays. A more detailed discussion of predicted impacts is presented in Appendix D.

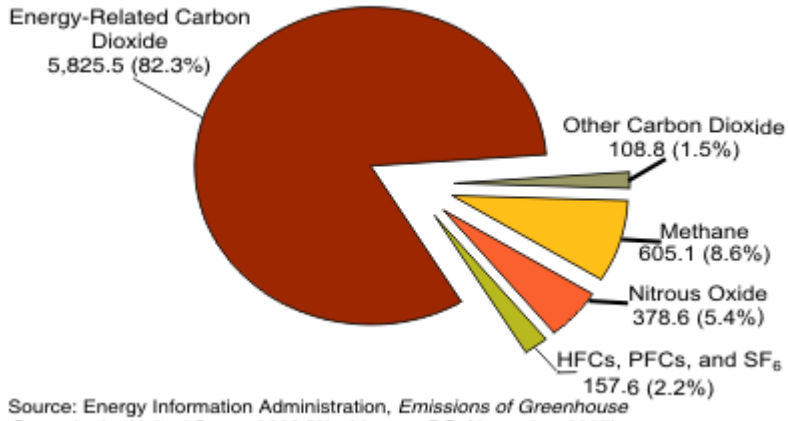
Greenhouse Gases and Their Sources

Carbon dioxide is the most dominant greenhouse gas; however a number of other gases also contribute significantly to climate change, including methane (CH4), nitrous oxide (N2O), sulfur hexafluoride (SF6), hydrochlorofluorocarbons (HFCs) and perfluorocarbons (PFCs). Each gas has a different heat trapping capacity compared to CO2. For instance, methane is 21 times more effective at trapping heat in the atmosphere compared to the same mass of CO2, while some of the fluorocarbons have thousands of times more heat trapping capacity as CO2. To account for these differences when

comparing emissions for the different compounds, the emissions are generally expressed in terms of CO2 equivalents (CO2e). Thus, generic references to GHG emissions generally mean CO2 equivalent emissions.

As shown in Figure 5, CO2 makes up approximately 84% of total GHG emissions by volume, with nitrous oxide and methane contributing about 6% and 7% respectively. SF6, HFCs and PFCs, collectively referred to as high global warming potential (GWP) gases, represent the remaining 3% of statewide GHG emissions. High GWP gases are compounds with significantly higher heat-trapping capacity than CO2.

Figure 5: US Greenhouse Gas Emissions by Gas, 2006



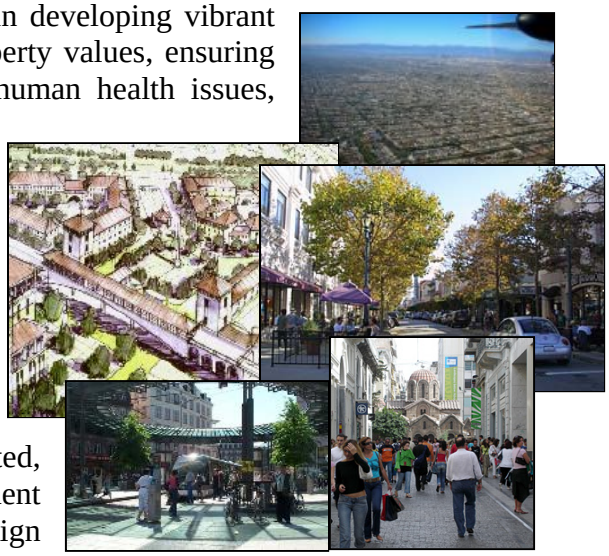
Source: Energy Information Administration, *Emissions of Greenhouse Gases in the United States 2006* (Washington, DC, November 2007)

From a land use standpoint, carbon dioxide and methane are the most important GHGs that local government has the potential to significantly influence and will be the primary focus of the recommended policies and reduction strategies identified in this document.

Increasing CO2 concentrations in the atmosphere primarily result from increased combustion of fossil fuels. Fossil fuel combustion accounts for 98 percent of California CO2 emissions, generating 360 million metric tons of CO2 in 2002; this represents approximately 7 percent of total U.S. emissions from this source category. The transportation sector is the largest contributor in California, accounting for 38% of CO2 emissions, with gasoline combustion the greatest portion of those emissions.

Methane accounted for approximately 6 percent of California's total GHG (CO2e) emissions in 2002. Methane is produced during anaerobic decomposition of organic matter in biological systems. Decomposition occurring in landfills accounts for the majority of anthropogenic CH4 emissions in California and in the United States as a whole. Agricultural processes such as enteric fermentation, manure management, and rice cultivation are also significant sources of CH4 in California.

What Is The Land Use Connection?



Land use planning is a critical element in developing vibrant and livable communities, increasing property values, ensuring economic vitality, addressing potential human health issues, promoting transportation efficiency, ensuring affordable housing, and improving environmental protection. The distribution of different types of land uses, their design, their accessibility, and their intensity can have profound effects on energy use, water use, and vehicle miles of travel.

When properly designed and located, compact, accessible, mixed-use development using energy and water-saving design techniques requires less energy and less vehicle travel than the typical development patterns over the past 60 years. Thus, land use planning is an area of opportunity for guiding development and land use decisions in a manner that considers the heat-trapping emissions of human activity and aims to reduce such emissions. Unfortunately, there is no "one size fits all," cookie cutter approach to effective land use planning. A project that might be beneficial, and reduce VMT and other energy needs, in one situation can actually work in the negative, increasing VMT and energy demands, if sited without proper regard to the circumstances and needs of the site, the community, and the region. For this reason, recommended strategies and approaches should always be considered in context, and evaluated for their appropriateness based on the specific circumstances in which they would be implemented.

What Does This Document Contain?

The California Air Pollution Control Officers Association (CAPCOA) Model Policies for GHGs in General Plans (Model Policies Report) is a resource document intended to help cities and counties address climate change and GHG emissions in their General Plans. The Model Policies Report provides a variety of useful information, including a toolbox of policies, strategies and model language that can be used in General Plans. The Model Policies Report identifies the various issues related to GHG emissions that may cut across several elements of a General Plan; interrelationships of these elements were considered when developing the set of potential development policies for consideration. In addition, the Model Policies Report reviews and analyzes the efficacy of the different goals, objectives, policies & implementation measures available to reduce GHG emissions.

Finally, the Model Policies Report provides model language for GHG policies in General Plan elements, including a list/menu of approaches that are currently being used so that jurisdictions can choose which approaches are most appropriate to them. The Model Policies Report is intended to offer flexible guidance to allow for different approaches to address GHG in General Plans.

This document is focused on issues surrounding the reduction of greenhouse gas emissions. An equally important challenge related to climate change is planning for adaptation to environmental change (such as sea level rise and other climate effects) that is inevitable, regardless of success in reducing greenhouse gas emissions. Local land use planning should also consider how to plan for climate-resilient communities in light of foreseeable environmental change, but that is not the focus of this document.

What Is the Purpose of This Document?

This document provides local jurisdictions with relevant information for considering climate change and GHG reductions in General Plan development and updates. Since the passage of the Global Warming Solutions Act of 2006 (Assembly Bill 32, or AB 32), and Executive Order S-03-05 (EO S-03-05), there has been substantial interest at the State level in finding ways to reduce statewide GHG emissions. The California Air Resources Board (ARB) is given the primary responsibility to develop strategies and regulations to reduce California's overall GHG emissions to 1990 levels by 2020. As required under AB 32, the ARB adopted a Scoping Plan calling for targeted reductions of CO2 from various sectors, including a proposed 2 million metric ton reduction from land use and local government.

The California Attorney General's Office (AG) has taken an active role in the cause of climate change and GHG emissions reductions. The AG has written over 20 extensive project comment letters concerning climate change, some of which were directed toward cities and counties addressing climate change in their General Plans. As an example of his commitment to this role, the AG litigated San Bernardino County based on its failure to analyze in its General Plan Environmental Impact Report (EIR) the increased greenhouse gas emissions that would result from the county's proposed General Plan update. The suit was settled, and although not binding on other communities, the precedent-setting settlement between the AG and San Bernardino County has led many to believe that an EIR for a General Plan must inventory GHG emissions, describe impacts due to the forecasted emissions, and identify feasible mitigation measures to reduce those emissions. Further, mitigations adopted in a General Plan EIR often will require the amendment of General Plan goals, objective, policies, or implementation measures in order to feasibly reduce GHG emissions.

Local governments will face many challenges ahead in reducing GHG emissions. To help provide foundational information, in January 2008, CAPCOA published a white paper entitled, "CEQA & Climate Change"-- a resource document developed to assist public agencies in establishing procedures for reviewing GHG emissions from projects subject to the California Environmental Quality Act (CEQA). This Model Policies Report

continues CAPCOA's efforts to provide meaningful information and tools to local jurisdictions in response to the rapidly evolving regulations in regards to GHGs and climate change. When developing the Model Policies Report, CAPCOA took into account the range of requirements a community must address in preparing or updating a General Plan: internal consistency; equal status among elements; consistency between elements; consistency within elements; area plan consistency; and long-term perspective.

For Whom Is This Document Intended?

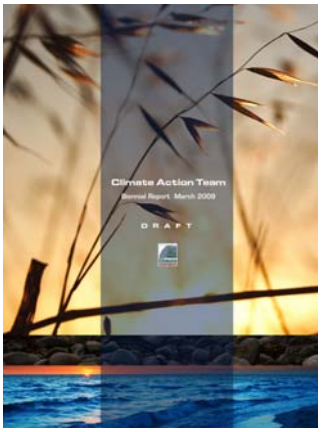
This document is intended for use by local city and county policy and decision makers. The State of California requires each city and county to prepare a comprehensive, long-term General Plan. One of the main purposes of a General Plan is for the jurisdiction to articulate its development goals, objectives, principles and policies for all land areas under its control. Decision and policy makers may find this document useful when evaluating how to incorporate policies and goals related to climate change in their General Plan. Planners and General Plan practitioners may also find this document useful as a general reference.

Colusa County

Over the last several years, a number of new programs have been established to reduce emissions of GHGs. While most of these do not operate directly on or through General Plans, they create a strong foundation upon which General Plan elements for GHGs can be built. This section of the report provides a brief summary of the key programs. Appendix B provides additional description of programs specifically implementing AB 32. Additional information on other programs is summarized in Appendix C. The appendices also provide links to respective program websites where more detailed information can be found.

State Reduction Targets for GHGs (Executive Order S-3-05)

The first comprehensive state policy to address climate change was established through an Executive Order of the Governor of California. In 2005, Governor Schwarzenegger issued California Executive Order S-3-05, which established ambitious GHG reduction targets for the state: reduce GHG emissions to 2000 levels by 2010, reduce to 1990 levels by 2020, and reduce emissions 80% below 1990 levels by 2050. These targets reflect the world-wide emission reduction trajectory identified by the International Panel on Climate Change (IPCC) as being necessary to avert catastrophic global climate change. Under the Executive Order, each state agency is directed to identify and pursue actions within their purview that could contribute to the necessary emission reductions. The Secretary of the California Environmental Protection Agency (Cal/EPA) has the role of coordinating the emission reduction efforts, through the Governor's Climate Action Team, which the Secretary chairs.



On April 1, 2009, California's Climate Action Team released a draft of its second report to the Governor and the Legislature.

This Executive Order is binding only on state agencies, and has no force of law for local governments; however, S-3-05 was important for two reasons. First, it obligated state agencies to implement GHG emission reduction strategies. Second, the signing of the Order sent a clear signal to the Legislature about the framework and content for legislation to reduce GHG emissions.

Global Warming Solutions Act of 2006 (AB 32)

California AB 32, the "Global Warming Solutions Act of 2006," codifies the State's GHG emissions target by directing the ARB to reduce the State's global warming emissions to 1990 levels by 2020. ARB regulations must begin phasing in by 2012. AB 32 was co-authored by Assembly Member Fran Pavley and Assembly Speaker Favian Núñez; it was signed and passed into law by Governor Arnold Schwarzenegger on September 27, 2006.

As shown in Figure 6, AB 32 defines a number of milestones to be met in the effort to achieve the 2020 emissions target. It vests the principle authority to implement the program in the ARB, but provides that the Secretary of Cal/EPA will coordinate across state agencies. The cornerstone of the program is the development and adoption by ARB of a Scoping Plan that identifies specific reduction strategies, implementation mechanisms, and timelines. The statute requires that ARB adopt the Scoping Plan by the end of 2008, and that regulations to implement the Plan's strategies must be enforceable by 2012. The statute also requires the ARB to adopt discrete early action measures in 2007, and to study the feasibility and effectiveness of market mechanisms to achieve the needed emission reductions. Finally, it provides that progress towards attainment of criteria air pollutant standards should not be impaired by the climate program, nor should the program create or exacerbate impacts on communities. Figure 7 shows the key GHG emitting sectors of California's economy.

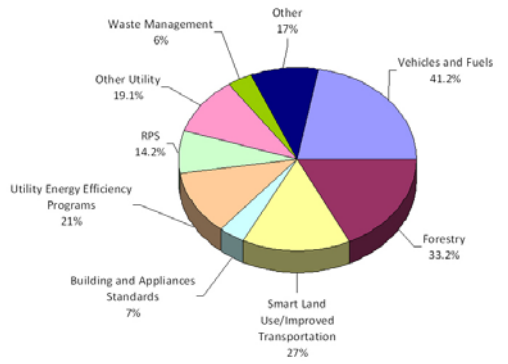
Source: ARB Staff Report on Early Action Measures

Figure 7:



Source: March 2006 Climate Action Team Report

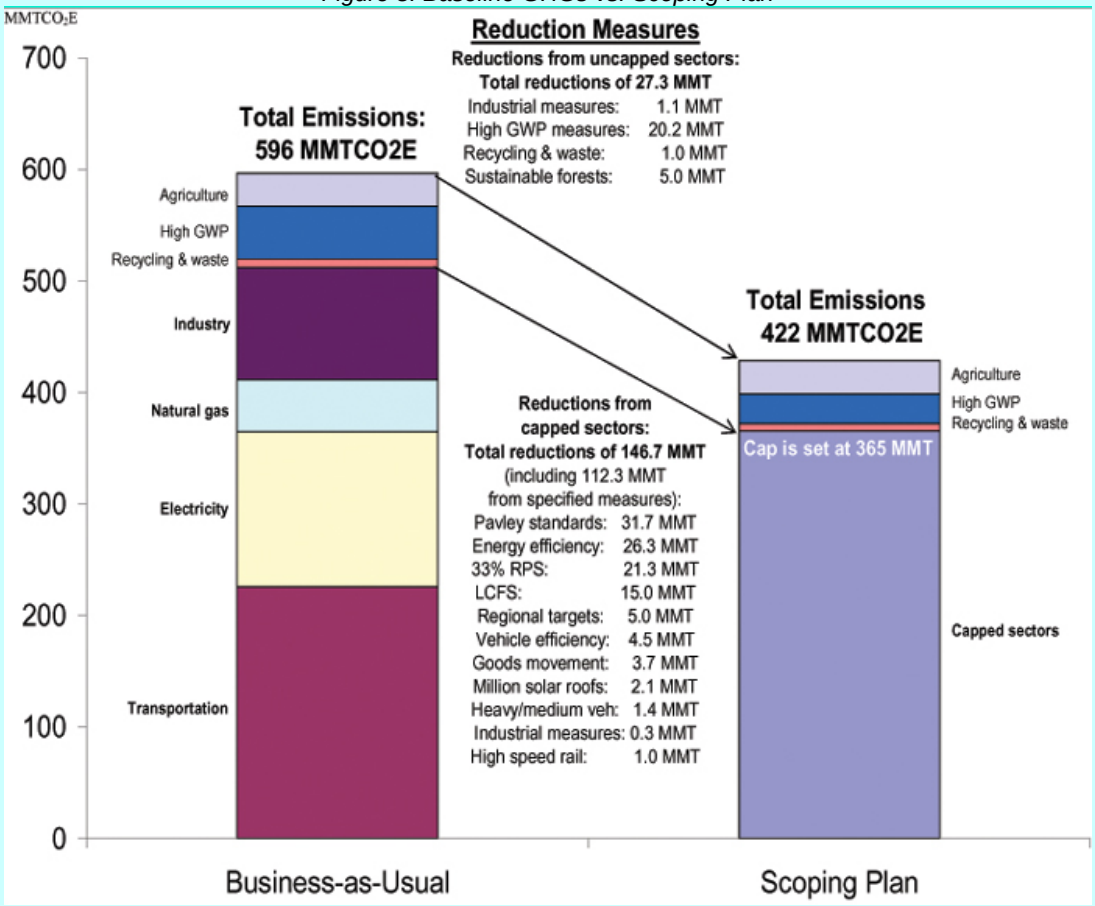
Early Action Measures:

The ARB approved a package of discrete early action measures in June, 2007. The core measures are three proposed rulemakings, including the codification of the Low Carbon Fuel Standard called for in the Governor's Executive Order S-1-07 (see discussion later in this chapter), the capture and recovery of refrigerants with high global warming potential during the servicing of automobile air conditioning systems, and the capture and recovery of methane from landfills, with additional reductions to come from other smaller scope regulations, and as co-benefits from criteria pollution rulemaking efforts. In October, 2007, the ARB added measures to the list, including reductions anticipated from improved energy efficiency at cement manufacturing plants, rulemaking on refrigerants, tire inflation programs, and other programs in trucking and at the ports. Further details on these programs are provided in Appendix B of this report.

Scoping Plan: The Scoping Plan was approved by the ARB Board in November, 2008. The Plan does several things. First, it specifies the target level of GHG emissions that must be achieved by 2020, and estimates the levels that would occur in the absence of measures to reduce emissions – the "business-as-usual" scenario. The difference represents the quantity of emissions that must be reduced by the measures in the plan. Second, the Plan identifies a mix of strategies to achieve the mandated reductions, and estimates the emission reductions that can be expected from each strategy or measure. Finally, the Plan provides general direction for the implementation of key strategies, recognizing that the details of the requirements will be developed through the public rulemaking process.

In December of 2007, the ARB approved the baseline inventory analysis of the GHG emissions in California in 1990; total GHG emissions were 427 MMTCO2(e). ARB estimates that under the business-as-usual scenario, GHG emissions will rise to 596 MMTCO2(e) by 2020. In order to comply with the mandates of AB 32, California must implement strategies sufficient to remove 169 MMTCO2(e). This represents an overall reduction of 30% from business-as-usual, and about 10% from the levels emitted today.

Figure 8: Baseline GHGs vs. Scoping Plan

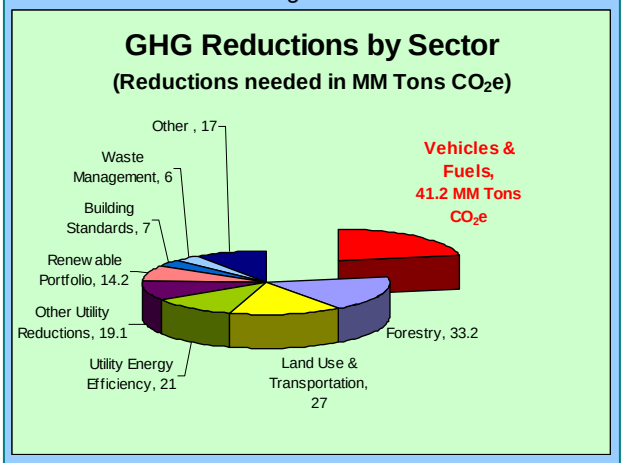


Source: ARB Scoping Plan, Fig. 3, p. 21

On a per capita basis, each Californian will be responsible for nearly 14 tons of CO2(e) in 2020 under a business-as-usual scenario, and that needs to be reduced to about 10 tons for each man, woman, and child. Figure 8 shows the GHG emissions under baseline conditions, and as they are projected to be in 2020, with full implement-tation of the Scoping Plan.

The Scoping Plan identifies measures and strategies in 19 basic categories, and Figure 9 shows the reductions needed from key categories. The greatest contribution comes from the transportation sector, which is responsible for about 60.2 MMTCO2(e) in reductions.

Figure 9



Data from CEC

The reductions (shown parenthetically in MMTCO2(e) for each category) come from implementation of GHG emission standards for vehicles (31.7), the Low Carbon Fuel Standard (15), vehicle efficiency measures (4.8), goods movement improvements (3.7), reductions from medium and heavy duty vehicles (2.5), and implementation of high speed rail (1). The electricity sector is the second largest contributor, with a total of 49.7 MMTCO2(e), coming from energy efficiency measures (26.4), acceleration of the Renewable Energy Portfolio Standard (21.2), and deployment of SB 1 (Murray) the Million Solar Roofs Initiative (2.1). Other sectors include reductions in emissions of GHGs with high global warming potential (16.2), sustainable forestry (5), efficiencies in water movement, treatment, and storage (4.8), improvements in land use (5), direct local government actions to reduce GHGs (15% reduction below present levels; tons TBD), control of methane at landfills (1), and methane capture at large dairies (1). The amount of reductions from the large industrial sector is yet to be determined, and the balance of the needed emission reductions is expected to come from the market-based cap and trade program (34.4).

Specifically in regard to reductions from improvements in land use, the Scoping Plan discusses establishing Regional Targets for GHG reduction, and requiring an integrated planning process for transportation, air quality, and General Plans. This approach is further supported by SB 375 (Steinberg), which the Governor signed in September, 2008. The legislation is discussed below, and the concept of Regional Targets and integrated planning is further explored in Section 4 of this report.

The Scoping Plan discusses two primary ways in which local governments can achieve direct GHG reductions (that is, reductions that do not result from improved land use planning). Local governments can take actions to reduce energy use at their own facilities, increase their recycling, reduce their waste and water use, reduce the energy used in the handling and treatment of waste and

Toolkit available at:
www.coolcalifornia.org

water, and reduce the carbon emissions from their vehicle fleets and from trips to and from their facilities. Similarly, local governments can adopt policies that support reductions in these same areas by businesses and residents within their communities. These kinds of local government actions form the fabric of the Model Policies, and the effective development and integration of thee strategies is the focus of the remaining sections of this report.

There has been considerable interest in the market-based elements of the AB 32 program. Although many of the details remain to be determined through public rulemaking, the Scoping Plan provides certain basic information about market-based efforts. Market-based programs generally fall into three categories: incentives, fees and fee-bates, and cap-and-trade systems. The Scoping Plan envisions a role for all three. Incentives are contemplated for broad, consumer-based programs, such as installation of solar technology, or early adoption of energy efficiency technologies. Fees are envisioned primarily as a mechanism to fund program administration, not as an emission reduction strategy; however, some consideration is given to establishing a fee on upstream carbon (attached to distribution of fuels and electricity) as a backstop measure. The greatest attention is given to a cap-and-trade market mechanism, a system in which a limited number of "allowances" to emit GHG are available, and emitters must either reduce emissions to match the allowances they hold, or they must purchase allowances from another emitter who holds more than needed to cover emissions. The total available allowances would decrease as the 2020 deadline approaches. The Scoping Plan proposes a market that would initially cover a subset of sectors, but would expand to include essentially all sectors over time. The Plan also contemplates a market that is initially linked throughout the western U.S. and Canada, and in which initial allowances are assigned through a combination of targeted allocation and open auction, but which transitions to a market where all allowances are auctioned. It is not yet clear how local governments would be covered under a market system. Figure 10, above, gives a graphical representation of the baseline emissions over time (shown in red) compared to the declining cap (shown in purple). Additional discussion of the cap-and-trade program is provided in Appendix B.

Figure 10: Cap and Trade Program

Greenhouse Gas Emission Standards for Vehicles (AB 1493)

Passed in 2002, before the overarching climate program was established, AB 1493 (Chapter 200, Statutes of 2002) was authored by Assembly Member Fran Pavley. The bill required ARB to develop and adopt the nation's first GHG emission standards for automobiles, and the emission

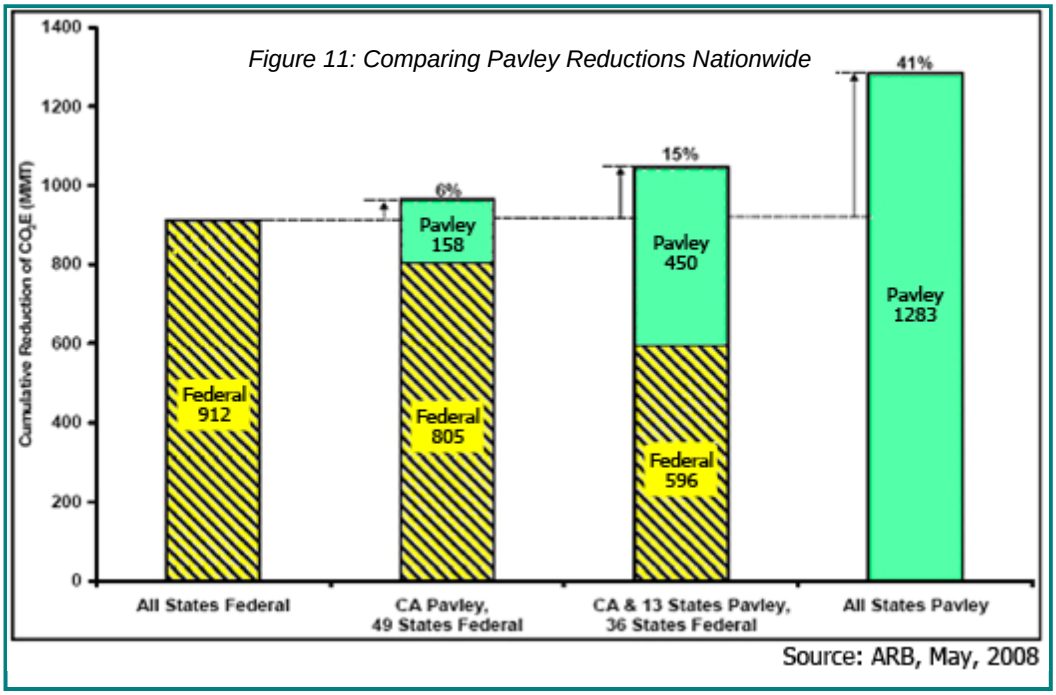
limits it requires are commonly referred to as the Pavley Standards. The ARB approved GHG emission limits for light duty vehicles in 2004. The standards become effective in 2009 and would reduce GHG emissions from California passenger vehicles by about 22 percent by 2012 and about 30 percent by 2016.

Although the federal government generally reserves the authority to establish tailpipe emission standards for motor vehicles, the federal Clean Air Act provides that California may establish such standards; however, any standards adopted by the state must be granted a waiver from the federal preemption by the U.S. EPA before they can be enforced. In December, 2007, EPA denied California's waiver request for the Pavley standards and in early 2008 California's Attorney General filed a petition in federal court to challenge that denial. Seventeen states supported the petition, and the U.S. Congress lodged inquiries into the EPA decision. The Obama administration agreed to review the matter, and in February, 2009, the Administrator of EPA requested comments on the reconsideration of the waiver petition.

In addition to the waiver denial, implementation of the standards has also been challenged in court in a lawsuit filed by automobile manufacturers. The suit alleges that the standards are de facto fuel efficiency standards, which are the exclusive purview of the federal government.

The Pavley standards account for about 19 percent of the emission reductions specified in the Scoping Plan. Although the federal government has adopted new fuel efficiency standards, ARB estimates that between 2009 and 2016, Pavley standards will achieve 56% more reduction in GHG emissions in California (about 19 million metric tons) compared to the federal standards, and by 2020 the difference is 49%. Figure 11 compares the total national emission reductions achieved by different implementation scenarios for the Pavely standards. If the Pavley standards are not ultimately

Figure 11: Comparing Pavley Reductions Nationwide



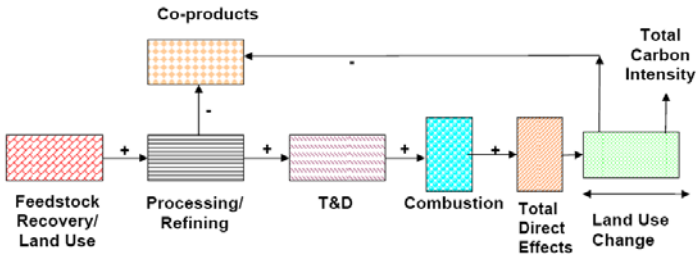
implemented, the lost reductions of GHG will need to be recovered through additional measures, beyond the reductions already identified in the Scoping Plan. ARB suggests the use of a carbon fee on the sale of new vehicles with GHG emissions greater than would have been allowed under the Pavley standards; the fees would be rebated back to the purchasers of vehicles with GHG emissions lower than the Pavley standards. The fees would have to be established at a price point that would inventivize purchasing behavior that results in the same emissions profile as the Pavley standards would have.

Low Carbon Fuel Standard (Executive Order S-1-07)

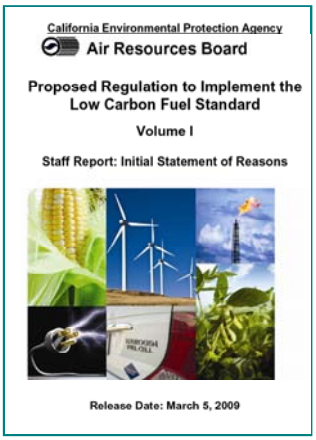
In his January 2007 State of the State message, Governor Schwarzenegger asserted California's leadership in clean energy and environmental policy by establishing a Low-Carbon Fuel Standard (LCFS) by Executive Order. This first-in-the-world greenhouse gas standard for transportation fuels will spark research in alternatives to oil and reduce GHG emissions. Executive Order S-1-07, the Low Carbon Fuel Standard (LCFS) (issued on January 18, 2007), calls for a reduction of at least 10 percent in the carbon intensity of California's transportation fuels by 2020. The carbon intensity of a fuel is a direct measure of the GHGs emitted during the full life-cycle of the fuel, including directly emitted CO2 as well as other GHG associated with each step in the fuel cycle (a.k.a., "well-to-wheels" for fossil fuels and "seed-to-wheel" or "field-to-wheel" for biofuels). Figure 12 shows the components of a combustion fuel life cycle. The Executive Order instructed the California Environmental Protection Agency to coordinate activities between the University of California, the California Energy Commission and other state agencies to develop and propose a draft compliance schedule to meet the 2020 target. Furthermore, it directed ARB to consider initiating regulatory proceedings to establish and implement the LCFS.

Figure 12:

Block Diagram for the various Components for a Fuel Pathway



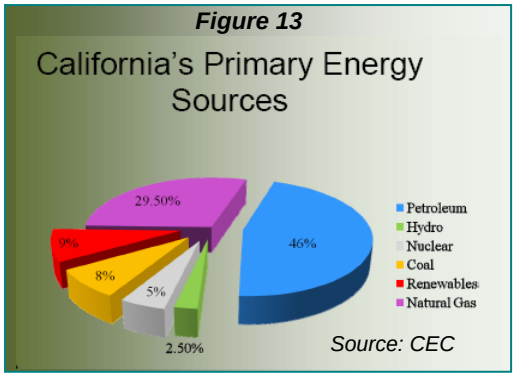
source: ARB LCFS Staff Report



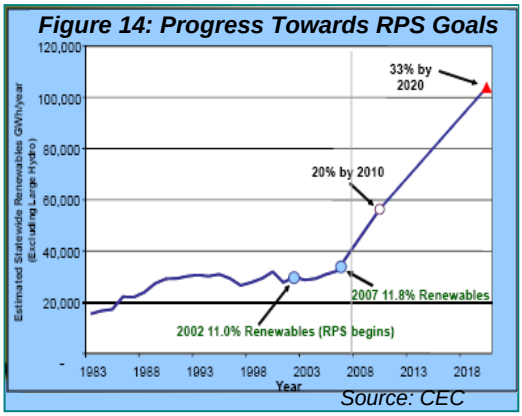
In response, ARB identified the LCFS as an early action item with a regulation to be adopted and implemented by 2010. The standard was approved by the Board in April, 2009. It establishes a baseline level of carbon intensity for affected providers, and places a declining cap on that intensity where each year fewer GHGs may be emitted. This is a market-based program that uses carbon intensity credits for fuels sold, where fuels that have lower carbon intensity than required yield "excess" credits that may be used to offset other, higher intensity fuels, or may be banked for use in future years, or sold to other providers who have not been able to reduce the intensity of their fuels to meet the cap.

Renewable Energy Portfolio (SB 1078 and SB 107)

Established in 2002 under SB 1078 (Sher, see: Chapter 516, Statutes of 2002) and accelerated in 2006 under SB 107 (Simitian, see: Chapter 464, Statutes of 2006), California's Renewable Portfolio Standard (RPS) obligates investor-owned utilities (IOUs), energy service providers (ESPs) and community choice aggregators (CCAs) to procure an additional 1% of retail sales per year from eligible renewable sources until 20% is reached, no later than 2010. ARB's Scoping Plan identifies a target RPS of 33% by 2020.



The California Public Utilities Commission (CPUC) and California Energy Commission (CEC) are jointly responsible for implementing the program. Figure 14a shows the mix of energy sources in California in 2008, and Figure 14b shows progress towards the RPS goals. As of July, 2008, the largest IOUs in California had renewable portfolios as follows: Pacific Gas and Electric (PG&E) - 11.4% ; Southern California Edison (SCE) - 15.7%; San Diego Gas & Electric (SDG&E) - 5.2%.



Improved Land Use Planning (SB 375)

In September, 2008, the Governor signed Senate Bill 375 (Steinberg). This bill has five main provisions:

1. It requires ARB to establish regional targets for reductions in greenhouse gas emissions from use of light duty vehicle (passenger cars and small trucks) associated with land use decisions.

2. It requires that metropolitan planning agencies (MPOs) create a Sustainable Communities Strategy (SCS) in their Regional Transportation Plans (RTPs) to meet the reduction targets established by ARB.

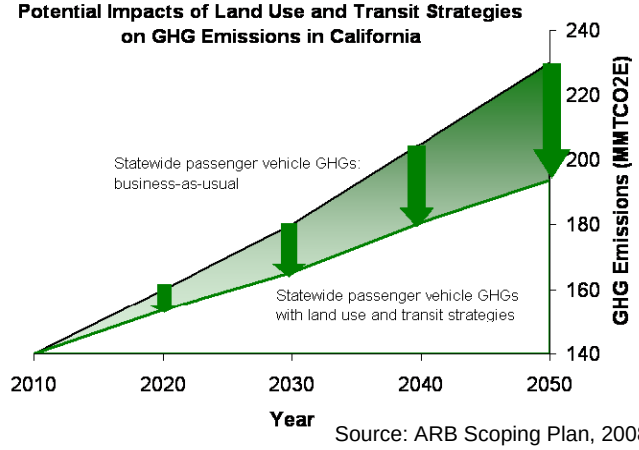
3. It requires that funding decisions for regional transportation projects be internally consistent within the RTP.

4. It aligns the Regional Housing Needs Assessment (RHNA) with the RTP.

5. It provides CEQA relief, in the form of streamlining and exemptions, for projects that are consistent with the SCS.

Targets- ARB is required to approve regional GHG emission reduction targets by September 30, 2010, and to review them, and update them as appropriate, on an eight-year schedule. The targets may be expressed in terms of total tons of emissions to be reduced, reductions per capita, per household, or another metric identified by the air board. ARB has already indicated that the reductions attributed to land use in the Scoping Plan are not, necessarily, the same as the reduction targets that will be assigned to regions under SB 375. ARB believes the Scoping Plan is not an enforceable commitment (unlike the State Implementation Plan for attaining national ambient air quality standards, for example); rather, it is a best estimate, and a general road map. ARB believes the SB 375 process will result in more accurate and specific assessments of the magnitude of reductions that are achievable through sustainable transportation planning. Figure 15 shows the emissions projected from passenger vehicles between 2010 and 2050, and the reductions targeted in the Scoping Plan for that sector.

Figure 15:
Potential Impacts of Land Use and Transit Strategies on GHG Emissions in California



Source: ARB Scoping Plan, 2008

To guide the establishment of the regional targets, from which all other provisions flow, SB 375 creates a Regional Targets Advisory Committee (RTAC) with representation from affected stakeholders, including local government, air districts, and MPOs. The committee will make recommendations to ARB on the factors to be considered by ARB in setting the targets, and on the methodologies to be used. The RTAC does not give explicit recommendations about the targets themselves; however, individual MPOs may make recommendations regarding their own specific target. The RTAC recommendations are due to the ARB by September 30, 2009, which leaves the ARB one year to establish the targets after the RTAC makes its recommendations.

Sustainable Communities Strategy- Metropolitan Planning Organizations (or their subdivisions) are required to develop a Sustainable Communities Strategy that will constitute the land use element of the Regional Transportation Plan. The SCS is required to do all of the following:

- Identify the general location of uses, residential densities, and building intensities within the region;

- Identify areas within the region sufficient to house all the population of the region, including all economic segments of the population, over the course of the planning period of the RTP (i.e., 25 years), taking into account net migration into

the region, population growth (presumably referring to natural increase), household formation, and employment growth;

- Identify areas within the region sufficient to house an eight-year projection of the regional housing need (i.e., an eight-year RHNA);
- Identify a transportation network to service the transportation needs of the region;
- Gather and consider the best practically available scientific information regarding resource areas and farmland in the region;
- Consider state housing goals;
- Forecast a development pattern for the region, which when integrated with the transportation network and other transportation measures and policies, will achieve, to the extent practicable, the targeted greenhouse-gas emission reduction from automobiles and light trucks, while also permitting the RTP to comply with the Clean Air Act;
- In doing all of the above, consider spheres of influence that have been adopted by Local Area Formation Commissions (LAFCOs).

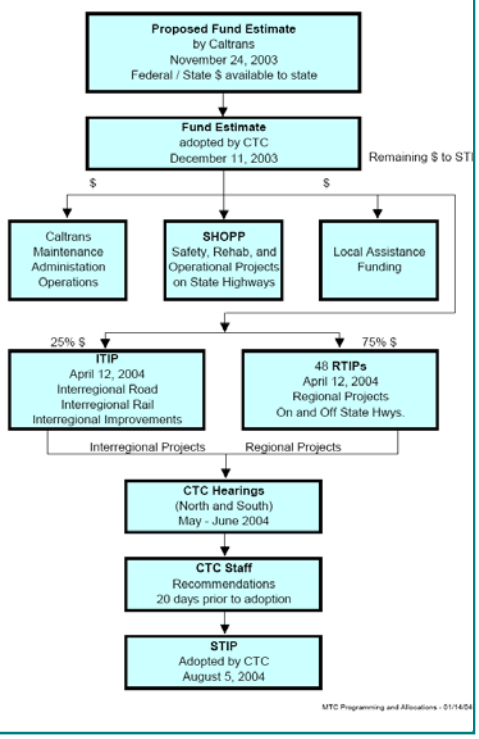
The SCS will also embody the plan to achieve the GHG reductions needed to meet the region's target. It must contain all feasible measures to reduce GHG, but the determination of feasibility is left to the MPOs. The MPOs are required to quantify the emissions reductions that will result from implementation of the SCS, and compare the expected reductions to what is required to meet the targets established by ARB. The bill acknowledges that implementing all feasible strategies under the SCS may not yield sufficient emission reductions to meet the regional target. If that is the case, the MPO is required to develop an Alternative Planning Strategy (APS) that includes additional strategies (including those that were rejected from the SCS on the basis of feasibility) sufficient to reach the target.

Because the SCS is part of the RTP, it is tied to federal transportation planning law and structures. The bill specifies, however, that the SCS is *not* a land use plan, and SB 375 does not confer land use authority on the MPOs. Technically, SB 375 does not require the local General Plan to conform to the SCS. Conformity is strongly encouraged, however, through funding incentives and CEQA streamlining. It is important to note here that the APS is not part of the SCS, and is therefore not part of the RTP. Under SB 375, the APS is not a binding

commitment; however, consistency with the APS can provide some streamlining and regulatory relief under CEQA. Finally, both the SCS and the APS are subject to approval by ARB, but ARB's role is limited to a determination of whether the measures included in the SCS and/or the APS will achieve the target ARB established for the region.

Funding- Although SB 375 does not explicitly direct transportation funding to specific types of projects or measures, it does affect the flow of transportation dollars indirectly. The bill requires that the RTP be internally consistent, meaning that transportation funding allocated under the umbrella of the RTP must be allocated consistent with the programmatic elements of the plan, including the SCS. So if the SCS calls for or prioritizes a specific type of transportation project, funding must be allocated to that type of project, rather than a project type that is not included in the RTP or has been awarded low priority. The same construct does not extend to the APS, however, because it is explicitly not part of the RTP. Figure 16 is a diagram of the process by which the RTIP is created in the Bay Area; for further information, see www.mtc.ca.gov.

Figure 16:
2004 STIP PROCESS
(State Highway Account)



Source: MTC

Affordable Housing- The bill makes specific changes to the requirements for the housing element of the General Plan, to align the Regional Housing Needs Assessment (RHNA) with the RTP. Broadly, it does the following:

- In areas where the RTP is on a four-year review cycle, the bill changes the review cycle under RHNA to eight years, such that the RTP and the RHNA will be reviewed together on a regular basis. In areas where the RTP remains on a five-year review cycle, the RHNA cycle remains at five years.

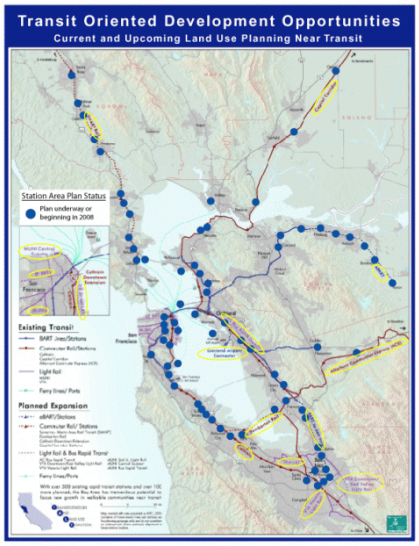
- Requires that the concurrent review of the RTP and the RHNA begin in the first RTP update after 2010, and that two assessments be consistent. Cities and counties are required to amend the Housing Element in their General Plans within the specified time frame, or to be placed on a more frequent four-year RHNA review cycle.

- Establishes a timeline for completing zoning changes to reflect the RHNA, and severely restricts the local authority on project review for affordable housing if the timeline is not met. Specifically, the local authority may only act to disapprove a project, and only if the project would result in a serious health risk.

Streamlining of CEQA- To incentivize projects that are consistent with the SCS or APS, the bill provides certain exemptions from, or streamlining of, requirements under CEQA. Specifically, streamlining is provided for residential projects meeting certain criteria, and for projects that fall under the newly defined category of "transit priority project."

Residential Projects Consistent with SCS/APS: The bill reduces CEQA requirements for a residential development (or a mixed-use development that devotes at least 75% of the square footage to residential uses) if it meets both of the following requirements: 1) the project is consistent with an SCS or APS that ARB has determined will achieve the regional targets, and 2) the project implements the mitigation measures required under an applicable prior environmental document. A project meeting these criteria does not have to describe or discuss in any CEQA document growth-inducing impacts, any project-specific or cumulative vehicle impacts on global warming or the regional transportation network, or a reduced residential density alternative to vehicle impacts.

Transit Priority Projects: The bill defines a new category of project, "Transit Priority Projects," and establishes a categorical exemption from review under CEQA for such projects, provided they meet additional specified criteria. Projects that meet the definition of the category, but not the additional criteria, are afforded other streamlining of CEQA requirements, but are not fully exempt. The definition of "Transit Priority Projects" is based on four factors:



- The project is consistent with the SCS or APS, whichever has been determined by ARB to meet the assigned reduction targets; and
- The project meets specified mixed-use criteria; and
- The project has a minimum net density of at least 20 units per acre; and
- The project is within a half mile of a major transit stop (existing or planned), or a "high quality" transportation corridor.

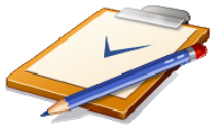
A categorical exemption is provided for TPPs that conform to all criteria on a specified list, as well as at least one additional criterion from a list of options. The TPP must meet all of the following criteria:

- The project is no larger than 8 acres and not more than 200 units;
- The project can be served by existing utilities and has paid all applicable in-lieu and development fees;
- The project does not have a significant effect on historical or environmental resources (e.g. natural habitat);

- The project has remediated any environmental hazards to applicable standards and is not subject to significant and defined catastrophic risks;
- The project is not located on developed open space;
- The buildings in the project are 15 percent more energy efficient than required by California law and the project is designed to achieve 25 percent less water usage than the average household use in the region;
- The project does not result in the net loss of affordable housing units in the area;
- The project does not include any single-story building larger than 75,000 square feet;
- The project incorporates mitigation measures from previous environmental impact reports;
- The project does not conflict with nearby industrial uses.

To meet the categorical exemption, the TPP must also conform to at least one of the following:

- At least 20 percent of the housing units will be sold to families of moderate income, or not less than 10 percent of the housing will be rented to families of low income, or not less than 5 percent of the housing will be rented to families of very low income and the developer commits to the continued availability of the non-market units (55 years for rental units, 30 years for ownership units); **or**



- The developer pays in-lieu fees equivalent to costs of meeting the first requirement; **or**
- The project provides public open space equal to or greater than five acres per 1,000 residents.

TPPs that do not meet the criteria for a full categorical exemption from CEQA can qualify for streamlining under a Sustainable Communities Environmental Assessment or by implementing approved Traffic Mitigation Measures.

A TPP may be reviewed under a Sustainable Communities Environmental Assessment (SCEA) if the project incorporates all feasible mitigation measures, performance standards, or criteria from an applicable prior environmental impact report. The SCEA is similar to an EIR, but it does not have to address potential growth-inducing impacts, any project-specific cumulative impacts on climate change from the use of light duty

vehicles, or any other cumulative effects of the project that have been addressed and mitigated in prior environmental documents. In addition to this streamlining, the bill provides that a legal challenge of the SCEA is to be reviewed under a standard of "substantial evidence" rather than under the "fair argument" standard that is generally applied to EIRs.

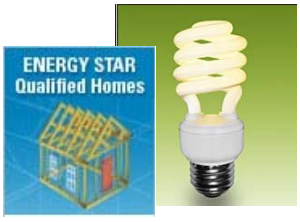
The bill also authorizes cities and counties to adopt specific Traffic Mitigation Measures (TMMs) to apply specifically to TPPs. The TMMs include such measures as requirements for the installation of traffic control improvements, street or road improvements, transit passes for future residents, or other measures that will avoid or mitigate the traffic impacts of transit priority projects. Any TPP that implements the approved TMMs is not required to identify or implement any additional measures to mitigate traffic impacts under CEQA.

Alternative and Renewable Fuel & Vehicle Technology Program (AB 118)

In October 2007, Governor Schwarzenegger signed AB 118 (Nunez, Statutes of 2007), into law. AB 118 provides approximately $200 million annually through 2015 for three new programs to fund air quality improvement projects and develop and deploy technology and alternative and renewable fuels. The bill creates a dedicated revenue stream for the programs via increases to the smog abatement, vehicle registration, and vessel registration fees. The three new programs are: the Air Quality Improvement Program administered by ARB, the Alternative and Renewable Fuel and Vehicle Technology Program administered by the California Energy Commission, and the Enhanced Fleet Modernization Program administered by the Bureau of Automotive Repair.

The Air Quality Improvement Program will provide about $50 million per year for grants to fund clean vehicle and equipment projects which reduce criteria and toxic air pollutants as well as research on the air quality impacts of alternative fuels and advanced technology vehicles. ARB will be developing guidelines for the Air Quality Improvement Program and the Alternative and Renewable Fuel and Vehicle Technology Program to ensure that both programs complement efforts to meet the federal and state ambient air quality standards and to reduce air toxics.

California Energy Efficiency Standards (Title 24, Chapter 6)



Title 24, Part 6 (California's Energy Efficiency Standards for Residential and Nonresidential Buildings) of the California Code of Regulations was first established in 1978 in response to a legislative mandate to reduce California's energy consumption. The standards are updated periodically to allow consideration and

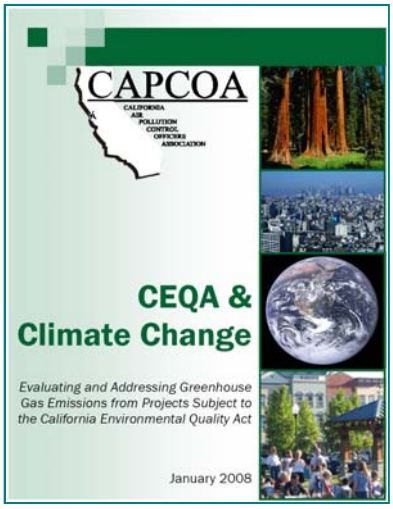
incorporation of new energy efficiency technologies and methods. These standards are mandatory and thus new building permitted by City and County governments must comply with the standards in effect at the time. These standards also promote cost-effective means to reduce energy use and thus GHG emissions for new development relative to business as usual conditions.

The Energy Commission adopted the 2008 Standards on April 23, 2008, and the Building Standards Commission approved them for publication on September 11, 2008. These new Standards will be in effect as of July 1, 2009. The requirement for when the 2008 Standards must be followed is dependent on when the application for the building permit is submitted. If the application is submitted after 7/1/09, the 2008 Standards must be met.

California Environmental Quality Act

The California Environmental Quality Act (CEQA) (Pub. Res. Code §21000 et seq.) is not specific to GHG regulation and does not create specific new mandates for General Plans; however, its basic goal is to ensure that environmental impacts of proposed projects are evaluated, and significant impacts are mitigated and disclosed to the public. CEQA substantially influences the approval process for General Plans. The evaluation is done through an Environmental Impact Report (EIR) which provides State and local agencies and the general public with detailed information on potentially significant environmental impacts a proposed project is likely to have and ways to mitigate those impacts, and also to evaluate potential alternatives to the project.

Because of the global nature of the climate change problem, most projects will not result in GHG emissions that are individually significant. CEQA also requires consideration of whether impacts are *cumulatively* significant, however. The determination of significance is made by the agency with primary jurisdiction over the project. CEQA allows the agency to establish thresholds for significance, based upon sufficient scientific evidence, but thresholds are not required.



In January of 2008, CAPCOA released a resource document called *CEQA and Climate Change*, that reviewed the various options available to lead agencies to determine significance of a project. The document also evaluated tools and methodologies, and provided a list of mitigation strategies. A more comprehensive discussion of CEQA and its applicability to GHG emissions is provided in that document.

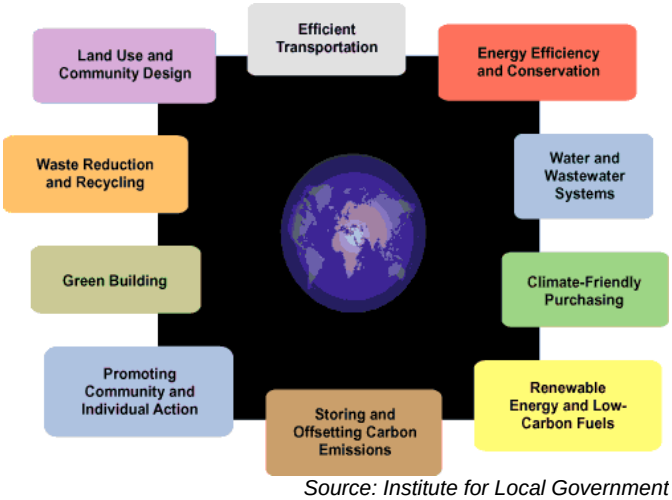
On April 13, 2009, the Governor's Office of Planning and Research sent proposed amendments of the CEQA Guidelines to the Secretary of the Resources Agency for promulgation. The proposed amendments contain

recommended changes to fourteen sections of the existing guidelines, including: the determination of significance as well as thresholds; statements of overriding consideration; mitigation; cumulative impacts; and specific streamlining approaches. Overall, the proposal includes the same basic approaches covered in the CAPCOA document. The proposed Guidelines also include an explicit requirement that EIRs analyze GHG emissions resulting from a project when the incremental contribution of those emissions may be cumulatively considerable. A copy of the full proposal, as well as the letter of transmittal, may be found at: www.opr.ca.gov.

An important consideration of CEQA with respect to planning is the growing consensus that a robust effort to address GHG emissions at the General Plan level can substantially streamline subsequent project review under CEQA, provided the project is consistent with the GHG reduction policies in the Plan. This is specifically allowed in the OPR proposal, and is being further developed in the context of SB 375. Although the specifics of what is entailed here have yet to be established, the concept is important to consider in shaping the policies included in the General Plan.

Local government has an enormously important role to play in reaching the goals of AB 32, and more importantly, in the achieving the greater long term goal of preventing catastrophic climate change. There are many strategies a local government can undertake that will reduce GHG emissions, and help minimize the extent of climate change that does occur. Some of the strategies depend on coordinated action with other agencies and levels of government; others can be implemented independently.

This section of the report is mainly focused on the more immediate actions local governments can take, including direct reductions from local government operations; the role of local government in fostering reductions in the business sector and in local communities; and lead agency obligations to address GHG emissions under CEQA. This chapter also touches briefly on the crucial, longer term role of local government: establishing over-arching plans that will achieve reductions through changes to land use and transportation, resource management, and the efficiency of the built environment. The Institute for Local Government provides resources and a forum for sharing ideas on many of these important topics (see www.cacities.org). The role of local government in planning for GHG reductions is explored more fully in Chapter 4.



Source: Institute for Local Government

Reductions in Local Government Operations

There are five core areas of local government operations that are responsible for GHG emissions. These include: energy use, waste and recycling, water delivery and wastewater treatment, transportation, and the build environment.

In addition, there are actions the local government can take to preserve open space and undertake reforestation, for example, that can mitigate or offset the emissions resulting from operations.

A brief discussion of each operational area is included below. These lists are not exhaustive; rather, they provide a sampling, and links are provided in the References section of this report where additional information and examples can be found. Finally, the discussion here is limited to emissions from operations as opposed to those associated with policies governed by the General Plan, a discussion of which follows.

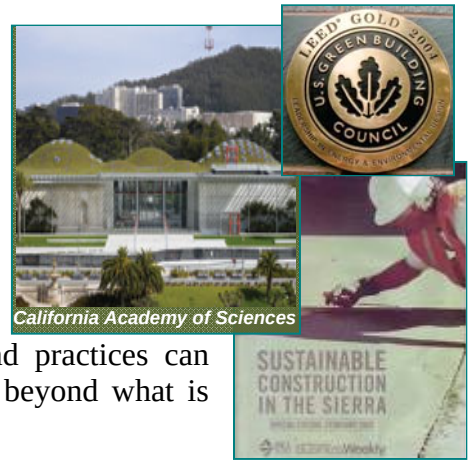
Energy Use: The buildings, equipment, and infrastructure of local government all use energy. In general, newer purchases and installations tend to be more energy efficient, but there are plenty of opportunities to enhance efficiency and cut energy use. Buildings can be made more efficient by upgrading insulation and installing low emissive glass, using high-efficiency lighting with timers and sensors, installing cool roofs, and simply adjusting heating and cooling levels. Alternative energy sources can be developed, such as installation of solar collectors, or landfill gas to energy projects. Local governments can also change the emissions profile of the energy they purchase from their energy providers. Equipment that heats and cools buildings can be upgraded to the most efficient models, as can computers, telecommunications, and office equipment. And infrastructure such as street lighting and traffic signals can be upgraded with state-of-the art technology such as halogen bulbs and solar collectors and storage at power or signal poles. Lifecycle carbon costs of maintaining infrastructure as diverse as roads, bridges, and transit facilities can be evaluated so that the least carbon-intensive materials and procedures are used.

Waste and Recycling: There are GHG emissions associated with the energy involved in waste handling, and due to methane from waste decomposition as well as some GHG with high global warming potential from foam products and refrigerants released during the handling of these materials. Local governments are users of waste and recycling systems for their own operational waste. To reduce emissions from their own operational waste stream, jurisdictions can enhance employee access to recycling, create purchasing guidelines to emphasize recycled materials, less packaging, and to avoid products that release more potent GHGs. In one creative example, the City of San Francisco is replacing bottled water at coolers and in dispensers with filters on drinking fountains. Local governments also may operate or exercise contractual control over waste handling programs, depending on how these services are structured and provided in their jurisdictions. Emissions from this portion of the waste stream can be reduced through methane recovery, recovery of potent GHG from foam and refrigerant systems, and other adjustments to collection systems.

Water Delivery and Wastewater Treatment: Movement, storage, and treatment of water and wastewater use significant amounts of energy. Local governments can reduce their own water use by installing low-flow fixtures, by inspecting, repairing and replacing leaking components, especially irrigation and other water supply at remote sites that often go unnoticed for long periods, and through xeriscaping. Water reclamation and graywater systems can also trim the carbon footprint from water use, and managing time of demand with large water users can significantly alter the energy needs at peak delivery times.

Transportation: Local governments can reduce the GHG emissions of their vehicles by replacing older vehicles with the highest efficiency vehicle that can perform the needed function. They can also reduce the overall size of the fleet by increasing the use of pooled vehicles instead of assigned vehicles, and encouraging carpooling when on government business. As employers, local governments can institute programs to increase employee use of alternate modes of transportation, such as transit, carpooling, biking, and walking to work, and they can offer compressed work schedules, telecommuting, and even satellite offices. If properly designed, many of these strategies can also help decrease GHG from the public accessing the jurisdiction's services, as can offering access to services online.

The Built Environment: Commitments to highly efficient construction in their own new facilities is one way local governments can reduce carbon emissions from the built environment. Many local governments are building or retrofitting their facilities to LEED certification standards. The siting of new facilities is also an opportunity to improve access by employees and the public and reduce transportation related emissions. In addition, when it establishes the building codes for its jurisdiction, local government has the opportunity to significantly alter the energy used in constructing, maintaining, and using the built environment. A careful review of local needs and practices can identify opportunities for energy performance well beyond what is required under California's Title 24 standards.



Mitigation Projects: Separate from its core operational mission, a local jurisdiction can undertake projects or actions for the purpose of mitigating or offsetting GHG emissions. Examples of these projects include securing the development rights to land that might otherwise be developed (especially where the site does not lend itself to sustainable transportation planning) and undertaking reforestation projects either in open space that has been previously deforested, or through urban forestry efforts. Advanced technology demonstration projects can also ease the transition to new technologies and enhance public acceptance of them, for example purchasing or leasing a plug-in hybrid, fuel cell, or full electric vehicle and demonstrating its use at public events. Some local governments purchase emissions offsets for certain transportation-related emissions, such as

air travel, although any GHG emissions can be offset. When offsets are purchased, the jurisdiction should take extra precaution in verifying the value of the offsets, as some are of dubious origin.

Fostering GHG Reductions in the Business and Community Sectors

In addition to implementing programs to reduce its own carbon emissions, local government has an important role to play in bringing others to the table and helping them to reduce their GHG emissions. Local governments can develop public education and outreach programs, can establish public-private partnerships and programs to publicly recognize achievements, and offer incentives (non-monetary as well as financial) for actions that reduce GHG emissions. Examples of these types of actions are also provided as model policies in Chapter 6, but they can also be implemented without the benefit of an overarching plan.

Education and outreach programs would include events such as conferences, workshops, or fairs, featured speakers, public service announcements, print messages, and online information or interactive sites. Ideally, topics will span a broad range, including the fundamentals of climate change and how our actions contribute to it, down specific actions or projects, such as a "lights out" campaign, a "green tip of the day" or a how-to workshop on gardening with drought-tolerant, native plants. Programs involving schools are also beneficial, and model units on climate and conservation are available; events like poster contests and recycle drives are a good way to get children involved.

Local governments are also in a unique position to work with local businesses on climate protection projects and partnerships. Many of the GHG reduction strategies that rely on improved efficiency in energy, water, fuel use, or waste reduction, can generate significant cost savings for businesses over a fairly short time frame. A local government that has implemented some of these strategies in its own municipal operations is in a good position to demonstrate savings, but even if the government does have data of its own to share, it can encourage business participation in these types of programs.

Small Business Toolkit available at: www.coolcalifornia.org

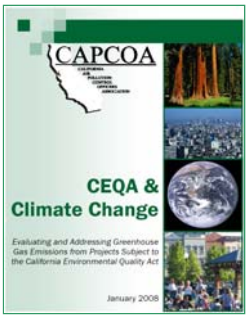
Suggestions include working with the local chamber of commerce, business associations, or business-focused civic groups to establish a forum to share efforts and results, such as

newsletters, or a monthly breakfast meeting or luncheon. Local government can also help establish demonstration projects, and can publicly recognize local leaders with awards or in public service messages.

Incentives are another important tool to encourage actions that reduce GHG emissions in the near term. To be effective, the incentive does not have to be monetary. As noted above, public recognition can be a powerful motivator, but local governments have other tools they can use to promote GHG emission reductions. Examples include preferred parking for electric or alternative fuel vehicles, and express permitting of projects on a "green project" list. Financial incentives can be small or large, beginning with free compact fluorescent light bulbs or reduced transit fairs on a designated "don't drive" day, to rebates for high efficiency toilets and electric lawn mowers, to creative financing for energy efficiency improvements or installation of solar panels. In some cases, the government can partner with the private sector for sponsorship of these kinds of efforts, which can help defray some of the costs.

Mitigating Impacts through Project Review

Local governments review proposed projects under CEQA, either as a lead or a responsible agency. Until recently, climate change was not considered an environmental impact under CEQA, and GHG emissions associated with projects were not quantified, disclosed, or mitigated. This has changed, however, and there is now broad recognition that these are potentially significant impacts, either individually or cumulatively, and that they do need to be addressed. Some jurisdictions recognized this early on and began to evaluate climate impacts during their CEQA review process. Following the passage of AB 32 in 2006, greater attention was paid to this issue, and in 2007, California's Attorney General put local governments on notice that these impacts could no longer be overlooked. There was a fair amount of confusion, however, about how to quantify GHG emissions, at what level they would be considered significant, and what steps could be taken to mitigate them.



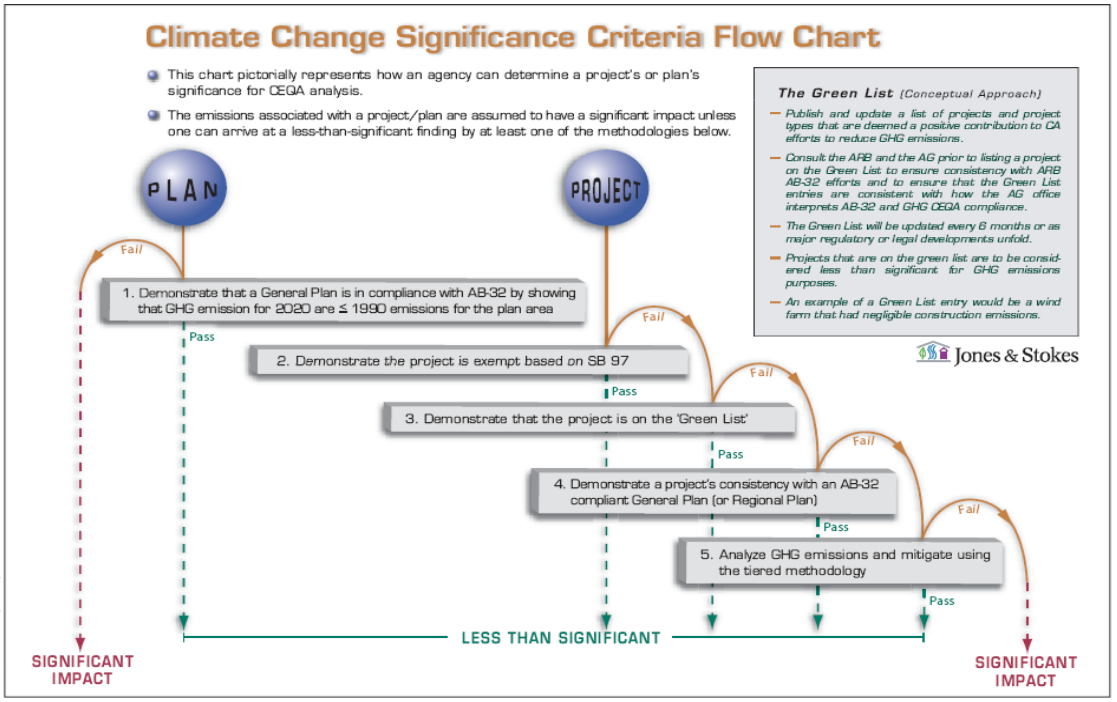
In January of 2008, CAPCOA released a resource document, *CEQA and Climate Change*, that collected and presented information to support local governments as they undertake a review of GHG emissions from projects subject to CEQA. The document considered approaches to determining significance of emissions, evaluated available methodologies and tools for quantifying GHG emissions, and provided a summary of GHG mitigation measures for projects.

Three approaches to determining significance are explored in the CAPCOA document, including the benefits and potential concerns associated with each. Significance can be determined without first establishing a significance threshold; in this case, the determination will be made on a case by case basis, which creates uncertainty and may be

vulnerable to challenge. A significance threshold can be set at zero, on the premise that any GHG emissions contribute in a cumulative way to the global problem; this approach is simple in its construct and provides certainty, but the work associated with preparing and reviewing EIRs on all projects is likely to overwhelm the system and lessen the effectiveness of review across the board. A significance threshold can be set at an emission level other than zero; the chief challenge for this approach is to identify and scientifically support an appropriate threshold, and the CAPCOA report evaluates several different options for doing this. Of particular interest are two elements discussed in the non-zero approach. These are: the role of robust treatment of GHG emission reduction policies in the General Plan, and the creation of a "Green List" of projects that will reduce or mitigate GHG emissions, both which could be used to substantially streamline the review process under CEQA. Figure 17 presents these non-zero threshold concepts in a flow diagram.

The CAPCOA report also evaluates a number of technical models and tools currently

Figure 17



Source: CEQA and Climate Change, CAPCOA 2008

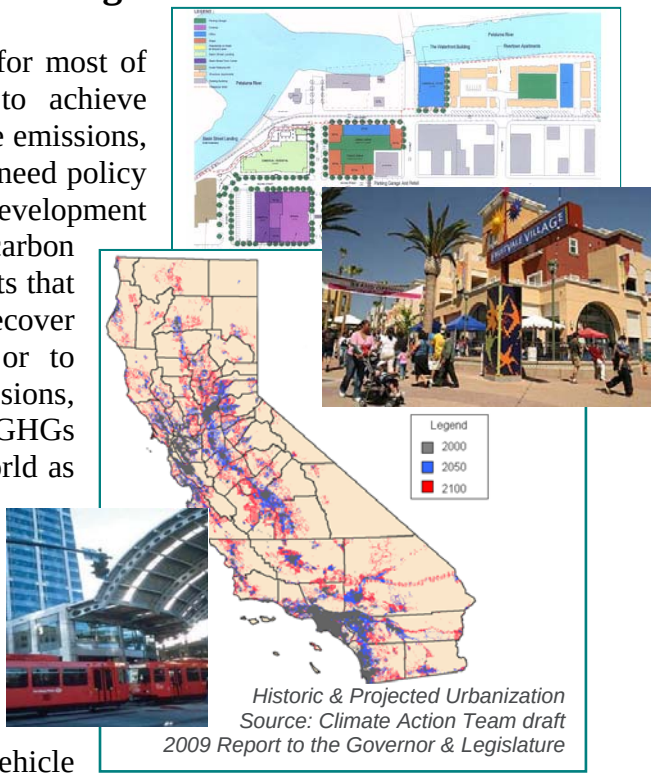
available for quantifying GHG emissions, as well as several that are still under development. The report concludes that there is currently sufficient information to quantify GHG emissions for the purposes of evaluating projects under CEQA, but that improvements in several key areas will greatly improve the sensitivity and usefulness of available methods.

Finally the CAPCOA report compiles and presents information on measures to mitigate GHG emissions. It includes tables that provide information on measure applicability, jurisdiction, feasibility, effectiveness, secondary effects, and cost.

CAPCOA will provide a supplement to its report in 2009, with a summary of new developments in CEQA review of GHG, including policies and thresholds adopted since the original report, advances in methods and tools, and innovative strategies to mitigate impacts. Readers interested in additional information about mitigating emissions of GHGs from projects subject to CEQA are encouraged review CAPCOA's report and the 2009 supplement. Readers should also keep in mind that many of the mitigation strategies that are summarized in the CAPCOA report can be implemented even if there is no project subject to CEQA review, on a voluntary basis.

Finally, as discussed in Chapter 2, on April 13, 2009, the Governor's Office of Planning and Research recommended CEQA Guidelines changes to the Secretary of Natural Resources. The proposed changes include a new section that specifies that previously established standards of mitigation apply to GHG emissions. They also address the use of General Plans to streamline mitigation requirements, and specify that in order to use this approach, the General Plan must be specific enough in its treatment of the project type in an actual measure. The OPR package also proposes revisions to Appendix F that contain specific energy efficiency measures that may reduce GHG emissions.

Reducing Emissions through Planning



Historic & Projected Urbanization
Source: Climate Action Team draft 2009 Report to the Governor & Legislature

Transportation and energy use account for most of the emissions of GHGs. In order to achieve substantial and lasting reductions in these emissions, we need technological advances and we need policy advances. On the technology front, development alternative energy sources and low carbon fuels, more efficient vehicles and products that use less energy, and mechanisms to recover energy lost without beneficial work, or to capture and sequester or destroy emissions, will make a significant cut in the GHGs emitted by living and working in our world as we do now. But that is not enough to avoid the worst impacts of global climate change. We also need innovative policies that change the patterns of our lives to produce fewer GHGs. This means creating communities that are designed to decrease the use of single occupancy vehicle travel, to encourage the use of local products, and to minimize waste. The key to creating these communities is the General Plan.

Powerful forces and competing needs have combined to create the land use patterns we see today across California. It is neither quick nor easy to change these patterns, and

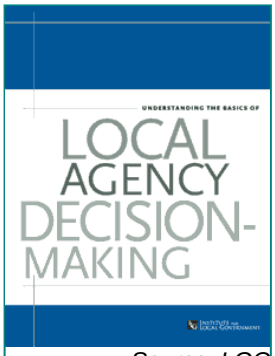
there are significant obstacles to overcome. Funding is one of the obstacles. In the Scoping Plan, ARB commits to work with other State agencies and with local governments to secure funding to support the planning needed to achieve real changes. Another obstacle is the uncertainty about outcome. Notwithstanding such obstacles, some local governments have moved forward with creative planning that has revitalized the urban core zones in their areas with transit-oriented, mixed-use, high-density development of brownfield sites. The results are vibrant, livable, walkable communities where local residents work, shop, and play, and which attract visitors and bring economic vitality along with quality of life. Examples can be seen in both urban settings such as Sacramento, as well as in suburban areas like Fruitvale in the San Francisco East Bay, and even more rural settings, such as Petaluma and Windsor in Sonoma County. By encouraging more of these models of sustainable design, we can demonstrate that they are not only feasible, but successful. In its Scoping Plan, ARB suggests that one possible use of revenue from the auction of credits in a cap and trade system, or from carbon fees, would be to provide incentives for sustainable land use design. Opportunities to support sustainable planning should be cultivated, to ensure that the most successful approaches are recognized and replicated.

The planning that local governments undertake, namely the General Plan, and any specific Area Plans or Climate Action Plans, can form the basis for thoughtful and effective actions to reduce GHG emissions from local activities. When this planning is undertaken in concert with broader regional planning, such as “Blueprint” planning, regional transportation planning, and air quality planning, the impact of GHG reduction efforts is multiplied many times. Chapter 4 discusses the role of these planning efforts, and how they interrelate to effectively respond to the challenge of climate protection.

Introduction

The commitment to reduce GHG emissions under AB 32, in and of itself, highlights the importance of effective long-term planning by local government to minimize GHG produced by land use and transportation patterns, use of natural resources, and the built environment. When it is considered together with the newly approved changes to regional transportation planning under SB 375, there is an overwhelming call to enhance our planning efforts and remake our communities so that they are sustainable, and sustaining. We have the tools to accomplish this, and now we have a substantial statutory underpinning to support the effort.

There are several key planning approaches a local agency can rely on to address climate protection goals. The intersection of AB 32 and SB 375 will result in regional GHG reduction targets in most metropolitan areas, with accompanying regional planning. This effort will be most effective if local governments support and reflect GHG reduction policies in their own local planning efforts. Local governments can also adopt separate Climate Action Plans that focus on an overarching commitment to greenhouse gas emissions reduction, and set forth the specific policies and mechanisms to achieve that reduction. Jurisdictions can incorporate climate protection goals into their General Plans, either through a stand-alone element or by integrating into existing elements. They can also rely on, draw from, and align with the measures in other regional plans, including "Blueprint" plans, air quality plans, and transportation plans. These options are not mutually exclusive; in fact, they will provide the most robust reductions in greenhouse gases if they are implemented in concert, with careful attention to coordination of goals and optimizing limited resources. An added benefit of a more comprehensive approach is the potential to simplify the administrative process associated with review of projects under CEQA, while ensuring the highest standard of environmental protection.



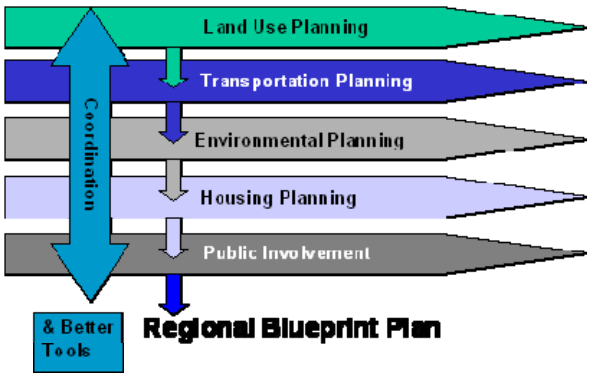
Source: LGC

Finally, as this coordinated planning effort moves forward it is important not to lose sight of the potential for unintended consequences, and to ensure a mechanism to review progress and outcomes, and to ensure those consequences, specifically any that would harm environmental justice goals, are addressed with prompt, mid-course corrections.

Regional Targets and Planning

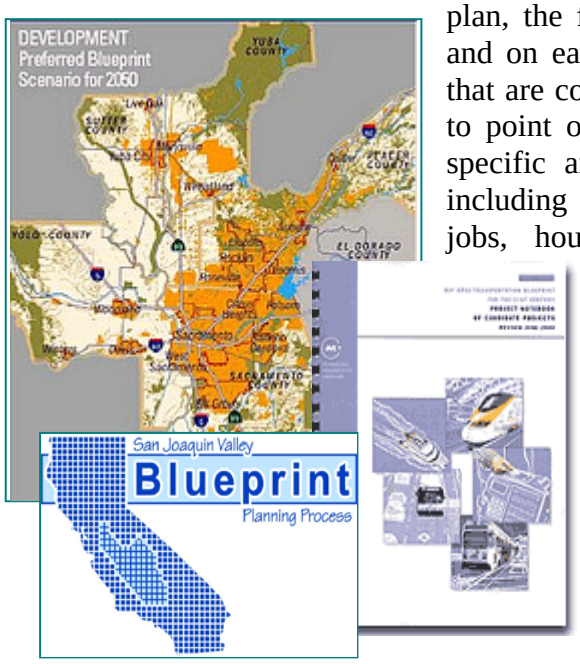
Recent studies with models of land use and transportation related emissions show that improved planning and design can reduce GHG from this sector by a significant amount. In the near term, that is by 2020, the emission reductions are relatively modest, on the order of 4% from the business-as-usual scenario. But because the benefits from these types of improvements accrue incrementally over time, as new planning policies are implemented and transportation patterns and habits change in response, the emission

reductions in out years are much greater. By 2030, reductions are projected to double, and by 2050, could be as much as 18%.



Source: www.fhwa.dot.gov

In order to actually achieve these reductions, air quality, land use, and transportation planning will need to be integrated regionally. These efforts have already begun in several large metropolitan areas, using a "Blueprint" planning model. This model allows the cities and counties within the region to collectively select future growth scenarios for land use and transportation that lead to more sustainable communities and cleaner air, including fewer emissions of GHGs. The plans are developed through a public process and provide for local accountability. Each jurisdiction incorporates the agreed-upon growth scenario into its General Plan. The success of the effort depends on the robustness of the Blueprint plan, the faithful incorporation into each General Plan, and on each jurisdiction making project-level decisions that are consistent with its General Plan. It is important to point out here that the planning needs to be highly specific and consider a number of important factors, including (but certainly not limited to) where current jobs, housing, and transportation infrastructure are placed, and the relationship of those things to the residents the project is intended to serve. While "high density" development is generally considered a product of "good" planning, if it is the wrong project, in the wrong place – that is, if it is implemented without consideration of all of the elements that contribute to the current pattern of land use and transportation – that high density project could actually exacerbate existing problems.



Recognizing the potential for long-term, durable reductions, ARB has proposed to establish regional GHG emission reduction targets. According to the Scoping Plan, ARB envisions a regional planning process that will: (1) Use integrated scenario modeling to align regional transportation plans and local General Plans; (2) Take into consideration other State policy goals; (3) Incorporate performance indicators to monitor progress; (4) Coordinate local and regional planning efforts to achieve maximum emission reductions; and (5) Establish priorities for and direct State resources to help local and regional governments meet the regional GHG targets.

As discussed in Chapter 2 of this report, SB 375 (Steinberg) establishes a statutory framework for this integrated regional planning approach. The Steinberg bill requires that ARB assign regional GHG reduction targets to specified metropolitan areas. Among other things, the bill also provides that ARB must approve the emission reduction quantification that underpins the Sustainable Communities Strategy (SCS) developed by these regions, or their alternate plan that contains additional reduction measures if the primary strategy fails to meet the assigned targets.

Under SB 375, the ARB is not given the authority or responsibility to determine the land use and transportation policies for any given region, nor is the regional planning body (the MPO) given any specific land use authority under SB 375. Land use decisions are still vested in the local city or county government. Because the SCS is part of the Regional Transportation Plan, however, and because SB 375 requires that funding allocated under the RTP be consistent with the programmatic and policy elements of the RTP, the bill essentially ties transportation funding for the RTP to implementation of the SCS policies.

Another important clarification is that the Alternate Plan is not part of the RTP, and therefore transportation funding is not linked to implementation of this plan. In order to incentivize its implementation, the bill provides exemptions from certain CEQA review requirements for projects consistent with SCS and ACS that achieve the regional target reductions in GHG emissions, as approved by ARB.

Finally, while there is material overlap between the policies that will be embodied in the regional SCS and the GHG reductions from measures in the city or county's General Plan or Climate Action Plan, they are not the same. The SCS is a transportation driven strategy, whereas the General Plan and the Climate Action Plan address other important opportunities for GHG reduction in addition to transportation. In the best case, the measures in the SCS will be reflected in and complemented by the measures in the General Plan and the Climate Action Plan.

Climate Action Plans and Commitments

In the Scoping Plan, ARB recognizes the value of local Climate Action Plans and commitments to reduce GHG emissions. Climate Action Plans provide an overarching policy direction for local governments committed to reducing GHG emissions within their jurisdictions. Many areas have

already established these plans; examples and references are included in Appendix G.

An effective Climate Action Plan will have several core elements, including an inventory of emissions, a target for reductions, timeframes, milestones, and tracking and accountability mechanisms, and strategies for achieving the reductions. First, as its foundation, the Plan will rely on a complete inventory of GHG emissions in what will become the Plan's base year. Although AB 32 identifies 1990 as a base year for California, most local jurisdictions do not have the underlying data necessary to establish GHG emissions in 1990. Rather than approximate emissions in that year, local governments are better served by selecting a year for which they have complete and accurate data on energy use, vehicle miles traveled, and other key parameters that affect GHG emissions. In selecting the year, it is helpful to also choose a year that is not heavily influenced by an unusual event or circumstance.

The inventory should include GHG emissions from three aspects of the local jurisdiction. There are emissions that result directly from local government operations, emissions associated with local government policies and decisions, and emissions from the community within the jurisdiction. Working with ICLEI and CCAR, ARB has adopted a reporting protocol for local government operations' GHG emissions. Information on calculating emissions associated with policies and decisions (essentially, land use and transportation emissions, as well as other sectors address in the General Plan) can be found in the CAPCOA report, *CEQA and Climate Change*, in the section on Analytical Methodologies. ARB is currently developing a reporting protocol for local communities, as well as a "Local Government Toolkit" which is available at www.coolcalifornia.org. Examples of Climate Action Plans that have baseline inventories are provided in Appendix G. There are also businesses and organizations that provide consulting services in this area.

In choosing emission reduction targets, the jurisdiction should consider the statewide GHG reduction targets, any assigned regional targets, and what is feasible for the jurisdiction to achieve. ARB has estimated that reductions of 28% from business-as-usual are needed on a statewide basis to reach the goals of AB 32. But the business-as-usual scenario may be difficult for a local jurisdiction to calculate. If the goals of AB 32 are presented as a reduction from the average statewide GHG emissions between 2002 and 2004, a reduction of almost 10% is needed. If a local government can establish a baseline looking at average annual emissions between 2002 and 2004, a reduction target to reduce the total GHG emissions from the jurisdiction by 10% by 2020 would be

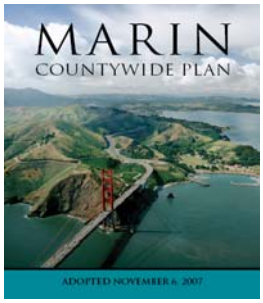
consistent with AB 32. While 10% may not sound like a large number, it is important to remember that the current trend is one of significant emissions growth. Regional targets for metropolitan areas will be developed and assigned pursuant to SB 375. Local feasibility will need to be assessed based on the jurisdiction's inventory and in consideration of local input through a public process.

AB 32 provides a fairly straightforward timeframe for achieving reductions in GHG emissions. Areas that adopted Climate Action Plans before the passage of AB 32 may have identified other deadlines for reaching their targets. For those areas, it may be useful to review their reduction targets and deadlines to ensure that the local commitments are consistent with statewide goals to the extent feasible. In addition to overall deadlines, however, intermediate milestones are important, and the Plan should specify mechanisms to measure progress, as well as make midcourse corrections if reductions are not being realized as anticipated. Milestones can be based on actual reductions in GHG, but because some analysis is needed to determine GHG emissions and reductions, there should also be performance milestones that reflect progress implementing plan elements.

Climate Protection in General Plans

Whether or not a local government adopts a Climate Action Plan, its General Plan should address climate change, its potential impacts, and local contributions to the problem. The Governor's Office of Planning and Research (OPR) is preparing guidance on this, which will be forwarded to the California Resources Agency for formal adoption. In addition, the California Attorney General has challenged the EIRs for General Plans that have failed to address climate change. Policies to mitigate climate change should be incorporated into the General Plan either within existing elements, or in a separate Greenhouse Gas Reduction element.

Incorporating Policies into Existing General Plan Elements- Existing General Plans will invariably contain policies (and any associated goals, objectives, policies, standards and implementation measures) that help to reduce GHG emissions. However, they are just as likely to contain policies that work against that goal. There are opportunities to strengthen existing General Plan policies and/or incorporate new policies that reduce emissions. Several options exist for integrating additional policies, including the three discussed below.



Policies may be incorporated into a jurisdiction's existing General Plan elements through a General Plan amendment. In this scenario, no additional elements would be necessary. Identifying existing policies in each General Plan element that already do or could help reduce GHG emissions would be a critical first step in assessing the type and nature of new policies needed. Categorizing existing helpful policies by their function would greatly aid this assessment; the following are important categories to include: land use, circulation, energy efficiency, alternative energy, municipal operations, waste reduction, conservation, and education. Incorporation of these policies should include a comprehensive review of all elements of

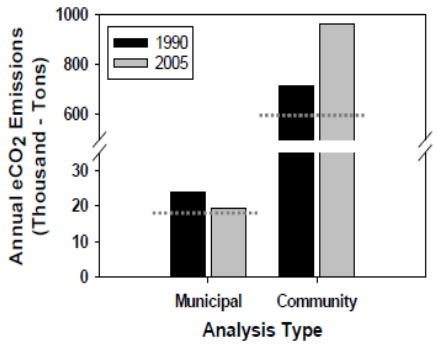
the General Plan to ensure that conflicting policies are eliminated as part of the amendment, in the interest of maintaining internal consistency.

Creating a Climate Change Element- A new climate change element could be added as an amendment to an existing General Plan. This should again be accompanied by a comprehensive review of the General Plan to identify and revise or eliminate conflicting policies. The element could include an introduction about climate change, a GHG inventory if feasible, and new and existing policies organized into the following categories: land use, circulation, energy efficiency, alternative energy, municipal operations, waste reduction, conservation, and education. These three main components of a climate change element are discussed further below.

The Introduction*:* The introduction should provide descriptive background information on climate change and its impacts to inform the reader on the issue and the need for incorporating new General Plan policies to reduce GHG emissions. Information needed for the introduction can be found in the first chapter in this report, as well as in Appendix D. Additional information is available from the Air Resources Board (www.arb.ca.gov), the Energy Commission (www.energy.ca.gov) the Climate Action Team (www.climatechange.ca.gov), and the National Academies of Science, Division of Earth and Life Science (www.dels.nas.edu/dels/).

The GHG Inventory*:* As described for Climate Action Plans, above, a greenhouse gas inventory is an important tool for establishing a baseline of existing emissions within the jurisdiction. This will greatly aid the process of determining the type, scope and number of GHG reduction policies to be included, particularly in the context of meeting regional GHG targets; it will also facilitate tracking of policy implementation and effectiveness. GHG inventories for local jurisdictions typically consist of two distinct components: one for the city/county as a whole defined by its geographical borders, and the second for emissions resulting from the city/county's municipal operations.

Fig. 18: Example Display of Municipal & Community Emissions

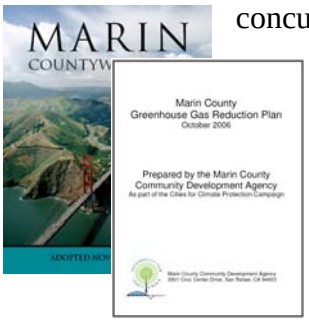


The municipal inventory would effectively be a subset of the community-scale inventory (the two are not mutually exclusive). Preparing an inventory is not required in order to incorporate General Plan policies that reduce GHG emissions, but it's highly advisable and is a critical component of any Climate Action Plan. The inventory may be included as an appendix to the General Plan. Figure 18 shows municipal and community emissions as calculated for the City of Chula Vista.

Objectives and Policies: As mentioned above, identifying existing General Plan objectives and policies that could or do reduce GHG emissions and categorizing them appropriately is a key step in determining what new policies may be needed to achieve established GHG reduction goals. The following eight category designations are recommended for this purpose: land use, circulation, energy efficiency, alternative energy, municipal operations, waste reduction, conservation, and education. These categories help associate the identified policies with how the reductions are achieved and indicate which General Plan element would contain related policies. Figure 19 shows how reductions in different categories add together to reach the overall target. The new objectives and policies developed for inclusion in this element would also be categorized in the same fashion, with the document structure similar to the other elements in the existing General Plan. Including a matrix or table of all the new and existing/revised policies in the element and the categories under which they fall is a helpful tool in developing implementation mechanisms.

Preparing a Climate Action Plan and Updating the General Plan

A jurisdiction may prepare a Climate Action Plan (CAP) prior to a General Plan update, concurrently with a General Plan update, or following a General Plan update. As described above, the Climate Action Plan would: provide background information on the causes of climate change and projections of its impacts on California and the jurisdiction; present estimates of the jurisdiction's baseline greenhouse gas emissions inventory and reduction target; describe recommended emission reduction actions in the key target sectors; and, identify next steps required over the near term to implement the plan.



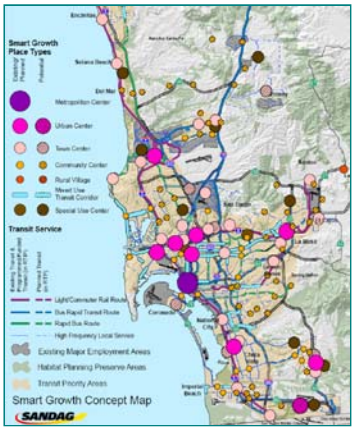
Preparation of a CAP prior to updating the General Plan would provide much of the information needed to incorporate appropriate GHG reduction policies into the update. That may not be feasible, however, and is not essential to the preparation of an effective General Plan update with sufficient climate protection measures. However, developing a CAP subsequent to completing the General Plan update may necessitate further revision of the General Plan to provide a general policy basis for the CAP actions.

Coordination with Other Regional Plans

Coordination with regional blueprint plans, regional transportation plans and air district attainment plans, is critical to ensuring the measures within each plan support and do not conflict with the other plans, and that they are working together to reduce GHG emissions. Communication and coordination can improve effectiveness and reduce costs.

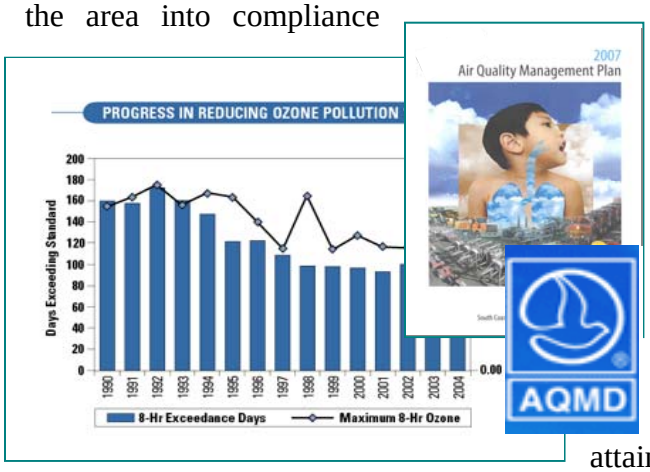
Association of Bay Area Governments
Bay Area Air Quality Management District
Bay Conservation and Development Commission
Metropolitan Transportation Commission

Coordination with Blueprint Plans: As discussed above, the AB 32 Draft Scoping Plan encourages local governments to incorporate regional "blueprint plans" into their General Plans. Blueprint plans are envisioned as regional guidance for land use decision-making that would be adopted by the applicable Regional Transportation Planning Agency or Metropolitan Planning Organization. Each regional blueprint would establish recommended land use patterns, transportation systems, and transportation investments to reduce GHG emissions, as well as other air pollutants and congestion within the defined region. The Proposed Scoping Plan does not identify specific mandates for General Plans, but recommends incentives for promoting consistency with one another, such as CEQA streamlining. Cities and counties should take an active part in drafting the blueprint plans through cooperation with the Regional Transportation Planning Agency or Metropolitan Planning Organization so that the plans reflect the cities' and counties' approaches to GHG emissions reductions.



Coordination with Air Quality Management Plans: California has 35 air pollution control districts (APCDs) and air quality management districts (AQMDs), each covering one or more counties. Air districts are governed by locally elected officials (or individuals appointed by locally elected officials) and have regulatory control over stationary sources of air pollutants such as industrial and manufacturing facilities. They are also responsible under CEQA for evaluating and recommending appropriate mitigation for air quality impacts of new development. Air districts also administer a variety of incentive programs to reduce emissions from diesel equipment, including engines, trucks, construction equipment, commercial vessels and other local emission sources.

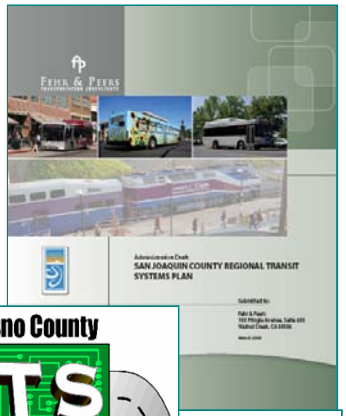
Air quality attainment plans are prepared by an air pollution control district or air quality management district for a county or region designated as a nonattainment area. The plans identify the control measures and market mechanisms that will be implemented to bring the area into compliance with the national and /or California ambient air quality standards within a specified timeframe. There are often policies, regulations, and programs within an attainment plan that may affect or influence local government activities. Participation by jurisdictions in the public review process required prior to adoption of an attainment plan is important to ensure all the planning efforts work together in achieving mutual goals. The local attainment plan can also be an important resource for jurisdictions embarking on GHG planning efforts. Many of the GHG



reduction strategies also reduce other air pollutants, and may therefore already be addressed in the local attainment plan, which can then be a starting point from which to expand the GHG plan. Even if the attainment plan does not contain some of the measures where there is overlap, coordination is important to determine how the two plans will impact each other, and if there are efficiencies, synergies, or even disbenefits between them. For this reason, it is important to contact your local air district when embarking on your GHG Plan.

Coordination with Regional Transportation Plans: The Regional Transportation Plan (RTP) is a long-term blueprint of a region's transportation system. These plans are normally the product of recommendations and studies carried out and put forth by a Metropolitan Planning Organization (MPO) or Regional Transportation Planning Agency (RTPA). The Plan identifies and analyzes the mobility needs of the metropolitan region and creates a framework for prioritizing and funding transportation projects to meet those needs during the timeframe of the plan. RTPs are typically updated every four to five years and have a twenty to thirty year planning horizon.

In developing the RTP, the MPO or RTPA must analyze population and growth trends and projections, regional land use and development patterns, existing transportation system efficiency for travel and goods movement, and the projected funding available to accomplish needed improvements. Thus, the MPO or RTPA must coordinate closely with local governments to ensure the RTP reflects the growth and development expectations of local General Plans. The adopted RTP must also be consistent with federal transportation planning requirements, and the projected emissions from transportation projects listed in the Plan must be incorporated into the local or regional air quality attainment plan.

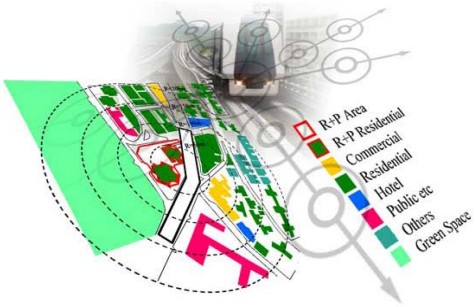


As described in Chapter 2 and at the beginning of this chapter, SB 375 requires RTPs to also contain a Sustainable Communities Strategy and (if needed) an Alternative Planning Strategy designed to meet the regional GHG reduction targets established by ARB. Although the legislation does not require local governments to incorporate the SCS into its own local planning efforts, there are strong incentives to do so.

CEQA Streamlining

The previous discussion of SB 375 outlined specific CEQA streamlining it affords. Even greater streamlining is possible, however, when the local government has adopted a Climate Action Plan, used it as the basis for addressing climate change in its General Plan, and made sure that those efforts reflect, to the extent possible, regional reduction targets and planning for transportation sustainability. When done in a thoughtful and comprehensive way, this integrated planning effort will yield a robust GHG mitigation

strategy with a programmatic EIR that, applied consistently to individual projects, can significantly reduce the procedural and administrative burden of review under CEQA, while ensuring full environmental protection.



The degree to which CEQA requirements can be streamlined will be directly proportional to the specificity of the applicable plans, and the extent to which they are consistent with each other. For example, the exemptions and streamlining under SB 375 generally rely upon the quantitative demonstration that the SCS/APS meets the regional target, and the existence of approved mitigation measures for transportation projects. In order to demonstrate that the target is met, the transportation models will require more detailed information about demand, use patterns, and other specific factors than is typically used in RTPs today. Some of this detail will have to come from local land use patterns and growth commitments. If the coordination between the local and regional plans is poor, the data will either not be available or will be conflicting, which will render the demonstration unapprovable.

The opportunity for CEQA streamlining also calls for greater specificity in the General Plan. For example, by including a "Green List" of projects in the plan and conducting the environmental review of the projects upfront, the local government can provide downstream relief from further review. This saves resources while preserving environmental protection, and it also enhances the viability of desirable projects.

The application of CEQA to a ubiquitous pollutant with such serious global impacts has raised a number of difficult policy questions, not the least of which concerns the appropriate basis for establishing a threshold of significance. Without engaging in a discussion of the various arguments here, it should be pointed out that the debate can be substantially minimized by undertaking a more thorough and coordinated planning effort upfront and limiting the involvement with CEQA for specific projects.

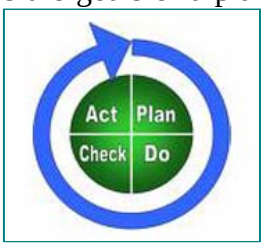
Unintended Consequences and Assuring Environmental Justice

Many of the measures that will be implemented to reduce GHG emissions will have co-benefits reducing criteria and toxic air pollution, and others are specifically designed to enhance the livability of local communities. But sometimes there are conflicts instead of co-benefits, and sometimes changes to communities can adversely affect some groups within the community, especially those who have lower incomes or are people of color. This kind of unintended consequence should be avoided.

A first step in avoiding environmental justice impacts is to actively seek and incorporate participation from all sectors of the community. This should include outreach efforts in

non-traditional as well as traditional media, and may rely on local advocacy groups, and religious and civic organizations. Where languages other than English are used, efforts should be made to provide information and materials in the language(s) most used. The goal of these outreach efforts is true communication, which is two-way. When done successfully, the agency will have explained what it is proposing and what the expected impacts are, and the community members will not only understand those things, but will have the opportunity to have their suggestions and concerns heard and addressed.

In addition to the existing mechanisms for tracking progress towards the goals of a plan or group of plans, it is important to establish a process and a schedule to review the impacts of implementation and especially to look for unintended and potentially adverse outcomes. This review should also include communication with the community. In the unfortunate, and hopefully rare situation where unintended and potentially adverse outcomes are found, steps should be taken to eliminate or mitigate those outcomes right away.



Although addressing climate change is a very important goal, it is not the only goal, and in certain circumstances it is expressly not the goal that governs. Specifically, AB 32 clearly states that climate protection will not come at the expense of air quality and public health protection. In addition, California law guarantees equal environmental protection to all Californians regardless of income status or ethnic background.

(page intentionally left blank)

The General Plan is the gateway to transforming our communities into more efficient, low-carbon, sustainable, vital places for us, our families, and our neighbors to live, work, and play. It is within this framework that the web of interactions between policies can be examined and aligned to produce the world we want for our future. The remainder of this report is devoted to exploring the General Plan process and ways to maximize its effectiveness for reducing GHG emissions and lessening the impact of climate change. This chapter discusses legal requirements for General Plans in California and their relation to potential new goals, objectives, policies, and implementation mechanisms to reduce GHG emissions. The General Plan requirements are set out in Section 65300 et seq. of the California Government.

Introduction

Every city and county must adopt "a comprehensive, long term General Plan" (§65300). The General Plan must cover a local jurisdiction's entire planning area and address the broad range of issues associated with a city's or county's development. The General Plan includes diagrams that illustrate the distribution of land uses, location of hazards, and location of the traffic circulation system. A city or county General Plan is expected to reflect local conditions and circumstances, while meeting the minimum requirements set out in state law (§65300.7).

These requirements are discussed in detail in the *General Plan Guidelines* issued by the Governor's Office of Planning and Research, which offers advisory, not mandatory, suggestions for the content of General Plans. In a broad sense, a General Plan is made up of text describing goals, objectives, policies, standards, and/or implementation measures, as well as a set of maps and diagrams. Together, these constituent parts paint a picture of the community's future development. In framing the model policies set forth in Chapter 6 of this report, CAPCOA used the following framework of goals, objectives, policies, standards, and implementation measures:

- Goal - A goal is a general direction for the jurisdiction. It is an ideal future end related to health, safety, or general welfare. "The General Plan shall consist of a statement of development policies and shall include a diagram or diagrams and text setting forth objectives, principles, standards, and plan proposals." (§65302) A goal is a general expression of community values and, therefore, may be abstract in nature and is generally not quantified or time-dependent. *Example: The County shall reduce its greenhouse gas emissions consistent with state and federal planning to reduce the scale and intensity of climate change effects on the County, the state, and the planet.*

- Objective - An objective is a specified end. It should be achievable, measurable and time-specific. An objective may pertain to one particular aspect of a goal or it may be one of several successive steps toward goal achievement. Consequently, there may be more than one objective for each goal. *Example: The County shall reduce its greenhouse gas emissions by 30 percent relative to business as usual emissions projected for year 2020.*

- Policy - A policy is a specific statement that guides decision-making. It indicates a commitment of the local legislative body to a particular course of action. A policy is based on and helps implement a General Plan's objectives. *Example: The County shall require new residential and commercial buildings to be energy-efficient in order to reduce greenhouse gas emissions.*

- Standards - A standard is a rule or measure establishing a level of quality or quantity that must be complied with or satisfied. Standards define the abstract terms of objectives and policies with concrete specifications. *Example: All new residential buildings shall achieve a minimum of 50 points on the Greenpoints rating system and all new commercial buildings shall achieve a minimum standard of LEED certification.*

- Implementation Measures - An implementation measure is an action, procedure, program, or technique that carries out General Plan policy. The General Plan is a policy document and is implemented by other governmental regulations and actions. Many General Plans include at least one corresponding implementation measure for each policy. *Example: The County shall establish a Green Building Ordinance that includes minimum requirements for residential and commercial energy efficiency within 24 months of adoption of the General Plan.*

Consistency

The overriding legal requirement for a General Plan is that it be internally consistent. "In construing the provisions of this article, the Legislature intends that the General Plan and elements and parts thereof comprise an integrated, internally consistent and compatible statement of policies for the adopting agency." (§65300.5). This requirement will come into play as GHG reducing measures are introduced into a General Plan, because so many of the measures cut across elements. So, for example, a land use policy supporting pedestrian-friendly streetscapes in a neighborhood center must be aligned with the transportation measures affecting that same neighborhood center, to ensure that they are compatible. If the transportation measures called for the removal of a planted median strip and the addition of traffic lanes through the neighborhood center, the elements would not be internally consistent.
Consistency is evaluated in five ways:

- All elements are equal - No element can supersede other elements or be the "default" element for resolution of conflicts between General Plan policies.

- Consistency between elements – The requirements of one element may not conflict with the requirements nor hinder the furtherance of goals and objectives of another element.

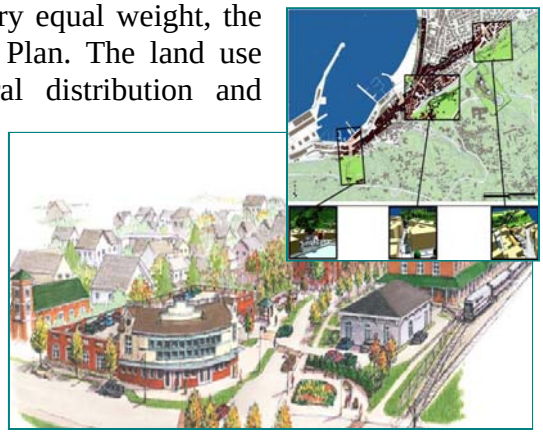
- Consistency within elements – Each element must be internally consistent between its various goals, objectives, and policies.

- Area Plan Consistency – If the General Plan includes Community or Area Plans, those must also be consistent with the overall General Plan.

- Text/Diagram consistency - Diagrams must be consistent with the General Plan's text and vice-versa.

GHG Reduction Opportunities in General Plan Mandatory Elements

Land Use Element



Although all elements of the General Plan carry equal weight, the land use element is the heart of the General Plan. The land use element must address the "proposed general distribution and general location and extent of the uses of the land for housing, business, industry, open space, including agriculture, natural resources, recreation, and enjoyment of scenic beauty, education, public buildings and grounds, solid and liquid waste disposal facilities, and other categories of public and private uses of land" (§65302[a]). The land use element shall include a statement of the standards of population density and building intensity recommended for the various districts and other territory covered by the plan. In addition, the land use element must identify and annually review those areas covered by the plan that are subject to flooding.

The land use element should, consistent with §65302(a), address each of the following issues to the extent that it is relevant:

- Distribution of housing, business, and industry;

- Distribution of open space, including agricultural land;

- Distribution of mineral resources and provisions for their continued availability;

- Distribution of recreation facilities and opportunities;
- Location of educational facilities;
- Location of public buildings and grounds;
- Location of future solid and liquid waste facilities;
- Identify areas subject to flooding;
- Identify existing Timberland Preserve Zone lands; and
- Other categories of public and private uses of land.

The key opportunities in the land use element related to GHG reductions include:

- Foster land use intensity near, along with connectivity to, retail and employment centers and services to reduce vehicle miles travelled and increase the efficiency of delivery of services through adoption and implementation of smart growth principles and policies;
- Improve the local jobs/housing balance to reduce vehicle miles travelled;
- Zone for appropriate mixed use development to encourage walking and bicycling for short trips, rather than vehicles;
- Link residential and commercial development to transit facilities;
- Reduce parking requirements to facilitate higher density development that fosters access by walking, biking and public transit;
- Identify potential sites for renewable energy facilities and transmission lines;
- Promote recycling to reduce waste and energy consumption; and
- Identify appropriate sites for waste recovery facilities to minimize escape of GHGs.

Conservation Element

Generally stated, the conservation element must address "the conservation, development, and utilization of natural resources including water and its hydraulic force, forests, soils, rivers and other waters, harbors, fisheries, wildlife, minerals, and other natural resources" (§65302[d]). This

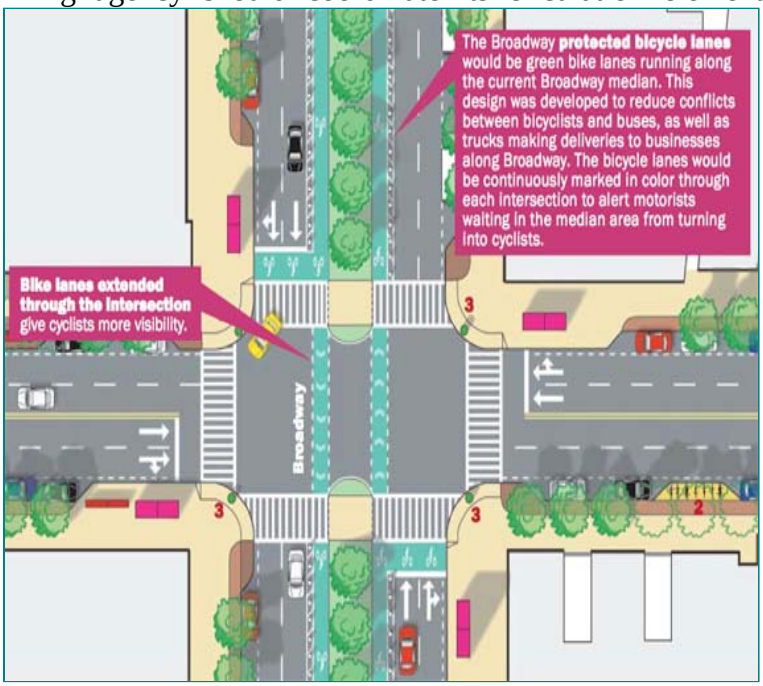
includes, but is not limited to, consideration of water supply to meet future needs, flood protection, the effects of development on water resources, erosion control, pollution prevention, and watershed protection.

The key opportunities in the conservation element related to GHG reductions include:

- Conserve natural lands for carbon sequestration;
- Identify lands suitable for wind power generation;
- Conserve water to promote energy efficiency;
- Promote recycling and waste recovery; and
- Promote urban forestry and reforestation as feasible.

Circulation Element

The circulation element is required "to identify the general location and extent of existing and proposed major thoroughfares, transportation routes, terminals, any military airports and ports, and other local public utilities and facilities, all correlated with the land use element of the plan" (§65302[b]). Typically, the circulation element describes the road system and its minimum development standards, as well as provisions for non-motorized transportation. The local planning agency should coordinate its circulation element provisions with applicable state and regional transportation plans (see §65103[f] and §65080, et seq.). Likewise, the state must coordinate its plans with those of local governments (§65080(a)). The federal government is under a similar obligation (Title 23 USC §134). If the circulation element is to be an effective basis for exactions, it must be based upon traffic studies that are sufficiently detailed to link land uses and related demand to future dedications.



The circulation element's policies can be a means of reducing vehicle miles traveled, a substantial indicator of GHG production from transportation. Key opportunities in the circulation element related to GHG reductions include:

- Identify and prioritize infrastructure improvements needed to support increased use of alternatives to private vehicle travel, including transit, bicycle, and pedestrian modes;
- Coordinate with adjacent municipalities, transit providers, and regional transportation planning agencies to develop mutual policies and funding mechanisms to increase the use of alternative transportation;
- Establish higher priorities for transit funding relative to street and road construction and maintenance;
- Incorporate "Complete Streets" policies that foster equal access by all users, including pedestrians and bicyclists;
- Promote linkages between development locations and transportation facilities;
- Preserve transportation corridors for renewable energy transmission and for new transit lines;
- Identify appropriate locations for intermodal transportation stations; and
- Identify opportunities, in cooperation with transit providers, to provide financing for transit operations and maintenance.

Open Space Element

The open space element is to identify open space for: (1) the preservation of natural resources; (2) the managed production of resources, including but not limited to, forest lands, rangeland, agricultural lands, areas required for recharge of groundwater basins, bays, estuaries, marshes, rivers and streams, and areas containing major mineral deposits; (3) outdoor recreation, including but not limited to, areas of outstanding scenic, historic and cultural value, areas particularly suited for park and recreation purposes, including access to lakeshores, beaches, and rivers and streams; and areas that link major recreation and open-space reservations; (4) for public health and safety; (5) open space in support of the mission of military installations, that comprises areas adjacent to military installations, military training routes, and underlying restricted airspace that can provide additional buffer zones to military activities and complement the resource values of the military lands; and (6) for

the protection of places, features, and objects of cultural value to Native American tribes (§65560).

The key opportunities in the open space element related to GHG reductions include:

- Identify existing and potential future urban growth boundaries to limit sprawling development patterns and foster a more compact urban form;
- Conserve natural lands for carbon sequestration; and
- Promote trail systems to facilitate bicycle and pedestrian trips in lieu of vehicle travel.

Housing Element

A General Plan is required to include a housing element "that facilitate[s] the improvement and development of housing to make adequate provision for the housing needs of all economic segments of the community" (§65580[d]). The housing element must provide opportunities for the private and public sectors to develop sufficient housing meet the jurisdiction's allocated share of the region's housing needs. Unlike the other elements of the General Plan, the housing element requirements are quite detailed and must be followed carefully. In addition, the housing element is subject to review by the state's Housing and Community Development Department for consistency with state law. The housing element must be updated every five years.

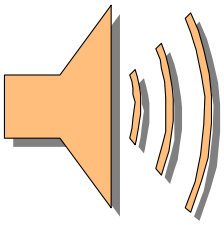
The key opportunities and constraints in the housing element related to GHG reductions include:

- Identify sites for higher density housing closer to employment centers, retail and services, and transit facilities;
- Identify sites for affordable housing for workers close to employment centers;
- Establish or support programs to assist in the energy-efficient retrofitting of older affordable housing units; and
- Balance additional upfront costs for energy efficiency and affordable housing economic considerations by providing or supporting programs to finance energy-efficient housing.

Noise Element

The noise element must identify and appraise noise problems in the community for the purpose of avoiding conflicts with noise-sensitive land uses (§65302[f]).

The noise element does not contain any measures that directly reduce GHG emissions. However, some of the potential GHG reduction strategies in other elements such as increased residential density, mixed use, expanded transit services, and wind energy could adversely affect the noise environment, which would be an issue for the noise element to address. The noise element's development standards may need to be strengthened to ensure that higher densities and mixed uses avoid excessive noise exposure for residents. At the same time, some GHG reduction strategies, for example, those that increase energy efficiency by adding insulation, may have a positive impact on the noise environment.



Safety Element

The safety element is to provide for the protection of the community from any unreasonable risks associated with the effects of seismically induced surface rupture, ground shaking, ground failure, tsunami, seiche (wave), and dam failure; slope instability leading to mudslides and landslides; subsidence, liquefaction, and other seismic hazards, and other geologic hazards known to the legislative body; flooding; and wildland and urban fires (§65302[g]).

With inevitable climate change impacts already occurring and predicted to occur in the future, adaptation to changes in safety hazards, such as potential increase in wildland fire potential or coastal or delta flooding resulting from sea level rise, would be topics of discussion in future safety elements. Adaptation planning for climate change impacts is an important and growing issue area that should be incorporated into local and regional planning processes. As this paper only focuses on GHG reductions, issues related to adaptation are not discussed further.

Air Quality Element (Mandatory Only in the San Joaquin Valley)

Many cities and counties throughout the State have adopted air quality elements. They establish policies for reducing emissions from stationary, mobile, and area sources of air pollution. In most cases, the local air district either provides model elements, or assists the city or county in development of the element. The cities and counties within the jurisdiction of the San Joaquin Valley Air Pollution Control District are required to adopt an air quality element. Under statute, the element is to integrate land use plans, transportation plans, and air quality plans, as well as provide for multimodal transportation options that will reduce vehicle trips (§65302.1). Cities and counties

should contact their local air district when developing an air quality element.

The key opportunities and constraints in an air quality element related to GHG reductions include:

- Integrate land use plans and transportation plans;
- Provide multimodal transportation options;
- Co-benefits of criteria pollutant reduction strategies that also reduce GHG emissions and vice versa; and
- Disbenefits of potential GHG emissions reductions strategies on criteria and other pollutants.

GHG Reduction Opportunities in Non-Mandatory Elements

State planning law authorizes cities and counties to adopt additional elements that "address any other subjects which, in the judgment of the legislative body, relate to the physical development of the county or city" (§65303). There are no statutory requirements for the subjects or content of any of these optional elements. Following are some of the common optional elements. Keep in mind that each city and county has its own definition of what the element should contain.

Energy

A number of cities and counties have adopted energy elements as part of their General Plans. There are no energy element guidelines or standard set of required contents. In some jurisdictions, these elements establish policies for energy extraction. In others, they are concerned with the conservation of energy.

The key opportunities in an energy element related to GHG reductions include:

- Energy-efficiency requirements for residential, commercial, and industrial construction under local jurisdiction that exceed current standards;
- Facilitate residential and commercial renewable energy facilities (solar array installations, individual wind energy generators, etc.);
- Promote cogeneration facilities for combined heating and electricity;
- Facilitate renewable energy facilities and transmission line siting;
- Establish energy-efficiency standards for public facilities;

- Establish policies to reduce municipal and community petroleum consumption through changes in the vehicle fleet; enhancement and promotion of public transit, carpooling and other transportation modes to reduce employee and student commute trips;

- Establish policies to reduce GHG production by city and county operations, such as improved energy efficiency of public buildings, recycling at public buildings.

Economic Development

Economic development elements generally establish policies intended to encourage economic development within the community. These may include establishing incentives for development, identifying areas of greatest development potential, and creating the basis for other economic development activities to be undertaken by the jurisdiction.

The key opportunities in an economic element related to GHG reductions include:

- Incentives for investment in and deployment of renewable energy technologies;

- Incentives for development of local green technology businesses and locally produced green products;

- Incentives for investment in residential and commercial energy efficiency improvements;

- Incentives for employers to provide workforce housing, thereby reducing the length of trips to work;

- Policies to enhance sales tax revenues that promote incorporation of larger retail uses within downtown areas and mixed use developments to facilitate access by alternative transportation, in favor of larger retail or mixed use developments on the urban fringe;

- Establish financing districts (in charter cities) to encourage installation of solar panels and other energy-efficient improvements (e.g., City of Berkeley Solar Financing District, 11/07);

- Encourage implementation of AB 811 (Levine, see Chapter 159, Statutes of 2008), Renewable Energy Resource Credit (7/08), for low interest loans for energy improvements; and

- Use AB 811 to finance the installation of distributed generation renewable energy sources or energy efficiency improvements to lots or parcels which are developed and where the costs and time delays involved in creating an assessment district pursuant to other provisions of law would be prohibitively large relative to the cost of the public improvements to be financed.

Capital Improvements/Public Facilities

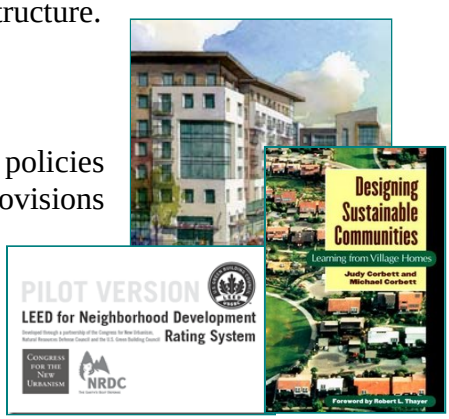
Capital improvements are often discussed in the circulation element of the General Plan. However, some cities and counties have adopted separate capital improvements or public facilities elements that discuss expected demand resulting from growth under the General Plan and identify necessary facilities to serve that growth. In some cases, the element will estimate costs and recommend implementation methods for raising the needed funding.

The key opportunities in a capital improvements/public facilities element related to GHG reductions include:

- Establish energy-efficiency standards for public facilities;
- Promote solar installation opportunities for public facilities;
- Other building design energy and water efficiency standards for public facilities;
- Establish purchasing and procurement policies that support the use of green products and services; and
- Identify needs and funding sources for alternative transportation modes such as bicycle facilities and improved transit infrastructure.

Community Design

Community design elements typically provide a set of policies that promote better urban design. These often include provisions for aesthetic treatments, architectural design guidelines, and preferred street design.



The key opportunities in a community design element related to GHG reductions include:

- Incorporate urban design principles that promote higher residential densities in attractive forms with easily accessible parks and recreation opportunities nearby;

- Use urban design standards to facilitate clustered, higher-density, mixed use communities with greater potential for transit ridership, alternatives to vehicle travel, and shorter trips;

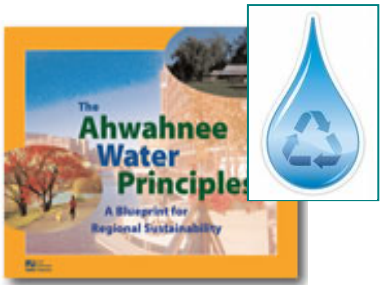
- Establish policies and design principles to incorporate inviting public spaces in high density, mixed use communities;

- Incorporate "Complete Streets" policies that foster equal access by all users, including pedestrians and bicyclists; and

- Promote water-efficient and energy-efficient housing and commercial areas.

Water

A water element typically identifies projected water demand based on the General Plan growth. It describes water supplies within the city or county (most water elements have been adopted by counties) and policies for matching future demand.



Available from: Local Government Commission

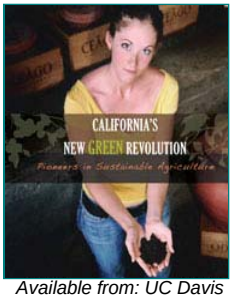
The key opportunities in a water element related to GHG reductions include:

- Incorporate water conservation measures for municipal operations and throughout the community to reduce GHG emissions from pumping and water delivery; and

- Adopt policies and standards to facilitate water recycling for use on landscaping, agricultural operations, and other applications where potable water is not required, to reduce pumping-related GHG emissions.

- Because energy used in moving water through the system is a major component of the GHG inventory, include measures that reduce peak demand for water, and therefore allow for smaller pumps that use less energy overall.

Agriculture



Available from: UC Davis Small Farm Center

Agricultural elements typically identify the highest quality farmland within the city or county (most agricultural elements have been adopted by counties) and establish policies that protect that land from premature conversion to other uses. The goals of an agricultural element are usually aimed at preserving the long-term viability of the agricultural economy of the city or county.

The key opportunities in an agricultural element related to GHG reductions include:

- Establishment of minimum parcel sizes for agricultural lands outside of Agricultural Preserves and restrictions on non-agriculture related development and uses on agricultural parcels to enhance the viability of local agriculture and prevent additional sprawl development that increases dependence on and emissions from private vehicles;

- Development of policies and incentives (e.g., carbon credit programs) to promote voluntary preservation of farmland for carbon sink purposes;

- Adoption of policies and programs that facilitate local farmers markets and farmer co-ops that allow residents to purchase local farm goods and reduce emissions from transportation of agricultural products; and

- Support for agricultural industries that reduce the need to move agricultural products long distances for processing or packaging.

- To the extent the agricultural element addresses water use, it should be noted that efficiencies here, or use of alternatives, can provide substantial GHG reductions.

Element Interrelationships

This section discusses the interrelationships between the mandated General Plan elements by identifying the cross-cutting issues for GHG emissions and opportunities for reductions, categorized by each required element. As previously described, a General Plan must be internally consistent across all adopted elements; thus, cross-cutting issues must be evaluated closely to ensure the goals, objectives, policies and implementation measures in one element do not conflict with, or hinder the implementation of, the requirements of other elements. Cross-cutting issues are first identified in a matrix format; those issues are then matched with the critical relationships that must be established across the elements in a General Plan to identify appropriate linkages and enhance internal consistency. Some examples of consistency considerations include the following:

- Density and Transit-Oriented Development – If increased density and transit-oriented development are strategies used to reduce vehicle miles travelled (and their associated GHG emissions), then the General Plan must provide the land use designations to allow such density to occur, identify the locations where those strategies are to be applied, and identify the land and other infrastructure necessary to facilitate transit connections. This requires consistency between the land use, circulation, housing, and possibly other elements of the General Plan. Further, site constraints such as toxics contamination, noise, or air quality emissions hot spots need to be considered before designating sites for high density and transit-oriented development in order to maintain consistency with the noise and safety elements.

- Specific Plans, Community Plans, and Area Plans: These types of land use plans are used to implement the General Plan. Where the General Plan provides for the preparation of any of these more specific land use plans to implement its strategies, those plans must be consistent with the policies of the General Plan. In particular, development intensity, population density, and location within the community, and roads and transportation facilities will be important facets of plan consistency.

- Energy-Efficiency Requirements – If new policies are added to increase the energy-efficiency requirements beyond that established in current Title 24 standards, these requirements could raise the cost of housing, which could affect the jurisdiction's ability to meet its mandatory requirements for the provision of affordable housing under the housing element. Those policies must not impede the jurisdiction's ability to meet its assigned share of the regional housing need. This requires coordination between the land use, housing, and energy (if one exists) elements.

- Renewable Energy – If new policies require further reliance on renewable energy for municipal and community electricity, then the General Plan must also address the availability of land for new facilities and transmission lines and their compatibility with existing and future adjacent uses. This requires coordination between the land use, circulation, and energy (if one exists) elements and possibly the open space and agriculture elements for transmission lines.

Table 1 (on the next page) summarizes the key element interrelationships relevant to broad GHG reduction strategies. This is also not a comprehensive list of GHG reduction approaches, but is intended to highlight the key linkages between General Plan elements for the strategies with greatest potential for GHG reductions that are under the control or influence of local land use authorities.

Table 1. Element Interrelationships for Greenhouse Gas Emission Reduction Strategies

Reduction Strategy	Key Element Interrelationships
Promotion of jobs/housing balance	Local governments can promote economic development to provide employment for the future workforce of the county and housing appropriate to that workforce to reduce out-of-area and out-of County commute miles and associated vehicle emissions. Mandatory Elements: LAND USE, HOUSING Optional Elements: ECONOMIC DEVELOPMENT
Increased housing density/mixed use/TOD/infill development	Local governments can designate areas of increased density in proximity to employment centers, services, transit linkages, and alternatives to single-occupancy vehicle travel. Mandatory Elements: LAND USE, CIRCULATION, HOUSING, OPEN SPACE Optional Elements: COMMUNITY DESIGN, ECONOMIC DEVELOPMENT
Increased transit	Local government can facilitate increased transit use through efficient links between employment centers, services, and clustered residential areas and to different modes of travel in cooperation with adjacent cities/counties, transportation providers, and regional transportation agencies. Local governments must also address safety and noise issues for new facilities. Mandatory Elements: CIRCULATION, LAND USE, NOISE, SAFETY. AIR QUALITY Optional Elements: AIR QUALITY
Alternative vehicles and alternatives to vehicle travel other than transit	Local government can facilitate bicycle and pedestrian linkages between residential areas, schools, services, centers of employment and recreation. Local government can also utilize alternatively-fueled vehicles for municipal operations and require recharging stations for electric vehicles at new private development Mandatory Elements: CIRCULATION, LAND USE, OPEN SPACE Optional Element: PUBLIC FACILITIES, AIR QUALITY
Energy-Efficiency (public)	Local governments can undertake cost-effective energy-efficient investments, while saving energy costs over the long run. Mandatory Element: LAND USE Optional Elements: ENERGY, PUBLIC FACILITIES, COMMUNITY DESIGN
Energy-Efficiency (private)	Local governments can promote or require energy-efficiency in new residential, commercial, and industrial development that will reduce GHG emissions related to electricity and natural gas consumption. This can include support for programs to retrofit existing residences and businesses. Mandatory Elements: HOUSING, LAND USE Optional Elements: ENERGY, COMMUNITY DESIGN

Reduction Strategy	Key Element Interrelationships
Renewable Energy (utility)	Local governments can identify sites for new renewable energy facilities and transmission lines. Mandatory Elements: LAND USE, CIRCULATION, CONSERVATION Optional Element: ENERGY, AGRICULTURE
Renewable Energy (residential/commercial)	Local governments must balance between the GHG reductions from residential/commercial solar and wind installations and concerns about safety, noise, and aesthetics. Policies should encourage these uses while establishing safety, noise, and aesthetics standards, consistent with state law. Mandatory Elements: LAND USE, NOISE, SAFETY Optional Element: ENERGY
Waste Reduction, Recycling, Reuse, and Recovery	Local governments can promote waste reduction, increased recycling, waste diversion, waste to energy and waste recovery through direct action. Mandatory Elements: LAND USE, CONSERVATION, SAFETY Optional Elements: ENERGY, PUBLIC FACILITIES, AIR QUALITY
Water Conservation and Recycling	Local governments can promote water conservation and recycling through landscaping and irrigation requirements and limitations, fixture and appliance requirements, and expanded use of reclaimed water. Plan policies would set the stage for water conservation and recycling ordinances. Mandatory Elements: LAND USE, CONSERVATION, SAFETY Optional Elements: ENERGY, PUBLIC FACILITIES, AIR QUALITY

Introduction

This chapter provides a presentation of an overarching climate change goal (to reduce municipal greenhouse gas emissions in a manner that is consistent with AB 32) and related objectives, policies, and implementation measures for incorporation into a General Plan - whether as part of an Air Quality element, as a separate Climate Change element, or interspersed throughout other existing elements as appropriate within a General Plan. The model policies provided in this section are grouped by General Plan element, and are provided in a format that should be readily included in a city or county's General Plan. The city or county has full discretion on where to place the policies, whether to change their format or content, and, indeed, whether to incorporate them at all. This report and policies in it are not intended in any way to dictate what a city or county chooses to include in its plan; that choice remains the purview of the locally elected officials who approve the city or county's General Plan.

However, if and when a city or county chooses to incorporate GHG reduction strategies into its General Plan, or into another guiding document, such as a Climate Action Plan, the following policies represent the best practices and current knowledge in land use planning. The climate change policies presented here were compiled through an extensive review of General Plans and Climate Action Plans from cities and counties throughout the State that are already moving forward to address climate change and GHG emissions. CAPCOA, with the help of its contractors, surveyed current practices in the field and aggregated them into model policies to ease the burden on staff at already strapped city and county land use agencies. Those staff remain the experts on their local land use circumstances and needs, however, and their knowledge and judgment, with the oversight of their policy boards, will shape when and how GHG reduction strategies are applied within their jurisdictions. This is not an exhaustive list -- local governments are encouraged to address climate change and GHG emissions through additional or reworked policies and implementation measures according to their unique needs.

The Model Policies

The menu of objectives, policies, and implementation measures is grouped around nine General Plan elements, including one new element, "Greenhouse Gas Reduction Planning." A city or county can place the policies it selects into the most relevant existing General Plan element, if the city or county is integrating GHG reduction strategies throughout its General Plan. On the other hand, the city or county may choose to group all GHG reduction policies under one element, in which case the Greenhouse Gas Reduction Planning element could be broadened to accommodate that. The nine greenhouse gas reduction categories for which model policies are provided are as follows:

1) Greenhouse Gas Reduction Planning (overall);
2) Land Use and Urban Design;
3) Transportation;

4) Energy Efficiency;
5) Alternative Energy;
6) Municipal Operations;
7) Waste Reduction and Diversion;
8) Conservation and Open Space; and
9) Education.

These categories do not correspond exactly to standard California General Plan elements. Some of the policies in this chapter correspond to multiple standard elements, and some do not correspond to any of the required California General Plan elements. These policies could be included in a separate Climate Change element. Please see the table at the end of this chapter for suggestions on which standard elements some of the policies may correspond to. A broad policy goal is identified for GHG reductions in each of these nine categories; more specific objectives are identified within each category; and the model policies are grouped by objective, and are numbered accordingly.

Focus of Policies for Different Communities

There are over 500 cities and counties in California. These jurisdictions range in size from the City of Los Angeles, with over 4 million residents, to the City of Dorris, with less than 900 residents. The eastern portion of the state north of San Bernardino County, and the northern tier of counties from Modoc to Mendocino are generally rural, with only small cities. Although climate change is a global concern and activities throughout the state are contributors, the capability to incorporate and implement climate-related General Plan policies and the applicability of those policies varies among cities and counties.

Policies suitable in urban and suburban areas in the Bay Area, San Joaquin Valley, SCAG region, and San Diego may be infeasible in rural areas that have different land use and resource bases . For that reason, the policies discussed above cannot be considered “one size fits all” solutions. Therefore, providing suggestions about the suitability of policies by general region of the state makes sense.

Air Quality Co-benefits from Greenhouse Gas Reduction Measures

When considering the implementation of a climate change measure, it is vital to consider and discuss the environmental co-benefits associated with GHG reduction measures. If one does not clearly show the co-benefits, then a third party could assume that the only function of a GHG reduction measure is to reduce GHG emissions.

It is well known within the environmental planning community that almost all efforts to reduce GHG emissions result in significant reductions in conventional air pollutant emissions. For instance, most efforts to reduce automobile use through smart growth design principles or improvements in public transit should result in reductions in both

GHG emissions and conventional pollutants associated with smog (such as NOx, PM, VOCs, and ozone). Additionally, efforts to conserve electricity will reduce both GHG emissions and conventional pollutant emissions from power plants.

There are limited scenarios where GHG reductions may cause local air quality impacts. For example, efforts to increase certain types of distributed power generation through the non-optimal combustion of landfill gas may produce localized NOx emissions that contribute to regional smog. Likewise, increasing densities near transit hubs and transportation corridors could increase exposure to unhealthy diesel emissions in certain areas. Fortunately, the potential for adverse air quality impacts from GHG reduction programs and plans is small; in the overwhelming majority of cases, measures implemented to reduce GHG emissions will also contribute to improved air quality.

Since a majority of Californians live in areas where air quality does not meet state and federal health standards for at least one pollutant, GHG reduction measures make sense from a direct and *local* public benefit perspective since they would likely contribute to improved local air quality. Clearly identifying the co-benefits of implementing such measures will potentially engender the support of a broader range of the community.

The communities surrounding the major California ports are a good example. Given the public health concern regarding diesel particulate matter emissions from ships and heavy duty vehicle use near ports, it is highly likely that local residents would prefer and support GHG programs that reduce exposure to pre-existing and well-known local air quality problems to a greater extent than GHG reduction programs that do not have local air quality improvement benefits. Addressing both GHG emissions and local health concerns simultaneously should be encouraged and may determine the selection of optimal multi-target reduction measures.

In general, public support and acceptance of GHG reduction efforts will be enhanced by the clear presentation of the co-benefits associated with these actions. This presents a significant opportunity to local decisionmakers to help improve public health and welfare in their local communities while simultaneously addressing the critical issue of climate change.

Worksheet for Evaluating Policies

Table 2 provides a worksheet for evaluating the expected impact of these policies, as well as factors that affect their implementation. The impacts will vary depending on a number of factors specific to each city and county. As stated previously, the effectiveness of many of these policies depends on how they are applied. For example, a number of the model land use policies are designed to support high-density development near the city center. Done properly, this strategy will result in a workforce that lives near the jobs it fills, and that relies on transit, biking, and walking to commute to work and school, and to reach a broad range of nearby services. If, for example, the housing is not in the proper price range for the workers who fill the local jobs, or if those jobs cannot be easily and safely reached using transit or other modes of transportation, the effect of the strategy

will be much less, and may even be negative. In the worst case, the housing could be purchased by people who work in remote areas and commute to their workplaces in single-occupancy vehicles, and this new housing could displace other housing that was in better balance with the local jobs, causing those workers to commute into the urban core. In the worksheet, each policy is referenced by number and name. For more detail on the policy, please refer to the text of the corresponding model policy, following in this chapter. The worksheet addresses the following factors:

- Implementation Examples: To the extent that CAPCOA has information, this information is already entered in the worksheet, to show the reader/practitioner examples of places this policy has been adopted or implemented in practice.

- Appropriate General Plan Element: This information is also already entered into the worksheet, to suggest (but not dictate) the most appropriate element or elements where the referenced model policy could be incorporated.

- Relative Effectiveness Reducing GHGs: We suggest ranking measures based on your estimate of their relative effectiveness, considering the local environment and constraints. This does not have to be quantitative; a rating of 1 to 3, or 1 to 5, could be used, or Low-Medium-High, for example. For more information on estimating effectiveness, consult the CAPCOA document on CEQA and Climate Change, the California Climate Action Registry, ICLEI[1], or the ARB Local Government Toolkit.

- Relative Difficulty to Implement: This is intended to be a measure of how prepared a jurisdiction is to implement a measure (do you have the necessary authority, knowledge, infrastructure, and resources, for example) as well as the expected political acceptability and the acceptance by the community.

- Relative Time for Reductions to Occur: This is not intended to be a precise measure, rather a qualitative one. We suggest "near term," "mid term," and "long term" for example, or another system for sorting and ranking measures based on when the return is expected to occur.

- Relative Cost: Measures could be rated qualitatively, for example as low, medium, or high costs, or between $ and $$$$$, with more dollar signs indicating a higher relative cost. Alternatively, a rough cost range could be used.

As cities and counties review these model policies and select the ones that are most appropriate for their jurisdictions, they should make clear and careful decisions about criteria that will properly target the policies to best achieve their intended result.

The model policies are provided in a form that begins, "The City/County will…" To reiterate, this is not meant to dictate what any city or county will do; rather, if a city or

[1] ICLEI is Local Governments for Sustainability

county wishes to incorporate a model policy, the policy has been written to allow the city or county to simply insert its name into the policy in place of "The City/County." As already stated, if other language or another format is preferred, the city or county has full discretion to make any such changes.

As previously noted, the California Air Resources Board has developed an online toolkit of measures for local governments to reduce global warming pollution, available at www.coolcalifornia.org. This toolkit contains emissions inventory utilities, case studies of local governments who have effectively reduced their global warming pollution, financial assistance available for conservation efforts, and other valuable information.

Greenhouse Gas Reduction Planning Policies

Goal: Reduce GHG emissions from all activities within the City/County boundaries to support the State's efforts under AB-32 and to mitigate the impact of climate change on the City/County, State, and world.

Objective GHG-1: By 2020, the City/County will reduce greenhouse gas emissions from within its boundaries to a level 30% less than the level that would otherwise occur if all activities continued under a "business as usual" scenario.

GHG-1.1 Emission Inventories: The City/County will establish GHG emissions inventories including emissions from all sectors within the City/County, using methods approved by, or consistent with guidance from, the ARB; the City/County will update inventories every 3 years to incorporate improved methods, better data, and more accurate tools and methods, and to assess progress.

1.1.1 The City/County will establish a baseline inventory of GHG emissions including municipal emissions, and emissions from all business sectors and the community.

1.1.2 The City/county will define a "business as usual" scenario of municipal, economic, and community activities, and prepare a projected inventory for 2020 based on that scenario.

GHG-1.2 Climate Action Plans: The City/County will establish plans to reduce or encourage reductions in GHG emissions from all sectors within the City/County.

1.2.1 The City/County will establish a Municipal Climate Action Plan which will include measures to reduce GHG emissions from municipal activities by at least 30% by 2020 compared to the "business as usual" municipal emissions (including any reductions required by ARB under AB 32).

1.2.2 The City/County will, in collaboration with the business community, establish a Business Climate Action Plan, which will include measures to reduce GHG emissions from business activities, and which will seek to reduce emissions by at least 30% by 2020 compared to "business as usual" business emissions.

1.2.3 The City/County will, in collaboration with the stakeholders from the community at large, establish a Community Climate Action Plan, which will include measures reduce GHG emissions from community activities, and which will seek to reduce emissions by

at least 30% by 2020 compared to "business as usual" community emissions.

1.2.4 Or: The City / County will, in collaboration with the stakeholders from the community at large, establish a CCAP, which will include measures to reduce GHG from community, municipal and business activities by at least 30% by 2020, compared to "business as usual".

GHG-1.1*A* **Emission Inventories:** *(Alternative form)* The City/County will establish GHG emissions inventories including emissions from all sectors within the City/County, using methods approved by, or consistent with guidance from, the ARB; the City/County will update inventories every 4 years to incorporate improved methods, better data, and more accurate tools and methods, and to assess progress.

1.1.1 The City/County will establish a baseline inventory of GHG emissions including municipal emissions, and emissions from all business sectors and the community.

GHG-1.2*A* **Climate Action Plans:** *(Alternative form)* The City/County will establish plans to reduce or encourage reductions in GHG emissions from all sectors within the City/County.

1.2.1 The City/County will establish a Municipal Climate Action Plan which will include measures to reduce GHG emissions from municipal activities by at least 15% by 2020 compared to the baseline municipal emissions inventory (including any reductions required by ARB under AB 32).

1.2.2 The City/County will, in collaboration with the business community, establish a Business Climate Action Plan, which will include measures to incentivize and support reductions in GHG emissions from business activities, and which will seek to reduce emissions by at least 15% by 2020 compared to the baseline business emissions inventory (including any reductions required by ARB under AB-32).

1.2.3 The City/County will, in collaboration with the stakeholders from the community at large, establish a Community Climate Action Plan, which will include measures to incentivize and support reductions in GHG emissions from community activities, and which will seek to reduce emissions by at least 15% by 2020 compared to the baseline community emissions inventory (including any reductions any reductions required by ARB under AB-32).

Objective GHG-2 The City/County will ensure that its local Climate Action, Land Use, Housing, and Transportation Plans are aligned with, support, and enhance any regional plans that have been developed consistent with state guidance to achieve reductions in GHG emissions.

GHG-2.1 Sustainable Communities Strategy/Regional Blueprint Planning: The City/County will participate in the Sustainable Communities Strategy/Regional Blueprint Planning effort and will ensure that local plans are consistent with the Regional Plan.

Land Use and Urban Design Policies

Goal: Promote land use strategies that decrease reliance on automobile use, increase the use of alternative modes of transportation, maximize efficiency of urban services provision and reduce emissions of GHGs.

Objective LU-1: The City/County will adopt and implement a development pattern that utilizes existing infrastructure; reduces the need for new roads, utilities and other public works in new growth areas; and enhances non-automobile transportation.

LU-1.1 Urban Growth Boundary: The City will establish an urban growth boundary (UBG) with related ordinances or programs to limit suburban sprawl; the City/County will restrict urban development beyond the UGB and streamline entitlement processes within the UGB for consistent projects.

1.1.1 Urban development should occur only where urban public facilities and services exist or can be reasonably made available.

1.1.2 The improvement and expansion of one urban public facility or service should not stimulate development that significantly precedes the City's, or other affected jurisdiction's, ability to provide all other necessary urban public facilities and services at adequate levels.

LU-1.2 Reserve Limits: The City/County will redirect new growth into existing city/urban reserve areas.

LU-1.3 Infill: The City/County will encourage high-density, mixed-use, infill development and creative reuse of brownfield, under-utilized and/or defunct properties within the urban core.

LU-1.4 Urban Service Lines: The City/County will maintain a one dwelling unit per 10 acre minimum lot size or lower density in areas outside designated urban service lines.

1.4.1 Adopt an urban-rural transition zone along the urban service line to ensure that land uses within the City / County are compatible with adjacent open space and agricultural uses.

LU-1.5 Density: The City/County will increase densities in urban core areas to support public transit.

1.5.1 Remove barriers to the development of accessory dwelling units in existing residential neighborhoods inside urban service lines.

LU-1.6 Road Width: The City/County will reduce required road width standards wherever feasible to calm traffic and encourage alternative modes of transportation.

LU-1.7 Parking Spaces: The City/County will reduce parking space requirements, unbundle parking from rents and charge for parking in new developments.

LU-1.8 Bicycle Facilities: The City/County will add bicycle facilities to city streets and public spaces.

LU-1.9 Levels of Service: The City/County will discourage the extension of urban levels of service for new development beyond existing urban service lines, and, if necessary, use zoning to assure that development occurs only if public services are adequate.

Objective LU-2: Promote infill, mixed-use, and higher density development, and provide incentives to support the creation of affordable housing in mixed use zones.

LU-2.1 Mixed-Use Development: The City/County will plan for and create incentives for mixed-use development.

2.1.1 The City/County will identify sites suitable for mixed-use development within an existing urban service line and will establish appropriate site-specific standards to accommodate the mixed uses. Site-specific standards could include:

2.1.1.1 Increasing allowable building height or allowing height limit bonuses;

2.1.1.2 Allowing flexibility in applying development standards (such as FAR[2] and lot coverage) based on the location, type, and size of the units, and the design of the development;

2.1.1.3 Allowing the residential component to be additive rather than within the established FAR for that zone, and eliminating maximum density requirements for residential uses in mixed use zones;

2.1.1.4 Allowing reduced and shared parking based on the use mix, and establishing parking maximums where sites are located within 0.25 miles of a public transit stop;

2.1.1.5 Allowing for tandem parking, shared parking and off-site parking leases;

[2] FAR is Floor Area Ratio

2.1.1.6 Requiring all property owners in mixed-use areas to unbundle parking from commercial and residential leases;

2.1.1.7 Creating parking benefit districts, which invest meter revenues in pedestrian infrastructure and other public amenities;

2.1.1.8 Establishing performance pricing of street parking, so that it is expensive enough to promote frequent turnover and keep 15 percent of spaces empty at all times.

2.1.2 The City/County will seek funding to prepare specific plans and related environmental documents to facilitate mixed-use development at selected sites, and to allow these areas to serve as receiver sites for transfer of development rights away from environmentally sensitive lands and rural areas outside established urban growth boundaries.

2.1.3 The City/County will enable prototype mixed-use structures for use in neighborhood center zones that can be adapted to new uses over time with minimal internal remodeling.

2.1.4 The City/County will identify and facilitate the inclusion of complementary land uses not already present in local zoning districts, such as supermarkets, parks and recreational fields, schools in neighborhoods, and residential uses in business districts, to reduce the vehicle miles traveled and promote bicycling and walking to these uses.

EMPHASIS OF DEVELOPMENT

	COMMERCIAL	OFFICE	RESIDENTIAL
USE			
Retail	50-70%	10-30%	10-30%
Office	0-20%	50-70%	0-30%
Residential	20-40%	0-30%	50-80%
Public	10-30%	10-30%	10-30%

2.1.5 The City/County will work with employers developing larger projects to ensure local housing opportunities for their employees, and engage employers to find ways to provide housing assistance as part of their employee benefits packages; major projects in mixed-use areas should include work-force housing where feasible.

2.1.6 The City/County will revise zoning ordinance(s) to allow local-serving businesses, such as childcare centers, restaurants, banks, family medical offices, drug stores, and other similar services near employment centers to minimize midday vehicle use.

2.1.7 The City / County will develop form-based community design standards to be applied to development projects and land use plans, using a comprehensive community outreach, for areas designated mixed-use

2.1.8 Mix affordable housing units with market rate units as opposed to building segregated affordable housing developments.

Objective LU-3: Promote greater linkage between land uses and transit, as well as other modes of transportation.

LU-3.1 Transit-Supportive Density: The City/County will implement a Housing Overlay Zone for transit centers and corridors. This shall include average minimum residential densities of 25 units per acre within one quarter mile of transit centers; average minimum densities of 15 units per acre within one quarter mile of transit corridors; and minimum FAR of 0.5:1 for non-residential uses within a quarter mile of transit centers or corridors.

LU-3.2 Transit-Oriented Development: The City/County will identify transit centers appropriate for mixed-use development, and will promote transit-oriented, mixed use development within these targeted areas, including:

3.2.1 Amending the Development Code to encourage mixed-use development within one-half mile of intermodal hubs and future rail stations; to offer flexible standards for affordable housing; and to establish minimum residential densities and non-residential FAR;

3.2.2 Rezoning commercial properties to residential and/or mixed-use where appropriate;

3.2.3 Providing expanded zoning for multi-family housing;

3.2.4 Providing maximum parking standards and flexible building height limitations;

3.2.5 Providing density bonus programs;

3.2.6 Establishing guidelines for private and public spaces;

3.2.7 Providing incentives for redevelopment of underutilized areas, such as surface parking lots;

3.2.8 Establishing a minimum pedestrian and bicycle connectivity standard;

3.2.9 Creating parking benefit districts, which invest meter revenues in pedestrian infrastructure and other public amenities;

3.2.10 Establishing performance pricing of street parking, so that it is expensive enough to promote frequent turnover and keep 15 percent of spaces empty at all times;

3.2.11 Discouraging auto-oriented development.

LU-3.3 Transit-oriented Brownfield Development: The City/County will promote the development of brownfield sites and other underused or defunct properties near existing public transportation.

LU-3.4 Public Transit Development Focus: The City/County will ensure new development is designed to make public transit a viable choice for residents, including:

3.4.1 Locating medium-high density development near activity centers that can be served efficiently by public transit and alternative transportation modes;

3.4.2 Locating medium-high density development near streets served by public transit whenever feasible;

3.4.3 Linking neighborhoods to bus stops by continuous sidewalks or pedestrian paths.

LU-3.5 City-centered Corridors: The City/County will establish city-centered corridors, directing development to existing transportation corridors.

LU-3.6 Transit-oriented Development Design Standards: The City / County will develop form-based community design standards to be applied to development projects and land use plans, using a comprehensive community outreach program, for areas designated mixed-use *(suggestion: check language with FBCI[3])*

LU-3.7 Affordable Housing: Affordable housing will be located in transit-oriented development whenever feasible.

Objective LU-4: Promote development and preservation of neighborhood characteristics that encourage walking and bicycle riding in lieu of automobile-based travel.

LU-4.1 Pedestrian-oriented Character: The City/County will create and preserve distinct, identifiable neighborhoods whose characteristics support pedestrian travel, especially within, but not limited to, mixed-use and transit-oriented development areas, including:

[3] FBCI is the Form-Based Codes Institute

4.1.1 Designing or maintaining neighborhoods where the neighborhood center can be reached in approximately five minutes of walking;

4.1.2 Increasing housing densities from the perimeter to the center of the neighborhood;

4.1.3 Directing retail, commercial, and office space to the center of the neighborhood;

4.1.4 Encouraging pedestrian-only streets and/or plazas within developments, and destinations that may be reached conveniently by public transportation, walking, or bicycling;

4.1.5 Allowing flexible parking strategies in neighborhood activity centers to foster a pedestrian-oriented streetscape;

4.1.6 Providing continuous sidewalks with shade trees and landscape strips to separate pedestrians from traffic;

4.1.7 Encouraging neighborhood parks and recreational centers near concentrations of residential areas (preferably within one quarter mile) and include pedestrian walkways and bicycle paths that encourage non-motorized travel.

LU-4.2 Pedestrian Access: The City/County will ensure pedestrian access to activities and services, especially within, but not limited to, mixed-use and transit-oriented development areas, including:

4.2.1 Ensuring new development that provides pedestrian connections in as many locations as possible to adjacent development, arterial streets, thoroughfares;

4.2.2 Ensuring a balanced mix of housing, workplaces, shopping, recreational opportunities, and institutional uses, including mixed-use structures;

4.2.3 Locating schools in neighborhoods, within safe and easy walking distances of residences served;

4.2.4 For new development, primary entrances shall be pedestrian entrances, with automobile entrances and parking located to the rear;

4.2.5 Support development where automobile access to buildings does not impede pedestrian access, by consolidating driveways between buildings or developing alley access;

4.2.6 Street parking provided shall be utilized as a buffer between sidewalk pedestrian traffic and the automobile portion of the roadway;

4.2.7 Establish pedestrian and bicycle connectivity standards for new development, with block sizes between 1 and 2 acres;

4.2.8 For existing areas that do not meet established connectivity standards, prioritize the physical development of pedestrian connectors;

4.2.9 Prioritizing grade-separated bicycle / pedestrian crossings where appropriate to enhance connectivity or overcome barriers such as freeways, railways and waterways.

Objective LU-5: Review fee structures and other opportunities to provide financial and administrative incentives to support desired land uses, development patterns, and alternative modes of transportation.

LU-5.1 Developer Fees: The City/County will promote desired land uses by scaling developer fees based on desired criteria, for example:

5.1.1 Increasing or reducing fees proportionally with distance from the city center or preferred transit sites;

5.1.2 Increasing or reducing fees based on the degree to which mixed uses are incorporated into the project;

5.1.3 Reducing fees for creative re-use of brownfield sites;

5.1.4 Increasing fees for the use of greenfield sites.

LU-5.2 Administrative Fees and Streamlining: The City/County will provide fast-track permitting and reductions in processing fees for desired projects. The City/County will research and implement a program of incentives for development projects that are fully consistent with the Sustainable Communities Strategy / Regional Plan.

LU-5.3 Incentives and Loans: The City/County will provide incentive funding and/or infrastructure loans to support desired projects.

LU-5.4 Infrastructure Preference: The City/County will give preference for infrastructure improvements that support or enhance desired land uses and projects.

Objective LU-6: The City/County will mitigate climate change by decreasing heat gain from pavement and other hard surfaces associated with infrastructure.

LU-6.1 Hardscape Heat Gain: The City/County will reduce heat gain from pavement and other hardscaping, including:

6.1.1 Reduce street rights-of-way and pavement widths to pre-World War II widths (typically 22 to 34 feet for local streets, and 30 to 35 feet for collector streets, curb to curb), unless landscape medians or parkway strips are allowed in the center of roadways;

6.1.2 Reinstate the use of parkway strips to allow shading of streets by trees;

6.1.3 Include shade trees on south- and west-facing sides of structures;

6.1.4 Include low-water landscaping in place of hardscaping around transportation infrastructure and in parking areas;

6.1.5 Install cool roofs, green roofs, and use cool paving for pathways, parking, and other roadway surfaces;

6.1.6 Establish standards that provide for pervious pavement options;

6.1.7 Remove obstacles to xeriscaping, edible landscaping and low-water landscaping.

Transportation Policies

Goal: Reduce GHG emissions by reducing vehicle miles traveled and by increasing or encouraging the use of alternative fuels and transportation technologies.

Objective TR-1: The City/County will reduce VMT-related emissions by encouraging the use of public transit through adoption of new development standards that will require improvements to the transit system and infrastructure, increase safety and accessibility, and provide other incentives.

TR-1.1 Transportation Planning: The City/County will ensure that new developments incorporate both local and regional transit measures into the project design that promote the use of alternative modes of transportation.

TR-1.1.1 Project Selection: The City / County shall give priority to transportation projects that will contribute to a reduction in vehicle miles traveled per capita, while maintaining economic vitality and sustainability.

TR-1.1.2 Equal Pedestrian Access: The City / County shall include sidewalks, separated sidewalks whenever possible, on both sides of all new street improvement projects, except where there are severe topographic or natural resource constraints.

TR-1.1.3 Public Involvement: Carry out a comprehensive public involvement and input process that provides information about transportation issues, projects, and processes to community members and other stakeholders, especially to those traditionally underserved by transportation services.

TR-1.2 System Interconnectivity: The City/County will create an interconnected transportation system that allows a shift in travel from private passenger vehicles to alternative modes, including public transit, ride sharing, car-sharing, bicycling and walking.

1.2.1 Ensure transportation centers are multi-modal to allow transportation modes to intersect;

1.2.2 Provide adequate and affordable public transportation choices, including expanded bus routes and service, as well as other transit choices such as shuttles, light rail, and rail;

1.2.3 To the extent feasible, extend service and hours of operation to underserved arterials and population centers or destinations such as colleges;

1.2.3A Focus transit resources on high-volume corridors and high-boarding destinations such as colleges, employment centers and regional destinations;

1.2.4 Coordinate schedules and routes across service lines with neighboring transit authorities;

1.2.5 Support programs to provide "station cars" for short trips to and from transit nodes (e.g., neighborhood electric vehicles);

1.2.6 Study the feasibility of providing free transit to areas with residential densities of 15 dwelling units per acre or more, including options such as removing service from less dense, underutilized areas to do so;

1.2.7 Employ transit-preferential measures, such as signal priority and bypass lanes. Where compatible with adjacent land use designations, right-of-way acquisition or parking removal may occur to accommodate transit-preferential measures or improve access to transit. The use of access management should be considered where needed to reduce conflicts between transit vehicles and other vehicles;

1.2.8 Provide safe and convenient access for pedestrians and bicyclists to, across, and along major transit priority streets;

1.2.9 Use park-and-ride facilities to access transit stations only at ends of regional transitways or where adequate feeder bus service is not feasible.

TR-1.3 Transit System Infrastructure: The City/County will upgrade and maintain transit system infrastructure to enhance public use, including:

1.3.1 Ensure transit stops and bus lanes are safe, convenient, clean and efficient;

1.3.2 Ensure transit stops have clearly marked street-level designation, and are accessible;

1.3.3 Ensure transit stops are safe, sheltered, benches are clean, and lighting is adequate;

1.3.4 Place transit stations along transit corridors within mixed-use or transit-oriented development areas at intervals of three to four blocks, or no less than one-half mile.

TR-1.4 Customer Service: The City/County will enhance customer service and system ease-of-use, including:

1.4.1 Develop a Regional Pass system to reduce the number of different passes and tickets required of system users;

1.4.2 Implement "Smart Bus" technology, using GPS and electronic displays at transit stops to provide customers with "real-time" arrival and departure time information (and to allow the system operator to respond more quickly and effectively to disruptions in service);

1.4.3 Investigate the feasibility of an on-line trip planning program.

TR-1.5 Transit Funding: The City/County will prioritize transportation funding to support a shift from private passenger vehicles to transit and other modes of transportation, including:

1.5.1 Give funding preference to improvements in public transit over other new infrastructure for private automobile traffic;

1.5.2 Before funding transportation improvements that increase roadway capacity and VMT, evaluate the feasibility and effectiveness of funding projects that support alternative modes of transportation and reduce VMT, including transit, and bicycle and pedestrian access.

TR-1.6 Transit and Multimodal Impact Fees: The City/County will assess transit and multimodal impact fees on new developments to fund public transportation infrastructure, bicycle infrastructure, pedestrian infrastructure and other multimodal accommodations.

Objective TR-2: The City/County will implement traffic and roadway management strategies to improve mobility and efficiency, and reduce associated emissions.

TR-2.1 System Monitoring: The City/County will monitor traffic and congestion to determine when and where the city needs new transportation facilities in order to increase access and efficiency.

TR-2.2 Arterial Traffic Management: The City/County will modify arterial roadways to allow more efficient bus operation, including bus lanes and signal priority/ preemption where necessary.

TR-2.3 Signal Synchronization: The City/County will expand signal timing programs where emissions reduction benefits can be demonstrated, including maintenance of the synchronization system, and will coordinate with adjoining jurisdictions as needed to optimize transit operation while maintaining a free flow of traffic.

TR-2.4 HOV Lanes: The City/County will encourage the construction of high-occupancy vehicle (HOV) lanes or similar mechanisms whenever necessary to relieve congestion and reduce emissions.

TR-2.5 Delivery Schedules: The City/County will establish ordinances or land use permit conditions limiting the hours when deliveries can be made to off-peak hours in high traffic areas.

Objective TR-3: The City/County will reduce VMT related-emissions by implementing and supporting trip reduction programs.

TR-3.1 Ride-Share Programs: The City/County will promote ride sharing programs, including:

3.1.1 Designate a certain percentage of parking spaces for ride-sharing vehicles;

3.1.2 Designate adequate passenger loading, unloading, and waiting areas for ride-sharing vehicles;

3.1.3 Provide a web site or message board for coordinating shared rides;

3.1.4 Encourage private, for-profit community car-sharing, including parking spaces for car share vehicles at convenient locations accessible by public transit;

3.1.5 Hire or designate a rideshare coordinator to develop and implement ridesharing programs.

TR-3.2 Employer-based Trip Reduction: The City/County will support voluntary, employer-based trip reduction programs, including:

3.2.1 Provide assistance to regional and local ridesharing organizations;

3.2.2 Advocate for legislation to maintain and expand incentives for employer ridesharing programs;

3.2.3 Require the development of Transportation Management Associations for large employers and commercial/ industrial complexes;

3.2.4 Provide public recognition of effective programs through awards, top ten lists, and other mechanisms.

TR-3.3 Ride Home Programs: The City/County will implement a city/county wide “guaranteed ride home” program for those who commute by public

transit, ride-sharing, or other modes of transportation, and encourage employers to subscribe to or support the program.

TR-3.4 Local Area Shuttles: The City/County will encourage and utilize shuttles to serve neighborhoods, employment centers and major destinations.

3.4.1 The City/County will create a free or low-cost local area shuttle system that includes a fixed route to popular tourist destinations or shopping and business centers;

3.4.2 The City/County will work with existing shuttle service providers to coordinate their services.

TR-3.5 Low- and No-Travel Employment Opportunities: The City/County will facilitate employment opportunities that minimize the need for private vehicle trips, including:

3.5.1 Amend zoning ordinances and the Development Code to include live/work sites and satellite work centers in appropriate locations;

3.5.2 Encourage telecommuting options with new and existing employers, through project review and incentives, as appropriate.

TR-3.6 Congestion Pricing: Advocate for a regional, market-based system to price or charge for auto trips during peak hours

Objective TR-4: The City/County will support bicycle use as a mode of transportation by enhancing infrastructure to accommodate bicycles and riders, and providing incentives.

TR-4.1 Development Standards for Bicycles: The City/County will establish standards for new development and redevelopment projects to support bicycle use, including:

4.1.1 Amending the Development Code to include standards for safe pedestrian and bicyclist accommodations, including:

4.1.1.1 "Complete Streets" policies that foster equal access by all users in the roadway design;

4.1.1.2 Bicycle and pedestrian access internally and in connection to other areas through easements;

4.1.1.3 Safe access to public transportation and other non-motorized uses through construction of dedicated paths;

4.1.1.4 Safe road crossings at major intersections, especially for school children and seniors;

4.1.1.5 Adequate, convenient and secure bike parking at public and private facilities and destinations in all urban areas;

4.1.1.6 Street standards will include provisions for bicycle parking within the public right of way;

4.1.2 Require new development and redevelopment projects to include bicycle facilities, as appropriate with the new land use, including:

4.1.2.1 Construction of weatherproof bicycle facilities where feasible, and at a minimum, bicycle racks or covered, secure parking near the building entrances;

4.1.2.2 Provision and maintenance of changing rooms, lockers, and showers at large employers or employment centers.

4.1.3 Prohibit projects that impede bicycle and pedestrian access, such as large parking areas that cannot be safely crossed by non-motorized vehicles, and developments that block through access on existing or potential bicycle and pedestrian routes;

4.1.4 Encourage the development of bicycle stations at intermodal hubs, with attended or "valet" bicycle parking, and other amenities such as bicycle rental and repair, and changing areas with lockers and showers;

4.1.5 Conduct a connectivity analysis of the existing bikeway network to identify gaps, and prioritize bikeway development where gaps exist.

TR-4.2 Bicycle and Pedestrian Trails: The City/County will establish a network of multi-use trails to facilitate safe and direct off-street bicycle and pedestrian travel, and will provide bike racks along these trails at secure, lighted locations.

TR-4.3 Bicycle Safety Program: The City/County will develop and implement a bicycle safety educational program to teach drivers and riders the laws, riding protocols, routes, safety tips, and emergency maneuvers.

TR-4.4 Bicycle and Pedestrian Project Funding: The City/County will pursue and provide enhanced funding for bicycle and pedestrian facilities and access projects, including, as appropriate:

4.4.1 Apply for regional, State, and federal grants for bicycle and pedestrian infrastructure projects;

4.4.2 Establish development exactions and impact fees to fund bicycle and pedestrian facilities;

4.4.3 Use existing revenues, such as state gas tax subventions, sales tax funds, and general fund monies for projects to enhance bicycle use and walking for transportation.

TR-4.5 Bicycle Parking: Adopt bicycle parking standards that ensure bicycle parking sufficient to accommodate 5 to 10% of projected use at all public and commercial facilities, and at a rate of at least one per residential unit in multiple-family developments *(suggestion: check language with League of American Bicyclists).*

Objective TR-5: The City/County will establish parking policies and requirements that capture the true cost of private vehicle use and support alternative modes of transportation.

TR-5.1 Parking Policy: The City/County will adopt a comprehensive parking policy to discourage private vehicle use and encourage the use of alternative transportation, including:

5.1.1 Reduce the available parking spaces for private vehicles while increasing parking spaces for shared vehicles, bicycles, and other alternative modes of transportation;

5.1.2 Eliminate or reduce minimum parking requirements for new buildings;

5.1.3 "Unbundle" parking (require that parking is paid for separately and is not included in the base rent for residential and commercial space);

5.1.4 Use parking pricing to discourage private vehicle use, especially at peak times;

5.1.5 Create parking benefit districts, which invest meter revenues in pedestrian infrastructure and other public amenities;

5.1.6 Establish performance pricing of street parking, so that it is expensive enough to promote frequent turnover and keep 15 percent of spaces empty at all times;

5.1.7 Encourage shared parking programs in mixed-use and transit-oriented development areas.

TR-5.2 Event Parking Policies: The City/County will establish policies and programs to reduce onsite parking demand and promote ride-sharing and public transit at large events, including:

5.2.1 Promote the use of peripheral parking by increasing on-site parking rates and offering reduced rates for peripheral parking;

5.2.2 Encourage special event center operators to advertise and offer discounted transit passes with event tickets;

5.2.3 Encourage special event center operators to advertise and offer discount parking incentives to carpooling patrons, with four or more persons per vehicle for on-site parking;

5.2.4 Promote the use of bicycles by providing space for the operation of valet bicycle parking service.

TR-5.3 Parking "Cash-out" Program: The City/County will require new office developments with more than 50 employees to offer a Parking "Cash-out" Program to discourage private vehicle use.

TR-5.4 Electric/Alternative Fuel Vehicle Parking: The City/County will require new commercial and retail developments to provide prioritized parking for electric vehicles and vehicles using alternative fuels.

Objective TR-6: The City/County will support and promote the use of low- and zero-emission vehicles, and alternative fuels, and other measures to directly reduce emissions from motor vehicles.

TR-6.1 Low and Zero Emission Vehicles: The City/County will support and promote the use of low- and zero-emission vehicles, including:

6.1.1 Develop the necessary infrastructure to encourage the use of zero-emission vehicles and clean alternative fuels, such as development of electric vehicle charging facilities and conveniently located alternative fueling stations;

6.1.2 Encourage new construction to include vehicle access to properly wired outdoor receptacles to accommodate ZEV and/or plug in electric hybrids (PHEV);

6.1.3 Encourage transportation fleet standards to achieve the lowest emissions possible, using a mix of alternate fuels, PZEV or better fleet mixes;

6.1.4 Establish incentives, as appropriate, to taxicab owners to use alternative fuel or gas-electric hybrid vehicles.

TR-6.2 Vehicle Idling: The City/County will enforce State idling laws for commercial vehicles, including delivery and construction vehicles.

Energy Efficiency Policies

Goal: Reduce emissions from the generation of electricity by reducing electricity use through increased efficiency.

Objective EE-1 The City/County will establish green building requirements and standards for new development and redevelopment projects, and will work to provide incentives for green building practices and remove barriers that impede their use.

EE-1.1 Green Building Ordinance: The City/County will adopt a Green Building Ordinance that requires new development and redevelopment projects for both residential and commercial buildings to incorporate sufficient green building methods and techniques to qualify for the equivalent of a current LEED Certified rating, GreenPoints, or equivalent rating system.

EE-1.2 Green Building Flexibility: The City/County will allow increased height limits and/or flexibility in other standards for projects that incorporate energy efficient green building practices.

EE-1.3 Green Building Barriers: The City/County will identify and remove regulatory or procedural barriers to implementing green building practices within its jurisdiction, such as updating codes, guidelines, and zoning, and will ensure that all plan review and building inspection staff are trained in green building materials, practices, and techniques.

EE-1.4 Green Building Incentives: The City/County will support the use of green building practices by:

1.4.1 Providing information, marketing, training, and technical assistance about green building practices;

1.4.2 Establishing guidelines for green building practices in residential and commercial development;

1.4.3 Providing financial incentives, including reduction in development fees, administrative fees, and expedited permit processing for projects that use green building practices.

Objective EE-2 The City/County will establish policies and standards to increase energy efficiency at new developments.

EE-2.1 Improved Building Standards: The City/County will adopt energy efficiency performance standards for buildings that achieve a greater reduction in energy and water use than otherwise required by state law, including:

2.1.1 Standards for the installation of "cool roofs";

2.1.2 Performance standards for heat transfer across the building envelope that result in increased insulation and the use of low-emissive windows;

2.1.3 Requirements to install high-efficiency plumbing fixtures and tankless water heaters;

2.1.4 Performance standards that specify high-efficiency space heating and cooling systems;

2.1.5 Requirements for improved overall efficiency of lighting systems;

2.1.6 Requirements for the use of Energy Star® appliances and fixtures in discretionary new development;

2.1.7 New lots shall be arranged and oriented to maximize effective use of passive solar energy.

EE-2.2 Affordable Housing Energy Efficiency: Affordable housing development shall incorporate energy efficient design and features to the maximum extent feasible.

2.2.1 The City/County will target local funds, including redevelopment and community development block grant resources, to assist affordable housing developers in meeting the energy efficiency requirements.

EE-2.3 Outdoor Lighting: The City/County will establish outdoor lighting standards in the Zoning Ordinance, including:

2.3.1 Requirements that all outdoor lighting fixtures be energy efficient, such as:

2.3.1.1 Full cut-off light fixtures at parking lots and on buildings;

2.3.1.2 Photocells or astronomical time switches on all permanently installed exterior lighting;

2.3.1.3 Directional and shielded LED lights for exterior lighting *(for example, see: www.nightwise.org)*, and install exterior and security lights with motion detectors.

2.3.2 Requirements that light levels in all new development, parking lots, and street lighting not exceed state standards;

2.3.3 Requirements that lighting at the urban-rural boundary be designed to provide one-half the light standard for urban areas;

2.3.4 Prohibition against continuous all-night outdoor lighting in sports stadiums, construction sites, and rural areas unless required for security reasons.

EE-2.4 Residential Wood Burning: The City/County will establish or enhance local ordinances that prohibit solid fuel wood-burning devices in mixed-use high-density development and restrict the installation of wood-burning appliances in new or redeveloped single family residential properties to those that burn pellets, natural gas, or propane, or at a minimum, EPA certified wood-burning units.

Objective EE-3: The City/County will establish policies and standards to reduce exterior heat gain and heat island effects.

EE-3.1 Exterior Heat Gain: The City/County will establish standards for new development and for large redevelopment or rehabilitation (for example, additions of more than 25,000 square feet commercial or 100,000 square feet industrial), to reduce exterior heat gain for 50% of non-roof impervious site landscape (roads, sidewalks, courtyards, parking lots, and driveways), including:

3.1.1 Achieving 50% paved surface shading with vegetation within 5 years, in consultation with city/county arborist;

3.1.2 Use of paving materials with a Solar Reflective Index (SRI) of at least 29, or open grid paving systems;

3.1.3 Covered parking (underground, beneath decking or roofs, or beneath a building), where any roof-covered parking uses roofing material with SRI of at least 29.

EE-3.2 Heat Island Mitigation: The City/County will adopt a Heat Island Mitigation Plan that requires cool roofs, cool pavements, and strategically placed shade trees, and will actively inspect and enforce state requirements for cool roofs on non-residential re-roofing projects.

Objective EE-4: The City/County will pursue policies and programs to improve energy efficiency of existing buildings.

EE-4.1 Energy Audits: The City/County will require the performance of energy audits for residential and commercial buildings prior to completion of sale, and that audit results and information about opportunities for energy efficiency improvements be presented to the buyer.

EE-4.2 Energy Efficiency Funding: The City/County will pursue incentives, grants, and creative financing for projects that improve energy efficiency, including, for example, the option for property owners to pay for such improvements through long-term assessments on their property tax bills.

EE-4.3 Community Energy Program: The City/County will implement an outreach and incentive program to promote energy efficiency and conservation in the community, including:

4.3.1 Launch an "energy efficiency challenge" campaign for community residents;

4.3.2 Implement a low-income weatherization assistance program;

4.3.3 Implement conservation campaigns specifically targeted to residents, and separately to businesses;

4.3.4 Promote the purchase of Energy Star® appliances, including, where feasible, incentive grants and vouchers;

4.3.5 Promote participation in the local "Green Business" program;

4.3.6 Distribute free CFL bulbs or other efficiency fixtures to community members;

4.3.7 Offer exchange programs for high-energy-use items, such as halogen torchiere lamps;

4.3.8 Adopt an ordinance requiring energy upgrades at time of property sale.

Alternative Energy Policies

Goal: The City/County will seek to reduce emissions associated with electrical generation by promoting and supporting the generation and use of alternative energy.

Objective AE-1: The City/County will establish policies and programs that facilitate the siting of new renewable energy generation.

AE-1.1 Site Designation: The City/County will identify possible sites for production of renewable energy (such as solar, wind, small hydro, and biogas), as compatible with surrounding uses, and will protect and promote that use, including:

1.1.1 Designate suitable sites to prioritize their development for renewable energy generation;

1.1.2 Evaluate potential land use, environmental, economic, and other constraints on that use, and mitigate such constraints, as feasible;

1.1.3 Adopt measures to protect the renewable energy use of the sites and their resources, such as utility easements, rights-of-way, and land set-asides.

AE-1.2 Removing Barriers: The City/County will identify and remove or otherwise address barriers to renewable energy production, including:

1.2.1 Review and revise building and development codes, design guidelines, and zoning ordinances to remove such barriers;

1.2.2 Work with related agencies, such as fire, water, health and others that may have policies or requirements that adversely impact the development or use of renewable energy technologies;

1.2.3 Develop protocols for safe storage of renewable and alternative energy products with the potential to leak, ignite or explode, such as biodiesel, hydrogen, and/or compressed air.

AE-1.3 Zoning Flexibility: The City/County will allow renewable energy projects in areas zoned for open space, where consistent with the Open Space element, and other uses and values.

Objective AE-2 The City/County will promote and require renewable energy generation, and co-generation projects where feasible and appropriate.

AE-2.1 **On-site Renewable Energy Generation:** The City/County will require that new office/retail/commercial or industrial development, or major rehabilitation (e.g., additions of 25,000 square feet commercial, or 100,000 square feet industrial) incorporate renewable energy generation either on- or off-site to provide 15% or more of the project's energy needs.

AE-2.2 **Co-generation Projects:** The City/County will promote and encourage co-generation projects for commercial and industrial facilities, provided they meet all applicable air quality standards and provide a net reduction in GHG emissions associated with energy production.

AE-2.3 **Green Utilities:** The City/County will promote and support green utilities, and will evaluate the creation of a locally or regionally owned green utility, perhaps in coordination with other regional strategies.

Objective AE-3: The City/County will promote, support, and require, as appropriate, the development of solar energy.

AE-3.1 **Solar-ready Buildings:** The City/County will require that, where feasible, all new buildings be constructed to allow for easy, cost-effective installation of solar energy systems in the future, using such "solar-ready" features as:

3.1.1 Designing the building to include optimal roof orientation (between 20 to 55 degrees from the horizontal), with sufficient south-sloped roof surface;

3.1.2 Clear access without obstructions (chimneys, heating and plumbing vents, etc.) on the south sloped roof;

3.1.3 Designing the roof framing to support the addition of solar panels;

3.1.4 Installation of electrical conduit to accept solar electric system wiring;

3.1.5 Installation of plumbing to support a solar hot water system and provision of space for a solar hot water storage tank.

AE-3.2 **Solar Homes Partnership:** The City/County will require that residential projects of 6 units or more participate in the California Energy Commission's New Solar Homes Partnership, which provides rebates to developers who offer solar power in at least 50% of new units, or a program with similar provisions.

AE-3.3 **Passive Solar Design:** The City/County will require that any building constructed in whole or in part with City/County funds incorporate passive solar design features, such as daylighting and passive solar heating, where feasible.

AE-3.4 Protection of Solar Elements: The City/County will protect active and passive solar design elements and systems from shading by neighboring structures and trees, as consistent with existing tree shading requirements.

Objective AE-4: The City/County will pursue and provide economic incentives and creative financing for renewable energy projects, as well as other support for community members or developers seeking funding for such projects.

AE-4.1 Renewable Energy Incentives: The City/County will provide, where possible, grants, rebates, and incentives for renewable energy projects, including reduced fees and expedited permit processing.

AE-4.2 Creative Financing: The City/County will provide, where feasible, creative financing for renewable energy projects, including subsidized or other low-interest loans, and the option to pay for system installation through long-term assessments on individual property tax bills.

AE-4.3 Partnerships: The City/County will pursue partnerships with other governmental entities and with private companies and utilities to establish incentive programs for renewable energy.

AE-4.4 Information and Support: The City/County will establish and maintain a clearinghouse of information on available funding alternatives for renewable energy projects, rates of return, and other information to support developers and community members interested in pursuing renewable energy projects.

Objective AE-5: The City/County will implement measures to support the purchase and use of renewable and alternative energy.

AE-5.1 Green Electricity Purchasing: The City/County will establish targets for the purchase of renewable energy, in excess of the state Renewable Portfolio Standards, using such mechanisms as green tags or renewable energy certificates.

AE-5.2 Community Choice Aggregation: The City/County will evaluate the feasibility and effectiveness of using Community Choice Aggregation as a model for providing renewable energy to meet the community's electricity needs, including potential partnerships with other jurisdictions.

Municipal Operations Policies

Goal: Reduce GHG emissions from municipal facilities and operations, and by purchasing goods and services that embody or create fewer GHG emissions.

Objective MO-1: The City/County will enhance the energy efficiency of its facilities.

MO-1.1 Energy Efficiency Plan: The City/County will prepare and implement a comprehensive plan to improve energy efficiency of municipal facilities, including:

1.1.1 Conduct energy audits for all municipal facilities;

1.1.2 Retrofit facilities for energy efficiency where feasible and when remodeling or replacing components, including increased insulation, installing green or reflective roofs and low-emissive window glass;

1.1.3 Implement an energy tracking and management system;

1.1.4 Install energy-efficient exit signs, street signs, and traffic lighting;

1.1.5 Install energy-efficient lighting retrofits and occupancy sensors, and institute a "lights out at night" policy;

1.1.6 Retrofit heating and cooling systems to optimize efficiency (e.g., replace chillers, boilers, fans, pumps, belts, etc.);

1.1.7 Install Energy Star® appliances and energy-efficient vending machines;

1.1.8 Improve efficiency of water pumping and use at municipal facilities, including a schedule to replace or retrofit system components with high-efficiency units (i.e., ultra-low-flow toilets, fixtures, etc.);

1.1.9 Provide chilled, filtered water at water fountains and taps in lieu of bottled water;

1.1.10 Install a central irrigation control system and time its operation for off-peak use;

1.1.11 Adopt an accelerated replacement schedule for energy inefficient systems and components.

MO-1.2 Efficiency Requirement for New Facilities: The City/County will require that any newly constructed, purchased, or leased municipal space meet minimum standards as appropriate, such as:

1.2.1 Requirements for new commercial buildings to meet LEED criteria established by the U.S. Green Building Council;

1.2.2 Requirements for new residential buildings to meet criteria of the Energy Star® New Homes Program established by U.S. EPA;

1.2.3 Incorporation of passive solar design features in new buildings, including daylighting and passive solar heating;

1.2.4 Retrofitting of existing buildings to meet standards under Title 24 of the California Building Energy Code, or to achieve a higher performance standard as established by the City/County;

1.2.5 Retrofitting of existing buildings to decrease heat gain from non-roof impervious surfaces with cool paving, landscaping, and other techniques.

MO-1.3 Training & Support: The City/County will ensure that staff receives appropriate training and support to implement objectives and policies to reduce GHG emissions, including:

1.3.1 Provide energy efficiency training to design, engineering, building operations, and maintenance staff;

1.3.2 Provide information on energy use and management, including data from the tracking and management system, to managers and others making decisions that influence energy use;

1.3.3 Provide energy design review services to departments undertaking new construction or renovation projects, to facilitate compliance with LEED standards.

Objective MO-2: The City/County will improve efficiency at municipal systems and reduce GHG emissions from vehicle and equipment engines.

MO-2.1 Wastewater System Efficiency: The City/County will maximize efficiency of wastewater treatment and pumping equipment.

MO-2.2 Drinking Water System Efficiency: The City/County will maximize efficiency at drinking water treatment, pumping, and distribution facilities, including development of off-peak demand schedules for heavy commercial and industrial users.

MO-2.3 Fleet Replacement: The City/County will establish a replacement policy and schedule to replace fleet vehicles and equipment with the most fuel-

efficient vehicles practical, including gasoline hybrid and alternative fuel or electric models.

MO-2.4 Small Tools and Equipment: Install outdoor electrical outlets on buildings to support the use of electric lawn and garden equipment, and other tools that would otherwise be run with small gas engines or portable generators.

Objective MO-3: The City/County will implement measures to reduce employee vehicle trips and to mitigate emissions impacts from municipal travel.

MO-3.1 Trip Reduction Program: The City/County will implement a program to reduce vehicle trips by employees, including:

3.1.1 Providing incentives and infrastructure for vanpooling and carpooling, such as pool vehicles, preferred parking, and a website or bulletin board to facilitate ride-sharing;

3.1.2 Providing subsidized passes for mass transit;

3.1.3 Offering compressed work hours, off-peak work hours, and telecommuting, where appropriate;

3.1.4 Offer a guaranteed ride home for employees who use alternative modes of transportation to commute.

MO-3.2 Bicycle Transportation Support: The City/County will promote and support the use of bicycles as transportation, including:

3.2.1 Providing bicycle stations with secure, covered parking, changing areas with storage lockers and showers, as well as a central facility where minor repairs can be made;

3.2.2 Providing bicycles, including electric bikes, for employees to use for short trips during business hours;

3.2.3 Implementing a police-on-bicycles program;

3.2.4 Providing a bicycle safety program, and information about safe routes to work.

MO-3.3 Municipal Parking Management: The City/County will implement a Parking Management Program to discourage private vehicle use, including:

3.3.1 Encouraging carpools and vanpools with preferential parking and a reduced parking fee;

3.3.2 Institute a parking cash-out program;

3.3.3 Renegotiate employee contracts, where possible, to eliminate parking subsidies;

3.3.4 Install on-street parking meters with fee structures designed to discourage private vehicle use;

3.3.5 Establish a parking fee for all single-occupant vehicles.

MO-3.4 Travel Mitigation: The City/County will mitigate business-related travel, especially air travel, through the annual purchase of verified carbon offsets.

MO-3.5 Transit Access to Municipal Facilities: Municipal employment and service facilities shall be located on major transit corridors, unless their use is plainly incompatible with other uses located along major transit corridors.

Objective MO-4: The City/County will enhance renewable energy generation, and implement programs for load management and demand response.

MO-4.1 Load Management and Demand Response: The City/County will design and implement peak load management and demand response programs for water pollution control, supply and treatment, and distribution, including interface with existing automated systems for building energy management and SCADA systems.

MO-4.2 Renewable Energy Installation: The City/County will install renewable energy systems at its facilities where feasible, including:

4.2.1 Solar collection systems on municipal roofs;

4.2.2 Solar water heating for municipal pools;

4.2.3 Waste-to-energy systems at waste handling operations.

Objective MO-5: The City/County will manage its stock of vegetation to reduce GHG emissions.

MO-5.1 Urban Tree Management: The City/County will conduct a comprehensive inventory and analysis of the urban forest, and coordinate tree maintenance responsibilities with all responsible departments, consistent with best management practices.

MO 5.2 Landscaping: The City/County will evaluate existing landscaping and options to convert reflective and impervious surfaces to landscaping, and will install or replace vegetation with drought-tolerant, low-maintenance

native species or edible landscaping that can also provide shade and reduce heat-island effects.

Objective MO-6: The City/County will use its purchasing power to promote reductions in GHG emissions by the suppliers of its goods and services.

MO-6.1 Purchasing Practices: The City/County will adopt purchasing practices and standards to support reductions in GHG emissions, including preferences for energy-efficient office equipment, and the use of recycled materials and manufacturers that have implemented green management practices.

MO-6.2 Contracting Practices: The City/County will establish bidding standards and contracting practices that encourage GHG emissions reductions, including preferences or points for the use of low or zero emission vehicles and equipment, recycled materials, and provider implementation of other green management practices.

Waste Reduction and Diversion Policies

Goal: Reduce GHG emissions waste through improved management of waste handling and reductions in waste generation.

Objective WRD-1: The City/County will improve emissions control at waste handling facilities.

WRD-1.1 Methane Recovery: The City/County will establish methane recovery at all wastewater and solid waste treatment facilities.

WRD-1.2 Waste to Energy: The City/County will implement waste-to-energy projects where characteristics meet criteria for effective energy generation.

WRD-1.3 Best Management Practices: The City/County will utilize best management practices at all waste handling facilities.

Objective WRD-2: The City/County will implement enhanced programs to divert solid waste from landfill operations.

WRD-2.1 Diversion Targets: The City/County will achieve a solid waste diversion of 75% of the waste stream by 2020.

WRD-2.2 Diversion Services: The City/County will expand jurisdiction-wide waste diversion services to include, for example, single stream curbside recycling, and curbside recycling of food and greenwaste.

WRD-2.3 Construction and Demolition Waste: The City/County will adopt a Construction and Demolition Waste Recovery Ordinance, requiring building projects to recycle or reuse a minimum percentage of unused or leftover building materials, including:

2.3.1 Require all new development and major rehabilitation projects (additions of 25,000 square feet commercial or 100,000 square feet industrial) to recycle or salvage XX% of non-hazardous construction and demolition debris (excluding excavated soil and land-clearing debris);

2.3.2 Require preparation of a construction waste management plan identifying materials to be diverted from disposal, and how material will be stored and handled;

2.3.3 Establish clear and consistent guidelines for calculation methods, recordkeeping, and reporting to document compliance with the plan;

2.3.4 Establish clear and consistent guidelines for how and when used construction materials can be used in new or remodel construction.

WRD-2.4 Reuse Center: The City/County will establish a reuse/recycling center where furniture, appliances, building materials, and other useful, non-hazardous items may be dropped off or purchased for a nominal fee.

WRD-2.5 Program Promotion: The City/County will promote and expand recycling programs, purchasing policies, and employee education to reduce the amount of waste produced.

Objective WRD-3: The City/County will enhance regional coordination on waste management.

WRD-3.1 Regional Coordination: The City/County will coordinate with other agencies in its region to develop and implement effective waste management strategies and waste-to-energy technologies.

Conservation and Open Space Policies

Goal: Conserve natural resources such as water and open space to minimize energy used and GHG emissions and to preserve and promote the ability of such resources to remove carbon from the atmosphere.

Objective COS-1: The City/County will adopt and implement a comprehensive strategy to increase water conservation and the use of recycled water.

COS-1.1 Water Consumption Reduction Target: The City/County will reduce per capita water consumption by X% by 2020.

COS-1.2 Water Conservation Plan: The City/County will establish a water conservation plan that may include such policies and actions as:

1.2.1 Tiered rate structures for water use;

1.2.2 Restrictions on time of use for landscape watering, and other demand management strategies;

1.2.3 Performance standards for irrigation equipment and water fixtures;

1.2.4 Requirements that increased demand from new construction be offset with reductions so that there is no net increase in water use.

COS-1.3 Recycled Water Use: The City/County will establish programs and policies to increase the use of recycled water, including:

1.3.1 Create an inventory of non-potable water uses within the jurisdiction that could be served with recycled water;

1.3.2 Produce and promote the use of recycled water for agricultural, industrial, and irrigation purposes, including grey water systems for residential irrigation;

1.3.3 Produce and promote the use of treated, recycled water for potable uses where GHG emissions from producing such water are lower than from other potable sources.

COS-1.4 Water Conservation Outreach: The City/County will implement a public education and outreach campaign to promote water conservation, and will highlight specific water-wasting activities to discourage, such as the watering of non-vegetated surfaces and using water to clean sidewalks and driveways.

Objective COS-2: The City/County will ensure that building standards and permit approval processes promote and support water conservation.

COS-2.1 Water-Efficient Design: The City/County will establish building design guidelines and criteria to promote water-efficient building design, including minimizing the amount of non-roof impervious surfaces around the building(s).

COS-2.2 Water-Efficient Infrastructure and Technology: The City/County will establish menus and check-lists for developers and contractors to ensure water-efficient infrastructure and technology are used in new construction, including low-flow toilets and shower heads, moisture-sensing irrigation, and other such advances.

COS-2.3 Gray Water System Standards: The City/County will establish criteria and standards to permit the safe and effective use of gray water (on-site water recycling), and will review and appropriately revise, without compromising health and safety, other building code requirements that might prevent the use of such systems.

Objective COS-3: The City/County will establish programs and policies to ensure landscaping and forests are installed and managed to optimize their climate benefits.

COS-3.1 Water-Efficient Landscapes: The City/County will install water-efficient landscapes and irrigation, including:

3.1.1 Planting drought-tolerant and native species, and covering exposed dirt with moisture-retaining mulch;

3.1.2 Installing water-efficient irrigation systems and devices, including advanced technology such as moisture-sensing irrigation controls;

3.1.3 Installing edible landscapes that provide local food.

COS-3.2 Shade Tree Planting: The City/County will promote the planting of shade trees and will establish shade tree guidelines and specifications, including:

3.2.1 Recommendations for tree planting based on the land use (residential, commercial, parking lots, etc.);

3.2.2 Recommendations for tree types based on species size, branching patterns, whether deciduous or evergreen, whether roots are invasive, etc.;

3.2.3 Recommendations for placement, including distance from structures, density of planting, and orientation relative to structures and the sun.

COS-3.3 Urban Forestry Management: The City/County will develop an Urban Forestry Program to consolidate policies and ordinances regarding tree planting, maintenance, and removal, including:

3.3.1 Establish a tree-planting target and schedule to support the goals of the California Climate Action Team to plant 5 million trees in urban areas by 2020;

3.3.2 Establish guidelines for tree planting, including criteria for selecting deciduous or evergreen trees low-VOC-producing trees, and emphasizing the use of drought-tolerant native trees and vegetation.

Objective COS-4: The City/County will establish policies and programs to develop and preserve conservation areas, including forested areas, agricultural lands, wildlife habitat and corridors, wetlands, watersheds, and groundwater recharge areas, that remove and sequester carbon from the atmosphere.

COS-4.1 Conservation Area Development: The City/County will establish programs and funding mechanisms to create protected conservation areas, including:

4.1.1 Imposing mitigation fees for development on lands that would otherwise be conservation areas, and use the funds generated to protect other areas from development;

4.1.2 Proposing for voter approval a small tax increment (e.g., a quarter cent sales tax, perhaps for a finite time period that could be renewed) to fund the purchase of development rights in conservation areas, or purchase of the land outright.

COS-4.2 Conservation Area Preservation: The City/County will establish policies to preserve existing conservation areas, and to discourage development in those areas.

Education and Outreach Policies

Goal: Increase public awareness of climate change and climate protection challenges, and support community reductions of GHG emissions through coordinated, creative public education and outreach, and recognition of achievements.

Objective EO-1: The City/County will establish a coordinated, creative public outreach campaign, including publicizing the importance of reducing GHG emissions and steps community members can take to reduce their individual impacts.

EO-1.1 Outreach Methods: The City/County will use a variety of media and methods to promote climate awareness and GHG reduction, including:

1.1.1 TV and radio spots with local celebrities and community leaders;

1.1.2 Advertising "Green Tips" in the local paper;

1.1.3 Collaborating with utilities, business associations, civic groups, and non-profits to place tips and articles in billing materials or newsletters;

1.1.4 Designing and maintaining an interactive Climate Protection website and collaborating with other organizations to link to the website.

EO-1.2 Outreach Topics: The City/County will coordinate with other agencies and outreach efforts to align messages on topics such as:

1.2.1 Energy efficiency and conservation, and green energy;

1.2.2 Trip reduction, public transit, carpooling, vanpooling, and alternative modes of transportation;

1.2.3 Green building and energy-efficient design;

1.2.4 Waste reduction, recycling, and composting;

1.2.5 Water conservation and water-efficient design and products;

1.2.6 The benefits of buying local, and information about locally grown, prepared, and manufactured goods and local services.

Objective EO-2: The City/County will work with local businesses and energy providers on specific, targeted outreach campaigns and incentive programs.

EO-2.1 Energy Efficiency Campaigns: The City/County will collaborate with local energy suppliers and distributors to establish energy conservation

programs, Energy Star® appliance change-out programs, rebates, vouchers, and other incentives to install energy-efficient technology and products and to cooperate on advertising.

EO-2.2 **Pedestrian and Bicycle Promotion:** The City/County will work with local community groups and downtown business associations to organize and publicize walking tours and bicycle events, and to encourage pedestrian and bicycle modes of transportation.

Objective EO-3: The City/County will organize events and workshops to promote GHG-reducing activities.

EO-3.1 **Waste Reduction:** The City/County will organize workshops on waste reduction activities for the home or business, such as backyard composting, or office paper recycling, and will schedule recycling dropoff events and neighborhood chipping/mulching days.

EO-3.2 **Water Conservation:** The City/County will organize workshops on water conservation activities, such as selecting and planting drought-tolerant, native plants in landscaping, and installing advanced irrigation systems.

EO-3.3 **Energy Efficiency:** The City/County will organize workshops on steps to increase energy efficiency in the home or business, such as weatherizing the home or building envelope, installing smart lighting systems, and how to conduct a self-audit for energy use and efficiency.

EO-3.4 **Climate Protection Summit/Fair:** The City/County will organize an annual Climate Protection Summit or Fair, to educate the public on current climate science, projected local impacts, and local efforts and opportunities to reduce GHG emissions, including exhibits of the latest technology and products for conservation and efficiency.

EO-3.5 **Schools Programs:** The City/County will develop and implement a program to present information to school children about climate change and ways to reduce GHG emissions, and will support school-based programs for GHG reduction, such as school based trip reduction and the importance of recycling.

Objective EO-4: The City/County will sponsor competitions and awards to encourage GHG reductions and recognize success.

EO-4.1 **Climate Champions Awards:** The City/County will establish a Climate Champions Awards program to acknowledge outstanding private and public efforts to reduce GHG emissions.

EO-4.2 **GHG Reduction / Climate Protection Competitions:** The City/County will sponsor competitions and contests with prizes for promoting climate protection and reducing GHG emissions, including such contests as:

4.2.1 Poster contests at schools, with winning entrants receiving scholarship grants and recognition at the Climate Protection Summit/Fair, and posters used in outreach campaigns or compiled in calendars;

4.2.2 Waste diversion contests between schools, businesses, civic organizations, and Scout troops or other groups, with prizes for the greatest percent waste diverted and recognition at the Climate Protection Summit/Fair, and similar contests for planting trees, reducing vehicle trips, or other desired behaviors;

4.2.3 Walkathons, relays, or other similar fundraising challenges, with funds raised to support community climate protection programs and activities.

Table 2: Worksheet for Model Policies Evaluation

Greenhouse Gas Reduction Planning Policies							
Goal: Reduce GHG emissions from all activities within the City/County boundaries to support the State's efforts under AB32 and to mitigate the impact of climate change on the City/County, State, and world.							
Objective: GHG-1 By 2020, the City/County will reduce greenhouse gas emissions from within its boundaries to a level 30% less than the level that would otherwise occur if all activities continued under a "business as usual" scenario, or to a level 15% less than the levels in 2009.

Transportation Policies							
Goal: Reduce GHG emissions by reducing vehicle miles traveled and by increasing or encouraging the use of alternative fuels and transportation technologies.							
Objective: TR-1 The City/County will reduce VMT-related emissions by encouraging the use of public transit through adoption of new development standards that will require improvements to the transit system and infrastructure, increase safety and accessibility, and provide other incentives.

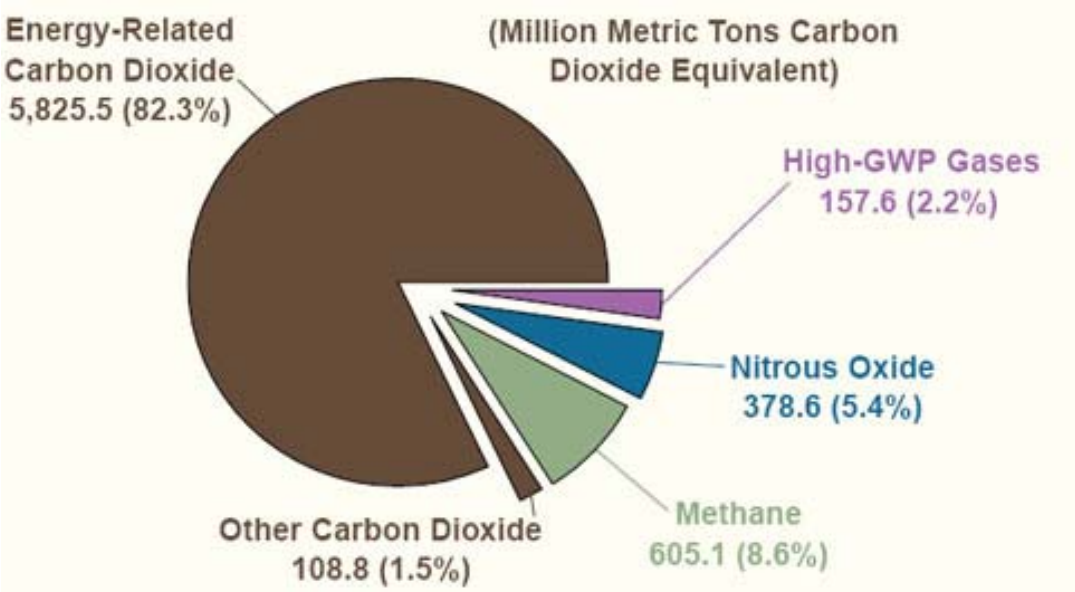
Appendix A

Greenhouse Gas Emissions in California

The characteristics, sources, and units used to quantify the six greenhouse gases (GHGs) listed in AB 32 are documented in this section in order of abundance in the atmosphere: carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O), hydrofluorocarbons (HFCs), perfluorocarbons (PFCs), and sulfur hexafluoride (SF_6). (Water vapor, the most abundant GHG, is not included because natural concentrations and fluctuations far outweigh anthropogenic influences). Figure A-1 below shows U.S. emissions of these gases in 2006, with HFCs, PFCs and SF_6 collectively referred to as high-GWP (global warming potential) gases.

Figure A-1. U.S. Greenhouse Gas Emissions by Gas, 2006



Source: Energy Information Administration estimates,
http://www.eia.doe.gov/oiaf/1605/ggrpt/figure_1.html.
Note: High-GWP Gases include HFCs, PFCs, and SF_6.

In order to simplify reporting and analysis, methods have been set forth to describe emissions of GHGs in terms of a single gas. The most commonly accepted method to compare GHG emissions is the GWP methodology developed by the Intergovernmental Panel on Climate Change (IPCC). The IPCC defines the GWP of every GHG on a normalized scale of CO2e that compares the atmospheric heating potential of each GHG over a 100-year period to that of the same mass of CO2. (CO2 has a GWP of 1 by definition.) Generally, GHG emissions are quantified in terms of metric tons of CO2 equivalent (CO2e) emitted per year. For example, the IPCC finds that nitrous oxide has a GWP of 310 and methane has a GWP of 21. Thus, one ton of nitrous oxide emissions is represented as 310 tons of CO2e, and one ton of methane is 21 tons of CO2e. This allows for the summation of different GHG emissions into a single total.

Table A-1, below, lists the GWP of each GHG, its atmospheric life and concentration. Atmospheric concentration of a given compound is commonly described in units of parts

per million (ppm), parts per billion (ppb) or parts per trillion (ppt), referring to the number of molecules of the compound in a sampling of one million, one billion or one trillion molecules of air.

Table A-1: Global Warming Potentials, Lifetimes and Abundances of Several Significant GHGs

Gas	Global Warming Potential (100 years)	Atmospheric Life (years)	1998 Atmospheric Concentration (ppt[1])
CO_2	1	50–200	365,000,000
CH_4	21	9–15	1,745
N_2O	310	120	314
HFC-23	11,700	264	14
HFC-134a	1,300	14.6	7.5
HFC-152a	140	1.5	0.5
CF_4	6,500	50,000	80
C_2F_6	9,200	10,000	3
SF_6	23,900	3,200	4.2

[1] ppt is a mixing ratio unit indicating the concentration of a pollutant in parts per trillion by volume.
Source: IPCC 1996; IPCC 2001.

Table A-2, below, lists the anthropogenic (man-made) emissions of GHGs as CO2e equivalents. As shown, CO2 is by far the largest component of worldwide CO2e emissions, followed by CH4, N2O, and high-GWP gases.

Table A-2: Global Anthropogenic Greenhouse Gas Emissions (CO_2 e)

Gas	CO_2e Percentage
CO_2 (deforestation, decay of biomass, etc)	17.3%
CO_2 (other)	2.8%
CO_2 (fossil fuel use)	56.6%
CH_4	14.3%
N_2O	7.9%
High-GWP[1] Gases (includes HFCs, PFCs, and SF6)	1.1%

[1] GWP stands for Global Warming Potential. Source: Olivier et al., 2005, 2006 in IPCC 2007b.

CO_2

CO2 is the most important GHG and accounts for more than 75% of all anthropogenic GHG emissions. Its long atmospheric lifetime (on the order of decades to centuries) ensures that atmospheric concentrations of CO2 will remain elevated for decades after

GHG mitigation efforts to reduce GHG concentrations are implemented (Olivier et al. 2005, 2006 in IPCC 2007b).

Increasing concentrations of CO2 in the atmosphere are largely due to emissions from the burning of fossil fuels, gas flaring, cement production, and land use changes. Three quarters of anthropogenic CO2 emissions are the result of fossil burning (and to a very small extent, cement production and gas flaring); the remainder results from land-use changes (IPCC 2007a).

Anthropogenic emissions of CO2 have increased concentrations in the atmosphere most notably since the industrial revolution; the concentration of CO2 has increased from about 280 ppm to 379 ppm over the last 250 years (IPCC 2001). IPCC estimates that the present atmospheric concentration of CO2 has not been exceeded in the last 650,000 years and is likely to be the highest ambient concentration in the last 20 million years (IPCC 2007a; IPCC 2001).

CH_4

CH4 , the main component of natural gas, is the second largest contributor to anthropogenic GHG emissions and has a GWP of 21 (Association of Environmental Professionals 2007; IPCC 1996). Anthropogenic emissions of methane primarily result from growing rice, raising cattle, combusting natural gas, and coal mining (National Oceanic and Atmospheric Administration 2005). Atmospheric methane has increased from a pre-industrial concentration of 715 parts per billion to 1,775 parts per billion in 2005 (IPCC 2001). Though it is unclear why, atmospheric concentrations of CH4 have not risen as quickly as anticipated (National Oceanic and Atmospheric Administration 2005).

N_2O

N2O is a powerful GHG, with a GWP of 310 (IPCC 1996). Anthropogenic sources of N2O include agricultural processes, nylon production, fuel-fired power plants, nitric acid production and vehicle emissions. Nitrous oxide is also used in rocket engines, racecars, and as an aerosol spray propellant. Agricultural processes which result in anthropogenic N2O emissions are fertilizer use and microbial processes in soil and water (Association of Environmental Professionals 2007). N2O concentrations in the atmosphere have increased from pre-industrial levels of 270 parts per billion to 319 parts per billion in 2005 (IPCC 2001).

HFCs

HFCs are man-made chemicals used in commercial, industrial and consumer products and have high GWPs (EPA 2006a). HFCs are generally used as substitutes for ozone depleting substances (ODS) in automobile air conditioners and refrigerants. As seen in Table A-1, the most abundant HFCs, in order from most abundant to least, are HFC-134a (35 parts per trillion), HFC-23 (17.5 parts per trillion), and HFC-152a (3.9 parts per

trillion). Concentrations of HFCs have risen from zero to current levels. Because these chemicals are man-made, they do not exist naturally in ambient conditions.

PFCs

The most abundant PFCs include CF4 (PFC-14) and C2F6 (PFC-116). These man-made chemicals are emitted largely from aluminum production and semiconductor manufacturing processes. PFCs are extremely stable compounds that are only destroyed by very high-energy ultraviolet rays, which result in the very long lifetimes of these chemicals, as shown in Table A-1 (Environmental Protection Agency 2006). PFCs have large GWPs and have risen from zero to the current concentration levels shown in Table A-1.

SF_6

SF6, another man-made chemical, is used as an electrical insulating fluid for power distribution equipment, in the magnesium industry, in semiconductor manufacturing and also as a trace chemical for study of oceanic and atmospheric processes (Environmental Protection Agency 2006a). In 1998, atmospheric concentrations of sulfur hexafluoride were 4.2 parts per trillion, and steadily increasing in the atmosphere. SF6 is the most powerful of all GHGs listed in IPCC studies with a GWP of 23,900 (IPCC 1996).

Appendix B

AB 32 Programs

California's major law for reducing greenhouse gas (GHG) emissions is stipulated in Assembly Bill 32 (AB 32, Nunez) approved by Governor Schwarzenegger in 2006. The goals in AB 32 aim at reducing GHG emissions to 1990 levels by 2020 - a reduction of approximately 30 percent. The main strategies for making these reductions are outlined in the Scoping Plan adopted by the California Air Resources Board (ARB) in December 2008 and in the Discrete Early Action measures identified by ARB in 2007. The following are summaries of AB 32 Programs for reducing GHG emissions.

Discrete Early Action Measures

AB 32 established a statewide target for GHG reductions by 2020. AB 32 further required the ARB to adopt a plan and individual measures to achieve the maximum technologically feasible and cost-effective reductions in GHG emissions. AB 32 required ARB to identify a list of Discrete Early Action measures for implementation by January 1, 2010. ARB identified in 2007 nine Discrete Early Action measures, including potential regulations affecting landfills, motor vehicle fuels, refrigerants in cars, port operations and other sources. Refer to the ARB website at http://www.arb.ca.gov/cc/ccea/ccea.htm for detailed information about each measure and the timeline for implementation. Short descriptions of the Discrete Early measures follows.

Low Carbon Fuel Standard (LCFS)

The LCFS requires fuel providers to ensure that the mix of fuel they sell into the California market meets, on average, a declining standard for carbon intensity. By 2020, the LCFS will produce a 10 percent reduction in the carbon content of all passenger vehicle fuels sold in California. This is expected to replace 20 percent of on-road gasoline consumption with lower-carbon fuels, more than triple the size of the state's renewable fuels market, and place more than 7 million alternative fuel or hybrid vehicles on California's roads. The LCFS will use market-based mechanisms that allow providers to choose how they reduce emissions while responding to consumer demand. For example, providers may purchase and blend more low-carbon ethanol into gasoline products, purchase credits from electric utilities supplying low-carbon electrons (i.e., low carbon fuels used in the generation of electricity) to electric passenger vehicles, or diversify into low-carbon hydrogen as a product. In addition, new strategies yet to be developed will be included.

Landfill Methane Capture

This control measure will reduce methane emissions from municipal solid waste landfills by requiring gas collection and control systems on landfills where these systems are not currently required and will establish statewide performance standards to maximize methane capture efficiencies. Additionally, as part of this process, ARB and California Integrated Waste Management Board (CIWMB) staff will explore opportunities to increase energy recovery from landfill methane gas.

Reductions from Mobile Air Conditioning

These measures will control HFC release from do-it-yourself motor vehicle air conditioning (MVAC) servicing; require addition of leak tightness testing and repair during Smog Checks; enforce federal regulations on banning HFC release from MVAC servicing and dismantling; and require the use of low global warming potential (GWP) refrigerants for new MVAC.

Semiconductor Reduction

This measure proposes to reduce perfluorocarbon (PFC) and fluorinated gas from the semiconductor industry. The regulation will be designed to achieve the maximum reductions in PFC fluorinated gas emissions that are technically feasible and cost-effective.

SF_6 Reductions

SF6 is a potent GHG with a GWP of 23,900, one of the highest GWPs currently identified. SF6 is a versatile gas used in a multitude of sectors including the electric utility and semiconductor industries. (Utility and semiconductor industry-related emissions will be addressed under separate strategies.) This early action focuses on the non-utility and semiconductor-related emissions of SF6. Specifically, the strategy reduction measures will consider a potential ban on the use of SF6 where technologically feasible and cost-effective alternatives are available. The main uses of SF6 in California that are not directly related to utilities or semiconductor manufacturing include: magnesium casting operations; consumer products (tennis balls); medical uses (ultrasounds, eye surgery); tracer gas in leak testing (including fume hood testing), research and bioterrorism studies; insulator for particle accelerators; and etchant for flat panel display units.

High-GWP Consumer Products

Measures under this Discrete Early Action focus on reducing the use of compounds with high GWP in consumer products. This will be done by adding and modifying product category definitions in the existing consumer products regulation and establishing new or lower volatile organic compound (VOC) limits for multiple categories. The measures would also reduce the use of compounds with high GWP in pressurized gas duster products. A number of other modifications or clarifications are also proposed, including prohibiting the use of specified toxic air contaminants in carpet and upholstery cleaners, fabric protectants, multi-purpose lubricants, penetrants, sealant or caulking compounds, and spot removers. The consumer products measure is estimated to reduce CO2 equivalent emissions by 250,000 metric tons per year.

Heavy Duty Vehicle Measures

Under this Early Action measure, new and existing on-road tractors and trailers operating on California highways would need to be equipped with technologies to improve fuel efficiency. It is based on the U.S. EPA's SmartWay Program, which approves technologies, such as aerodynamic equipment and low-rolling resistance tires, and certifies tractors and trailers that incorporate these technologies. The proposed regulation would provide GHG and NOx emission reductions throughout California. Tractors and trailers that comply with the proposed regulation by proper use of aerodynamic equipment and low-rolling resistance tires are expected to achieve a fuel efficiency improvement ranging from 7 to 10 percent and provide GHG and oxides of nitrogen (NOx) emission reductions throughout California.

Tire Pressure Program

Maintaining proper tire pressure on vehicles improves fuel economy, and therefore reduces GHG emissions. This measure would place requirements on the automotive service industry regarding tire pressure checks and inflation pressure retention. While current federal law requires auto manufactures to install tire pressure monitoring systems in all new vehicles beginning September 1, 2007, owners of older vehicles lack this important tool.

Shore Power

Port electrification was identified as a Discrete Early Action measure. The proposed regulation, while reducing diesel PM and NOx emissions, would also result in significant reductions of CO2 emissions as a co-benefit of requiring cleaner grid supplied electrical generation for ocean-going vessels while docked. Auxiliary engines typically power lighting, ventilation, pumps, communication, and other onboard equipment while a ship is docked at a berth. The proposed regulations would require some vessels to turn off their auxiliary engines; it is expected, but not required, that many of those vessels would then receive their electrical power from shore while at berth.

AB 32 Scoping Plan

The Scoping Plan outlines a variety of measures and programs to reduce GHG emissions to 1990 levels by 2020. The plan includes development of a California cap-and-trade program that will be integrated with a broader regional market to maximize cost-effective opportunities to achieve GHG emissions reductions. The plan also includes transformational measures designed to help pave the path toward California’s clean energy future. The following are summaries of the proposed AB 32 measures and programs.

California Cap-and-Trade Program

A cap-and-trade program sets the total amount of GHG emissions allowable for facilities under the cap and allows covered sources, including producers and consumers of energy, to determine the least expensive strategies to comply. The emissions allowed under the cap will be denominated in metric tons of CO2e. The currency will be in the form of allowances which the State will issue based upon the total emissions allowed under the cap during any specific compliance period. Emission allowances can be banked for future use, encouraging early reductions and reducing market volatility. The ability to trade allows facilities to adjust to changing conditions and take advantage of reduction opportunities when those opportunities are less expensive than buying additional emissions allowances. California is working closely with other states and provinces in the Western Climate Initiative (WCI) to design a regional cap-and-trade program that can deliver reductions of GHG throughout the region. ARB will develop a cap-and-trade program for California that will link with the programs in the other WCI Partner jurisdictions to create a regional cap-and-trade program. In addition, a federal cap-and-trade program is being contemplated, and legislation (the Waxman-Markey Bill) is being developed. If the federal program is enacted, the development and implementation of the program will need to be closely coordinated with California. Federal preemption is a possibility.

California Light-Duty Vehicle GHG Standards

There are a number of programs identified under AB 32 that reduce GHGs by the way of light-duty vehicle emission standards. These programs include the AB 1493 (Pavley) GHG vehicle standards, zero-emission vehicle (ZEV) program, and the AB 118 (Nunez) Air Quality Improvement Program/Alternative and Renewable Fuel and Vehicle Technology Program.

AB 1493 directed ARB to adopt vehicle standards that lowered GHG emissions to the maximum extent technologically feasible, beginning with the 2009 model year. ARB adopted regulations in 2004 and applied to the U.S. EPA in 2005 for a waiver under the federal Clean Air Act to implement the regulation. The Pavley regulations incorporate both performance standards and market-based compliance mechanisms. To obtain additional reductions from the light-duty fleet, ARB plans to adopt a second, more stringent, phase of the Pavley regulations. U.S. EPA however, denied the California waiver in 2008 the issues entered litigation. As of February 2009, EPA began reconsidering the waiver request.

The ZEV program will play an important role in helping California meet its 2020 and 2050 GHG emissions reduction requirements. Through 2012, the program requires placement of hundreds of ZEVs (including hydrogen fuel cell and battery electric vehicles) and thousands of near-zero emission vehicles (including plug-in hybrids, conventional hybrids, compressed natural gas vehicles). In the mid-term (2012-2015), the program will require placement of increasing numbers of ZEVs and near-zero emission vehicles in California. In 2009, the Board will review the ZEV program to ensure it is

optimally designed to help the State meet its 2020 target and put us on the path to meeting our 2050 target of an 80 percent reduction in GHG emissions from 1990 levels.

Under AB 118 (Núñez, Chapter 750, Statutes of 2007), ARB is administering the Air Quality Improvement Program, which provides approximately $50 million per year for grants to fund clean vehicle/equipment projects and research on the air quality impacts of alternative fuels and advanced technology vehicles. AB 118 also created the Alternative and Renewable Fuel and Vehicle Technology Program and authorized CEC to spend up to $120 million per year over seven years (2008-2015) to develop, demonstrate, and deploy innovative technologies to transform California's fuel and vehicle types.

Energy Efficiency Programs

The Scoping Plan relies heavily on energy efficiency to reach its GHG emissions reduction goals. Programs include the California Long Term Energy Efficiency Strategic Plan and the Solar Hot Water and Efficiency Act of 2007.

Renewables Portfolio Standard

California's current Renewables Portfolio Standard (RPS) is intended to increase procurement from eligible renewable energy resources to reach 20 percent by 2010. Increased use of renewables will decrease California's reliance on fossil fuels, thus reducing emissions of GHGs from the electricity sector. Based on Governor Schwarzenegger's call for a statewide 33 percent RPS, the Scoping Plan anticipates that California will have 33 percent of its electricity provided by renewable resources by 2020, and includes the reduction of GHG emissions based on this level. Achieving the 33 percent goal will require broad-based participation from many parties and the removal of certain barriers. The CEC, CPUC, California Independent System Operator (CAISO), and ARB are working with California utilities and other stakeholders to formally establish and meet this goal.

Regional Transportation-Related GHG Targets

On September 30, 2008, Governor Arnold Schwarzenegger signed SB 375 (Steinberg) which establishes mechanisms for the development of regional targets for reducing passenger vehicle GHG emissions. Through the SB 375 process, regions will work to integrate development patterns and the transportation network in a way that achieves the reduction of GHG emissions while meeting housing needs and other regional planning objectives. This new law reflects the importance of achieving significant additional reductions of GHG emissions from changed land use patterns and improved transportation to help achieve the goals of AB 32. SB 375 requires ARB to develop, in consultation with metropolitan planning organizations (MPOs), passenger vehicle GHG emissions reduction targets for 2020 and 2035 by September 30, 2010. It sets forth a collaborative process to establish these targets, including the appointment by ARB of a Regional Targets Advisory Committee (RTAC) to recommend factors to be considered and methodologies for setting GHG emissions reduction targets. RTAC members were

appointed in January 2009. An explanation of SB 375 from bill author Darrell Steinberg can be found at the Institute for Local Government website at http://www.ca-ilg.org/sb375 .

Million Solar Roofs Program

The Million Solar Roofs Program is a ratepayer-financed incentive program aimed at transforming the market for rooftop solar systems by driving down costs over time. Created under Senate Bill 1, the Million Solar Roofs Program includes CPUC's California Solar Initiative and CEC's New Solar Homes Partnership, and requires publicly-owned utilities (POUs) to adopt, implement and finance a solar incentive program. This measure would offset electricity from the grid, thereby reducing GHG emissions.

Industrial Emissions

These measures would be implemented through a regulation requiring each facility to conduct an energy efficiency audit of individual combustion and other direct sources of GHGs within the facility to determine the potential reduction opportunities, including criteria air pollutants and toxic air contaminants. The audit would include an assessment of the impacts of replacing or upgrading older, less-efficient units such as boilers and heaters, or replacing units with combined heat and power units. In addition, ARB has identified four specific measures for development and implementation, two for oil and gas recovery operations and gas transmission, and two for refineries.

High-Speed Rail

The Safe, Reliable High-Speed Passenger Train Bond Act for the 21st Century was approved by California voters in 2008. A high-speed rail (HSR) system is part of the statewide strategy to provide more mobility choice and reduce GHG emissions. This measure supports implementation of plans to construct and operate an HSR system between northern and southern California. As planned, the HSR is a 700-mile-long rail system capable of speeds in excess of 200 miles per hour on dedicated, fully-grade separated tracks with state-of-the-art safety, signaling and automated rail control systems. The system would serve the major metropolitan centers of California in 2030 and is projected to displace between 86 and 117 million riders from other travel modes in 2030.

Green Building Strategy

A Green Building strategy offers a comprehensive approach to reducing direct and upstream GHG emissions that cross-cut multiple sectors including Electricity/Natural Gas, Water, Recycling/Waste, and Transportation. Green buildings are designed, constructed, renovated, operated, and maintained using an integrated approach that reduces GHG emissions by maximizing energy and resource efficiency. Employing a whole-building design approach can create synergies that result in multiple benefits at

little or no net cost, allowing for efficiencies that would never be possible on an incremental basis.

Recycling and Waste

ARB will work with the California Integrated Waste Management Board (CIWMB) to develop and implement programs to reduce waste and materials at the source of generation and increase recycling which will result in the reduction of GHG emissions and other co-benefits. ARB will also work with the California Department of Food and Agriculture, the Department of Transportation, and others to provide direct incentives for the use of compost in agriculture and landscaping. Further, CIWMB will explore the use of incentives for all recycling and waste management measures, including commercial recycling, and for local jurisdictions to encourage the collection of residentially and commercially generated food scraps for composting and in-vessel anaerobic digestion.

Sustainable Forests

The 2020 Scoping Plan target for California's forest sector is to maintain the current 5 MMTCO2e of sequestration through sustainable management practices, including reducing the risk of catastrophic wildfire, and the avoidance or mitigation of land use changes that reduce carbon storage. California's Board of Forestry and Fire Protection has the existing authority to provide for sustainable management practices, and will, at a minimum, work to maintain current carbon sequestration levels. The Resources Agency and its departments will also have an important role to play in implementing this measure.

Water

Six GHG emission reduction measures are proposed for the water sector: water use efficiency; water recycling; water system energy efficiency; reuse urban runoff; increased renewable energy production; and public goods charge. Three of the measures target reducing energy requirements associated with providing reliable water supplies and two measures are aimed at reducing the amount of non-renewable electricity associated with conveying and treating water. The final measure focuses on providing sustainable funding for implementing these actions.

Agriculture

The Scoping Plan encourages the capture of methane (CH_4) through use of manure digester systems at dairies to provide emission reductions on a voluntary basis. This measure is also a renewable energy strategy to promote the use of captured gas for fuels or power production. Nitrogen fertilizer, which produces N2O emissions, is the other significant source of GHGs in the agricultural sector. ARB has begun a research program to better understand the variables affecting fertilizer N2O emissions, and based on the findings, will explore opportunities for emission reductions.

(page intentionally left blank)

Appendix C

Other Programs to Reduce GHG Emissions

There are many programs already underway in California at the state, regional and local levels to reduce GHG emissions. These programs seek new and innovative ways to require or promote reductions in GHG emissions through new standards and incentives designed to increase energy efficiencies and renewable energy production, advance green technologies and cleaner fuels, and improve our land use development patterns and waste management, among others. Such programs are occurring worldwide. Appendix C focuses only on the major GHG emission reduction programs in California.

State of California

Assembly Bill 118(Nunez) - Alternative and Renewable Fuel and Vehicle Technology Funding

This program is intended to increase the use of alternative and renewable fuels and innovative technologies that will transform California's fuel and vehicle types to help attain the state's climate change policies. Upon appropriation by the State, approximately $120 million will be allocated annually as incentives to public agencies, vehicle and technology consortia, businesses, public-private partnerships, workforce training partnerships and collaboratives, fleet owners, consumers, recreational boaters, and academic institutions, for projects that:

Develop and improve alternative and renewable low-carbon fuels;

- Optimize alternative and renewable fuels for existing and developing engine technologies;
- Produce alternative and renewable low-carbon fuels in California;
- Decrease the overall impact of an alternative and renewable fuel's life-cycle carbon footprint and increase sustainability;
- Expand fuel infrastructure, fueling stations, and equipment;
- Improve light-, medium-, and heavy-duty vehicle technologies;
- Retrofit medium and heavy-duty on-road and non-road vehicle fleets;
- Expand infrastructure connected with existing fleets, public transit, and transportation corridors; and
- Establish workforce training programs, conduct public education and promotion, and create technology centers.

Senate Bill 1368 (Peralta) - GHG Emissions Performance Standards

The law limits long-term investments in baseload generation by the state's utilities to power plants that meet an emissions performance standard (EPS) jointly established by the California Energy Commission (CEC) and the California Public Utilities Commission (PUC).

The CEC has designed regulations that:

- Establish a standard for baseload generation owned by, or under long-term contract to, publicly owned utilities, of 1,100 lbs CO2 per megawatt-hour (MWh). This will encourage the development of power plants that meet California's growing energy needs while minimizing their emissions of GHGs;

- Require posting of notices of public deliberations by publicly owned utilities on long-term investments on the CEC website. This will facilitate public awareness of utility efforts to meet customer needs for energy over the long term while meeting the State's standards for environmental impact, and;

- Establish a public process for determining the compliance of proposed investments with the EPS.

California Solar Initiative

The California Solar Initiative a collaborative effort between the PUC and CEC initiated in 2006, has a statewide goal to install 3,000 MW of new solar electricity capacity by 2016 - moving the state toward a cleaner energy future and helping lower the cost of solar systems for consumers. The initiative has a statewide budget of $3.3 billion over 10 years. The California Solar Initiative provides solar incentives to customers in investor-owned utility territories of Pacific Gas & Electric, Southern California Edison, and San Diego Gas & Electric. These three utilities represent about 75-80% of California's electricity use. The California Solar Initiative provides cash back for solar for existing homes, and existing and new commercial, industrial, government, non-profit, and agricultural properties.

Executive Order S-14-08

On November 17, 2008 Governor Schwarzenegger signed Executive Order (EO) S-14-08 directing all state agencies to work toward a 33% RPS by 2020. A 33% renewable energy target would further California’s efforts to address climate change and lead the nation in clean energy policy. Specifically, the Executive Order stated the following:

- The EO calls for a new, more aggressive renewable energy target, increasing the current goal of obtaining 20% of California’s energy from clean, renewable resources by 2010 to 33% by 2020.

- The EO directs a restructuring of the process for developing specific renewable energy sites. The EO has a goal of reducing permitting process times for developing renewable energy sites by 50 percent.

- The Governor will propose legislation that will codify the new higher standards and reform the renewable pricing structure at the PUC to make them competitive and get projects built sooner.

Landfill Methane Capture Strategies

The California Integrated Waste Management Board (CIWMB) has identified strategies for increasing landfill methane capture to reduce methane emissions by 2020. The Landfill Methane Capture Strategy includes three core components:

- Install New Methane Control Systems at Landfills Currently Without Control Systems. The control measure will reduce methane emissions from landfills by requiring gas collection and control systems on landfills generating significant methane where these systems are not currently required; it will also establish statewide performance standards to maximize methane capture efficiencies.

- Maximize Landfill Methane Capture Efficiencies. The CIWMB is developing a guidance document to help landfill operators and regulators evaluate potential actions to achieve additional GHG emission reductions from landfills beyond what are currently occurring with existing landfill practices. The study is based on an evaluation of existing state-of-the-practice technologies, as reflected in published literature, reports to regulatory agencies, and the project team's familiarity and experience with specific landfill and landfill gas practices and projects.

- Increase Recovery of Landfill Gas as a Biomass Renewable Energy Source. The CIWMB is providing technical assistance and incentives, and further developing options, in consultation with ARB, CEC, and PUC, to increase recovery of landfill gas. The CIWMB awarded two grants totaling $1 million to demonstrate commercial scale production of liquefied natural gas (LNG) vehicle fuel from landfill gas. The CIWMB is also providing matching funding to demonstrate an innovative anaerobic composting design and process sited at a landfill to increase recovery of biogas for energy and recover a residual compost product from yard wastes otherwise used as landfill alternative daily cover.

California Adaptation Strategy

The California Resources Agency is currently developing a California Adaptation Strategy. The strategy will be developed by collecting, synthesizing, and communicating to the greatest extent possible, how sea level rise, temperature rise and duration, and precipitation changes due to climate change will exacerbate existing fire, flood, water quality, air quality, habitat loss, human health and drought. The Strategy will also

examine how risks associated with these changes will impact the state's economy, infrastructure, human populations, and environment. In addition, it will also outline those solutions which can be implemented that promote resiliency to climate change impacts posing the greatest risks to California and consider key economic, health, and environmental issues.

Caltrans Climate Action Program

The California Department of Transportation (Caltrans) Office of Policy Analysis and Research (OPAR) Climate Action Program coordinates the department's effort in response to AB 32, the Climate Action Team (CAT), the Governor's executive orders, Administration policies, and related legislative rulings. OPAR works with the CAT, ARB, regional agencies, and other stakeholders on cross-agency policy framework and research focusing on GHG emissions reduction and energy-efficiency measures. The program's functional responsibilities include:

- Coordinating and monitoring climate activities and strategies across departmental programs, including planning functions statewide;
- Serving as a primary point of contact for issues related to climate change and transportation energy; and
- Working to mainstream GHG emissions reduction and energy-efficiency measures into transportation planning and project development.

California Water Plan

The California Department of Water Resources (DWR) addresses climate change in its California Water Plan, which is updated every five years. The plan provides a framework for water managers, legislators, and the public to consider options and make decisions regarding California's water future. In addition, DWR in October 2008 released its report *Managing an Uncertain Future; Climate Change Adaptation Strategies for California's Water* which focuses discussion on the need for California's water managers to adapt to impacts of climate change. The report proposes 10 adaptation strategies in four categories which may be incorporated into the California Water Plan

Air Districts

Air Pollution Control Districts and Air Quality Management Districts throughout the state have implemented a variety of climate protection programs over the past several years. The following is a small sampling of some air district programs.

Bay Area Air Quality Management District

In 2005, the Bay Area Air Quality Management District (BAAQMD) initiated a Climate Protection Program that acknowledges the link between climate protection and programs to reduce air pollution in the greater San Francisco Bay Area. The Board of Directors also formed a standing Committee on Climate Protection to provide direction on BAAQMD climate protection activities. BAAQMD is continually seeking ways to integrate climate protection into current District functions, including grant programs, CEQA commenting, regulations, inventory development, and outreach. In addition, the District's climate protection program emphasizes collaboration with ongoing climate protection efforts at the local and State level, public education and outreach and technical assistance to cities and counties. The following are some of BAAQMD's Climate Protection Programs:

- *Climate Protection Grant Program:* In 2007 the BAAQMD awarded $3 million to fund 53 local projects that will significantly reduce the Bay Area's carbon footprint. This $3 million represents the largest single source of funding available for climate protection projects in the Bay Area, and makes the District one of the top funders of climate protection activities in the country.

    - *4th and 5th Grade Curriculum: Protect Your Climate* is a climate protection curriculum targeted at 4th and 5th graders. The curriculum's 16 lessons investigate the science and causes of climate change and how students can take action to protect our climate. Through hands-on activities, students learn ways to reduce GHG emissions from energy, waste, and transportation. Lessons are connected to the California state content standards. After successfully completing a pilot year in 2007-2008, the curriculum program was expanded to include 40 classrooms in the 2008-2009 school year. The participating teachers and approximately 1,000 students in the program are learning how to take action for climate protection in their classrooms, homes, and communities

    - *GHG Regional Inventory*: In 2006 the BAAQMD published *Source Inventory of Bay Area GHG Emissions*, the Bay Area Regional GHG Emission Inventory for base year 2002. The District is developing an updated regional GHG emission inventory which will reflect Bay Area emissions from the year 2005.

    - *ICLEI-BAAQMD Workshop Series:* The BAAQMD has an ongoing partnership with ICLEI-Local Governments for Sustainability to host a series of local government workshops on developing GHG emission inventories and selecting climate protection strategies. Workshops have been hosted for local governments in San Mateo, Santa Clara, and Marin counties. The District and partners ICLEI, PG&E and MTC have provided workshop participants with city-specific data sets and hands-on training. Over 30 local government staff have participated and developed GHG emission inventories for their communities.

- *GHG Fee for Stationary Sources Adopted:* On May 21, 2008, BAAQMD's Board of Directors approved a new fee on air pollution sources in the region to help defray the costs of the District's climate protection work. Industrial facilities and businesses that are currently required to submit an air quality permit to operate will have the modest fee of 4.4 cents per metric ton of GHG emissions added to their permit bill. The fee will apply to Climate Protection Program activities related to stationary sources.

Sacramento Metropolitan Air Quality Management District

The Sacramento Metropolitan Air Quality Management District (SMAQMD) has started a formal program to address climate change. Elements include GHG inventory, work practices, commute incentives, building retrofits and education. Currently SMAQMD is researching and developing enhancements to the District's Climate Protection Program. Those enhancements include: 1) the creation of a GHG emissions "bank," 2) the creation of a program which would facilitate GHG mitigation for CEQA purposes, 3) an enhanced reporting system and; 4) assurances that climate protection measures do not cause increases in criteria pollutants. In addition, SMAQMD has done the following in regards to the Climate Protection Program.

- *California Climate Action Registry (CCAR) and The Climate Registry* The SMAQMD joined the CCAR in March of 2006 and is a founding member of The Climate Registry. The Climate Registry consists of organizations that are voluntarily taking actions to reduce their GHGs. Among the required actions are annually tracking and reporting their GHGs and having them certified by an independent auditer. The District has completed its emissions inventory for 2005, 2006 and 2007 and all three years of data have been certified.

- *Greenergy® member* The SMAQMD subscribes to this Sacramento Metropolitan Utility District program which matches electricity use with renewable electricity sources.

- *Clean Vehicles* Most of the SMAQMD vehicles are hybrids. Employees regularly use these vehicles to conduct air quality inspections at the sites. (Currently, of the District's 23 vehicles, 19 are 2005 Toyota Priuses. When their lease ends in February 2011, the District will look to replace the Priuses with even greener vehicles.)

- *Alternate Transportation Policies* The SMAQMD provides incentives to employees to commute using public transit, car or van pools, and bicycles or by walking. Over 60% of the District's employee work trips are made by alternate modes instead of driving alone.

- *Building Retrofits* The SMAQMD has already implemented several measures at its main office building to improve energy efficiency and reduce its carbon footprint, including: 1) replacing light bulbs with more energy-efficient bulbs, 2)

installing motion sensors on the majority of its light switches and placing other lights on timers and 3) installing a new digitally-based HVAC control system. The District is pursuing LEED EB (Existing Building) certification (level still TBD) for its building and a next step is to have a LEED EB Gap Analysis performed to determine what steps remain to achieve LEED EB certification.

San Joaquin Valley Unified Air Pollution Control District

In August 2008 the San Joaquin Valley Air Pollution (SJVAPCD) Control District's Governing Board adopted a Climate Change Action Plan (CCAP). The CCAP directed the Air Pollution Control Officer to develop guidance documents to assist land use and other permitting agencies in addressing GHG emissions as part of the CEQA process; investigate the development of a GHG banking program; enhance the existing emissions inventory process to include GHG emissions reporting consistent with new state requirements; and administer voluntary GHG emission reduction agreements. These items would then be brought before the District's Governing Board for their consideration in late summer 2009. The goals of the CCAP are to assist local land use agencies comply with CEQA for projects with GHG emissions, assist Valley businesses in complying with state law related to GHGs, and to ensure that collateral emissions from GHG emission reduction projects do not adversely impact public health or environmental justice communities in the Valley. The following are potential programs considered within the CCAP: (1) GHG guidance for CEQA; (2) carbon exchange program; (3) GHG emissions reporting; and (4) voluntary GHG mitigation agreements. The implementation of these actions, if determined to be warranted and feasible, will be determined with extensive stakeholder input.

South Coast Air Quality Management District

The South Coast Air Quality Management District (SCAQMD) is actively engaged in Climate Change activities to maximize the synergies between strategies to reduce criteria pollutants, toxics, and greenhouse gases (GHG). The following highlights selected SCAQMD efforts:

- *Climate Change Committee*: In Spring 2008, the SCAQMD established a Board-level Climate Change Committee to oversee SCAQMD's efforts related to implementation of AB 32 and provide enhanced guidance to local governments regarding climate change issues.

- *Climate Change Policy*: In September 2008, the SCAQMD Board approved a formal Climate Change Policy. It states: *"It is the policy of the South Coast Air Quality Management District (SCAQMD) to actively seek opportunities to reduce emissions of criteria, toxic, and climate change pollutants and maximize synergistic effects of strategies that reduce emissions in more than one of these categories. It is the policy of the SCAQMD to assist businesses and local governments implementing climate change measures, decrease the agency's*

carbon footprint and provide information regarding climate change to the public. If greenhouse gas reduction strategies have potential negative impacts or slow progress in reducing criteria or toxic pollutants, the impacts must be carefully evaluated and disclosed. In these instances, public health protection should prevail in the majority of circumstances. This policy provides additional direction to staff relative to future actions related to greenhouse gas emission reductions and climate change."

The Policy includes 8 specific action areas to implement the above policy.

- *Inventory*: To show its support for efforts to inventory and reduce GHG emissions, SCAQMD has voluntarily prepared a GHG inventory. The SCAQMD has also reported voluntarily to the California Climate Action Registry (CCAR) for the last several years.

- *SoCal Climate Solutions Exchange*: The objective of the SoCal Climate Solutions Exchange is to ensure real, surplus, verifiable GHG reductions from voluntary, early actions. This provides incentives for local investments and assists local businesses in capturing voluntary early GHG reductions. Added benefits are the retention of co-pollutant benefits and stimulus for the local economy. Three rules were adopted in late 2008 and early 2009 to implement this program – Rule 2700 – General; Rule 2701 – SoCal Climate Solutions Exchange; and Rule 2702 – GHG Reduction Program. SCAQMD staff serves as the verifiers for emission reductions that follow pre-approved protocols.

- *California Environmental Quality Act (CEQA)*: To provide guidance to local lead agencies on determining significance for GHG emissions in their CEQA documents, the SCAQMD convened a GHG CEQA Significance Threshold Working Group. Members of the working group include government agencies implementing CEQA and representatives from various stakeholder groups that will provide input to the SCAQMD staff on developing GHG CEQA significance thresholds. On December 5, 2008, the SCAQMD Governing Board adopted an interim GHG significance threshold for projects where the SCAQMD is lead agency. Work is underway regarding recommendations for a GHG threshold for other applications.

- *Technology Advancement Assistance:* SCAQMD oversees a comprehensive program to co-sponsor public-private demonstration and deployment projects for lower-emission fuels, vehicles, and technologies in local fleets. Co-funded fleet acquisitions include low-emission natural gas school & transit buses, clean heavy-duty vehicles, plug-in hybrid electric conversions, and other advanced propulsion vehicles & equipment.

- *Technical and Policy Forums*: The SCAQMD periodically holds clean-energy forums and roundtables to bring together experts on a variety of topics, including GHG reduction strategies. Archived event materials can be viewed at the

SCAQMD website: visit aqmd.gov, click on upper tab "Technology," then select "Technology Forums" from the drop-down menu.

- *Leading by Example*: The SCAQMD headquarters facility is considered a "green building" because of its unique design and state-of-the art features such as fuel cells, 60-kilowatt micro turbines, high efficiency chillers, and energy efficient lighting. The building's exterior design includes windows of a high-efficiency glass which allows light in, but keeps heat out. The building roof is a reflective material which aids in reducing air conditioning load during sunny days. The SCAQMD maintains one of the largest alternatively-fueled fleets in the country, with vehicles running on electricity, compressed natural gas, gasoline, hydrogen or other hybrid combinations.

San Luis Obispo County Air Pollution Control District

In November 2005, the SLOAPCD Board adopted its Climate Protection Plan. Implementation of the plan has been given a high priority and resulted in the following activities and accomplishments:

- *Community Outreach:* A comprehensive outreach program for climate protection was developed, with a countywide survey conducted to determine the level of public knowledge and action on the issue. Presentations have been made to every city council and the county as well as at various public forums regarding the impacts of climate change and how to reduce greenhouse gas emissions locally. A community stakeholder group has been formed with representatives from all local jurisdictions meeting regularly to discuss development of GHG inventories and action plans.

- *GHG Inventory Development:* Municipal and communitywide GHG inventories are being compiled for all local jurisdictions in the region, with a regional emissions report and action plan to be developed based on the inventories.

- *Grant Funding for GHG Reduction Programs:* The District has allocated $440,000 in grant funds for climate protection to provide incentive grants for reducing GHGs in the county; a third of those funds will be used as seed money for implementation of community climate action plans initiated by local jurisdictions.

- *Evaluation of Existing District Programs:* District staff have completed a review of existing regulations and programs to determine the level of GHG reductions already achieved by those programs and what changes can be made to enhance those reductions.

- *Regional Planning:* The District is working with the Council of Governments, LAFCO and the County to develop a preliminary Sustainable Communities

Strategy to include in the 2010 update of the Regional Transportation Plan.

- *Community Partnerships and Programs:* The District is a founding member or on the steering committee for several community groups working to reduce energy consumption and GHG emissions, including the following: The Strategic Energy Alliance for Change (SEAChange) which sponsors public forums and outreach on renewable energy and clean fuels; the Central Coast Clean Cities Coalition, which fosters the advancement and use of clean fuels; the 2030 Challenge Task Force, whose mission is to promote the achievement of carbon free, zero energy buildings by 2030; and SLO Car Free, whose goal is to promote car-free tourism throughout the County.

Ventura County APCD

- *Air – the search for one clean breath***:** a 41-minute award-winning high-definition film produced by the District and funded primarily by a U.S. Environmental Protection Agency grant, features information on climate change via a visit to the British Antarctic Core Survey Program at Cambridge, England, to interview Dr. Robert Mulvaney, an international ice core expert. DVD copies were given to every air district in the country, and the film is being screened throughout the United States and internationally. Teacher lessons for the film will be available online this summer at www.airthefilm.org. They will be aligned with the California State content standards for science, history, and social science. Several of the lessons will concentrate on global climate change.

- *Climate Change Presentations:* The District markets a 20-minute PowerPoint presentation on Global Climate Change to service organizations, senior groups, schools and other organizations. Since its inception in 2008, the program has been presented to over 600 individuals.

- *District Legislative Platform*: The District has amended its legislative platform to allow for the support legislation that implements cost-effective measure to reduce greenhouse gases.

- *Green Urban Fleets*: The District is providing funding to support low-carbon alternative fuel fleets operating in urban environments.

Northern Sonoma County APCD

The Northern Sonoma County Air Pollution Control District participates in climate protection programs on its own as an air district and through CAPCOA. Most District efforts, however, are undertaken in partnership with the County of Sonoma, its nine cities, the Sonoma County Water Agency, and the Agriculture and Open Space Preservation District. Key District efforts include:

- Offering small grants for projects that reduce GHG emissions through its "Sustainability and Trip Reduction Program," approved by the District's Board in 2008.

- Working with local high schools and the Sonoma County Climate Protection Campaign to incorporate climate change awareness and analysis of student travel patterns into the curriculum, and to support campaigns to reduce VMT associated with commute to school.

- Participation in the steering committee overseeing the efforts to achieve the commitment made by Sonoma County and all of its nine cities to reduce GHG emissions by 25% by 2015.

- Participation in the county-wide effort to deploy a vehicle charging network to support electric vehicle technology.

- Participation in the partnership with Nissan to deploy 1,000 electric vehicles in Sonoma County by 2011.

Regional GHG Reduction Programs

The Western Climate Initiative (WCI)

The WCI is a cooperative effort of seven U.S. states and four Canadian provinces that are collaborating to identify, evaluate, and implement policies to reduce GHG emissions, including the design and implementation of a regional cap-and-trade program. The Initiative began in February 2007 with the governors of Arizona, California, New Mexico, Oregon, and Washington, who have since been joined by the premiers of British Columbia, Manitoba, Ontario, and Quebec, and the governors of Montana and Utah. Participation in the WCI reflects each partner's strong commitment to identify, evaluate, and implement collective and cooperative actions addressing climate change. In addition, WCI was created to focus on a market-based cap-and-trade system.

(page intentionally left blank)

Appendix D

Projected Climate Change Impacts to California

In California and throughout western North America, signs of a changing climate are evident. During the last 50 years, winter and spring temperatures have been warmer, spring snow levels in lower- and mid-elevation mountains have dropped, snowpack has been melting one to four weeks earlier, and flowers are blooming one to two weeks earlier. These regional changes are consistent with global trends. If left unchecked, by the end of the century CO2 concentrations could reach levels at which climate change impacts would severely impact our public health, economy, and environment.

State of the art climate modeling was performed for the California Energy Commission (CEC) to determine potential future impacts of climate change in California under three different scenarios: a low emissions scenario that assumes aggressive action is taken to reduce GHG emissions, a medium emissions scenario assuming moderate level GHG reductions, and a high emissions scenario that assumes little action is taken to reduce emissions. The range of potential impacts modeled was summarized in a 2006 CEC document called: "Our Changing Climate: Assessing the Risks to California." The document details the growing severity of consequences predicted statewide as temperature rises, and also identifies those impacts that may be unavoidable and for which we will need to develop coping and adaptation strategies. That information is summarized below to aid jurisdictions in determining the scope and focus of the policies needed to address climate change through the General Plan process.

Increase in the Number of Extreme Heat Days

Current models predict that extreme heat events in California will worsen in both frequency and intensity over the next several decades. Heat waves that once lasted days could last for weeks or even most of an entire season. Heat waves are especially dangerous to vulnerable groups, such as infants, the elderly and those with pre-existing health conditions.

The impacts of heat waves tend to be greater in urban areas because of the "heat island" effect and higher levels of air pollution from transportation. The heat island effect occurs when urban areas replace natural land cover with darker man-made materials such as pavement for parking lots and roads. These materials tend to collect and retain heat at a higher rate than a natural landscape, which causes the urban areas to be hotter than nearby open spaces. Heat island area impacts are expected to increase the frequency, duration, and intensity of conditions conducive to air pollution formation. Health impacts may be influenced by the timing and characteristics of heat waves. Extreme heat events that happen early in the summer tend to result in more deaths than those that occur later in the summer, as people have not yet acclimatized to warmer weather. Moreover, nighttime minimum temperatures are increasing more rapidly than daytime maximum temperatures, which can further increase temperature stress to the elderly and people with pre-existing health conditions, such as circulatory, respiratory and nervous system problems. Furthermore, extreme heat related illnesses place stress on health infrastructure and can lead to significant economic costs.

Increased electricity demand is an additional concern associated with extreme heat days, as the heavy demand to operate air conditioning raises the risk of power shortages. Heavy electricity usage, which is often generated using fossil fuels, means more pollutant emissions, including GHGs.

Increase in the Number and Intensity of Wildfires

Wildfires can have a severe impact on California's air quality and public health. In the coming years, wildfires are expected to increase in intensity and frequency due to climate change, producing more extreme bad air days and longer fire seasons. This negatively impacts the health of the population and results in higher economic costs to California.

Smoke is made up of a mixture of gases and fine particles produced when wood and other organic matter burn. Fine particulate matter (PM) from smoke can cause a variety of adverse health effects ranging from eye and respiratory tract irritation to serious illness, such as reduced lung function, bronchitis, aggravation of asthma, and premature death. aggravation of pre-existing respiratory and cardiovascular disease and increased mortality. PM can also affect the body's immune system and make it more difficult to remove inhaled foreign materials from the lungs, such as pollen and bacteria.

Wildfires also have major economic impacts, costing California hundreds of millions of dollars in firefighting and medical costs; damage to property, natural areas and agricultural lands; loss in tourism, other businesses and employment; increased insurance rates; and a host of other impacts.

Rise in Sea Level and Increased Risk of Flooding

California sea levels have risen about 7 inches over the past 150 years and are projected to rise an additional 4 to 28 inches over the next century as a result of climate change. As sea levels rise, California can expect species and habitat shifts, changes in intensity and frequency of rainfall and coastal storms, increased flooding and changes in runoff patterns. A rise in coastal water temperatures is also anticipated, which will affect water quality and conditions for all marine life that depend on oxygen.

California coastal areas are especially vulnerable to rising sea levels. Increasingly severe winter storms, high tides, and rising mean sea levels are expected to cause more frequent and severe erosion, flooding, and damage to coastal structures. California coastal areas are at risk for the following:

- Erosion of beaches and bay shores;
- Inundation of low-lying uplands;
- Increased flooding and erosion of marshes, wetlands and tidal flats;
- Increased flooding and storm damage in low-lying coastal areas;

- Vulnerable to episodic storm surges and destructive waves that penetrate further inland; and
- Increased salinity in estuaries, marshes, coastal rivers, and coastal aquifers.

Water supplies are also at risk. Rising sea levels would aggravate saltwater intrusion which would degrade California's estuaries, coastal aquifers, wetlands, and groundwater aquifers, and threaten the quality and reliability of the Sacramento-San Joaquin River Delta water transfer system. Higher tide levels caused by higher sea levels could also pose problems to the Delta levee systems with a risk of more inland inundation and the corresponding threat to water quality.

Decrease in Snowpack and Early Run-Off: Effects on Water Supply

Water is already a scarce resource in California and is likely to become more scarce in the coming decade. Water demand is expected to increase because of rising temperatures and increasing population; at the same time, water supply is expected to decrease. California's water supply system relies on a network of dams, reservoirs and canals which are dependent upon water supplied by the snowpack in the Sierra Nevada Mountains. The Sierra Nevada snowpack provides natural water storage, storing winter precipitation in the form of snow and releasing it in the spring and early summer as the snow melts. This system is estimated to hold about half the storage capacity of California's major reservoirs.

Recent studies show that if heat-trapping GHG emissions continue unabated, more precipitation will fall as rain instead of snow, and the snow that does fall will melt earlier, reducing the Sierra Nevada spring snowpack by as much as 70 to 90 percent by the end of this century. Decreasing snowmelt and spring stream flows coupled with increasing demand for water could lead to increasing water shortages, which could exacerbate drought conditions and increase the diversion of rivers in California. The Central Valley relies heavily on Sierra Nevada snowmelt in the summer for drinking water and agriculture. As river flows decrease, competition for scarce water resources increases. California Energy Commission reports project a 15% to 30% reduction in surface water supply to California's cities and farms over this century as a result of climate change.

Increase in the Intensity of Severe Storms

The IPCC predicts changes in precipitation due to increasing global surface temperatures. Rising global surface temperatures are expected to increase the activity of the world's hydrologic cycle and increase the moisture content of the atmosphere. In addition, rising temperatures are expected to increase water vapor in the atmosphere which is a GHG and will likely provide a positive feedback mechanism for climate warming. Global average precipitation is expected to increase during this century; however, it will not be

distributed evenly. Certain areas are expected to receive extra precipitation while others, including California and the southwestern deserts, are expected to receive less.

Research indicates that climate change can cause hurricanes and tropical storms to become more intense, last longer, and have stronger winds. Scientists hypothesize that higher water temperatures are one of the causes of longer and stronger storms, since hurricanes and tropical storms get their energy from warm water. As sea surface temperatures rise, developing storms will contain more energy. Weather patterns have also become more variable, causing longer and drier droughts and longer winter and spring flooding. In recent years, due to high-intensity storms, water flows on many California rivers have been the largest on record. Levees, dams, and flood bypasses are forced to manage flows for which they weren't designed.

Specifically to California, the Sacramento-San Joaquin River Delta is susceptible to flooding. The Delta is composed of 70 islands and tracts and has land surfaces at or below mean sea level. Some Delta Islands are now 25 feet below mean sea level as a result of farming and soil erosion. Levee failure is a significant threat and could result in potential loss of human life, damage to property, and agricultural crops, significant harm to the Delta's fragile ecosystem, disruption of utilities and highways, and water supply disruption due to levee failure and changes in salinity levels.

Effects on Human Health Due to Climate Change

Summer temperatures in California under some climate models are projected to increase by 2°C to 7°C (3.6°F to 12.6°F) by the end of this decade. These temperature increases are expected to affect human health in a number of ways including negative effects on air pollution, heat-related mortality, effects on various infectious diseases, and increase in wildfires.

Higher temperatures are expected to increase the frequency, duration, and intensity of conditions conducive to ozone formation, a pervasive air pollution problem in California causing a wide range of respiratory and cardiovascular problems, particularly for the elderly and very young. Considerable improvement in ozone levels has been achieved over the past three decades as a result of California's aggressive anti-pollution programs. However, under a moderate warming scenario, climate models predict a potential increase of 75 to 85 percent more days with weather conducive to ozone formation in Los Angeles and the San Joaquin Valley, relative to today's conditions.

Likewise, if temperatures rise to the higher warming range, by 2100 there could be up to 100 more days per year with temperatures above 90°F in Los Angeles and above 95°F in Sacramento. Extremely high temperatures increase the number of people who die on a given day by causing the cardiovascular system to work harder to keep the body cool, aggravating existing heart problems; increasing respiratory distress; and causing heat exhaustion. This is predicted to result in two to three times more heat-related deaths than occur today.

Climate change may also increase the risk of some infectious diseases, particularly those that thrive in warm areas. Diseases often associated with hot weather, including the West Nile virus, cholera, and Lyme disease are spreading rapidly throughout North America and Europe because increased temperatures in these areas allow disease carriers such as mosquitoes, ticks, and mice to thrive.

(page intentionally left blank)

Appendix E

Top 10 Actions by Local Governments and Communities

Top Ten Actions by Local Governments and Communities

The most effective and efficient greenhouse gas reductions within the control of local governments will depend on the particular greenhouse gas (GHG) profile within each community, the status of GHG reduction planning to date, and the economic conditions relative to different strategies. Not all strategies will work equally within the diversity of cities and counties in California. However, the following ten strategies are widely applicable throughout California in varying degrees and are the recommended initial local government focus for future General Plan policies, Climate Action Plan development, and Blueprint Planning:

1) promotion of smart growth, jobs/housing balance, transit-oriented development, and infill development through land use designations, zoning, and public-private partnerships;

2) support for and funding of transit, bicycle, and pedestrian connections through transit and trail planning and regional cooperation;

3) promotion of energy- and water-efficient buildings (e.g., LEED buildings) through green building ordinances, project timing prioritization, and other implementing tools;

4) promotion of green procurement and alternative fuel vehicle use through municipal mandates and voluntary bid incentives;

5) support for alternative fuel facilities and infrastructure through land use designations, zoning, and public-private partnerships;

6) support for renewable energy generation (utility and residential) through feasibility evaluations, land use designations, and zoning;

7) promotion of waste diversion, recycling, energy efficiency and energy recovery in cooperation with public services districts and private entities;

8) support for urban and rural forestry through tree planting requirements and programs;

9) community outreach and education to foster community involvement, input, and support for GHG reduction planning and implementation; and

10) regional cooperation to find cross-regional efficiencies in GHG reduction investments and to plan for regional transit, energy generation, and waste recovery facilities.

(page intentionally left blank)

Appendix F

Agency Responsibilities for Programs on Climate and GHGs

Appendix F: Agency Responsibilities for Programs on Climate and GHGs

Appendix F provides information on California State agencies and how they are addressing climate change and GHG reductions in their policies and programs. The following are thumbnail summaries of State programs for reducing GHG emissions. Links are provided at the end of each summary where additional information can be found.

Climate Action Team (CAT)

Established by Governor Schwarzenegger under an Executive Order S-05-05 on June 1, 2005, the CAT coordinates state-level actions relating to Climate Change. The Team is led by the Secretary of the California Environmental Protection Agency and includes the Secretary of the Business, Transportation and Housing Agency, Secretary of the Department of Food and Agriculture, Secretary of the Resources Agency, Chairperson of the Air Resources Board, Chairperson of the Energy Commission and President of the Public Utilities Commission. The CAT is charged with implementing global warming emission reduction programs and reporting on the progress made toward meeting the statewide GHG reduction targets that were established in the Executive Order. The CAT is divided into 11 subgroups which are focused on supporting the Scoping Plan--the roadmap to meet the state's GHG reduction goals. The CAT members will play a key role in developing and implementing the reduction measures adopted in the Scoping Plan. Furthermore, the Executive Order mandated the preparation of a biennial assessment on climate change science, impacts, and adaptation. The CAT has released the draft Climate Action Team Biennial Report for 2009. The draft report can be found at this link: http://www.energy.ca.gov/2009publications/CAT-1000-2009-003/CAT-1000-2009-003-D.PDF . The draft report addresses four climate change topics which include: impacts of climate change on California's public health, infrastructure and natural resources; economic impacts of climate change on California; climate change research in California; and state efforts to adapt to current and future effects of climate change.
http://www.climatechange.ca.gov/climate_action_team/index.html

California Air Resources Board (CARB)

CARB is tasked to oversee California's major initiatives for reducing climate change or GHG emissions as outlined in AB 32, and 2005 Executive Order S-3-05. These efforts aim at reducing GHG emissions to 1990 levels by 2020 - a reduction of approximately 30 percent, and then an 80 percent reduction below 1990 levels by 2050. The main strategies for making these reductions are outlined in the Scoping Plan which was adopted by the Board in December 2008.

The Scoping Plan provides an outline for actions to reduce California's GHG emissions. The Scoping Plan now requires the CARB and other state agencies to adopt regulations and other initiatives reducing GHGs. Many of these measures will be developed in 2009 and 2010 and go into effect in 2012. The following are some of the regulations and activities that CARB will be implementing: energy efficiency/co-benefits audits of large stationary sources; refinery flare recovery; SF6 emission reduction from the electrical

sector and particle accelerators; landfill methane control measures; stationary equipment refrigerant management program; and foam recovery and destruction program. For a complete list of regulations and measures that CARB is considering, please see the Scoping Plan at:
http://www.arb.ca.gov/cc/scopingplan/scopingplan.htm .

In addition to AB 32, CARB is involved with other state climate change programs which include SB 375 and Clean Car Standards (AB 1493—Pavley). As described in Chapter 2, SB 375 is a state law that requires CARB to set regional targets to reduce greenhouse gas emissions from passenger vehicles for 2020 and 2035. If regions develop integrated land use, housing and transportation plans that meet the SB 375 targets, new projects in these regions can be relieved of certain review requirements under CEQA. The targets apply to the regions in the State covered by the 18 metropolitan planning organizations (MPOs).

Under AB 1493, CARB adopted regulations that achieve the maximum feasible and cost-effective reduction in greenhouse gas emissions from motor vehicles. The regulations would reduce GHG emissions from California passenger vehicles by about 22 percent by 2012 and about 30 percent by 2016. For these regulations, however, the Federal Clean Air Act requires a waiver from the U.S. EPA. Initially, the request was denied, but the U.S. EPA as of February 2009 is currently reconsidering rehearing of the waiver request.
http://www.arb.ca.gov/cc/cc.htm

Board of Forestry

The Board of Forestry (BOF) has been involved in the development of forest protocols and how the Forest Practices Act could better address climate mitigation and adaptation policies. BOF has worked with Cal Fire to update the 2003 Assessment of Forests and Rangelands to provide more discussions and analysis on climate change; BOF also helps develop the State's Fire Management Plan which provides policy direction for the state on combating fires. In developing this plan, BOF will consider climate change in its considerations. Furthermore, CARB's Scoping Plan states that the forest sector must achieve a "no net loss" target, which means it must achieve reductions in CO2 equivalent to the current statewide forest carbon budget. BOF has further been tasked by CARB to implement approaches to reach this target. BOF plans to use a combination of regulatory, statutory and incentive-based approaches to meet these goals.
http://www.fire.ca.gov/resource_mgt/resource_mgt_EPRP_Climate/climate_change_board.php

California Coastal Commission

The California Coastal Commission is developing a planning manual for how stakeholders should address climate change within the California Coastal Act (CCA). The Coastal Commission is planning to develop a document and website that will help stakeholders interpret and implement projects under the CCA. In addition the Commission completed the following in connection with its climate change activities: a

workshop on climate change for the Commission Board; establishment of an internal climate change task force to better understand the relationship between climate change and the CCA; addressing how to incorporate GHG mitigation requests into permit conditions within large projects before the Commission; and participation on the Coastal States Organization Climate Change Work Group, which developed a report, "The Role of Coastal Zone Management Programs in Adaptation to Climate Change."
http://www.coastal.ca.gov/climate/climatechange.html

California Coastal Conservancy

The California Coastal Conservancy has taken the following actions in regards to climate change: developing Climate Change Grant Assessment Criteria for project design; reduction of the Conservancy's overall carbon footprint; and improved planning for future climate impacts to land and water management efforts. The Conservancy is also interested in the "permanent protection or restoration of important habitat corridors affecting significant populations of various species" as an important measure of success. The Conservancy will assess both land and freshwater species as pertaining to climate change impacts.
http://www.scc.ca.gov/index.php?cat=26

California Conservation Corps (CCC)

The CCC has taken the following actions in regards to climate change: implementing a number of programs to reduce its carbon footprint; promoting a more environmentally-friendly labor force by increasing spikes (work from mobile camps) to project work sites to reduce vehicle mileage and maximize time on tasks; increasing fleet vehicle use; developing demonstration projects that sequester carbon and reduce energy and water use; engaging in additional urban and wildland forestry projects, such as tree planting and fuel reduction activities and; participating in climate education that furthers climate action awareness through highly visible project work and public education strategies.
http://www.ccc.ca.gov/#

California Department of Food and Agriculture (CDFA)

The CDFA is addressing the issues of global warming through development of carbon sequestration strategies and GHG reduction strategies for agriculture, promotion of energy and water use efficiency in agriculture, biological control measures, and support for biofuels development. Some specific programs administered include the Rice Straw Utilization Program, which ties into carbon sequestration and biofuels production. Other projects in the Minor Crops Block Grant Program address carbon sequestration and energy efficiency in agriculture. The CDFA is also seeking to reduce the use of petrochemical-based pesticides and fertilizers, which release GHG to the atmosphere, through the Biological Control Program, which substitutes biological organisms for pesticides, and the Fertilizer Research and Education Program, which reduces fertilizer use and promotes carbon sequestration. The Drainage Water Reduction Program and

Reuse and Salt Utilization Program result in more efficient use of irrigation water, resulting in less energy used for water pumping. The CDFA promotes the California production and use of bioethanol and biodiesel as renewable fuels. The Dairy Digester Cost Share Program expands the use of dairy digesters, which convert dairy manure and the methane gas derived from it into electricity, process heat, compost, and carbon dioxide. The conversion of dairy methane to carbon dioxide reduces the global warming potential by about 90% while providing energy.
http://www.cdfa.ca.gov/AHFSS/Emergency_Preparedness/Climate_Change.html

California Department of Forestry and Fire Protection (Cal Fire)

Cal Fire has taken the following actions in regards to climate change: reducing Cal Fire's carbon footprint; participating as an active member of the CAT Forest and Land-Use Sector Groups; assisting in the development of the original forest carbon protocols that were recently adopted by CARB; actively developing new protocols on public lands, urban forestry, and working forests; developing the climate strategy for the Forestry CAT that included detailed descriptions on Reforestation/Afforestation, Forest Conservation, Forest Management, Urban Forestry, and Fuels Reduction/Biomass Production; and participating in several current programs that improve the ability of our forests to adapt to the projected impacts of climate change in California. These programs include the California Forest Improvement Program, the Vegetation Management Program, the Nursery and Seed Bank Program, the Urban Forestry Program, the Forest Legacy Program, and Fuel Hazard Reduction.
http://www.fire.ca.gov/index.php

California Energy Commission (CEC)

The CEC has played an important role in coordinating and implementing state activities addressing climate change. These activities include the following: involvement in a number of activities supporting implementation of AB 32 and other climate activities such as reductions in GHG emissions through energy efficiency, renewable energy and alternative transportation fuel programs; serving on the CAT and leading the Land Use Subgroup of the Climate Action Team (LUSCAT); participating on 11 CAT subgroups responsible for developing action items that will result in quantifiable greenhouse gas emission reductions; conducting a joint proceeding with the CPUC on AB 32 implementation in the electric sector and making joint recommendation to the ARB in February 2008; conducting scientific research on climate change through the Public Interest Energy Research Program (PIER) and the California Climate Change Center; developing climate research and a Development, Demonstration and Deployment Road Map with the ARB and other state agencies to achieve GHG emission reduction and adaptation goals; providing technical support to the California Climate Action Registry in developing greenhouse gas emission protocols; qualifying third-party organizations to provide technical assistance and certification of emissions baselines and inventories; supporting CARB's statewide greenhouse gas emissions inventory for updates and

accuracy; participating in the working groups of the Western Climate Initiative to identify, evaluate and implement collective and cooperative ways to reduce GHGs in the West; and providing policy guidance and monitoring international, national and regional developments and activities impacting clean energy and climate change issues.

Furthermore, the CEC's PIER Program supports research to produce environmentally sound, safe, reliable and affordable energy services and products. In conjunction with other state agencies, PIER is addressing climate change by leading the development of a long-term climate change research plan for California. Under PIER, energy efficiency and generation technologies are under development that could significantly contribute to the decline of in-state greenhouse gas emissions. In addition, PIER is seeking to improve understanding of the implications of climate change by supporting research on potential costs and impacts was well as possible adaptation and mitigation measures. http://www.energy.ca.gov/climatechange/index.html

California Environmental Protection Agency (Cal/EPA)

Under existing law, the CARB, CEC, and the California Climate Action Registry all have responsibilities with respect to control of greenhouse gas emissions. New legislation requires the Secretary for Environmental Protection to coordinate greenhouse gas emission reductions and climate change activity in state government. Cal/EPA is addressing climate change through its assessment of environmental indicators in the Environmental Protection Indicators for California (EPIC) project. EPIC was created to develop scientifically based measures that convey complex information on environmental status and trends in an easily understandable format. EPIC supports Cal/EPA's commitment to using measurable results in judging the effectiveness of the state's efforts directed at environmental protection. In its first year, EPIC developed a framework in which to select indicators that are important in tracking the state of California's environment. For climate change, the indicators selected were carbon dioxide emissions, air temperature, Sierra Nevada snowmelt runoff, and sea level rise in California. In the future, EPIC will investigate other greenhouse gas emissions, such as methane and nitrous oxides, and correlate different data sets that show increasing climate patterns in California. Cal/EPA will continue to evaluate, improve, and expand on the EPIC project to ensure that it provides meaningful information for understanding the state of the California environment for planning and decision making.
http://www.climatechange.ca.gov/

California Integrated Waste Management Board (CIWMB)

The CIWMB is addressing climate change issues through recycling programs, which avoid emissions from the energy-intensive processing of virgin raw materials; through sustainable building activities, which emphasize energy, water, and materials efficiency thereby reducing emissions from their production and transport; and through landfill gas collection, which directly uses landfill greenhouse gas emissions for fuel. The CIWMB is implementing the State Agency Buy Recycled Campaign (SABRC) program which,

under state law, requires all state agencies to use recycled products when available and increase acceptance and awareness of recycled-content product use in the private sector as well as state and local government. CIWMB runs the one of the largest recycled-content databases on the web, including construction and demolition recycling databases. The CIWMB has played a key role in the Sustainable Buildings Task Force, and is currently developing the Sustainable Building Training Program. In an interagency study, the CIWMB will develop a methodology to incorporate life-cycle costing into the state's capital outlay design. CIWMB participated in the Collaborative for High Performance Schools to assist in building energy and resource-efficient California schools and runs a program to promote efficient landscape design and maintenance practices among landscaping professionals. CIWMB also has been instrumental in the U.S. Green Building Council's Green Building Rating System. The CIWMB is pursing conversion technologies such as gasification and hydrolysis of solid waste to produce alternative fuels such as ethanol, thereby offsetting greenhouse gas emissions from fossil fuel sources. The conversion of solid waste destined for landfills to useful products such as ethanol reduces the organic fraction going into landfills. It is the organic fraction which generates landfill gas, a significant source of greenhouse gas emissions. The CIWMB also directly benefits greenhouse gas reduction by ensuring compliance with state minimum standards for landfill gas monitoring, collection, and control.
http://www.ciwmb.ca.gov/climate/

California Ocean Protection Council (OPC)

OPC has taken the following actions in regards to climate change: coordinating ocean impacts; establishing policies that will guide those agencies responsible for ocean protection; and helping to coordinate the state's efforts to adapt to the ocean impacts of climate change. OPC is working on determining potential impacts along the coast due to sea level rise, including impacts to public infrastructure.
http://www.opc.ca.gov/

California Public Utilities Commission (CPUC)

The CPUC is responsible for a number of energy-related policies and initiatives that benefit consumers and the economy, and have corresponding reductions in GHGs. Some of these policies and initiatives are described as follows:

- Energy Efficiency - The CPUC launched an energy efficiency and conservation campaign in which the agency allocated almost $3 billion in funding for energy efficiency programs in 2006-2008.

- Renewable Energy - California has the most ambitious goals in the nation for renewable energy. The State’s Renewable Portfolio Standard requires utilities to obtain 20% of their power from renewable resources by 2010, as mandated under SB 107 (Simitian). The CPUC oversees utility progress toward this goal and identifies steps toward meeting the Governor’s target of 33% by 2020.

- Emissions Performance - The CPUC instituted a new GHG emissions performance standard to regulate contracts with electricity generation facilities. Mandated by SB 1368 (Perata), the standard, known as EPS, ensures that any long-term power commitments to meet California's energy needs are at least as clean as California's existing energy portfolio.

- Emerging Technologies - The CPUC approved $11 million per year in funding support for emerging energy efficiency technologies from 2006 through 2008.

- Advanced Metering - The CPUC has authorized distribution tariffs since 2001 to fund utility incentives for customer-owned clean generation such as fuel cells and solar energy. This is a part of a plan for replacing conventional customer electric meters with an Advanced Metering Infrastructure (AMI), giving customer new access to information and greater control over their energy use and bills. http://www.cpuc.ca.gov/PUC/energy/climate+change/

California Resources Agency

The California Resources Agency is providing leadership in promoting and implementing climate policies across the state through its 25 departments, commissions, boards and conservancies, through the Governor's Climate Action Team efforts, and through engagement in national and international climate policy dialogues. These efforts range from working to reduce the Resource Agency's overall carbon footprint, to setting state climate policy direction through the development of a state climate adaptation strategy, to representing California in the recent U.N. Framework Convention on Climate Change Convention in Indonesia. The Resources Agency has been active in developing a climate adaptation strategy (CAS) for the state that begins to address how California can and should prepare for short-, medium-, and long-term risks from expected climate impacts. Mitigating carbon emissions has and should be a central focus of California climate policies, but helping California adapt to known climate impacts will need to be on equal footing to address climate risks to the state's resources. In addition, the Resources Agency is:

- In the process of accounting for all Resources-wide GHG emissions. At the same time, the Agency is working with all of its departments, commissions, boards, and conservancies to reduce its overall carbon footprint in internal operations, project activities, and amongst its grantees and contractors when possible;

- Leading the Forestry Climate Action Team Scoping Group. The Resources Agency has been Chairing the Forestry Climate Action Team (FCAT) sector group that has focused on developing a forest sector strategy for the Scoping Plan, revising the state's greenhouse gas inventory for the forests, developing new forest protocols, discussing offsets, and the climate adaptation strategy for the forest sector;

- Revising CEQA Guidelines to address greenhouse gas mitigation and adaptation. Under SB 97 (Dutton), the Resources Agency is working with the Governor's Office of Planning and Research to develop Technical Guidelines for how GHGs should be considered in the California Environmental Quality Act (CEQA). It is planned that this effort will be completed by 2010;

- Providing Climate Policy Coordination and Leadership within the Agency. Monthly "Climate Leaders" meetings with the Lead Climate person within each Resources organization are held to discuss recent happenings on climate-related topics;

- Revising bond-money grant guidelines to incorporate climate change. The Resources Agency is developing climate change grant criteria for several programs within its organization to begin to track the carbon emissions and sequestration from Resources programs;

- Initiating a forestry sub-group as part of the Western Climate Initiative, with Washington and Oregon;

- Partnering with the Coastal States Organization (CSO). The Resources Agency chairs the CSO where the Chair's Initiative proposes that coastal climate change be one of the three top priorities of the CSO. The organization has adopted the Adaptation to Climate Change Policy to better coordinate state and national efforts. The Coastal States Stewardship Foundation, in collaboration with the Coastal States Organization, is creating the Coastal States Campaign to Adapt to Climate Change;

- Involved with the West Coast Governors' Agreement on Ocean Health. Part of the recommendations from the West Coast Governors Agreement on Ocean Health Action Plan will be to address climate change adaptation by conducting a west-coast-wide assessment of anticipated impacts of climate change over the next several decades and setting a plan for how to adapt to such changes. http://resources.ca.gov/energy_and_climate_change.html

California Department of Transportation (Caltrans)

Caltrans is addressing climate change by reducing emissions through energy efficiency measures and use of alternative technologies to lessen the emissions from the state transportation system, vehicle fleet, and reduction of time spent in cars and in traffic. In fiscal year 2001/2002 Caltrans surpassed energy efficiency goals by saving $7.5 million, primarily due to the statewide Light Emitting Diode (LED) Traffic Signal upgrade project. This achievement has led to significant emissions reductions in energy generation, and is being expanded through implementation of non-vehicular energy conservation activities, such as reducing the energy to traffic signals, roadway and sign lighting, facility operations and procedures, and bridge and tunnel operations. Caltrans' Greening the Fleet Initiative uses viable, emerging technologies to reduce mobile source

emissions. So far, nineteen hybrids and 758-gas/propane bi-fuel trucks were purchased. Low emission trucks have replaced 54 diesel-powered trucks, and zero emission static inverters have replaced generators on 34 trucks. Solar panels have replaced fossil fuel-powered accessories. These efforts will continue with the goal of making significant emissions reductions and leading California fleet operators. Caltrans will also reduce mobile source emissions through its transportation energy efficiency program, the Smart Transportation and Livable Community Initiative, with the goal of reduced fuel consumption and vehicle miles traveled, and increased transit ridership and vehicle occupancy. The Transportation System Management and Congestion Relief programs seek to reduce emissions by minimizing travel demand and congestion while maximizing traffic efficiency. Applications include electronic toll collection on bridges, traffic signals, ramp meters, and many more. The New Technology Program will continue to research, demonstrate, and deploy new technologies to increase travel efficiency.
http://www.dot.ca.gov/hq/tpp/offices/opar/climate.html

Department of Conservation (DOC)

The DOC is addressing climate change issues and GHG reductions through a number of actions and programs which include the following:

- The DOC is working with The Climate Registry and several of its members in devising documentation procedures for several emission sources, such as work travel in personal vehicles and rental cars that are currently not required but strongly encouraged.

- Both the Division of Recycling and the Division of Land Resource Protection have revised their grant programs to include GHG reduction as a means to encourage and support lower-emitting projects.

- DOC participates on the following CAT subcommittees: Land Use, Recycling and Waste, Agriculture, Water, Energy and Economic.

- DOC's Division of Oil, Gas and Geothermal Resources is working with the California Energy Commission and other state and federal agencies, as mandated by AB 1925 (Blakesee). DOC is helping to assess the technical and economic feasibility of carbon sequestration in California.

- DOC established a department-wide Climate Action Team (CoolCATS) consisting of representatives from each Division. This team will measure DOC's carbon footprint and identify meaningful and feasible strategies to reduce that footprint.

- Each division within DOC is systematically educating their staff on the principles of sustainability. http://www.conservation.ca.gov/Index/Pages/Index.aspx

Delta Protection Committee (DPC)

The DPC has identified sea level rise as a central threat facing the Delta in the DPC 2006-2011 Strategic Plan. The DPC has initiated a process to update its 1995 Land Use and Resource Management Plan for the Primary Zone of the Delta and will include findings on climate change policies and recommendations for action that local and state government can take to address the impacts of climate change on the Delta.
http://www.delta.ca.gov/

Department of Fish and Game (DFG)

The DFG is addressing climate change issues and GHG reductions through a number of actions and programs which include the following:

- Implementing California's Wildlife Action Plan which identifies climate change as one of DFG's four primary stressors affecting wildlife (along with growth and development, water management conflicts, and invasive species) and makes recommendations to incorporate climate change science in restoration work.

- Providing climate leadership through personnel additions.

- Taking a lead among the state fish and wildlife agencies to begin to address the uncertainty associated with a changing climate through landscape scale efforts that support managing robust populations and healthy habitats. The Department also has many targeted efforts underway focused at climate change research, monitoring and other more specific actions.

- Creating a task force to provide the leadership to reduce or mitigate the production of greenhouse gases by the Department, and to prepare for the current and future harmful impacts of climate change on California's natural resources through policy and meaningful action.

- Convening stakeholders and partners from the NGO community, academia, state and federal agencies. This stakeholder group will provide direct input to the Director's Task Force as well as maintaining and increasing communication and collaboration among stakeholders and Department of Fish and Game.

- Developing a website that will serve as both a resource to Department employees as well as a message to the public and partners about the Department of Fish and Game's commitment to addressing the challenges of a changing climate in all of its endeavors.

- Evaluating the carbon impact of all departmental operations as part of the Climate Change Registry and as a Resources Agency-wide effort.

- Participating with the Resources Agency on the forestry, land-use and water, energy and transportation CAT subgroups, and advising the state on factors relating to adaptation and mitigation for climate change effects on wildlife and natural resources.

- Working with State Parks, Cal Fire and other Resources Agency departments and the Biodiversity Council to build a comprehensive library of published literature, popular articles, and other information on climate change effects that will be made available to the public. DFG has also developed complementary data and enhanced close collaboration with sister state agencies to help inform decisions ranging from levee placement to park management to highway interchange placement.

- Representing wildlife interests on the climate action working group of the Western Governors Association and the Climate Change subcommittee for the Association of Fish and Wildlife Agencies. http://www.dfg.ca.gov/climatechange/

Department of General Services (DGS)

The DGS is addressing climate change issues and GHG reduction through a number of actions and programs which include the following:

- Developing and implementing energy savings strategies such as the Better Buildings Program, ensuring energy savings in state building projects and schools.

- Assisting, through the Office of Fleet Administration's (OFA) Alternative Fuel Vehicle (AFV) Program, state agencies in meeting federal AFV purchasing requirements, which helps reduce dependence on foreign oil and help reduce GHG emissions.

- Establishing a vehicle purchase policy which requires gasoline vehicles purchased for the state fleet to meet the Air Resources Board’s ultra low-emission vehicle standard.

- Promoting the use of recycled products in the construction and maintenance of state buildings

- Monitoring in real time the energy use in state facilities to foster conservation efforts. http://www.green.ca.gov/default.htm

Department of Toxic Substances Control (DTSC)

The DTSC is addressing climate change issues through its Pollution Prevention and Technology Development Program. Hazardous waste reduction and recycling activities reduce impacts on the environment as well as the impacts from transportation, management and disposal. As one example, the development of water-based cleaning systems in lieu of solvent-based systems reduces resource consumption and promotes sustainability. Through the incorporation of life-cycle thinking, DTSC's pollution prevention activities take a holistic, multi-media approach, incorporating energy and materials efficiency as well as air, land and water emissions reductions.
http://www.dtsc.ca.gov/

Department of Water Resources (DWR)

The DWR is addressing climate change issues through a number of actions and programs which include the following:

- Developing a DWR Renewable Resources Policy that would meet the intent of the State's Renewable Portfolio Standards by establishment of a goal under which a percentage of load would be met by use of renewable resources.
- Refurbishing generating and pumping units to increase their efficiency as part of the State Water Project Energy Efficiency Improvements.
- Promoting combined-cycle plants and renewable resources at its facilities.
- Developing an adaptation plan for the state's water resources within the State Water Plan effort.
- Serving as a co-leader and actively participating in the CAT Water and Energy Scoping Group.
- Actively pursuing projects and research that promote carbon sequestration on DWR lands. www.water.ca.gov/climatechange/

Office of Planning and Research (OPR)

OPR is addressing climate change through education about using renewable energy sources, and through Smart Growth, and Vital Communities Initiatives. Innovative Clean Air Technologies (ICAT), GIS State Energy Map, Energy Educational Forum, and Stationary Fuel Cell Collaborative are among the initiatives led by the office. OPR held renewable energy forums from May through November of 2001 in an effort to meet the Governor's goal to increase renewable sources to supply twenty percent of all California's energy needs by 2010. The forums focused on biomass, wind, geothermal, solar, and fuel cell energy, which lead to significant reductions in greenhouse gas emissions as

compared to fossil fuel generated energy. OPR led an Interagency Task Force on Green Accounting that revised the 1987 Standard Practices Manual (2001) which provided finance and accounting procedures for using life-cycle analysis for state projects. The same Task Force is worked on a Comprehensive Energy Efficiency and Renewable Plan for the State On-Site State Buildings and a "Renewable Grid Connected Generation Plan" which supports the financial potential of the Governor's Renewable Portfolio Standard. Furthermore, addressing climate change and GHGs in CEQA projects has emerged as a major issue. Pursuant to Senate Bill 97 (Dutton)(Chapter 185, 2007) OPR is in the process of developing CEQA guidelines "for the mitigation of greenhouse gas emissions or the effects of greenhouse gas emissions." OPR is required to "prepare, develop, and transmit" the guidelines to the Resources Agency on or before July 1, 2009. As part of its continuing service to professional planners, land use officials, and CEQA practitioners, OPR, in collaboration with the California Resources Agency, Cal/EPA, and ARB, has published a technical advisory containing informal guidance for public agencies as they address the issue of climate change in their CEQA documents.
http://opr.ca.gov/index.php?a=ceqa/index.html

State and Consumer Services Agency (SCSA)

SCSA which also houses the Department of General Services (DGS) and the Department of Consumer Affairs, has used the emissions reductions of energy savings programs such as the Building Better Buildings program, energy conservation awareness programs such as the Flex Your Power campaign, as well as emissions reduced from mobile sources in the "Green Fleet" program to address climate change in California. Along with the CIWMB, the SCSA has ensured significant energy and resource savings in major state building projects which amount to over $1 billion, substantially cutting emissions from energy generation. An example of this is the Capitol Area East End project. DGS, as property managers for numerous state government buildings, is cutting energy use through building electricity metering, energy control systems, and extensive recycling. Through the DGS, the Alternative Fuel Vehicle Program is creating a government fleet that produces less greenhouse gas emissions than standard gasoline powered cars by relying on Ultra Low Emission and Super Ultra Low Emission vehicles. The program is also working to deploy fuel cell vehicles as part of the state fleet and to promote the use of electric vehicles. SCSA also promotes energy conservation and efficiency in homes and schools through education and awareness programs. An example is the Flex Your Power campaign implemented by the Department of Consumer Affairs.
http://www.scsa.ca.gov/

State Lands Commission

The State Lands Commission is addressing climate change issues through a number of actions and programs which include the following:

- Inclusion of GHG emissions from leases in environmental impact reports (EIRs). The Commission is requiring greenhouse gas reports for leases involving major

projects. For projects that completed their EIRs before AB 32, the Commission is requiring a supplemental report on greenhouse gases. For example, a supplemental greenhouse gas report was produced for the Poseidon desalination project since the EIR was completed before passage of AB 32.

- Sea Level Rise Planning. The Commission is requiring that oil terminals be modified so that they can accommodate anticipated sea level rise over the life of the terminal. The Commission is beginning to consider the effects rising sea levels will have on the mean high tide line and, consequently, State Lands' jurisdiction. http://www.slc.ca.gov/

State Parks

The State Parks is addressing climate change issues and GHG reductions through a number of actions and programs which include the following:

- Planning a reduction strategy by using solar power systems, installing better insulation, and by buying lower-emission vehicles. In addition, the buildings Parks hopes to build (e.g., restrooms, visitor centers, etc., using bond funds) will have to meet high energy-efficiency standards by Executive Order of the Governor.

- Promoting carbon sequestration in State Park projects. Because forests and other plants absorb and store carbon dioxide from the atmosphere, Parks is trying to reduce its total amount of GHGs affecting our climate through Parks land stewardship and land acquisition strategies.

- Working with universities to monitor the success of different species at different altitudes in the face of climate change. And, consistent with Parks' educational mission, the entire project will be interpreted to visitors as a working example of climate change adaptation and mitigation.

- Modifying its land stewardship priorities to help species adapt to the effects of climate change. The available science suggests Parks need to be purchasing and protecting habitat corridors that move up in elevation so species have somewhere to migrate as the temperatures increase. State Parks also have to consider how an increase in sea level could affect our properties, in particular coastal properties. Sea level rise may require relocating our coastal infrastructure.

- Hosting a seminar with UC Berkeley's California Center for Environmental Law and Policy and the Resources Legacy Fund that brought together public land managers, non-profits and significant donors (who collectively will be spending hundreds of millions of dollars in the coming several years) together with scientists, academics and other experts to develop new acquisition priorities and restoration practices.

- Engaging the public in a meaningful way to help them understand the issue of climate change and to inspire them to constructive action. Parks can teach visitors about the impacts of climate change on parks and inspire them to adapt to climate change by making positive lifestyle changes. Parks can become models of climate-change best practices showcasing both what is at risk and what can be done about it. Parks is beginning to consider how climate change fits into existing planning efforts. http://www.parks.ca.gov/?page_id=21491

State Water Resources Control Board (SWRCB)

The SWRCB is addressing adaptation to climate change with increased environmental data collection and information management that assist in determining correlation between climate change, water supply changes and water quality effects. Through the Surface Water Ambient Monitoring Program (SWAMP), water quality monitoring has increased the gathering of data about overall surface water conditions. SWRCB is also implementing the System for Water Information Management (SWIM) that will increase the availability of such information to researchers, the public, and other interests. The SWRCB is working through the Joint Agency Climate Team and other forums, to identify and coordinate water quality related issues. Increased climate variability and warming has the potential to significantly affect water quality in the state, therefore this data collection and management system will assist in the planning of adaptations to meet water quality objectives.

Appendix G

Examples and Resources

(intentionally left blank)

Appendix G: Examples and Resources

Appendix G provides an example of a General Plan approach from Marin County. A link has been provided at the end of the Marin County excerpt for readers who wish to view the Marin County General Plan in its entirety. In addition there are several additional reference links for General Plans and Climate Action Plans. The intent is to augment the guidance in the main body of this report with real-world examples of what others have done.

(intentionally left blank)

2.7 Atmosphere and Climate

Background

Although air quality in Marin County is generally very good, emissions from within the county may contribute to pollution problems elsewhere in the region and climate changes that are occurring on a global scale. In some parts of the Bay Area, ozone levels exceed National Ambient Air Quality Standards and particulate concentrations exceed State standards (Figures 2-9 and 2-13). Vehicle traffic produces most of the emissions leading to increased ozone levels, while construction activities, wood burning, off-road travel, and agriculture generate some measured particulate matter.

The Bay Area Air Quality Management District (BAAQMD) encourages local jurisdictions to implement policies that will help improve regional air quality, and to especially recognize sensitive receptors. This Section of the Countywide Plan provides a regulatory framework for articulating air quality objectives consistent with regional air quality programs. The Transportation, Energy and Green Building, Public Facilities and Services, and Community Development sections of the Built Environment Element also include policies and programs intended to reduce the impact of future development on air quality and global warming.

On a global scale, data indicate an increase in mean surface air temperatures over historic levels and climate models predict this warming will continue. Scientists expect that the average global surface temperature could rise 1°F to 4.5°F in the next 50 years, and 2.2° to 10°F in the next century. A rise of this magnitude is significant: For example, the difference in temperature between 1995 and the temperature during the ice ages was 5°F to 8°F. Mounting scientific evidence suggests that the discharge by human activities of gases that trap heat in the atmosphere is largely responsible for this trend. A major consequence of global warming is melting glaciers and warmer waters, which cause the oceans to expand and rise. Sea level rise and higher evaporation rates are expected to increase storm frequency and severity. The resulting economic loss from increased storm activity will be equally dramatic: It has already increased tenfold over the past 40 years. Climate change will amplify existing environmental problems, such as erosion, storm-surge floods, and landslide risk, and changes to the water cycle will further stress domestic water supply as well as indigenous plant and animal populations. Further complicating the issue of climate change is the high level of complexity and uncertainty associated with modeling and predicting climate behavior. While it is clear that damage resulting from weather-related events is already on the rise, it is not known whether future changes will be gradual or abrupt. Nor is it clearly understood what the full spectrum of impacts will be. Given the global risks to economic, environmental, and social stability, it is imperative that climate change be addressed at all levels of government.

> *"Everybody talks about the weather, but nobody does anything about it."*
>
> — Mark Twain

Fortunately, local governments can play a meaningful role in addressing climate change, by instituting measures that reduce the vulnerability and increase the adaptability of Marin's physical infrastructure, economic activities, and natural systems. Furthermore, steps taken to address climate change will yield positive benefits in local efforts to improve air quality, as vehicle traffic and energy generation are major contributors to both greenhouse gases and air pollution. For example, construction of a modern world class transportation system in Marin County will contribute to further reducing greenhouse gas emissions and improving air quality.

The issue of climate change is ultimately part of the larger challenge of fostering sustainable communities. Climate change goals are more effectively accomplished when efforts are focused on integrating principles of sustainability within sectors such as transportation, buildings, ecosystems, and water systems. While the aim of this Section is to provide a framework for addressing atmosphere and

climate change, the detailed policies and programs that address climate protection are located throughout the Countywide Plan and are referenced here in this section.

Key Trends and Issues

How clean is the air in Marin?

Air quality indicators show improvement. Marin has experienced a drop both in the total number of days exceeding State Ambient Air Quality Standards and in the number of days exceeding safe levels of ozone since 1996. Marin also has had a reduction in the number of days that safe levels of particulate matter have been exceeded in the county since 1996 (Figure 2-9). Ozone precursor pollutants have decreased locally, and are expected to continue to decline.

Figure 2-9 Summary of Measured Air Quality Exceedances

Pollutant	Standard	Monitoring Station	Days Exceeding Standard				
			2000	2001	2002	2003	2004
Ozone (O_3)	NAAQS 1-hr	San Rafael	0	0	0	0	0
		BAY AREA	3	1	2	1	0
	NAAQS 8-hr	San Rafael	0	0	0	0	0
		BAY AREA	4	7	7	7	0
	CAAQS 1-hr	San Rafael	0	0	0	0	0
		BAY AREA	12	15	16	19	7
Fine Particulate Matter (PM_{10})	NAAQS 24-hr	San Rafael	0	0	0	0	0
		BAY AREA	0	0	0	0	0
	CAAQS 24-hr	San Rafael	0	2	2	0	1
		BAY AREA	7	10	6	6	7
Fine Particulate Matter ($PM_{2.5}$)	NAAQS 24-hr	San Rafael	0	--	--	--	--
		BAY AREA	1	5	7	0	1
All Other (CO, NO_2, Lead, SO_2)	All Other	San Rafael	0	0	0	0	0
		BAY AREA	0	0	0	0	0

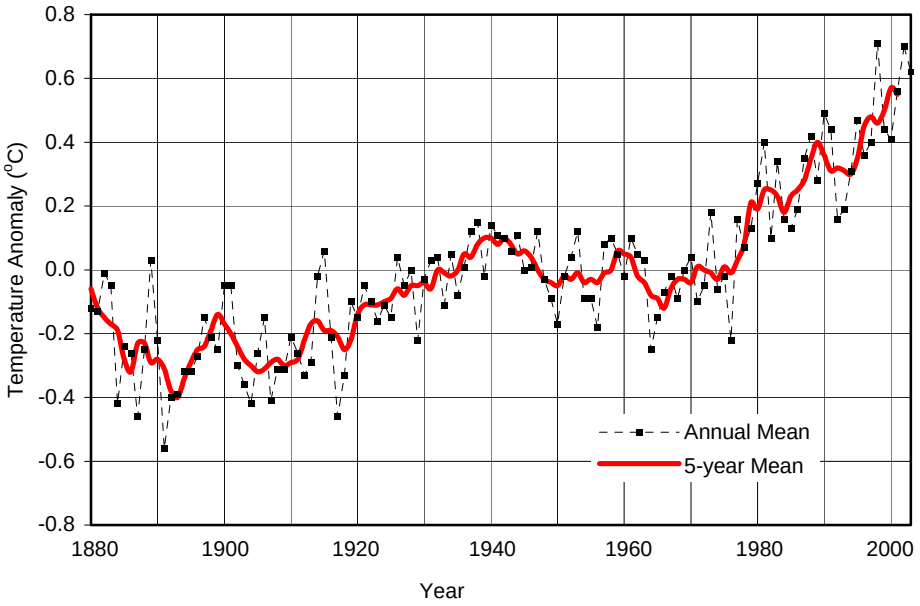
Source: 2000-2004 Bay Area Air Quality Management District.

Pollution levels can be reduced. Most particulate matter comes from areawide sources, such as combustion of wood and other nonclean fuels, and from homes and businesses without emission-control devices. Simple measures such as requiring clean-burning stoves can achieve improvements in air quality. Reducing motor vehicle use can result in significantly cleaner air.

Are temperatures rising globally?

The 10 warmest years of the 20th century all occurred after 1985, with 1998 the warmest year on record. The average of all global climate models suggests about a 3°F to 10°F rise in global temperature over the next 50 to 100 years. Global surface temperatures have increased about 1°F over the 20th century, with approximately 70% (or 0.7°F) of that change occurring in the last 25 years. The following graph illustrates the increasing rate and magnitude of global surface air temperatures.

Figure 2-10 Global Temperature



Source: NASA Goddard Institute for Space Studies.

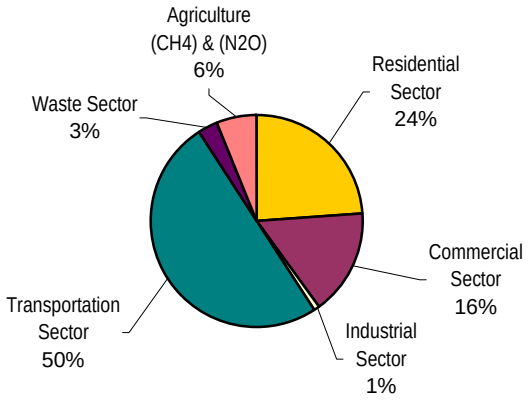
Is sea level rising?

Globally, sea level has risen 4 to 8 inches over the past century. The Intergovernmental Panel on Climate Change (IPCC) notes it is very likely that the 20th-century warming has contributed significantly to rising sea levels, through thermal expansion of seawater and loss of land ice. The EPA estimates that sea level is likely to rise 1.8 feet along most of the West Coast by 2100. By comparison, the San Francisco Bay level has increased about 4 inches since 1850. Given a 1-foot rise in sea level, the current 100-year high in the storm surge felt on the levee system of inland San Francisco Bay and Delta would become the 10-year high. In other words, the frequency of a 100-year event would increase tenfold.

What activities are contributing to the greenhouse gases in Marin?

Marin emits nearly 3 million tons of carbon dioxide every year. Vehicle traffic accounts for 50% of the total emissions, and energy use by buildings (residential, commercial and industrial combined) accounts for 41%.

Figure 2-11 Countywide Emissions Analysis



Source: Community Development Agency,
Greenhouse Gas Emissions Analysis Report 2000.

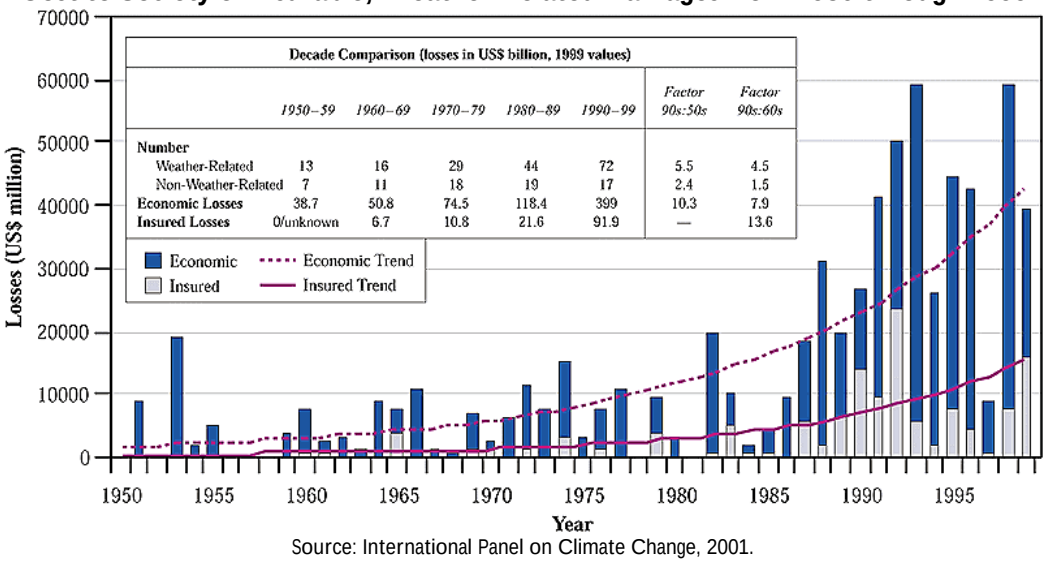
Has climate change affected the global economy?

Challenges resulting from weather- and climate-related events include changes to world food production and supply, migration, and access to clean water and energy. As indicated in the table below, costs have increased substantially since 1980.

"The climate system is being pushed hard enough that change will become obvious to the man in the street in the next decade."

– James E. Hansen, director of NASA's Goddard Institute for Space Studies, quoted in *Newsweek*, January 22, 1996

Figure 2-12
Cost to Society of Insurable, Weather-Related Damages from 1950 through 1999



Source: International Panel on Climate Change, 2001.

What Are the Desired Outcomes?

GOAL AIR-1

Improved Regional Air Quality. Promote planning and programs that result in the reduction of airborne pollutants measured within the county and the Bay Area.

Policies

AIR-1.1 Coordinate Planning and Evaluation Efforts. Coordinate air quality planning efforts with local, regional, and State agencies, and evaluate the air quality impacts of proposed plans and development projects.

AIR-1.2 **Meet Air Quality Standards.** Seek to attain or exceed the more stringent of federal or State Ambient Air Quality Standards for each measured pollutant (Figure 2-13).

AIR-1.3 **Require Mitigation of Air Quality Impacts.** Require projects that generate potentially significant levels of air pollutants, such as quarry, landfill operations, or large construction projects, to incorporate best available air quality mitigation in the project design.

Why is this important?

It is essential to use a regional approach to improving air quality, since polluted air flows from one place to another.

Environment: Cleaner air and water mean healthier marine and terrestrial ecosystems.

Economy: Poor air quality is linked to a higher incidence of public health costs associated with respiratory illnesses. The California Air Resources Board (CARB) suggests that the annual health impacts of exceeding state health-based standards for ozone and particulate matter include 6,500 premature deaths, 4,000 hospital admissions for respiratory disease, and 350,000 asthma attacks. The loss of productive workdays also affects the local economy. The American Lung Association (ALA) states that asthma accounts for an estimated three million lost workdays for adults nationally.

Equity: Poor air quality is linked to a higher incidence of respiratory illnesses. Asthma, which can be triggered and/or caused by poor air quality, currently affects 2.3 million Californians. In Marin, there were 17,083 cases of asthma in 2004, which translates to an impact on 7% of the population.

How will results be achieved?

Implementing Programs

AIR-1.a ***Inform Local and Regional Agencies.*** Notify local and regional jurisdictions of proposed projects in unincorporated areas that may affect regional air quality, as identified by project type and size thresholds in the *BAAQMD CEQA Guidelines, Assessing the Air Quality Impacts of Projects and Plans* (Figure 2-14).

AIR-1.b ***Evaluate Air Quality Impacts of Proposed Projects and Plans.*** As part of the Environmental Review Process, use the current BAAQMD CEQA Guidelines to evaluate the significance of air quality impacts from projects or plans, and to establish appropriate minimum submittal and mitigation requirements necessary for project or plan approval.

AIR-1.c ***Take Part in Regional Programs.*** Continue to participate in the Cities for Climate Protection and Spare the Air programs.

AIR-1.d ***Cooperate to Enforce Air Quality Standards.*** Cooperate with the U.S. Environmental Protection Agency (EPA), the California Air Resources Board, and the BAAQMD to measure air quality at emission sources (including transportation corridors) and to enforce the provisions of the Clean Air Act and State as well as regional policies and established standards for air quality.

Figure 2-13 California and National Ambient Air Quality Standards

Pollutant	Averaging Time	California Standards	National Standards [a]	
			Primary [b,c]	Secondary [b,d]
Ozone	8-hour	0.07 ppm (154 µg/m^3)	0.08 ppm (176 µg/m^3)	—
	1-hour	0.09 ppm (180 µg/m^3)	— [e]	Same as primary
Carbon Monoxide	8-hour	9 ppm (10 µg/m^3)	9 ppm (10 µg/m^3)	—
	1-hour	20 ppm (23 µg/m^3)	35 ppm (40 µg/m^3)	—
Nitrogen Dioxide	Annual	—	0.053 ppm (100 µg/m^3)	Same as primary
	1-hour	0.25 ppm (470 µg/m^3)	—	—
Sulfur Dioxide	Annual	—	0.03 ppm (80 µg/m^3)	—
	24-hour	0.04 ppm (105 µg/m^3)	0.14 ppm (365 µg/m^3)	—
	3-hour	—	—	0.5 ppm (1,300 µg/m^3)
	1-hour	0.25 ppm (655 µg/m^3)	—	—
PM_{10}	Annual	20 µg/m^3	50 µg/m^3	Same as primary
	24-hour	50 µg/m^3	150 µg/m^3	Same as primary
$PM_{2.5}$	Annual	12 µg/m^3	15 µg/m^3	—
	24-hour	—	65 µg/m^3	—
Lead	Calendar quarter	—	1.5 µg/m^3	Same as primary
	30-day average	1.56 µg/m^3	—	—

Notes: (a) Standards, other than four ozone and those based on annual averages, are not to be exceeded more than once a year. The ozone standard is attained when the expected number of days per calendar year with maximum hourly average concentrations above the standard is equal to or less than one.
(b) Concentrations are expressed first in units in which they were promulgated. Equivalent units given in parenthesis.
(c) Primary Standards: The levels of air quality necessary, with an adequate margin of safety to protect the public health. Each state must attain the primary standards no later than three years after that state's implementation plan is approved by the EPA.
(d) Secondary Standards: The levels of air quality necessary to protect the public welfare from any known or anticipated adverse effects of a pollutant.
(e) The national one-hour ozone standard was revoked by U.S. EPA on June 15, 2005.

Source: 2004 Bay Area Air Quality Management District.

Other		
Hospital	13.8/1000 sq.ft.	240,000 sq.ft.
Hotel	8.7/room	460 rooms

Note: Trip rates for many land uses will vary depending upon size of project. See latest edition of Trip Generation, Institute of Transportation Engineers.

Source: 1999 Bay Area Air Quality Management District.

AIR-1.e ***Conduct Public Education Program.*** Educate regarding the reason for requiring using best management practices to improve air quality.

AIR-1.f ***Limit Residential Wood Burning.*** Continue to implement the ordinance that phases out the use of older, polluting wood-burning appliances and limits the installation of wood-burning devices in new or renovated homes to pellet stoves, EPA-certified woodstoves and fireplace inserts, or natural gas or propane appliances.

AIR-1.g ***Require Control Measures for Construction and Agricultural Activity.*** Require reasonable and feasible measures to control particulate emissions (PM-10 and PM-2.5) at construction sites and during agricultural tilling activity, pursuant to the recommendations in the BAAQMD CEQA Guidelines, which may include the following:

- Watering active construction or agricultural tilling areas.
- Covering hauled materials.
- Paving or watering vehicle access roads.
- Sweeping paved and staging areas.

What Are the Desired Outcomes?

GOAL AIR-2

Protection from Emissions. Minimize the potential impacts from land uses that may emit pollution and/or odors on residential and other land uses sensitive to such emissions (see Map 2-16, Sensitive Receptor Sites in Unincorporated Marin County).

Policy

AIR-2.1 Buffer Emission Sources and Sensitive Land Uses. Consider potential air pollution and odor impacts from land uses that may emit pollution and/or odors when locating (a) air pollution sources, and (b) residential and other pollution-sensitive land uses in the vicinity of air pollution sources (which may include freeways, manufacturing, extraction, hazardous materials storage, landfill, food processing, wastewater treatment, and other similar uses).

Why is this important?

People and sensitive plants and animals need to be protected from sources of air pollution.

Environment: Air pollution creates stress on fragile and sensitive ecosystems by reducing reproductive capacity and food sources.

Economy: Lowering pollutants from area-wide and point sources would lower public health costs associated with respiratory illnesses and lead to fewer sick days at the workplace.

Equity: Children, people who are ill, and elderly people are particularly sensitive to air pollution. Places where they congregate need protection from polluted air.

How will results be achieved?

Implementing Programs

AIR-2.a ***Require Separation Between Air Pollution Sources and Other Land Uses.*** Only allow (a) emission sources or (b) other uses in the vicinity of air pollution or odor sources if the minimum screening distances between sources and receptors established in the BAAQMD CEQA Guidelines can be met, unless detailed project-specific studies demonstrate compatibility with adjacent uses despite separations that do not meet the screening distance requirements.

AIR-2.b ***Protect Sensitive Receptors Near High-Volume Roadways.*** Amend the Development Code to require mitigation measures such as increased indoor air filtration to ensure the protection of sensitive receptors (facilities where individuals are highly susceptible to the adverse effects of air pollutants, such as housing, child care centers, retirement

homes, schools, and hospitals) near freeways, arterials, and other major transportation corridors.

AIR-2.c *Health Risk Analysis for Sensitive Receptors.* Require that projects involving sensitive receptors proposed within 150 feet of freeways shall include an analysis of the potential health risks. Mitigation measures that comply with adopted standards of the BAAQMD for control of odor/toxics for sensitive receptors shall be identified in order to reduce these risks to acceptable levels.

What Are the Desired Outcomes?

GOAL AIR-3

Reduction of Vehicle-Generated Pollutants. Reduce vehicle trips and emissions, and improve vehicle efficiency, as means of limiting the volume of pollutants generated by traffic.

Policy

AIR-3.1 **Institute Transportation Control Measures.** Support a transportation program that reduces vehicle trips, increases ridesharing, and meets or exceeds the Transportation Control Measures recommended by BAAQMD in the most recent Clean Air Plan to reduce pollutants generated by vehicle use.

Why is this important?

Vehicle emissions are a major source of air pollution, and reduction of vehicle trips will improve air quality.

Environment: Vehicle travel is responsible for 54% of nitrogen oxides, 73% of carbon monoxide, and 79% of the particulate matter released in Marin. These pollutants create stress on Marin's marine and terrestrial ecosystems through a loss of species diversity and reproduction capacity.

Economy: In addition to alleviating the economic burden of public health costs, a reduction in vehicle trips will reduce traffic congestion. In 2006, over 9,400 productive hours were lost each weekday as a result of traffic congestion and delay.

Equity: Based on EPA's most current data, vehicle generated sources are responsible for 91% of the air-related cancer risk in Marin County. Furthermore, lower income neighborhoods tend to be nearest to major transportation routes; thus, these residents are exposed to higher levels of mobile source pollutants. One study finds that in the Bay Area, prevalence of asthma and bronchitis symptoms is about 7% higher for children in neighborhoods with higher levels of traffic pollutants compared with other children in the study.

How will results be achieved?

Implementing Programs

AIR-3.a *Support Voluntary Employer-Based Trip Reduction.* Provide assistance to regional and local ridesharing organizations, and advocate legislation to maintain and expand employer ridesharing incentives, such as tax deductions or credits.

AIR-3.b *Utilize Clean Vehicle Technology.* Promote new technologies and other incentives, such as allowing zero or partial zero emission vehicles rated at 45 miles or more per gallon in Marin County carpool lanes, and replacing fleet vehicles with these and similar clean vehicles.

"Adding lanes to solve traffic congestion is like loosening your belt to solve obesity."

– Glen Hemistra

AIR-3.c *Consider Model Clean Vehicle Requirements.* Research and consider adoption of an ordinance or standards that provide a set of voluntary measures to incorporate clean vehicles in fleets and promote the use of clean alternative fuels.

AIR-3.d *Reduce Peak-Hour Congestion.* Implement recommended Bay Area Air Quality Management District (BAAQMD) Transportation Control Measures in the Clean Air Plan to reduce vehicle emissions and congestion during peak commute periods.

AIR-3.e *Improve Arterial Traffic Management.* Modify arterial roadways to allow more-efficient bus operation, including possible signal preemption, and expand signal-timing programs where air quality benefits can be demonstrated.

What Are the Desired Outcomes?

GOAL AIR-4

Minimization of Contributions to Greenhouse Gases. Prepare policies that promote efficient management and use of resources in order to minimize greenhouse gas emissions. Incorporate sea level rise and more extreme weather information into the planning process.

Policies

AIR-4.1 **Reduce Greenhouse Gas Emissions.** Adopt practices that promote improved efficiency and energy management technologies; shift to low-carbon and renewable fuels and zero emission technologies.

AIR-4.2 **Foster the Absorption of Greenhouse Gases.** Foster and restore forests and other terrestrial ecosystems that offer significant carbon mitigation potential.

Why is this important?

Major contributors to greenhouse gas emissions, such as vehicle traffic and building energy use, can be reduced on a local level through the implementation of sustainable development policies.

Environment: Increased greenhouse gas emissions lead to climate change, which could include increases in temperature and shifting amounts of rainfall. Changes in temperature and water availability affect terrestrial and marine ecosystems. Furthermore, higher temperatures lead to higher evaporation rates, as well as reductions in stream flow and an increased frequency of droughts. Droughts are a problem in Marin, where 80% of our water comes from rainfall.

Economy: Mitigation measures that reduce emissions can result in substantial savings. The Tellus Institute estimates that California can save 1.9 billion dollars annually by 2020 through adoption of more stringent building codes and standards, efficiency programs, and increased supply of energy from renewable sources.

Equity: Access to clean water, energy, and mineral resources, and availability of productive arable land are all threatened by changes in climate. Weather- and temperature-related issues will add strain to an already overburdened public health system. Furthermore, low income families will be disproportionately impacted as they will be the least able to adapt to the effects of climate change.

How will results be achieved?

Implementing Programs

AIR-4.a ***Reduce Greenhouse Gas Emissions Resulting from Energy Use in Buildings.*** Implement energy efficiency programs and use of renewable energy. (Also see EN-1, EN-2, PFS-2, and TR-4.)

Carbon Dioxide

The Ecological Footprint shows that the single largest human demand on ecosystems comes from carbon dioxide emissions. The land area required to absorb this waste product makes up over half the Ecological Footprint of the average Marin resident. If Marin County reduced its carbon dioxide emissions by 20%, it could reduce its total footprint by an area equal to almost the entire size of Marin County.

Changing Scientific Understanding of Human Influences on Climate Change

1990: "Our judgment is that global mean surface air temperature has increased [though] the unequivocal detection of the enhanced greenhouse effect is not likely for a decade or more."

1995: "The balance of evidence suggests a discernible human influence on global climate."

2001: "The Earth's climate system has demonstrably changed on both global and regional scales. There is new and stronger evidence that most of the warming observed over the last 50 years is attributable to human activities."

AIR-4.b ***Reduce Greenhouse Gas Emissions Resulting from Transportation.*** Increase clean-fuel use, promote transit-oriented development and alternative modes of transportation, and reduce travel demand. (Also see TR-4, AIR-3, DES-2, HS-2, HS-3, CD-2, CD-3, and EC-1.)

AIR-4.c ***Reduce Methane Emissions Released from Waste Disposal.*** Encourage recycling, decrease waste sent to landfills, require landfill methane recovery, and promote methane recovery for energy production from other sources. (See PFS-3.)

Cities for Climate Protection Milestones

In August 2002, the Board of Supervisors partnered with the Cities for Climate Protection Campaign to address climate change through five actions:

1. Analyze baseline greenhouse gas emissions.
2. Set a target for reducing emissions.
3. Develop a local action plan for pursuing emissions reductions measures.
4. Implement local action plan.
5. Monitor progress.

Source: www.iclei.org.

"New analyses suggest that 15%–37% of a sample of 1,103 land plants and animals would eventually become extinct as a result of climate changes expected by 2050."

— *Nature Medicine*, 2004

AIR-4.d ***Reduce Greenhouse Gas Emissions from Agriculture.*** Compile an inventory of agricultural greenhouse gas emissions. Partner with AgStar, the U.S. Department of Agriculture, and the U.S. Department of Energy to encourage the use of methane recovery technologies and determine potential use in energy production.

AIR-4.e ***Reduce County Government Contributions to Greenhouse Gas Emissions.*** Where feasible, replace fleet vehicles with hybrid fuel and other viable alternative fuel vehicles, increase energy efficiency of County-maintained facilities, increase renewable energy use at County-maintained facilities, adopt purchasing practices that promote emissions reductions, and increase recycling at County-maintained facilities. (Also see EN-1, EN-2, PFS-3, TR-4, EC-1 and PH-1.)

AIR-4.f ***Establish a Climate Change Planning Process.*** Continue implementation of the approved Marin County Greenhouse Gas Reduction Plan. Integrate this plan into long-range and current planning functions of other related agencies. Establish and maintain a process to implement, measure, evaluate, and modify implementing programs, using the Cities for Climate Protection Campaign as a model (see the sidebar).

AIR-4.g ***Work with Bay Area Governments to Address Regional Climate Change Concerns.*** Play a leading role to encourage other local governments to commit to addressing climate change. Participate in programs such as the Cities for Climate Protection Campaign to address local and regional climate change concerns.

AIR-4.h *Evaluate the Carbon Emissions Impacts of Proposed Developments.* Incorporate a carbon emissions assessment into land use plans and the environmental impact report for proposed projects.

AIR-4.i *Work with Appropriate Agencies to Determine Carbon Uptake and Storage Potential of Natural Systems.* Study Marin's wetlands, forests, baylands, and agricultural lands to determine the potential to sequester carbon over time. Determine their value as carbon sinks.

AIR-4.j *Acquire and Restore Natural Resource Systems.* Take and require all technically feasible measures to avoid or minimize potential impacts on existing natural resource systems that serve as carbon sinks. (Also see CD-1, BIO-2, BIO-3, BIO-4, BIO-5, OS-1, and OS-2.)

AIR-4.k *Encourage the Planting of Trees.* Adopt urban forestry practices that encourage re-forestation as a means of storing carbon dioxide. (Also see BIO-1, DES-3.)

AIR-4.l *Preserve Agricultural Lands.* Protect agricultural lands and soils that serve as carbon sinks. (Also see AG-1.)

AIR-4.m *Focus Development in Urban Corridors.* Build in urban corridors and limit development in natural resource areas. Encourage green spaces that serve as carbon sinks in urban corridors. (Also see CD-1, CD-2, and DES-3.)

AIR-4.n *Monitor for Carbon Storage Research.* Monitor federal and international research on technological approaches to carbon storage.

AIR-4.o *Implement Proposed State Programs to Reduce Greenhouse Gas Emissions.* Implement proposed State programs to reduce greenhouse gas emissions, including the Renewable Portfolio Standards, California Fuel Efficiency (CAFE) standards, and carbon cap and trade programs.

What Are the Desired Outcomes?

GOAL AIR-5

Adaptation to Climate Change. Adopt policies and programs that promote resilient human and natural systems in order to ease the impacts of climate change.

Policies

AIR-5.1 **Determine Marin-Specific Climate Change.** Participate in research that examines the effects of climate change on human and natural systems in Marin.

AIR-5.2 **Prepare Response Strategies for Impacts.** Prepare appropriate response strategies that aid systems in adapting to climate change based on sound scientific understanding of the potential impacts.

Why is this important?

Adapting to climate change will require accurate scientific understanding as well as an institutionalized policy framework.

Environment. Wildlife distributions, population size, population density, and behavior are directly affected by changes in climate and indirectly through changes in vegetation. As wildlife tries to adapt to changes in the environment caused by shifting temperature and precipitation patterns, the already high number of threatened and endangered species could see a marked increase. New analyses suggest that 15% to 37% of a sample of 1,103 land plants and animals would eventually become extinct as a result of climate changes expected by 2050.

"My interest is in the future, because I am going to spend the rest of my life there."

— Charles Kettering

Economy. Aquaculture products brought $2.4 million into Marin's economy, representing 5.4% of Marin's entire agriculture industry. Warmer ocean waters and saltwater inundation due to climate change may impact coastal ecosystems by speeding the decline in fish populations and marine ecosystems already stressed from habitat loss and reduced freshwater flows. A report sponsored by the United Nations stated that worldwide economic losses could soar to $150 billion a year within the next 10 years.

Equity. Adopting and fostering resilience within the natural and built environments will save significant resources, speed recovery, and protect public health and safety for people of all income levels.

How will results be achieved?

Implementing Programs

AIR-5.a ***Coordinate with Local and Regional Agencies.*** Coordinate with the U.S. Geological Survey, Bay Conservation and Development Commission, California Coastal Commission and other monitoring agencies to study near-term and long-term high-probability climate change effects. Explore funding and collaborations with Bay Area partners in the Cities for Climate Protection Campaign in order to share resources, achieve economies of scale, and develop plans and programs that are optimized to address climate change on a regional scale.

AIR-5.b ***Study the Effect of Climate Change.*** Determine how climate change will affect the following:

Natural Systems: Changes in water availability, shifting fog regimes (and the effect on coastal redwoods and fire ecology), temperature changes, and shifting seasons.

Biological Resources: Changes in species distribution and abundance in estuary ecosystems resulting from salinity changes and flooding. For marine ecosystems, determine changes in distribution and abundance resulting from warmer waters, rising sea level, and changes in ocean currents and freshwater inflows.

Environmental Hazards: Runoff, fire hazards, floods, landslides and soil erosion, and the impact on coastal and urban infrastructure.

Built Environment: Effect of flooding and rising sea level on sewage systems, property, and infrastructure.

Water Resources: Runoff, changes in precipitation, increases and decreases in drought, salinity changes, sea level rise, and shifting seasons.

Agricultural and Food Systems: Food supply, economic impacts, and effect on grazing lands.

Public Health: Temperature-related health effects, air quality impacts, extreme weather events, and vector-, rodent-, water-, and food-borne diseases.

AIR-5.c ***Prepare Response Strategies.*** In coordination with the California Coastal Commission, the Bay Conservation and Development Commission, water districts, wildlife agencies, and flood control districts, prepare response strategies for Marin's human and natural systems. Current response strategies include the following:

Water Resources: Improve drainage systems, harvesting flows, and recharge designs in order to direct runoff to landscaped areas where the water can percolate into the soil. (See WR-1.)

Biological Resources: Limit development such that coastal wetlands are able to migrate inland in response to sea level rise, wildlife corridors and ecotones are protected, and development impacts are minimized. Promote the restoration of wetlands and riparian areas to provide capacity for high water and flood flows. (Also see BIO-2, BIO-4, BIO-5, OS-2, DES-1, and DES-5.)

Public Health: General strengthening of public health infrastructure and health-oriented environmental management, such as with air and water quality, and community and housing design.

Built Environment: Assess development located in coastal areas that are subject to sea level rise and increased flooding, and develop a response strategy, such as a planned retreat program, for the relocation of facilities in low-lying areas. Work with the County flood control and water districts to prepare a plan for responding to a potential rise in the sea level, consider developing flood control projects, and amend County Code Chapters 11, 22, 23, and 24 to include construction standards for areas potentially subject to increased flooding from a rise in sea level.

Environmental Hazards: Develop response strategies that cope with increasing storm events, flooding, fire, landslides, and soil erosion. Establish surveillance systems. With the development of advanced (spatial) surveillance technology, it is conceivable that such systems will be expanded to address forest health and productivity, monitoring biotic vectors and natural elements, as well as tree and storm responses. (Also see EH-3, EH-4, BIO-1, and PH-1.)

"The causes and effects of climate change occur around the world. Individuals, communities, and nations must work together cooperatively to stop global climate change."

– The Environmental Justice and Climate Change Initiative

AIR-5.d ***Monitor Local Climate Change.*** Encourage appropriate local and regional agencies to track the following environmental indicators of climate change:

- Sea level (also see EH-3)
- Minimum and maximum temperature
- Precipitation
- Timing and volume of river flow
- River temperatures
- Sea surface temperatures
- Diversity and abundance of fish stocks and sea birds

AIR-5.e ***Seek Resources for Response Strategies.*** Explore funding and collaborative opportunities that share resources, to develop plans and programs that are optimized on a regional scale.

AIR-5.f ***Protect and Enhance Native Habitats and Biodiversity.*** Effectively manage and enhance native habitat, maintain viable native plant and animal populations, and provide for improved biodiversity throughout Marin. Require identification of sensitive biological resources and commitment to adequate protection and mitigation. (Also see BIO-1 and BIO-2.)

"It is not the strongest of the species that survive, nor the most intelligent, but the one most responsive to change."

– Charles Darwin

AIR-5.g ***Conduct Public Outreach and Education.*** Increase public awareness about climate change, and encourage Marin residents and businesses to become involved in activities and lifestyle changes that will aid in reducing greenhouse gas emissions.

AIR-5.h ***Implement Floodplain Ordinances.*** Continue to implement ordinances that regulate floodplain development to ensure that project-related and cumulative flooding impacts are minimized or avoided through conditions of project approval as required by the ordinances.

AIR-5.i ***Modify Construction Standards.*** Amend the Marin County Code to include construction standards for areas threatened by future sea level rise.

Figure 2-15 Relationships of Goals to Guiding Principles

This figure illustrates the relationships of each goal in this Section to the Guiding Principles.

Goals	Guiding Principles: 1. Link equity, economy, and the environment locally, regionally, and globally.	2. Minimize the use of finite resources and use all resources efficiently and effectively.	3. Reduce the use and minimize the release of hazardous materials.	4. Reduce greenhouse gas emissions that contribute to global warming.	5. Preserve our natural assets.	6. Protect our agricultural assets.	7. Provide efficient and effective transportation.	8. Supply housing affordable to the full range of our workforce and diverse community.	9. Foster businesses that create economic, environmental, and social benefits.	10. Educate and prepare our workforce and residents.	11. Cultivate ethnic, cultural, and socioeconomic diversity.	12. Support public health, safety, and social justice.

How Will Success Be Measured?

Indicator Monitoring

Nonbinding indicators, benchmarks, and targets[1] will help to measure and evaluate progress. This process will also provide a context in which to consider the need for new or revised implementation measures.

Indicators	Benchmarks	Targets
Number of days of poor air quality.	No exceedences in 2000.	No increase through 2015.
Amount of greenhouse gas emissions countywide.	2,849,000 tons CO_2 in 1990.	Reduce 15% by 2015.
Amount of greenhouse gas emissions from County government sources.	15,200 tons CO_2 in 1990.	Reduce 15% – 20% by 2015.

[1]Many factors beyond Marin County government control, including adequate funding and staff resources, may affect the estimated time frame for achieving targets and program implementation.

Program Implementation

The following table summarizes responsibilities, potential funding priorities, and estimated time frames for proposed implementation programs. Program implementation within the estimated time frame[1] will be dependent upon the availability of adequate funding and staff resources.

Figure 2-16
Atmosphere and Climate Program Implementation

Programs	Responsibility	Potential Funding	Priority	Time Frame
AIR-1.a – Inform Local and Regional Agencies.	CDA	Existing budget	High	Ongoing
AIR-1.b – Evaluate Air Quality Impacts of Proposed Projects and Plans.	CDA	Existing budget	High	Ongoing
AIR-1.c – Take Part in Regional Programs.	CDA	Existing budget	High	Ongoing
AIR-1.d – Cooperate to Enforce Air Quality Standards.	CDA, EPA, CA Air Resources Board, BAAQMD	Existing budget, State and federal funds	High	Ongoing
AIR-1.e – Conduct Public Education Program	CDA, BAAQMD	Existing budget and may require additional grants or revenue[2]	High	Ongoing
AIR-1.f – Limit Residential Wood Burning.	CDA	Existing budget, Tobacco Settlement Funds	Medium	Ongoing
AIR-1.g – Require Control Measures for Construction and Agricultural Activity.	CDA, Agricultural Commissioner	Existing budget	High	Ongoing
AIR-2.a – Require Separation Between Air Pollution Sources and Other Land Uses.	CDA, BAAQMD	Existing budget	High	Ongoing
AIR-2.b – Protect Sensitive Receptors Near High-Volume Roadways.	CDA	Existing budget	Medium	Long term
AIR-2.c – Health Risk Analysis for Sensitive Receptors.	CDA	Existing budget	Medium	Short term

[1]Time frames include: Immediate (0–1 years); Short term (1–4 years); Med. term (4–10 years); Long term (10–20 years); and Ongoing.

[2]Completion of this task is dependent on acquiring additional funding. Consequently, funding availability could lengthen or shorten the time frame and ultimate implementation of this program.

Programs	Responsibility	Potential Funding	Priority	Time Frame
AIR-3.a – Support Voluntary Employer-Based Trip Reduction.	DPW, Transportation Authority of Marin (TAM), CDA	Existing Budget, will require additional grants or other revenue[2]	Medium	Med. Term
AIR-3.b – Utilize Clean Vehicle Technology.	1. CDA/CalTrans-carpool lanes, 2. DPW- County fleet	1. Existing budget, 2. Will require additional grants or other revenue[2]	1. Medium, 2. Medium	1. Ongoing, 2. Long term
AIR-3.c – Consider Model Clean Vehicle Requirements.	DPW	Will require additional grants or other revenue[2]	Medium	Long term
AIR-3.d – Reduce Peak-Hour Congestion.	TAM	TFCA	Medium	Ongoing
AIR-3.e – Improve Arterial Traffic Management.	DPW, TAM	Grants, traffic mitigation fees, transportation sales tax[2]	Medium	Ongoing
AIR-4.a – Reduce Greenhouse Gas Emissions Resulting from Energy Use in Buildings.	CDA	Existing budget and may require additional grants or revenue[2]	Medium	Med. Term
AIR-4.b – Reduce Greenhouse Gas Emissions Resulting from Transportation.	1. TAM, CDA, 2. DPW	General Fund, TAM budget, TLC/HIP Grants, and will require additional grants or other revenue[2]	1. Medium, 2. Medium	1. Ongoing, 2. Long term
AIR-4.c – Reduce Methane Emissions Released from Waste Disposal.	DPW	Will require additional grants or other revenue[2]	Medium	Long term
AIR-4.d – Reduce Greenhouse Gas Emissions from Agriculture.	Agricultural Commissioner, CDA, USDA, USDOE	Grants, existing budget	Medium	Ongoing
AIR-4.e – Reduce County Government Contributions to Greenhouse Gas Emissions.	DPW	Will require additional grants or other revenue[2]	High	Pending
AIR-4.f – Establish a Climate Change Planning Process.	CDA	Existing budget and may require additional grants or revenue[2]	High	Immediate
AIR-4.g – Work with Bay Area Governments to Address Regional Climate Change Concerns.	CDA, ABAG, International Council for Local Environmental Initiatives (ICLEI)	Existing budget and may require additional grants or revenue[2]	High	Ongoing
AIR-4.h – Evaluate the Carbon Emissions Impacts of Proposed Developments.	CDA	Existing budget and may require additional grants or revenue[2]	High	Ongoing

Programs	Responsibility	Potential Funding	Priority	Time Frame
AIR-4.i – Work with Appropriate Agencies to Determine Carbon Uptake and Storage Potential of Natural Systems.	CDA, California Energy Commission (CEC), BAAQMD, other municipalities	Will require additional grants or revenue[2]	Low	Long term
AIR-4.j – Acquire and Restore Natural Resource Systems.	MCOSD	Will require additional grants or revenue[2]	High	Ongoing
AIR-4.k – Encourage the Planting of Trees.	CDA, NGO's, CBO's	Will require additional grants or revenue[2]	Medium	Ongoing
AIR-4.l – Preserve Agricultural Lands.	CDA, MALT, CBO's	Will require additional grants or revenue[2]	High	Ongoing
AIR-4.m – Focus Development in Urban Corridors.	CDA	Existing budget	High	Ongoing
AIR-4.n – Monitor for Carbon Storage Research.	CDA, ICLEI	Existing budget and may require additional grants or revenue[2]	Medium	Ongoing
AIR-4.o – Implement Proposed State Programs to Reduce Greenhouse Gas Emissions.	CDA	Existing budget and may require additional grants or revenue[2]	Medium	Ongoing
AIR-5.a – Coordinate with Local and Regional Agencies.	CDA, Bay Conservation and Development Commission (BCDC), CCC, BAAQMD, USGS, ICLEI	Existing budget and may require additional grants or revenue[2]	High	Ongoing
AIR-5.b – Study the Effect of Climate Change.	CDA, BCDC, CCC, BAAQMD, USGS, ICLEI	Will require additional grants or revenue[2]	Medium	Ongoing
AIR-5.c – Prepare Response Strategies.	CDA, CCC, BCDC, Water Districts, Resource Protection Agencies, ICLEI	Existing budget, will require additional grants or revenue[2]	High	Ongoing
AIR-5.d – Monitor Local Climate Change.	CDA, CCC, BCDC, Water Districts, Resource Protection Agencies, ICLEI	Existing budget and may require additional grants or revenue[2]	Medium	Ongoing
AIR-5.e – Seek Resources for Response Strategies.	CDA, CCC, BCDC, Water Districts, Resource Protection Agencies, ICLEI	Existing budget and may require additional grants or revenue[2]	Medium	Ongoing

Programs	Responsibility	Potential Funding	Priority	Time Frame
AIR-5.f – Protect and Enhance Native Habitats and Biodiversity.	Parks & Open Space, CDA, CBO's	Existing budget and may require additional grants or revenue[2]	High	Ongoing
AIR-5.g – Conduct Public Outreach and Education.	CDA, CBO's, ICLEI	Existing budget and may require additional grants or revenue[2]	Medium	Ongoing
AIR-5.h – Implement Floodplain Ordinances.	CDA/DPW	Existing budget	High	Ongoing
AIR-5.i – Modify Construction Standards.	CDA/DPW	Existing budget and may require additional grants or revenue[2]	Medium	Long term

(Note: This is an extract of the Marin County General Plan that highlights the applicability to air quality and greenhouse gases. The entire Marin County General Plan 2020 can be found at:
(http://www.co.marin.ca.us/depts/cd/main/fm/cwpdocs/CWP_CD2.pdf)

Additional Links to General Plans and Climate Action Plans:

The following examples of general plans and climate action plans were reviewed and were also found to be good resources. These examples have addressed climate change and have provided good goals, objectives, policies, standards and/or implementations measures for their jurisdiction and environment. These goals, objectives, policies, standards and implementation measures have been addressed in a stand-alone document as in the San Francisco Climate Action Plan, Sonoma County Climate Action Plan, and the City of Riverside General Plan; or the goals, objectives, policies, standards and implementation measures have been incorporated into the existing general plan elements as in the City of Beverly Hills Draft General Plan, City of Sacramento General Plan and Sonoma County General Plan.

City of Beverly Hills Draft General Plan can be found at:
http://www.ci.beverly-hills.ca.us/services/planning/plan/draft_general_plan.asp

City of Riverside General Plan can be found at:

Appendix H

California Attorney General Guidance on General Plans

(intentionally left blank)

Appendix H: California Attorney General Guidance on General Plans

The California Attorney General's Office has compiled a list of General Plan, CEQA-related Frequently Asked Questions and their answers to assist cities and counties in their General Plan updates. The following is the Attorney General Office's document entitled *'Climate Change, the California Environmental Quality Act, and General Plan Updates: Straightforward Answers to Some Frequently Asked Questions.'*

(intentionally left blank)

Climate Change, the California Environmental Quality Act, and General Plan Updates: Straightforward Answers to Some Frequently Asked Questions California Attorney General's Office

At any given time in this State, well over one hundred California cities and counties are updating their general plans. These are complex, comprehensive, long-term planning documents that can be years in the making. Their preparation requires local governments to balance diverse and sometimes competing interests and, at the same time, comply with the Planning and Zoning Law and the California Environmental Quality Act (CEQA).

Local governments have decades of experience in applying state planning law and excellent resources to assist them – such as the "General Plan Guidelines" issued by The Governor's Office of Planning and Research (OPR).[1] They are also practiced in assessing whether general plans may have significant localized environmental effects, such as degradation of air quality, reductions in the water supply, or growth inducing impacts. The impact of climate change, however, has only fairly recently shown up on the CEQA radar.

The fact that climate change presents a new challenge under CEQA has not stopped local governments from taking action. A substantial number of cities and counties already are addressing climate change in their general plan updates and accompanying CEQA documents. These agencies understand the substantial environmental and administrative benefits of a programmatic approach to climate change. Addressing the problem at the programmatic level allows local governments to consider the "big picture" and – provided it's done right – allows for the streamlined review of individual projects.[2]

Guidance addressing CEQA, climate change, and general planning is emerging, for example, in the pending CEQA Guideline amendments,[3] comments and settlements by the Attorney General, and in the public discourse, for example, the 2008 series on CEQA and Global Warming organized by the Local Government Commission and sponsored by the Attorney General. In addition, the Attorney General's staff has met informally with officials and planners from numerous jurisdictions to discuss CEQA requirements and to learn from those who are leading the fight against global warming at the local level.

Still, local governments and their planners have questions. In this document, we attempt to answer some of the most frequently asked of those questions. We hope this document will be useful, and we encourage cities and counties to contact us with any additional questions, concerns, or comments.

- **Can a lead agency find that a general plan update's climate change-related impacts are too speculative, and therefore avoid determining whether the project's impacts are significant?**

  No. There is nothing speculative about climate change. It's well understood that (1) greenhouse gas (GHG) emissions increase atmospheric concentrations of GHGs; (2) increased GHG concentrations in the atmosphere exacerbate global warming; (3) a project that adds to the atmospheric load of GHGs adds to the problem.

  Making the significance determination plays a critical role in the CEQA process.[4] Where a project may have a significant effect on the environment, the lead agency must prepare an Environmental Impact Report (EIR).[5] Moreover, a finding of significance triggers the obligation to consider alternatives and to impose feasible mitigation.[6] For any project under CEQA, including a general plan update, a lead agency therefore has a fundamental obligation to determine whether the environmental effects of the project, including the project's contribution to global warming, are significant.

- **In determining the significance of a general plan's climate change-related effects, must a lead agency estimate GHG emissions?**

  Yes. As OPR's Technical Advisory states:

  > Lead agencies should make a good-faith effort, based on available information, to calculate, model, or estimate the amount of CO2 and other GHG emissions from a project, including the emissions associated with vehicular traffic, energy consumption, water usage and construction activities.[7]

  In the context of a general plan update, relevant emissions include those from government operations, as well as from the local community as a whole. Emissions sources include, for example, transportation, industrial facilities and equipment, residential and commercial development, agriculture, and land conversion.

  There are a number of resources available to assist local agencies in estimating their current and projected GHG emissions. For example, the California Air Resources Board (ARB) recently issued protocols for estimating emissions from local government operations, and the agency's protocol for estimating community-wide emissions is forthcoming.[8] OPR's Technical Advisory contains a list of modeling tools to estimate GHG emissions. Other sources of helpful information include the white paper issued by the California Air Pollution Control Officers Association (CAPCOA), "CEQA and Climate Change"[9] and the Attorney General's website,[10] both of which provide information on currently available models for calculating emissions. In addition, many cities and counties are working with the International Council for Local Environmental Initiatives (ICLEI)[11] and tapping into the expertise of this State's many colleges and universities.[12]

- **For climate change, what are the relevant "existing environmental conditions"?**

  The CEQA Guidelines define a significant effect on the environment as "a substantial adverse change in the physical conditions which exist in the area affected by the proposed project."[13]

  For local or regional air pollutants, existing physical conditions are often described in terms of air quality (how much pollutant is in the ambient air averaged over a given period of time), which is fairly directly tied to current emission levels in the relevant "area affected." The "area affected," in turn, often is defined by natural features that hold or trap the pollutant until it escapes or breaks down. So, for example, for particulate matter, a lead agency may describe existing physical conditions by discussing annual average PM10 levels, and high PM10 levels averaged over a 24-hour period, detected at various points in the air basin in the preceding years.

  With GHGs, we're dealing with a global pollutant. The "area affected" is both the atmosphere and every place that is affected by climate change, including not just the area immediately around the project, but the region and the State (and indeed the planet). The existing "physical conditions" that we care about are the current atmospheric concentrations of GHGs and the existing climate that reflects those concentrations.

  Unlike more localized, ambient air pollutants which dissipate or break down over a relatively short period of time (hours, days or weeks), GHGs accumulate in the atmosphere, persisting for decades and in some cases millennia. The overwhelming scientific consensus is that in order to avoid disruptive and potentially catastrophic climate change, then it's not enough simply to stabilize our annual GHG emissions. The science tells us that we must <u>immediately and substantially reduce</u> these emissions.

- **If a lead agency agrees to comply with AB 32 regulations when they become operative (in 2012), can the agency determine that the GHG-related impacts of its general plan will be less than significant?**

  <u>No.</u> CEQA is not a mechanism merely to ensure compliance with other laws, and, in addition, it does not allow agencies to defer mitigation to a later date. CEQA requires lead agencies to consider the significant environmental effects of their actions and to mitigate them today, if feasible.

  The decisions that we make today do matter. Putting off the problem will only increase the costs of any solution. Moreover, delay may put a solution out of reach at any price. The experts tell us that the later we put off taking real action to reduce our GHG emissions, the less likely we will be able to stabilize atmospheric concentrations at a level that will avoid dangerous climate change.

- **Since climate change is a global phenomenon, how can a lead agency determine whether the GHG emissions associated with its general plan are significant?**

  The question for the lead agency is whether the GHG emissions from the project – the general plan update – are considerable when viewed in connection with the GHG emissions from past projects, other current projects, and probable future projects.[14] The effects of GHG emissions from past projects and from current projects to date are reflected in current atmospheric concentrations of GHGs and current climate, and the effects of future emissions of GHGs, whether from current projects or existing projects, can be predicted based on models showing future atmospheric GHG concentrations under different emissions scenarios, and different resulting climate effects.

  A single local agency can't, of course, solve the climate problem. But that agency can do its fair share, making sure that the GHG emissions from projects in its jurisdiction and subject to its general plan are on an emissions trajectory that, if adopted on a larger scale, is consistent with avoiding dangerous climate change.

  Governor Schwarzenegger's Executive Order S-3-05, which commits California to reducing its GHG emissions to 1990 levels by 2020 and to eighty percent below 1990 levels by 2050, is grounded in the science that tells us what we must do to achieve our long-term climate stabilization objective. The Global Warming Solutions Act of 2006 (AB 32), which codifies the 2020 target and tasks ARB with developing a plan to achieve this target, is a necessary step toward stabilization.[15] Accordingly, the targets set in AB 32 and Executive Order S-3-05 can inform the CEQA analysis .

  One reasonable option for the lead agency is to create community-wide GHG emissions targets for the years governed by the general plan. The community-wide targets should align with an emissions trajectory that reflects aggressive GHG mitigation in the near term and California's interim (2020) [16] and long-term (2050) GHG emissions limits set forth in AB 32 and the Executive Order.

  To illustrate, we can imagine a hypothetical city that has grown in a manner roughly proportional to the state and is updating its general plan through 2035. The city had emissions of 1,000,000 million metric tons (MMT) in 1990 and 1,150,000 MMT in 2008. The city could set an emission reduction target for 2014 of 1,075,000 MMT, for 2020 of 1,000,000 MMT, and for 2035 of 600,000 MMT, with appropriate emission benchmarks in between. Under these circumstances, the city could in its discretion determine that an alternative that achieves these targets would have less than significant climate change impacts.

- **Is a lead agency required to disclose and analyze the full development allowed under the general plan?**

  Yes. The lead agency must disclose and analyze the full extent of the development allowed by the proposed amended general plan,[17] including associated GHG emissions.

This doesn't mean that the lead agency shouldn't discuss the range of development that is likely to occur as a practical matter, noting, for example, the probable effect of market forces. But the lead agency can't rely on the fact that full build out may not occur, or that its timing is uncertain, to avoid its obligation to disclose the impacts of the development that the general plan would permit. Any other approach would seriously underestimate the potential impact of the general plan update and is inconsistent with CEQA's purposes.

- **What types of alternatives should the lead agency consider?**

  A city or county should, if feasible, evaluate at least one alternative that would ensure that the community contributes to a lower-carbon future. Such an alternative might include one or more of the following options:

  - higher density development that focuses growth within existing urban areas;
  - policies and programs to facilitate and increase biking, walking, and public transportation and reduce vehicle miles traveled;
  - the creation of "complete neighborhoods" where local services, schools, and parks are within walking distance of residences;
  - incentives for mixed-use development;
  - in rural communities, creation of regional service centers to reduce vehicle miles traveled;
  - energy efficiency and renewable energy financing (see, e.g., AB 811)[18]
  - policies for preservation of agricultural and forested land serving as carbon sinks;
  - requirements and ordinances that mandate energy and water conservation and green building practices; and
  - requirements for carbon and nitrogen-efficient agricultural practices.

  Each local government must use its own good judgment to select the suite of measures that best serves that community.

- **Can a lead agency rely on policies and measures that simply "encourage" GHG efficiency and emissions reductions?**

  No. Mitigation measures must be "fully enforceable."[19] Adequate mitigation does not, for example, merely "encourage" or "support" carpools and transit options, green building practices, and development in urban centers. While a menu of hortatory GHG policies is positive, it does not count as adequate mitigation because there is no certainty that the policies will be implemented.

  There are many concrete mitigation measures appropriate for inclusion in a general plan and EIR that can be enforced as conditions of approval or through ordinances. Examples are described in a variety of sources, including the CAPCOA's white paper,[20] OPR's Technical Advisory,[21] and the mitigation list on the Attorney General's website.[22] Lead agencies should also consider consulting with other cities and counties that have recently completed general plan updates or are working on Climate Action Plans.[23]

- **Is a "Climate Action Plan" reasonable mitigation?**

  Yes. To allow for streamlined review of subsequent individual projects, we recommend that the Climate Action Plan include the following elements: an emissions inventory (to assist in developing appropriate emission targets and mitigation measures); emission targets that apply at reasonable intervals through the life of the plan; enforceable GHG control measures; monitoring and reporting (to ensure that targets are met); and mechanisms to allow for the revision of the plan, if necessary, to stay on target.[24]

  If a city or county intends to rely on a Climate Action Plan as a centerpiece of its mitigation strategy, it should prepare the Climate Action Plan at the same time as its general plan update and EIR. This is consistent with CEQA's mandate that a lead agency must conduct environmental review at the earliest stages in the planning process and that it not defer mitigation. In addition, we strongly urge agencies to incorporate any Climate Action Plans into their general plans to ensure that their provisions are applied to every relevant project.

- **Is a lead agency also required to analyze how future climate change may affect development under the general plan?**

  Yes. CEQA requires a lead agency to consider the effects of bringing people and development into an area that may present hazards. The CEQA Guidelines note the very relevant example that "an EIR on a subdivision astride an active fault line should identify as a significant effect the seismic hazard to future occupants of the subdivision."[25]

  Lead agencies should disclose any areas governed by the general plan that may be particularly affected by global warming, e.g.: coastal areas that may be subject to increased erosion, sea level rise, or flooding; areas adjacent to forested lands that may be at increased risk from wildfire; or communities that may suffer public health impacts caused or exacerbated by projected extreme heat events and increased temperatures. General plan policies should reflect these risks and minimize the hazards for current and future development.

Endnotes

[15]See ARB, Scoping Plan at pp. 117-120, available at http://www.arb.ca.gov/cc/scopingplan/document/psp.pdf. (ARB approved the Proposed Scoping Plan on December 11, 2008.)

[16]In the Scoping Plan, ARB encourages local governments to adopt emissions reduction goals for 2020 "that parallel the State commitment to reduce greenhouse gas emissions by approximately 15 percent from current levels . . . ." Scoping Plan at p. 27; see *id.* at Appendix C, p. C-50. For the State, 15 percent below current levels is approximately equivalent to 1990 levels. *Id.* at p. ES-1. Where a city or county has grown roughly at

the same rate as the State, its own 1990 emissions may be an appropriate 2020 benchmark. Moreover, since AB 32's 2020 target represents the State's *maximum* GHG emissions for 2020 (see Health & Safety Code, § 38505, subd. (n)), and since the 2050 target will require substantial changes in our carbon efficiency, local governments may consider whether they can set an even more aggressive target for 2020. See Scoping Plan, Appendix C, p. C-50 [noting that local governments that "meet or exceed" the equivalent of a 15 percent reduction in GHG emissions by 2020 should be recognized].

Technical Advisory

CEQA AND CLIMATE CHANGE: Addressing Climate Change Through California Environmental Quality Act (CEQA) Review

This technical advisory is one in a series of advisories provided by the Governor's Office of Planning and Research (OPR) as a service to professional planners, land use officials and CEQA practitioners. OPR issues technical guidance from time to time on issues that broadly affect the practice of CEQA and land use planning. The emerging role of CEQA in addressing climate change and greenhouse gas emissions has been the topic of much discussion and debate in recent months. This document provides OPR's perspective on the issue.

I. PURPOSE

General scientific consensus and increasing public awareness regarding global warming and climate change have placed new focus on the California Environmental Quality Act (CEQA) review process as a means to address the effects of greenhouse gas (GHG) emissions from proposed projects on climate change. Many public agencies—along with academic, business, and community organizations—are striving to determine the appropriate means by which to evaluate and mitigate the impacts of proposed projects on climate change. Approaches and methodologies for calculating GHG emissions and addressing the environmental impacts through CEQA review are rapidly evolving and are increasingly available to assist public agencies to prepare their CEQA documents and make informed decisions.

JUNE 19, 2008

STATE OF CALIFORNIA
Arnold Schwarzenegger,
Governor

GOVERNOR'S OFFICE
OF PLANNING AND
RESEARCH
Cynthia Bryant, Director

1400 Tenth Street
Sacramento, CA 95814

PO Box 3044
Sacramento, CA 95812

(916)322-2318

www.opr.ca.gov

The Governor's Office of Planning and Research (OPR) will develop, and the California Resources Agency (Resources Agency) will certify and adopt amendments to the Guidelines implementing the California Environmental Quality Act ("CEQA Guidelines"), on or before January 1, 2010, pursuant to Senate Bill 97 (Dutton, 2007). These new CEQA Guidelines will provide regulatory guidance on the analysis and mitigation of GHG emissions in CEQA documents. In the interim, OPR offers the following informal guidance regarding the steps lead agencies should take to address climate change in their CEQA documents. This guidance was developed in cooperation with the Resources Agency, the California Environmental Protection Agency (Cal/EPA), and the California Air Resources Board (ARB).

II. BACKGROUND

Climate change refers to any significant change in measures of climate, such as average temperature, precipitation, or wind patterns over a period of time. Climate change may result from natural factors, natural processes, and human activities that change the composition of the atmosphere and alter the surface and features of the land. Significant changes in global climate patterns have recently been associated with global warming, an average increase in the temperature of the atmosphere near the Earth's surface, attributed to accumulation of GHG emissions in the atmosphere. Greenhouse gases trap heat in the atmosphere, which in turn heats the surface of the Earth. Some GHGs occur naturally and are emitted to the atmosphere through natural processes, while others are created and emitted solely through human activities. The emission of GHGs through the combustion of fossil fuels (i.e., fuels containing carbon) in conjunction with other human activities, appears to be closely associated with global warming.

State law defines GHG to include the following: carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O), hydrofluorocarbons, perfluorocarbons, and sulfur hexafluoride (Health and Safety Code, section 38505(g).) The most common GHG that results from human activity is carbon dioxide, followed by methane and nitrous oxide.

Requirements of AB 32 and SB 97

Assembly Bill 32 (AB 32), the California Global Warming Solutions Act of 2006 (Nunez, 2006), recognizes that California is the source of substantial amounts of GHG emissions. The statute begins with several legislative findings and declarations of intent, including the following:

> Global warming poses a serious threat to the economic well-being, public health, natural resources, and the environment of California. The potential adverse impacts of global warming include the exacerbation of air quality problems, a reduction in the quality and supply of water to the state from the Sierra snow pack, a rise in sea levels resulting in the displacement of thousands of coastal businesses and residences, damage to marine ecosystems and the natural environment, and an increase in the incidences of infectious diseases, asthma, and other human health-related problems. (Health and Safety Code, section 38501.)

In order to avert these consequences, AB 32 establishes a state goal of reducing GHG emissions to 1990 levels by the year 2020 (a reduction of approximately 25 percent from forecast emission levels) with further reductions to follow. The law requires the ARB to establish a program to track and report GHG emissions; approve a scoping plan for achieving the maximum technologically feasible and cost effective reductions from sources of GHG emissions; adopt early reduction measures to begin moving forward; and adopt, implement and enforce regulations – including market mechanisms such as "cap-and-trade" programs – to ensure the required reductions occur. The ARB recently adopted a statewide GHG emissions limit and an emissions inventory, along with requirements to measure, track, and report GHG emissions by the industries it determined to be significant sources of GHG emissions.

CEQA requires public agencies to identify the potentially significant effects on the environment of projects they intend to carry out or approve, and to mitigate significant effects whenever it is feasible to do so. While AB 32 did not amend CEQA to require new analytic processes to account for the environmental impacts of GHG emissions from projects subject to CEQA, it does acknowledge that such emissions cause significant adverse impacts to human health and the environment.

Senate Bill 97, enacted in 2007, amends the CEQA statute to clearly establish that GHG emissions and the effects of GHG emissions are appropriate subjects for CEQA analysis. It directs OPR to develop draft CEQA Guidelines "for the mitigation of greenhouse gas emissions or the effects of greenhouse gas emissions" by July 1, 2009 and directs the Resources Agency to certify and adopt the CEQA Guidelines by January 1, 2010.

Requirements of CEQA

CEQA is a public disclosure law that requires public agencies to make a

good-faith, reasoned effort, based upon available information, to identify the potentially significant direct and indirect environmental impacts—including cumulative impacts— of a proposed project or activity. The CEQA process is intended to inform the public of the potential environmental effects of proposed government decisions and to encourage informed decision-making by public agencies. In addition, CEQA obligates public agencies to consider less environmentally-damaging alternatives and adopt feasible mitigation measures to reduce or avoid a project's significant impacts.

The lead agency is required to prepare an Environmental Impact Report (EIR), a Mitigated Negative Declaration, or equivalent document, when it determines that the project's impacts on the environment are potentially significant. This determination of significance must be based upon substantial evidence in light of all the information before the agency.

Although the CEQA Guidelines, at Appendix G, provide a checklist of suggested issues that should be addressed in an EIR, neither the CEQA statute nor the CEQA Guidelines prescribe thresholds of significance or particular methodologies for performing an impact analysis. This is left to lead agency judgment and discretion, based upon factual data and guidance from regulatory agencies and other sources where available and applicable. A threshold of significance is essentially a regulatory standard or set of criteria that represent the level at which a lead agency finds a particular environmental effect of a project to be significant. Compliance with a given threshold means the effect normally will be considered less than significant. Public agencies are encouraged but not required to adopt thresholds of significance for environmental impacts. Even in the absence of clearly defined thresholds for GHG emissions, the law requires that such emissions from CEQA projects must be disclosed and mitigated to the extent feasible whenever the lead agency determines that the project contributes to a significant, cumulative climate change impact.

We realize that perhaps the most difficult part of the climate change analysis will be the determination of significance. Although lead agencies typically rely on local or regional definitions of significance for most environmental issues, the global nature of climate change warrants investigation of a statewide threshold of significance for GHG emissions. To this end, OPR has asked ARB technical staff to recommend a method for setting thresholds which will encourage consistency and uniformity in the CEQA analysis of GHG emissions throughout the state. Until such time as state guidance is available on thresholds of significance for GHG emissions, we recommend the following approach to your CEQA analysis.

III. RECOMMENDED APPROACH

Each public agency that is a lead agency for complying with CEQA needs to develop its own approach to performing a climate change analysis for projects that generate GHG emissions. A consistent approach should be applied for the analysis of all such projects, and the analysis must be based on best available information. For these projects, compliance with CEQA entails three basic steps: identify and quantify the GHG emissions; assess the significance of the impact on climate change; and if the impact is found to be significant, identify alternatives and/or mitigation measures that will reduce the impact below significance.

Lead agencies should determine whether greenhouse gases may be generated by a proposed project, and if so, quantify or estimate the GHG emissions by type and source. Second, the lead agency must assess whether those emissions are individually or cumulatively significant. When assessing whether a project's effects on climate change are "cumulatively considerable" even though its GHG contribution may be individually limited, the lead agency must consider the impact of the project when viewed in connection with the effects of past, current, and probable future projects. Finally, if the lead agency determines that the GHG emissions from the project as proposed are potentially significant, it must investigate and implement ways to avoid, reduce, or otherwise mitigate the impacts of those emissions. Although the scientific knowledge and understanding of how best to perform this analysis is rudimentary and still evolving, many useful resources are available (see Attachment 1).

Until such time as further state guidance is available on thresholds of significance, public agencies should consider the following general factors when analyzing whether a proposed project has the potential to cause a significant climate change impact on the environment.

Identify GHG Emissions

- Lead agencies should make a good-faith effort, based on available information, to calculate, model, or estimate the amount of CO_2 and other GHG emissions from a project, including the emissions associated with vehicular traffic, energy consumption, water usage and construction activities.
- Technical resources, including a variety of modeling tools, are available to assist public agencies to quantify GHG emissions. OPR recognizes that more sophisticated emissions models for particular types of projects are continually being developed and that the state-of-the-art quantification

models are rapidly changing. OPR will periodically update the examples of modeling tools identified in Attachment 2.

- There is no standard format for including the analysis in a CEQA document. A GHG/climate change analysis can be included in one or more of the typical sections of an EIR (e.g., air quality, transportation, energy) or may be provided in a separate section on cumulative impacts or climate change.

Determine Significance

- When assessing a project's GHG emissions, lead agencies must describe the existing environmental conditions or setting, without the project, which normally constitutes the baseline physical conditions for determining whether a project's impacts are significant.
- As with any environmental impact, lead agencies must determine what constitutes a significant impact. In the absence of regulatory standards for GHG emissions or other scientific data to clearly define what constitutes a "significant impact", individual lead agencies may undertake a project-by-project analysis, consistent with available guidance and current CEQA practice.
- The potential effects of a project may be individually limited but cumulatively considerable. Lead agencies should not dismiss a proposed project's direct and/or indirect climate change impacts without careful consideration, supported by substantial evidence. Documentation of available information and analysis should be provided for any project that may significantly contribute new GHG emissions, either individually or cumulatively, directly or indirectly (e.g., transportation impacts).
- Although climate change is ultimately a cumulative impact, not every individual project that emits GHGs must necessarily be found to contribute to a significant cumulative impact on the environment. CEQA authorizes reliance on previously approved plans and mitigation programs that have adequately analyzed and mitigated GHG emissions to a less than significant level as a means to avoid or substantially reduce the cumulative impact of a project.

Mitigate Impacts

- Mitigation measures will vary with the type of project being contemplated, but may include alternative project designs or locations that conserve energy and water, measures that reduce vehicle miles traveled

(VMT) by fossil-fueled vehicles, measures that contribute to established regional or programmatic mitigation strategies, and measures that sequester carbon to offset the emissions from the project.

- The lead agency must impose all mitigation measures that are necessary to reduce GHG emissions to a less than significant level. CEQA does not require mitigation measures that are infeasible for specific legal, economic, technological, or other reasons. A lead agency is not responsible for wholly eliminating all GHG emissions from a project; the CEQA standard is to mitigate to a level that is "less than significant".
- If there are not sufficient mitigation measures that the lead agency determines are feasible to achieve the less than significant level, the lead agency should adopt those measures that are feasible, and adopt a Statement of Overriding Considerations that explains why further mitigation is not feasible. A Statement of Overriding Considerations must be prepared when the lead agency has determined to approve a project for which certain impacts are unavoidable. These statements should explain the reasons why the impacts cannot be adequately mitigated in sufficient detail, and must be based on specific facts, so as not to be conclusory.
- Agencies are encouraged to develop standard GHG emission reduction or mitigation measures that can be applied on a project-by-project basis. Attachment 3 contains a preliminary menu of measures that lead agencies may wish to consider. This list is by no means exhaustive or prescriptive. Lead agencies are encouraged to develop their own measures and/or propose project alternatives to reduce GHG emissions, either at a programmatic level or on a case-by-case review.
- In some cases GHG emission reduction measures will not be feasible or may not be effective at a project level. Rather, it may be more appropriate and more effective to develop and adopt program-level plans, policies and measures that will result in a reduction of GHG emissions on a regional level.

IV. ADDITIONAL LAND USE CONSIDERATIONS

CEQA can be a more effective tool for GHG emissions analysis and mitigation if it is supported and supplemented by sound development policies and practices that will reduce GHG emissions on a broad planning scale and that can provide the basis for a programmatic approach to project-specific CEQA analysis and mitigation.

Local governments with land use authority are beginning to establish policies that result in land use patterns and practices that will result in less energy use and reduce GHG emissions. For example, some cities and counties have adopted general plans and policies that encourage the development of compact, mixed-use, transit-oriented development that reduces VMT; encourage alternative fuel vehicle use; conserve energy and water usage; and promote carbon sequestration. Models of such developments exist throughout the state (see OPR climate change website for examples of city and county plans and policies, referenced in Attachment 1).

For local government lead agencies, adoption of general plan policies and certification of general plan EIRs that analyze broad jurisdiction-wide impacts of GHG emissions can be part of an effective strategy for addressing cumulative impacts and for streamlining later project-specific CEQA reviews.

International, national, and statewide organizations such as ICLEI (Local Governments for Sustainability), the Cities for Climate Protection, and the Clean Cities Coalition —to name just a few — have published guidebooks to help local governments reduce GHG emissions through land use planning techniques and improved municipal operations. Links to these resources are provided at the end of this advisory.

Regional agencies can also employ a variety of strategies to reduce GHG emissions through their planning processes. For example, regional transportation planning agencies adopt plans and programs that address congestion relief, jobs-to-housing balance, reduction of vehicle miles traveled (VMT), and other issues that have implications for GHG emission reductions.

State agencies are also tackling the issue of climate change. Some have adopted or support policies and programs that take climate change into account, including the Department of Water Resources' State Water Plan; the Department of Transportation's State Transportation Plan; and the Business, Housing and Transportation Agency's Regional Blueprint Planning Program. These efforts not only raise public awareness of climate change and how the State can reduce GHG emissions, but also offer specific information and resources for lead agencies to consider.

V. NEXT STEPS

OPR has asked ARB technical staff to recommend a method for setting a threshold of significance for GHG emissions. OPR has requested that the ARB identify a range of feasible options, including qualitative and quantitative options.

OPR is actively seeking input from the public and stakeholder groups, as it develops draft CEQA Guidelines for GHG emissions. OPR is engaged with the Resources Agency and other expert state agencies, local governments, builders and developers, environmental organizations, and others with expertise or an interest in the development of the Guidelines.

OPR will conduct public workshops later this year to receive input on the scope and content of the CEQA Guidelines amendments. It is OPR's intent to release a preliminary draft of the CEQA Guidelines amendments for public review and comment in the fall. This will enable OPR to deliver a proposed package of CEQA Guidelines amendments to the Resources Agency as early as January 2009, well before the statutory due date of July 1, 2009.

We encourage public agencies and the public to refer to the OPR website at www.opr.ca.gov for information about the CEQA Guidelines development process and to subscribe to OPR's notification system for announcements and updates.

Technical Resources/Modeling Tools to Estimate GHG Emissions

TOOL	AVAILABILITY	SCOPE LOCAL/ REGIONAL	SCOPE TRANSPORTATION/ BUILDINGS	DATA INPUT REQUIREMENTS	DATA OUTPUT
URBEMIS	• Download • Public domain (free)	• Local project level	• Transportation • Some building (area source) outputs • Construction	• Land use information • Construction, area source, and transportation assumptions	• CO2 (pounds per day) • Mitigation impacts
Clean Air and Climate Protection (CACP) Software	• Download • Available to public agencies (free)	• Local project level	• Buildings • Communities • Governments	• Energy usage • Waste generation and disposal • Transportation fuel usage or VMT	• CO2e (tons per year)
Sustainable Communities Model (SCM)	• Custom model	• Regional • Scalable to site level	• Transportation • Buildings • Neighborhoods • Master planned communities	• Location and site specific information • Transportation assumptions • On-site energy usage	• CO2e (tons per year)
Internet-accessed Planning for Community Energy, Economic and Environmental Sustainability I-PLACE^{3}S	• Web-based • Small access fee • Full model now available in eight CA counties	• Regional • Scalable to site level	• Transportation • Housing • Land Use • Buildings • Energy • Economics	• Parcel level land use data (ability to work with less data) • Project-level data for alternative comparisons	• CO2 (any quantity over any time)
Climate Action Registry Reporting On-Line Tool (CARROT)	• Web-based • Available to Registry members • General public can view entity reports	• Regional, scalable to entity and facility level	• General Reporting and Certification Protocols o Transportation o Buildings/facilities • Specific protocols for some sectors	• Mobile source combustion (VMT or fuel usage) • Stationary combustion (fuel usage) • Indirect emissions (electricity usage)	• Each GHG and CO2e (tons per year)
EMFAC	• Download • Public domain (free)	• Statewide • Regional (air basin level)	• Transportation emission factors	• Travel activity data to calculate CO2 from projects.	• CO2 and methane (grams per mile) emission factors

VMT = Vehicle miles traveled
eCO2 = Carbon dioxide equivalent emissions
Note: This is not meant to be a definitive list of modeling tools to estimate climate change emissions impacts. Other tools may be available.

Description of Modeling Tools

URBEMIS

The Urban Emissions Model is used extensively during the CEQA process by local air districts and consultants to determine the impacts of projects on criteria pollutants. It was recently updated to calculate CO2 emissions as well. Future updates will include additional greenhouse gases. URBEMIS uses the ITE Trip Generation Rate Manual and the Air Resources Board's (ARB) motor vehicle emissions model (EMFAC) to calculate transportation-related CO2 emissions and ARB's OFFROAD2007 model for CO2 emissions from off-road equipment. Area source outputs include natural gas use, landscaping equipment, consumer products, architectural coatings, and fireplaces. It also estimates construction impacts and impacts of mitigation options. Web site: http://www.urbemis.com.

Clean Air and Climate Protection (CACP) Software

This tool is available to state and local governments and members of ICLEI, NACAA, NASEO and NARUC to determine greenhouse gas and criteria pollutant emissions from government operations and communities as a whole. The user must input aggregate information about energy (usage), waste (quantity and type generated, disposal method, and methane recovery rate) and transportation (VMT) for community analyses. CACP uses emission factors from EPA, DOE, and DOT to translate the energy, waste and transportation inputs into greenhouse gas (in carbon dioxide equivalents) and criteria air pollutant emissions. If associated energy, waste and transportation reduction are provided, the model can also calculate emission reductions and money saved from policy alternatives. Web site: http://cacpsoftware.org.

Sustainable Communities Model (SCM)

This model quantifies total CO2e emissions allowing communities the ability to optimize planning decisions that result in the greatest environmental benefit for the least cost. Total CO2e emissions are based on emissions from energy usage, water consumption and transportation. The model provides an interactive comparison of various scenarios to provide environmental performance, economic performance, and cost benefit analysis.

Web site: www.ctg-net.com/energetics/documents/doc_SCM_070731.pdf

I-PLACE^{3}S

This model is an internet-accessed land use and transportation model designed specifically for regional and local governments to help understand how their growth and development decisions can contribute to improved sustainability. It estimates CO2, criteria pollutant and energy impacts on a neighborhood or

regional level for existing, long-term baseline and alternative land use plans. The data input requirements are extensive and require a fiscal commitment from the Metropolitan Planning Organization and its member local governments. Once the data is available, the IPLACES tool can be developed for that region relatively quickly, in approximately one week. The benefits include a multifunctional tool that provides immediate outputs to compare alternatives during public meetings, multilevel password protected on-line access, as well as providing access for local development project CEQA analyses. This tool also supports regional travel models and integrated land use and transportation assessments. Web site: http://www.sacregionblueprint.org/sacregionblueprint/the_project/technology.cfm and http://www.places.energy.ca.gov/places

CARROT

The California Climate Action Registry offers the Climate Action Registry Reporting On-Line Tool (CARROT) for Registry members to calculate and report annual greenhouse gas (GHG) emissions. CARROT calculates direct and indirect GHG emissions for the following emission categories by source: stationary combustion, process emissions, mobile source combustion, fugitive emissions and electricity use by source. It calculates emissions using entity collected data such as fuel purchase records, VMT and utility bills. While reporting and certification through CARROT is only available to members, the public may access entity reports online. Reporting protocols are also available to the public, including the General Reporting Protocol (www.climateregistry.org/docs/PROTOCOLS/GRP%20V2-March2007_web.pdf) and cement, forestry and power/utility sector protocols. Additional sector protocols are under development. Website: www.climateregistry.org/CARROT/

EMFAC

The Air Resources Board's EMission FACtors (EMFAC) model is used to calculate emission rates from all motor vehicles in California. The emission factors are combined with data on vehicle activity (miles traveled and average speeds) to assess emission impacts. The URBEMIS model described above uses EMFAC to calculate the transportation emission impacts of local projects. Web site: http://www.arb.ca.gov/msei/onroad/onroad.htm

Attachment 3

Examples of GHG Reduction Measures

The following are examples of measures that have been employed by some public agencies to reduce greenhouse gas emissions, either as general development policies or on a project-by-project basis. These are provided for illustrative purposes only.

LAND USE AND TRANSPORTATION

- Implement land use strategies to encourage jobs/housing proximity, promote transit-oriented development, and encourage high density development along transit corridors. Encourage compact, mixed-use projects, forming urban villages designed to maximize affordable housing and encourage walking, bicycling and the use of public transit systems.
- Encourage infill, redevelopment, and higher density development, whether in incorporated or unincorporated settings
- Encourage new developments to integrate housing, civic and retail amenities (jobs, schools, parks, shopping opportunities) to help reduce VMT resulting from discretionary automobile trips.
- Apply advanced technology systems and management strategies to improve operational efficiency of transportation systems and movement of people, goods and services.
- Incorporate features into project design that would accommodate the supply of frequent, reliable and convenient public transit.
- Implement street improvements that are designed to relieve pressure on a region's most congested roadways and intersections.
- Limit idling time for commercial vehicles, including delivery and construction vehicles.

URBAN FORESTRY

- Plant trees and vegetation near structures to shade buildings and reduce energy requirements for heating/cooling.
- Preserve or replace onsite trees (that are removed due to development) as a means of providing carbon storage.

GREEN BUILDINGS

- Encourage public and private construction of LEED (Leadership in Energy and Environmental Design) certified (or equivalent) buildings.

ENERGY CONSERVATION POLICIES AND ACTIONS

- Recognize and promote energy saving measures beyond Title 24 requirements for residential and commercial projects
- Where feasible, include in new buildings facilities to support the use of low/zero carbon fueled vehicles, such as the charging of electric vehicles from green electricity sources.
- Educate the public, schools, other jurisdictions, professional associations, business and industry about reducing GHG emissions.
- Replace traffic lights, street lights, and other electrical uses to energy efficient bulbs and appliances.
- Purchase Energy Star equipment and appliances for public agency use.
- Incorporate on-site renewable energy production, including installation of photovoltaic cells or other solar options.
- Execute an Energy Savings Performance Contract with a private entity to retrofit public buildings. This type of contract allows the private entity to fund all energy improvements in exchange for a share of the energy savings over a period of time.
- Design, build, and operate schools that meet the Collaborative for High Performance Schools (CHPS) best practices.
- Retrofit municipal water and wastewater systems with energy efficient motors, pumps and other equipment, and recover wastewater treatment methane for energy production.
- Convert landfill gas into energy sources for use in fueling vehicles, operating equipment, and heating buildings.
- Purchase government vehicles and buses that use alternatives fuels or technology, such as electric hybrids, biodiesel, and ethanol. Where feasible, require fleet vehicles to be low emission vehicles. Promote the use of these vehicles in the general community.
- Offer government incentives to private businesses for developing buildings with energy and water efficient features and recycled materials. The incentives can include expedited plan checks and reduced permit fees.
- Offer rebates and low-interest loans to residents that make energy-saving improvements on their homes.

- Create bicycle lanes and walking paths directed to the location of schools, parks and other destination points.

PROGRAMS TO REDUCE VEHICLE MILES TRAVELED

- Offer government employees financial incentives to carpool, use public transportation, or use other modes of travel for daily commutes.
- Encourage large businesses to develop commute trip reduction plans that encourage employees who commute alone to consider alternative transportation modes.
- Develop shuttle systems around business district parking garages to reduce congestion and create shorter commutes.
- Create an online ridesharing program that matches potential carpoolers immediately through email.
- Develop a Safe Routes to School program that allows and promotes bicycling and walking to school.

PROGRAMS TO REDUCE SOLID WASTE

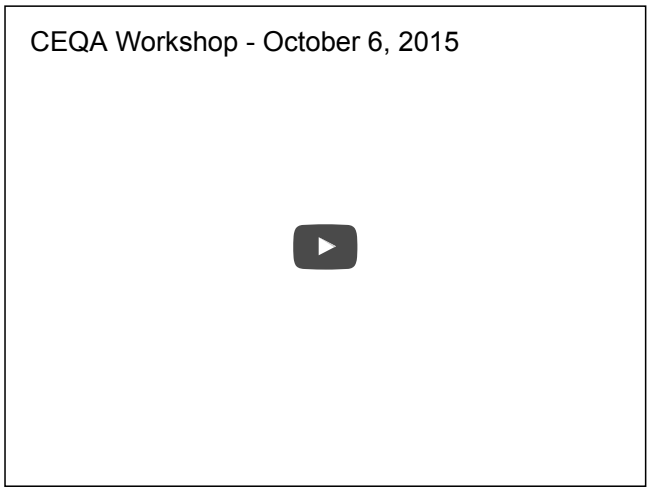
- Create incentives to increase recycling and reduce generation of solid waste by residential users.
- Implement a Construction and Demolition Waste Recycling Ordinance to reduce the solid waste created by new development.
- Add residential/commercial food waste collection to existing greenwaste collection programs.

CEQA Guidelines

CEQA GUIDELINES UPDATE

The Governor's Office of Planning and Research released a preliminary discussion draft of changes to the Guidelines Implementing the California Environmental Quality Act for public review on August 11, 2015. The comment period on that draft has now closed, and OPR is reviewing the input that it received. OPR wishes to thank those that participated in the review. Notice of future activity on the CEQA Guidelines will be posted on this website and distributed through the CEQA Guidelines List Serve.

OPR and the Natural Resources Agency conducted a public workshop on the preliminary discussion draft on October 6, 2015. (Click here for workshop detail.)A recording of the workshop can be viewed below. A copy of the presentation is available here. Additional information on the CEQA Guidelines and the process for updating them is provided below.



CEQA Guidelines Workshop - October 6, 2015

BACKGROUND

The CEQA Guidelines are administrative regulations governing implementation of the California Environmental Quality Act (Public Resources Code section 21000 and following). The CEQA Guidelines reflect the requirements set forth in the Public Resources Code, as well as court decisions interpreting the statute and practical planning considerations. Among other things, the CEQA Guidelines explain how to determine whether an activity is subject to environmental review, what steps are involved in the environmental review process, and the required content of environmental documents. The CEQA Guidelines apply to public agencies throughout the state, including local governments, special districts, and state agencies.

UPDATES TO THE CEQA GUIDELINES

Public Resources Code section 21083 requires the Office of Planning and Research and the Natural Resources Agency to periodically update the CEQA Guidelines. In recent years, updates have responded to specific statutory directives to address, for example, greenhouse gas emissions (SB 97, 2007) and streamlining for infill development (SB 226, 2011). This year, the Office of Planning and Research and the Natural Resources Agency will undertake a comprehensive review of the CEQA Guidelines. Because CEQA applies to such a diverse range of activities and decision-makers, and affects communities and project applicants throughout the state, your input is a crucial step in that review.

During the summer of 2013, OPR published a Solicitation for Input seeking suggestions from stakeholders and the public into what changes, if any, should be made to update the CEQA Guidelines. We received input from a broad range of interested stakeholders. Many of the comments submitted during the review period were thoughtful and constructive, and will contribute significantly to the development of draft amendments to the Guidelines. A summary of that input is available here.

The following is an index of all letters received. Please click on each link to view the letter.

OPR and the Natural Resources Agency also conducted a public workshop on July 29, 2013. Program materials included the agenda and presentation slides.

POSSIBLE TOPICS TO BE ADDRESSED IN THE 2014 UPDATE

OPR has received comments responding to the list of possible topics to be addressed in the 2014 CEQA Guidelines Update published in December 2013. We have also received comments on a preliminary evaluation of possible metrics to replace "level of service" in transportation analyses in response to SB 743.

OPR is currently reviewing and evaluating all of the comments that it received. Later this spring, OPR intends to release a draft proposal of changes to the CEQA Guidelines reflecting suggested updates and the new transportation metrics required by SB 743. Those that would like to receive notice of the availability of the draft proposal, as well as other future Guidelines activities, are encouraged to sign up on the CEQA Guidelines listserv (see below).

DOCUMENTS

- A Preliminary Evaluation of Alternative Methods of Transportation Analysis
- Possible Topics to be Addressed in the 2014 CEQA Guidelines Update
- Public Comments on CEQA Guidelines Update

- Public Comments on SB743 (preliminary evaluations)
- SB 743 Guidelines Discussion Draft

UPDATE LISTSERV

CLEVELAND NATIONAL FOREST FOUNDATION et al., Plaintiffs and Appellants, v. SAN DIEGO ASSOCIATION OF GOVERNMENTS et al., Defendants and Appellants; THE PEOPLE, Intervenor and Appellant.	D063288 (Super. Ct. No. 37-2011-00101593-CU-TT-CTL)
CREED-21 et al., Plaintiffs and Appellants, v. SAN DIEGO ASSOCIATION OF GOVERNMENTS et al., Defendants and Appellants; THE PEOPLE, Intervenor and Appellant.	(Super. Ct. No. 37-2011-00101660-CU-TT-CTL)

APPEAL from a judgment of the Superior Court of San Diego County, Timothy B. Taylor, Judge. Judgment modified and affirmed.

The Sohagi Law Group, Margaret M. Sohagi, Philip A. Seymour; and Julie D. Wiley for Defendants and Appellants San Diego Association of Governments et al.

Kamala D. Harris, Attorney General, Timothy R. Patterson and Janill L. Richards, Deputy Attorneys General, for Intervenor and Appellant.

Shute, Mihaly & Weinberger, Rachel B. Hooper, Amy J. Bricker, Erin B. Chalmers; Daniel P. Selmi; Coast Law Group, Marco Gonzalez; Kevin P. Bundy; and Cory J. Briggs for Plaintiffs and Appellants Cleveland National Forest et al.

INTRODUCTION

After the San Diego Association of Governments (SANDAG) certified an environmental impact report (EIR) for its 2050 Regional Transportation Plan/Sustainable Communities Strategy (transportation plan), CREED-21 and Affordable Housing Coalition of San Diego filed a petition for writ of mandate challenging the EIR's adequacy under the California Environmental Quality Act (CEQA) (Pub. Resources Code, § 21000 et seq.).[1] Cleveland National Forest Foundation and the Center for Biological Diversity filed a similar petition, in which Sierra Club and the People later joined.

The superior court granted the petitions in part, finding the EIR failed to carry out its role as an informational document because it did not analyze the inconsistency

---

1 Further statutory references are also to the Public Resources Code unless otherwise stated.

between the state's policy goals reflected in Executive Order S-3-05 (Executive Order) and the transportation plan's greenhouse gas emissions impacts after 2020. The court also found the EIR failed to adequately address mitigation measures for the transportation plan's greenhouse gas emissions impacts. Given these findings, the court declined to decide any of the other challenges raised in the petitions.

SANDAG appeals, contending the EIR complied with CEQA in both respects. Cleveland National Forest Foundation and Sierra Club (collectively, Cleveland) cross-appeal, contending the EIR further violated CEQA by failing to analyze a reasonable range of project alternatives, failing to adequately analyze and mitigate the transportation plan's air quality impacts, and understating the transportation plan's impacts on agricultural lands. The People separately cross-appeal, contending the EIR further violated CEQA by failing to adequately analyze and mitigate the transportation plan's impacts from particulate matter pollution. We conclude the EIR failed to comply with CEQA in all identified respects. We, therefore, modify the judgment to incorporate our decision on the cross-appeals and affirm. In doing so, we are upholding the right of the public and our public officials to be well informed about the potential environmental consequences of their planning decisions, which CEQA requires and the public deserves, before approving long-term plans that may have irreversible environmental impacts.

DISCUSSION

I

A

General Role of an EIR

"The Legislature has made clear that an EIR is 'an informational document' and that '[t]he purpose of an environmental impact report is to provide public agencies and the public in general with detailed information about the effect which a proposed project is likely to have on the environment; to list ways in which the significant effects of such a project might be minimized; and to indicate alternatives to such a project.' " (*Laurel Heights Improvement Assn. v. Regents of University of California* (1988) 47 Cal.3d 376, 391 (*Laurel Heights*); Guidelines, § 15002.)[2] "The EIR is the primary means of achieving . . . the policy of this state to 'take all action necessary to protect, rehabilitate, and enhance the environmental quality of the state.' [Citation.] The EIR is therefore 'the heart of CEQA.' [Citations.] An EIR is an 'environmental "alarm bell" whose purpose it is to alert the public and its responsible officials to environmental changes before they have reached ecological points of no return.' [Citations.] The EIR is also intended 'to demonstrate to an apprehensive citizenry that the agency has, in fact, analyzed and considered the ecological implications of its action.' [Citations.] Because the EIR must

---

2 All references to Guidelines are to the CEQA Guidelines, which are located in title 14 of the California Code of Regulations beginning at section 15000. "In interpreting CEQA, we accord the Guidelines great weight except where they are clearly unauthorized or erroneous." (*Neighbors for Smart Rail v. Exposition Metro Line Construction Authority* (2013) 57 Cal.4th 439, 448, fn. 4 (*Smart Rail*).)

be certified or rejected by public officials, it is a document of accountability. If CEQA is scrupulously followed, the public will know the basis on which its responsible officials either approve or reject environmentally significant action, and the public, being duly informed, can respond accordingly to action with which it disagrees. [Citations.] The EIR process protects not only the environment but also informed self-government." (*Laurel Heights*, *supra*, 47 Cal.3d at p. 392.)

B

Role of a Program EIR

The EIR at issue in this case is a program EIR. A "program EIR" is "an EIR which may be prepared on a series of actions that can be characterized as one large project" and are related in specified ways. (Guidelines, § 15168, subd. (a); *Town of Atherton v. California High-Speed Rail Authority* (2014) 228 Cal.App.4th 314, 343 (*Atherton*).) The use of a program EIR can: "(1) Provide an occasion for a more exhaustive consideration of effects and alternatives than would be practical in an EIR on an individual action, [¶] (2) Ensure consideration of cumulative impacts that might be slighted in a case-by-case analysis, [¶] (3) Avoid duplicative reconsideration of basic policy considerations, [¶] (4) Allow the lead agency to consider broad policy alternatives and program wide mitigation measures at an early time when the agency has greater flexibility to deal with basic problems or cumulative impacts, [and] [¶] (5) Allow reduction in paperwork." (Guidelines, § 15168, subd. (b); *Atherton*, *supra*, at pp. 343-344.)

"[W]here an agency prepares a 'program EIR' for a broad policy document . . . , Guidelines section 15168, subdivision (c)(2) allows agencies to limit future environmental review for later activities that are found to be 'within the scope' of the program EIR." (*Latinos Unidos de Napa v. City of Napa* (2013) 221 Cal.App.4th 192, 196; accord, *Citizens Against Airport Pollution v. City of San Jose* (2014) 227 Cal.App.4th 788, 801-802.) Further environmental review for such activities is required only where "(a) Substantial changes are proposed in the project which will require major revisions of the [EIR]. [¶] (b) Substantial changes occur with respect to the circumstances under which the project is being undertaken which will require major revisions in the [EIR]. [¶] (c) New information, which was not known or could not have been known at the time the [EIR] was certified as complete, becomes available." (§ 21166; *May v. City of Milpitas* (2013) 217 Cal.App.4th 1307, 1325-1326; accord, *Citizens Against Airport Pollution v. City of San Jose*, *supra*, at p. 802.)

Because of these limitations, once an EIR is finally approved, a court generally cannot compel an agency to perform further environmental review for any known or knowable information about the project's impacts omitted from the EIR. (*Citizens Against Airport Pollution v. City of San Jose*, *supra*, 227 Cal.App.4th at pp. 807-808; *Citizens for Responsible Equitable Environmental Development v. City of San Diego* (2011) 196 Cal.App.4th 515, 531-532.) A court also generally cannot compel an agency to perform further environmental review if new regulations or guidelines for evaluating the project's impacts are adopted in the future. (*Concerned Dublin Citizens v. City of*

Dublin (2013) 214 Cal.App.4th 1301, 1320; *Fort Mojave Indian Tribe v. Department of Health Services* (1995) 38 Cal.App.4th 1574, 1605.)

Hence, "[d]esignating an EIR as a program EIR . . . does not by itself decrease the level of analysis otherwise required in the EIR. 'All EIR's must cover the same general content. [Citations.] The level of specificity of an EIR is determined by the nature of the project and the "rule of reason" [citation], rather than any semantic label accorded to the EIR.' " (*Friends of Mammoth v. Town of Mammoth Lakes Redevelopment Agency* (2000) 82 Cal.App.4th 511, 533.) Consequently, in considering a challenge to a program EIR, "it is unconstructive to ask whether the EIR provided 'project-level' as opposed to 'program-level' detail and analysis. Instead, we focus on whether the EIR provided 'decision makers with sufficient analysis to intelligently consider the environmental consequences of [the] project.' " (*Citizens for a Sustainable Treasure Island v. City and County of San Francisco* (2014) 227 Cal.App.4th 1036, 1052.)

C

Standard of Review in CEQA Cases[3]

"[I]n a CEQA case, as in other mandamus cases, [our review] is the same as the trial court's: [we review] the agency's action, not the trial court's decision; in that sense [our review] is de novo. (*Vineyard*, *supra*, 40 Cal.4th at p. 427.) However, our inquiry extends " 'only to whether there was a prejudicial abuse of discretion.' ([§ 21168.5].)" (*Vineyard*, at p. 426.)

"[A]n agency may abuse its discretion under CEQA either by failing to proceed in the manner CEQA provides or by reaching factual conclusions unsupported by substantial evidence. (§ 21168.5.) Judicial review of these two types of error differs significantly: While we determine de novo whether the agency has employed the correct procedures, 'scrupulously enforc[ing] all legislatively mandated CEQA requirements' [citation], we accord greater deference to the agency's substantive factual conclusions." (*Vineyard*, *supra*, 40 Cal.4th at p. 435.) "In evaluating an EIR for CEQA compliance, then, [we] must adjust [our] scrutiny to the nature of the alleged defect, depending on whether the claim is predominantly one of improper procedure or a dispute over the facts.

---

3 The California Supreme Court is currently reviewing the standard and scope of judicial review under CEQA. (*Sierra Club v. County of Fresno* (2014) 226 Cal.App.4th 704 [172 Cal.Rptr.3d 271], review granted Oct. 1, 2014, S219783.) Pending further guidance, we endeavor to apply the review dichotomy most recently articulated by the Supreme Court. (*Vineyard Area Citizens for Responsible Growth, Inc. v. City of Rancho Cordova* (2007) 40 Cal.4th 412, 426-427, 435 (*Vineyard*); accord, *Save Tara v. City of West Hollywood* (2008) 45 Cal.4th 116, 131; *In re Bay-Delta etc.* (2008) 43 Cal.4th 1143, 1161-1162 (*Bay-Delta*); *Ebbetts Pass Forest Watch v. California Dept. of Forestry & Fire Protection* (2008) 43 Cal.4th 936, 944.)

For example, where an agency failed to require an applicant to provide certain information mandated by CEQA and to include that information in its environmental analysis, . . . the agency 'failed to proceed in the manner prescribed by CEQA.' [Citations.] In contrast, in a factual dispute over 'whether adverse effects have been mitigated or could be better mitigated' [citation], the agency's conclusion would be reviewed only for substantial evidence." (*Ibid*.)

II

Appeal

A

Background

1

In 2005 then Governor Arnold Schwarzenegger issued the Executive Order establishing greenhouse gas emissions reduction targets for California. Specifically, the Executive Order required reduction of greenhouse gas emissions to 2000 levels by 2010, to 1990 levels by 2020, and to 80 percent below 1990 levels by 2050.[4]

---

4 "[A]n executive order is generally regarded as 'a formal written directive of the Governor.' " (75 Ops.Cal.Atty.Gen. 263 (1992).) The Executive Order provided in relevant part: "I, ARNOLD SCHWARZENEGGER, Governor of the State of California, by virtue of the power invested in me by the Constitution and statutes of the State of California, do hereby order effective immediately . . . . That the following greenhouse gas emission reduction targets are hereby established for California: by 2010, reduce [greenhouse gas] emissions to 2000 levels; by 2020, reduce [greenhouse gas] emissions to 1990 levels; by 2050, reduce [greenhouse gas] emissions to 80 percent below 1990 levels . . . ." (http://gov.ca.gov/news.php?id=1861 [as of Nov. 21, 2014].)

The Legislature subsequently enacted the California Global Warming Solutions Act of 2006 (Health & Saf. Code, § 38500 et seq.), referred to by the parties as Assembly Bill No. 32 (AB 32). Among its provisions, AB 32 tasked the California Air Resources Board (CARB) with determining the state's 1990 greenhouse gas emissions level and approving an equivalent emissions level to be achieved by 2020. (Health & Saf. Code, § 38550.)

The Legislature intended for the emissions limit to "continue in existence and be used to maintain and continue reductions in emissions of greenhouse gases beyond 2020." (Health & Saf. Code, § 38551, subd. (b).) The Legislature also intended for the emissions limit to work in concert with other environmental protection laws, expressly stating AB 32 does not "relieve any person, entity, or public agency of compliance with other applicable federal, state, or local laws or regulations, including state air and water quality requirements, and other requirements for protecting public health or the environment." (Health & Saf. Code, § 38592, subd. (b).) The Legislature further intended for "the Climate Action Team established by the Governor to coordinate the efforts set forth under [the Executive Order] continue its role in coordinating overall climate policy." (Health & Saf. Code, § 38501, subd. (i).) Thus, the Legislature, through AB 32, effectively endorsed the Executive Order and its overarching goal of ongoing greenhouse gas emissions reductions as state climate policy. (See, e.g., *Professional Engineers in California Government v. Schwarzenegger* (2010) 50 Cal.4th 989, 1000, 1043-1044, 1051 [subsequent legislative endorsement operates to ratify and validate provisions in Executive Order].)

Bolstering this conclusion, the Legislature also enacted the Sustainable Communities and Climate Protection Act of 2008 (Stats. 2008, ch. 728; Stats. 2009, ch. 354, § 5), referred to by the parties as Senate Bill No. 375 (SB 375). In enacting SB 375, the Legislature found automobiles and light trucks are responsible for 30 percent of the state's greenhouse gas emissions. (Stats. 2008, ch. 728, § 1, subd. (a).) Accordingly, SB 375 directed CARB to develop regional greenhouse gas emission reduction targets for automobiles and light trucks for 2020 and 2035. (Gov. Code, § 65080, subd. (b)(2)(A).) The targets established by CARB for the San Diego region require a 7 percent per capita reduction in carbon dioxide emissions by 2020 and a 13 percent per capita reduction by 2035 (compared to a 2005 baseline).[5] CARB must update these targets every eight years until 2050, and may update the targets every four years based on changing factors. (Gov. Code, § 65080, subd. (b)(2)(A)(iv).)

2

The transportation plan, which SANDAG must prepare every four years (23 U.S.C. § 134, subd. (c); Gov. Code, § 65080, subds. (a) & (d)), "serves as the long-range plan designed to coordinate and manage future regional transportation improvements, services, and programs among the various agencies operating within the San Diego region." In enacting SB 375, the Legislature found the state's emissions reductions goals cannot be met without improved land use and transportation policy. Consequently, SB 375 (Gov. Code, § 65080, subd. (b)(2)(B)) mandates the transportation

---

5 The transportation plan meets these limited scope targets (see part II.C.1, *post*).

plan include a sustainable communities strategy to, as the EIR states, "guide the San Diego region toward a more sustainable future by integrating land use, housing, and transportation planning to create more sustainable, walkable, transit-oriented, compact development patterns and communities that meet [CARB's greenhouse gas] emissions targets for passenger cars and light-duty trucks." Once the sustainable communities strategy is approved, some transit priority projects consistent with the strategy are exempt from CEQA requirements. Other transit priority projects, residential projects, and mixed-use projects consistent with the strategy are subject to streamlined CEQA requirements. (§§ 21155-21155.4, 21159.28; Guidelines, § 15183.3.)

B

Greenhouse Gas Emissions Impacts Analysis

The EIR acknowledged the transportation plan's implementation would lead to an overall increase in greenhouse gas emissions levels; however, the EIR did not analyze whether this consequence conflicted with the Executive Order, or would impair or impede the achievement of the Executive Order's goals. As it did in the EIR and below, SANDAG contends on appeal its decision to omit an analysis of the transportation plan's consistency with the Executive Order (consistency analysis) did not violate CEQA because CEQA does not require such a consistency analysis. Whether the EIR's analysis complies with CEQA depends on whether the analysis reflects a reasonable, good faith effort to disclose and evaluate the transportation plan's greenhouse gas emissions impacts. We review the sufficiency of the analysis in light of what is reasonably foreseeable. (Guidelines, § 15151; *City of Maywood v. Los Angeles Unified School Dist.*

(2012) 208 Cal.App.4th 362, 386 (*City of Maywood*); *City of Long Beach v. Los Angeles Unified School Dist.* (2009) 176 Cal.App.4th 889, 897-898 (*City of Long Beach*).) As the focus of SANDAG's contention is whether the EIR's analysis was reasonable and not whether the EIR violated a specific statute or regulation, the contention presents a predominately factual question and our review is for substantial evidence. (*Vineyard*, *supra*, 40 Cal.4th at p. 435.)

Substantial evidence for CEQA purposes is "enough relevant information and reasonable inferences from this information that a fair argument can be made to support a conclusion, even though other conclusions might also be reached." (Guidelines, § 15384, subd. (a).) Substantial evidence includes "facts, reasonable assumptions predicated upon facts, and expert opinion supported by facts." (*Id*., subd. (b).) It does not include argument, speculation, unsubstantiated opinion or narrative, clearly erroneous or inaccurate evidence, or evidence of social or economic impacts which do not contribute to or are not caused by physical impacts on the environment. (*Id*., subd. (a).)

"In reviewing for substantial evidence, [we] 'may not set aside an agency's approval of an EIR on the ground that an opposite conclusion would have been equally or more reasonable,' for, on factual questions, our task 'is not to weigh conflicting evidence and determine who has the better argument.' " (*Vineyard, supra*, 40 Cal.4th at p. 435; *Laurel Heights, supra*, 47 Cal.3d at p. 393.) Rather, we must resolve any reasonable doubts and any conflicts in the evidence in favor of the agency's findings and decision. (*Laurel Heights*, at p. 393; *Citizens for Responsible Equitable Environmental Development v. City of San Diego, supra*, 196 Cal.App.4th at pp. 522-523.)

In this case, SANDAG's decision to omit an analysis of the transportation plan's consistency with the Executive Order did not reflect a reasonable, good faith effort at full disclosure and is not supported by substantial evidence because SANDAG's decision ignored the Executive Order's role in shaping state climate policy. The Executive Order underpins all of the state's current efforts to reduce greenhouse gas emissions. As SANDAG itself noted in its Climate Action Strategy, the Executive Order's 2050 emissions reduction goal "is based on the scientifically-supported level of emissions reduction needed to avoid significant disruption of the climate and *is used as the long-term driver for state climate change policy development*." (Italics added.)

Indeed, the Executive Order led directly to the enactment of AB 32, which validated and ratified the Executive Order's overarching goal of ongoing emissions reductions, recognized the Governor's Climate Action Team as the coordinator of the state's overall climate policy, and tasked CARB with establishing overall emissions reduction targets for 2020 and beyond. The Executive Order also led directly to the enactment of SB 375, which tasked CARB with establishing regional automobile and light truck emissions reduction targets for 2020 and 2035. CARB is required to revisit these targets every eight years through 2050, or sooner if warranted by changing circumstances. (Gov. Code, § 65080, subd. (b)(2)(A)(iv).) Thus, the Executive Order, with the Legislature's unqualified endorsement, will continue to underpin the state's efforts to reduce greenhouse gas emissions throughout the life of the transportation plan. The EIR's failure to analyze the transportation plan's consistency with the Executive Order, or more particularly with the Executive Order's overarching goal of ongoing

greenhouse gas emissions reductions, was therefore a failure to analyze the transportation plan's consistency with state climate policy. As evidence in the record indicates the transportation plan would actually be inconsistent with state climate policy over the long term, the omission deprived the public and decision makers of relevant information about the transportation plan's environmental consequences. The omission was prejudicial because it precluded informed decisionmaking and public participation. (*Smart Rail, supra*, 57 Cal.4th at p. 463; *City of Long Beach, supra*, 176 Cal.App.4th at p. 898.)

SANDAG contends the EIR cannot analyze the transportation plan's consistency with the Executive Order because there is no statute or regulation translating the Executive Order's goals into comparable, scientifically based emissions reduction targets. However, we do not agree the lack of such targets precludes the EIR from performing a meaningful consistency analysis in this instance. "Drafting an EIR . . . necessarily involves some degree of forecasting. While foreseeing the unforeseeable is not possible, an agency must use its best efforts to find out and disclose all that it reasonably can." (Guidelines, § 15144.) Although SANDAG may not know precisely what future emissions reduction targets the transportation plan will be required to meet, it knows from the information in its own Climate Action Strategy the theoretical emissions reduction targets necessary for the region to meet its share of the Executive Order's goals. It also knows state climate policy, as reflected in the Executive Order and AB 32, requires a continual *decrease* in the state's greenhouse gas emissions and the transportation plan after 2020 produces a continual *increase* in greenhouse gas emissions. With this knowledge, SANDAG could have reasonably analyzed whether the

transportation plan was consistent with, or whether it would impair or impede, state climate policy.[6]

SANDAG's attempts to disavow its responsibility for performing this analysis are unavailing. The Legislature specifically found reducing greenhouse gas emissions cannot be accomplished without improved land use and transportation policy. Accordingly, the transportation plan plays both a necessary and important role in achieving state climate policy. By failing to adequately inform the public and decision makers the transportation plan is inconsistent with state climate policy, the EIR deterred the decision makers from devising and considering changes to favorably alter the trajectory of the transportation plan's post-2020 greenhouse gas emissions. When the decision makers are inevitably faced with post-2020 requirements aligned with state climate policy, their task of complying with these requirements will be more difficult and some opportunities for compliance may be lost. As SANDAG explained in its Climate Action Strategy, "Once in place, land use patterns and transportation infrastructure typically remain part of the built environment and influence travel behavior and greenhouse gas emissions for several decades, perhaps longer." In this regard, the EIR falls far short of being "an

---

6 We do not intend to suggest the transportation plan must achieve the Executive Order's 2050 goal or any other specific numerical goal. Our concern is with the EIR's failure to recognize, much less analyze and attempt to mitigate, the conflict between the transportation plan's long-term greenhouse gas emissions increase and the state climate policy goal, reflected in the Executive Order, of long-term emissions reductions. In fact, the EIR does not even discuss the transportation plan's failure to maintain emissions reductions after 2020, which is AB 32's minimum expectation. (See Health & Saf. Code, § 38551, subd. (b).)

'environmental "alarm bell" whose purpose it is to alert the public and its responsible officials to environmental changes before they have reach ecological points of no return.' " (*Laurel Heights*, *supra*, 47 Cal.3d at p. 392.) It also falls far short of " 'demonstrat[ing] to an apprehensive citizenry that the agency has, in fact, analyzed and considered the ecological implications of its actions.' " (*Ibid.*)

We are likewise unpersuaded by SANDAG's assertion the EIR's analysis of the transportation plan's greenhouse gas emissions impacts fully complies with CEQA because it utilized significance thresholds specified in Guidelines section 15064.4, subdivision (b).[7] This Guideline states in relevant part: "A lead agency should consider the following factors, *among others*, when assessing the significance of impacts from greenhouse gas emissions on the environment: [¶] (1) The extent to which the project may increase or reduce greenhouse gas emissions as compared to the existing environmental setting[.] [¶] (2) Whether the project emissions exceed a threshold of significance that the lead agency determines applies to the project. [¶] (3) The extent to which the project complies with regulations or requirements adopted to implement a statewide, regional, or local plan for the reduction or mitigation of greenhouse gas emissions. Such requirements must be adopted by the relevant public agency through a public review process and must reduce or mitigate the project's incremental contribution

---

7 "A threshold of significance is an identifiable quantitative, qualitative or performance level of a particular environmental effect, non-compliance with which means the effect will normally be determined to be significant by the agency and compliance with which means the effect normally will be determined to be less than significant." (Guidelines, § 15064.7.)

of greenhouse gas emissions. If there is substantial evidence that the possible effects of a particular project are still cumulatively considerable notwithstanding compliance with the adopted regulations or requirements, an EIR must be prepared for the project." (Guidelines, § 15064.4, subd. (b), italics added.)

Although this Guideline specifies three means of determining whether a project's greenhouse gas emissions impacts are significant, the "among others" qualifying language indicates these means are not exclusive.[8] Moreover, "the fact that a particular environmental effect meets a particular threshold cannot be used as an automatic determinant that the effect is or is not significant . . . a threshold of significance cannot be applied in a way that would foreclose the consideration of other substantial evidence tending to show the environmental effect to which the threshold relates might be significant." (*Protect The Historic Amador Waterways v. Amador Water Agency* (2004) 116 Cal.App.4th 1099, 1109 (*Amador*).) Consequently, the use of the Guideline's thresholds does not necessarily equate to compliance with CEQA, particularly where, as here, the failure to consider the transportation plan's consistency with the state climate policy of ongoing emissions reductions reflected in the Executive Order frustrates the state climate policy and renders the EIR fundamentally misleading.

---

8 Indeed, in its statement of reasons for adopting the Guideline, the Natural Resources Agency explained the Guideline "reflects the existing CEQA principle that there is no iron-clad definition of 'significance.' [Citations.] Accordingly, lead agencies must use their best efforts to investigate and disclose all that they reasonably can regarding a project's potential adverse impacts." (California Natural Resources Agency, Final Statement of Reasons for Regulatory Action (Dec. 2009) p. 20 < http://resources.ca.gov/ceqa/docs/Final_Statement_of_Reasons.pdf > (as of Nov. 21, 2014).)

We are also unpersuaded by SANDAG's assertion it was not required to analyze the transportation plan's consistency with the state climate policy reflected in the Executive Order because SANDAG has broad discretion to select the criteria it uses to determine the significance of the transportation plan's impacts. While we agree SANDAG has such discretion (*North Coast Rivers Alliance v. Marin Municipal Water Dist. Bd. of Directors* (2013) 216 Cal.App.4th 614, 624), SANDAG abuses its discretion if it exercises it in a manner that causes an EIR's analysis to be misleading or without informational value. (See *Smart Rail*, *supra*, 57 Cal.4th at pp. 445, 457.) "A lead agency cannot avoid finding a potentially significant effect on the environment by rotely applying standards of significance that do not address that potential effect." (*Rominger v. County of Colusa* (2014) 229 Cal.App.4th 690, 717, citing *Amador*, *supra*, 116 Cal.App.4th at p. 1111.)

By disregarding the Executive Order's overarching goal of ongoing emissions reductions, the EIR's analysis of the transportation plan's greenhouse gas emissions makes it falsely appear as if the transportation plan is furthering state climate policy when, in fact, the trajectory of the transportation plan's post-2020 emissions directly contravenes it. "[O]mitting material necessary to informed decisionmaking and informed public participation" subverts the purposes of CEQA and "precludes both identification of potential environmental consequences arising from the project and also thoughtful analysis of the sufficiency of measures to mitigate those consequences." (*Lotus v. Department of Transportation* (2014) 223 Cal.App.4th 645, 658.) Such an omission is particularly troubling where, as here, the project under review involves long-term,

planned expenditures of billions of taxpayer dollars. No one can reasonably suggest it would be prudent to go forward with planned expenditures of this magnitude before the public and decision makers have been provided with all reasonably available information bearing on the project's impacts to the health, safety, and welfare of the region's inhabitants. We, therefore, conclude SANDAG prejudicially abused its discretion by omitting from the EIR an analysis of the transportation plan's consistency with the state climate policy, reflected in the Executive Order, of continual greenhouse gas emissions reductions.[9]

C

Mitigation of Greenhouse Gas Emissions Impacts

1

Although the EIR did not analyze the transportation plan's consistency with the state climate policy reflected in the Executive Order, the EIR nevertheless, analyzed the transportation plan's greenhouse gas emissions impacts against three significance thresholds for each of the planning years 2020, 2035, and 2050. Under the first

---

9 Our decision will not necessarily stop any project encompassed within the transportation plan. (See *Preserve Wild Santee v. City of Santee* (2012) 210 Cal.App.4th 260, 286-289.) Our decision also will not procedurally or substantively expand CEQA requirements in violation of section 21083.1 because the EIR is required to analyze the transportation plan's potential "to degrade the quality of the environment, curtail the range of the environment, *or to achieve short-term, to the disadvantage of long-term, environmental goals*." (§ 21083, subd. (b)(1), italics added; Guidelines, § 15065, subd. (a)(2), (c).) Rather, our decision is consistent with the intent CEQA "be interpreted to afford the fullest possible protection to the environment within the reasonable scope of the statutory language. (Guidelines, § 15003, subd. (f).)

threshold, the EIR posited the transportation plan's impacts would be significant if the transportation plan's implementation were to increase greenhouse gas emissions compared to existing, or 2010, conditions. Under the second threshold, the EIR posited the transportation plan's impacts would be significant if the transportation plan's implementation conflicted with CARB's regional automobile and light truck emissions reductions targets. Under the third threshold, the EIR stated the transportation plan's impacts would be significant if the transportation plan's implementation conflicted with either CARB's Climate Change Scoping Plan (Scoping Plan) or SANDAG's own Climate Action Strategy.[10]

The EIR concluded the transportation plan's greenhouse gas emissions impacts would be significant under the first significance threshold for the 2035 and 2050 planning years because the emissions would be higher in those planning years than in 2010. The EIR concluded the greenhouse gas emissions impacts would be less than significant in all other respects analyzed.[11]

---

10 The Scoping Plan is CARB's roadmap for achieving greenhouse gas emissions reductions. The Climate Action Strategy is SANDAG's guide for addressing climate change. The Climate Action Strategy emphasizes the areas where the greatest impact can be made at the local level, including transportation infrastructure.

11 The People and Cleveland have not challenged these conclusions and their propriety is not before us. Nonetheless, regarding the third significance threshold, we note the Climate Action Strategy expresses far stronger views than the transportation plan on the steps necessary to achieve the state's long-term greenhouse gas emissions reductions goals. For example, the Climate Action Strategy maintains achieving the goals "will require fundamental changes in policy, technology, and behavior" and "[b]y 2030, the region must have met and gone below the 1990 [emissions] level and be well on its way to doing its share for achieving the 2050 greenhouse gas reduction level."

To mitigate the significant greenhouse gas emissions impacts found under the first threshold, the EIR identified three mitigation measures it deemed feasible.[12] The first mitigation measure required SANDAG to update its future regional comprehensive plans, regional transportation plans, and sustainable communities plans to incorporate policies and measures leading to reduced greenhouse gas emissions. The second mitigation measure encouraged the San Diego region cities and the County of San Diego (County) to adopt and implement climate action plans for reducing greenhouse gas emissions to a level the particular city or the County determined would not be cumulatively considerable. The second mitigation measure also identified various provisions the plans should include and stated SANDAG would assist in the preparation of the plans and other climate strategies through the continued implementation of its own Climate Action Strategy and Energy Roadmap Program.[13] The third mitigation measure stated SANDAG would and other agencies should require the use of best available control technology to reduce greenhouse gas emissions during the construction and operation of projects.

---

[12] " 'Feasible' means capable of being accomplished in a successful manner within a reasonable period of time, taking into account economic, environmental, legal, social, and technological factors." (Guidelines, § 15364.)

[13] According to the record, the Energy Roadmap Program "identifies energy-saving measures that can be integrated into local planning and permitting processes, ordinances, outreach and education efforts, and municipal operations."

According to the EIR, these mitigation measures encourage reduction in greenhouse gas emissions, but they do not provide a mechanism guaranteeing such reductions. Consequently, the EIR concluded the significant impacts found under the first threshold would remain significant and unavoidable.

The EIR also considered and rejected three other mitigation measures deemed infeasible. These mitigation measures were: (1) requiring all vehicles driven within the region to be zero-emission vehicles or to be powered by renewable energy; (2) requiring all future construction to be net-zero energy use; and (3) requiring all future construction activity to include only equipment retrofitted to significantly reduce greenhouse gas emissions.

3

SANDAG contends the EIR adequately addressed mitigation for the transportation plan's significant greenhouse gas emissions impacts. Given our conclusion in part II.B, *ante*, this challenge is at least partially moot as the additional analysis necessary to properly address the transportation plan's consistency with the state climate policy reflected in the Executive Order will likely require revisions to related sections of the EIR, including the EIR's discussion of mitigation measures. (*Communities for a Better Environment v. City of Richmond* (2010) 184 Cal.App.4th 70, 91 [once a lead agency recognizes an impact is significant, the agency must describe, evaluate, and adopt

feasible mitigation measures to mitigate or avoid the impact].)[14] We, nonetheless, briefly address SANDAG's contention. As this contention is predominately factual, our review is for substantial evidence. (*Vineyard, supra*, 40 Cal.4th at p. 435.)

a

"The core of an EIR is the mitigation and alternatives sections." (*Citizens of Goleta Valley v. Board of Supervisors* (1990) 52 Cal.3d 553, 564; *Watsonville Pilots Assn. v. City of Watsonville* (2010) 183 Cal.App.4th 1059, 1089.) "Section 21002 requires agencies to adopt feasible mitigation measures to substantially lessen or avoid otherwise significant adverse environmental impacts. [¶] The CEQA guidelines state that to be legally adequate mitigation measures must be capable of: '(a) Avoiding the impact altogether by not taking a certain action or parts of an action. (b) Minimizing impacts by limiting the degree or magnitude of the action and its implementation. (c) Rectifying the impact by repairing, rehabilitating, or restoring the impacted environment. (d) Reducing or eliminating the impact over time by preservation and maintenance operations during the life of the action.' [Citation.]

"For each significant effect, the EIR must identify specific mitigation measures; where several potential mitigation measures are available, each should be discussed separately, and the reasons for choosing one over the others should be stated. If the

---

14 We do not express any view on precisely how SANDAG must remedy the analytical deficiencies identified in this opinion as we recognize a court may direct SANDAG to comply with CEQA, but a court may not direct SANDAG to exercise its discretion in a particular fashion or to produce a particular result. (§ 21168.9, subd. (c); *Schellinger Brothers v. City of Sebastopol* (2009) 179 Cal.App.4th 1245, 1266.)

inclusion of a mitigation measure would itself create new significant effects, these too, must be discussed, though in less detail than required for those caused by the project itself." (*Sacramento Old City Assn. v. City Council* (1991) 229 Cal.App.3d 1011, 1027.)

For significant greenhouse gas emissions effects, feasible mitigation measures may include: "(1) Measures in an existing plan or mitigation program for the reduction of emissions that are required as part of the lead agency's decision; [¶] (2) Reductions in emissions resulting from a project through implementation of project features, project design, or other measures . . . ; [¶] (3) Off-site measures, including offsets that are not otherwise required, to mitigate a project's emissions; [¶] (4) Measures that sequester greenhouse gases; [¶] [and] (5) In the case of the adoption of a plan, such as a general plan, long range development plan, or plans for the reduction of greenhouse gas emissions, mitigation may include the identification of specific measures that may be implemented on a project-by-project basis. Mitigation may also include the incorporation of specific measures or policies found in an adopted ordinance or regulation that reduces the cumulative effect of emissions." (Guidelines, § 15126.4, subd. (c).)

b

At one extreme, the EIR in this case considered and deemed feasible three measures requiring little to no effort to implement and assuring little to no concrete steps toward emissions reduction. In addition, according to the EIR, many of the suggestions contained in these measures have already been incorporated into the transportation plan and, by implication, the transportation plan's emissions estimates. "A 'mitigation measure' is a suggestion or change that would reduce or minimize significant adverse

impacts on the environment caused by the project as proposed." (*Lincoln Place Tenants Association v. City of Los Angeles* (2007) 155 Cal.App.4th 425, 445.) A mitigation measure is not part of the project. (*Lotus v. Department of Transportation*, *supra*, 223 Cal.App.4th at p. 656 & fn. 8.) Thus, it is questionable whether these measures even qualify as mitigation measures.

At the other extreme, the EIR considered and deemed infeasible three particularly onerous measures. Each of the measures would be difficult, if not impossible, to enforce and each requires implementation resources not readily available. Unrealistic mitigation measures, similar to unrealistic project alternatives, do not contribute to a useful CEQA analysis. (See *Watsonville Pilots Assn. v. City of Watsonville*, *supra*, 183 Cal.App.4th at p. 1089; 1 Kostka & Zischke, Practice Under the Cal. Environmental Quality Act (Cont.Ed.Bar 2014) § 15.10, pp. 15-16.) As none of these measures had any probability of implementation, their inclusion in the EIR was illusory.

Missing from the EIR is what CEQA requires: a discussion of mitigation alternatives that could both substantially lessen the transportation plan's significant greenhouse gas emissions impacts and feasibly be implemented. (*Lincoln Place Tenants Association v. City of Los Angeles*, *supra*, 155 Cal.App.4th at p. 445.) A few examples of potential alternatives identified in the Climate Action Strategy include: supporting the planning and development of smart growth areas through transportation investments and other funding decisions; offering incentives for transit-oriented developments in smart growth areas; coordinating the funding of low carbon transportation with smart growth development; and encouraging parking management measures that promote walking and

transit use in smart growth areas. Given the absence of any discussion of such mitigation alternatives, we conclude there is not substantial evidence to support SANDAG's determination the EIR adequately addressed mitigation for the transportation plan's greenhouse gas emissions impacts. The error is prejudicial because it precluded informed public participation and decisionmaking. (§ 21005, subd. (a); *City of Maywood, supra*, 208 Cal.App.4th at p. 386.)

III

Cross-Appeals

A

Forfeiture

The People's and Cleveland's pleadings and briefs below challenged many aspects of the EIR in addition to the EIR's analysis and mitigation of greenhouse gas emissions impacts. In its tentative ruling, the superior court acknowledged the other challenges, but determined it could resolve the case solely on the greenhouse gas emissions impacts analysis and mitigation issues and, consequently, it did not need to address the other challenges. The People and Cleveland through their cross-appeals now seek rulings from this court on many of the other challenges. SANDAG contends they forfeited these challenges by failing to attempt to obtain rulings on them below.

Even if SANDAG's contention were correct, the application of the forfeiture rule is not automatic and we may excuse forfeiture in cases presenting "an important legal issue." (*In re S.B.* (2004) 32 Cal.4th 1287, 1293.) We are persuaded the legal issues raised in the cross-appeals are sufficiently important we should exercise our discretion to

excuse any forfeiture. Moreover, we are mindful of the Legislature's intent "that any court, which finds, or, in the process of reviewing a previous court finding, finds, that a public agency has taken an action without compliance with [CEQA], shall specifically address each of the alleged grounds for noncompliance." (§ 21005, subd. (c).)

B

Project Alternatives

1

The EIR analyzed seven project alternatives. They were:

1. A no project alternative, which assumed the transportation plan would not be adopted and only transportation improvements under construction or development would be built (Alternative 1);

2. A modified funding strategy alternative, which deleted some highway improvements, delayed other highway improvements, added some transit projects, advanced other transit projects, and increased some transit service frequencies (Alternative 2a);

3. The same modified funding strategy alternative coupled with a modified "smart growth" land use pattern, which assumed added infill and redevelopment to increase residential development density in urban and town center areas and increased employment within job centers (Alternative 2b);

4. A transit emphasis alternative, which advanced the development of some transit projects, but did not add any new transit projects (Alternative 3a);

5. The same transit emphasis alternative, but assuming the modified smart growth land use pattern (Alternative 3b);

6. An alternative implementing the transportation plan's transportation network, but assuming the modified smart growth land use pattern (Alternative 4); and

7. A slow growth alternative, which assumed the application of regulations and/or economic disincentives to slow population and employment and delayed the complete implementation of the transportation plan by five years (Alternative 5).

2

Cleveland contends the EIR fails to comply with CEQA because the EIR did not analyze a reasonable range of project alternatives. As the focus of this contention is whether the analysis was reasonable and not whether it occurred, the contention presents a predominately factual question and our review is for substantial evidence. (*Vineyard*, *supra*, 40 Cal.4th at p. 435.)

"CEQA requires that an EIR, in addition to analyzing the environmental effects of a proposed project, also consider and analyze project alternatives that would reduce adverse environmental impacts. [Citations.] The [Guidelines] state that an EIR must 'describe a range of reasonable alternatives to the project . . . which would feasibly attain most of the basic objectives of the project but would avoid or substantially lessen any of the significant effects of the project . . . .' [Citation.] An EIR need not consider every conceivable alternative to a project or alternatives that are infeasible. [Citations.] [¶] . . . [¶]

" 'There is no ironclad rule governing the nature or scope of the alternatives to be discussed other than the rule of reason.' [Citation.] The rule of reason 'requires the EIR to set forth only those alternatives necessary to permit a reasoned choice' and to 'examine in detail only the ones that the lead agency determines could feasibly attain most of the basic objectives of the project.' [Citations.] An EIR does not have to consider alternatives 'whose effect cannot be reasonably ascertained and whose implementation is remote and speculative.' " (*Bay-Delta, supra*, 43 Cal.4th at p. 1163, fn. omitted.) A court will uphold the selection of project alternatives unless the challenger demonstrates " 'that the alternatives are manifestly unreasonable and that they do not contribute to a reasonable range of alternatives.' " (*California Native Plant Society v. City of Santa Cruz* (2009) 177 Cal.App.4th 957, 988.)

In this case, the EIR's discussion of project alternatives is deficient because it does not discuss an alternative which could significantly reduce total vehicle miles traveled. Although Alternatives 3a and 3b are labeled "transit emphasis" alternatives, the labeling is a misnomer. These alternatives mainly advance certain rapid bus projects, but leave the planned rail and trolley projects largely unchanged. In addition, these alternatives do not provide any new transit projects or significant service increases. In fact, the "transit emphasis" alternatives include fewer transit projects than some of the other non-"transit-emphasis" alternatives.

The omission of an alternative which could significantly reduce total vehicle miles traveled is inexplicable given SANDAG's acknowledgment in its Climate Action Strategy that the state's efforts to reduce greenhouse gas emissions from on-road

transportation will not succeed if the amount of driving, or vehicle miles traveled, is not significantly reduced. The Climate Action Strategy explained, "Lowering vehicle miles traveled means providing high-quality opportunities to make trips by alternative means to driving alone such as walking, bicycling, ridesharing, and public transit, and by shortening vehicle trips that are made. This can be accomplished through improved land use and transportation planning and related measures, policies and investments that increase the options people have when they travel." Accordingly, the Climate Action Strategy recommended policy measures to increase and prioritize funding and system investments for public transit and transit operations, increase the level of service on existing routes and provide new public transit service through expanded investments, and improve the performance of public transit with infrastructure upgrades. Given these recommendations, their purpose, and their source, it is reasonable to expect at least one project alternative to have been focused primarily on significantly reducing vehicle trips.

Instead, it appears the project alternatives focused primarily on congestion relief. The Climate Action Strategy provides evidentiary support for the consideration of congestion relief alternatives as it notes, "Eliminating or reducing congestion can lead to more efficient travel conditions for vehicles and greenhouse gas savings." However, the transportation plan is a long-term plan and congestion relief is not necessarily an effective long-term strategy. As the Climate Action Strategy explains, "Measures to relieve congestion also may induce additional vehicle travel during uncongested periods, particularly over the long-term, which can partially or fully offset the greenhouse gas reductions achieved in the short-term from congestion relief. Induced demand

(sometimes called the rebound effect) in transportation refers to the increase in travel that can occur when the level of service on a roadway or other facility improves. Travelers sometimes respond to faster travel times and decreased costs of travel by traveling more, resulting in increased vehicle miles traveled." (Fns. omitted.) Given the acknowledged long-term drawbacks of congestion relief alternatives, there is not substantial evidence to support the EIR's exclusion of an alternative focused primarily on significantly reducing vehicle trips. The error is prejudicial because it precluded informed public participation and decisionmaking. (§ 21005, subd. (a); *City of Maywood*, *supra*, 208 Cal.App.4th at p. 386.)

C

Air Quality Impacts

1

Eleven air quality monitoring stations throughout the region measure ambient air pollutant concentrations to determine whether the region's air quality meets federal and state standards. The region does not meet the state standards for emissions of respirable particulate matter with an aerodynamic resistance diameter of 10 micrometers or less (PM_{10}) and fine particulate matter with an aerodynamic resistance diameter of 2.5 micrometers or less ($PM_{2.5}$).[15] The EIR forecasted the daily tonnage of on-road mobile emissions of PM_{10} and $PM_{2.5}$ from the transportation plan's transportation network

15 According to the EIR, "respirable" means the particulate matter can "avoid many of the human respiratory system defense mechanisms and enter deeply into the lung."

improvements would steadily and substantially increase from 2010 to 2050. The EIR did not forecast whether there would be any increase in these emissions from regional growth or land use changes associated with the transportation plan. Instead, the EIR indicated such forecasting would be done during the next tier of environmental review.

Five of the region's air quality monitoring stations also sample toxic air contaminants (TACs), which are contaminants known or suspected to cause cancer or serious health problems, but for which there are no federal or state ambient air quality standards. State law also requires facilities to report any emissions of TACs in order to quantify the amount released, the location of the release, the concentrations to which the public is exposed, and the resulting potential health risk. (Health & Saf. Code, § 44300 et seq.) In 2009, annual emissions of TACs in the region were estimated to be more than 64.9 million pounds.

According to the EIR, exposure to TACs can cause cancer and other serious health problems. This is especially true of exposure to diesel particulate matter, which is respirable (see fn. 15, *ante*). The EIR further explained, "The carcinogenic potential of TACs is a particular public health concern because many scientists currently believe that there is no 'safe' level of exposure to carcinogens. Any exposure to a carcinogen poses some risk of contracting cancer."

One of the thresholds the EIR used to determine the significance of the transportation plan's air quality impacts was whether sensitive receptors would be exposed to substantial pollutant concentrations. For purposes of this threshold, "sensitive

receptors" included children, the elderly, and communities already experiencing high levels of air pollution and related diseases.

As to PM_{10} and $PM_{2.5}$ emissions, the EIR indicated sensitive receptors could be significantly impacted if they were located near congested intersections. As to TACs, the EIR indicated TACs emitted from highway vehicles and nonroad equipment tend to impact those closest to the emission sources. The EIR explained, "[a] growing body of scientific evidence shows that living or going to school near roadways with heavy traffic volumes is associated with a number of adverse effects. These include increased respiratory symptoms, increased risk of heart and lung disease, and elevated mortality rates."

Although the EIR recognized regional growth and land use changes associated with the transportation plan had the potential to expose sensitive receptors to substantial localized pollutant concentrations, the EIR stated the level of exposure could not and would not be determined until the next tier of environmental review when facility designs of individual projects became available. The EIR made identical statements regarding proposed transportation improvements associated with the transportation plan.

The EIR summarized several studies linking proximity to heavily traveled roads and freeways to harmful health effects to children. The EIR also noted CARB had estimated the region's health risk from diesel particulate matter in 2000 was 720 excess cancer cases per million and had recommended sensitive land uses not be sited within 500 feet of a freeway, urban roads with 100,000 vehicles per day, and rural roads with 50,000 vehicles per day.

Cleveland contends the EIR's air quality impacts analysis violates CEQA because the EIR's description of existing conditions does not adequately depict the public's existing exposure to TACs. Cleveland contends the existing conditions description also fails to identify the approximate number and location of sensitive receptors near planned transportation projects. SANDAG, however, asserts its existing conditions description is sufficiently detailed for a program level EIR. As these contentions focus on the reasonableness of the EIR's analysis, they present predominately factual questions and our review is for substantial evidence. (*Vineyard, supra,* 40 Cal.4th at p. 435; accord, *Smart Rail, supra,* 57 Cal.4th at pp. 447-449; *Communities for a Better Environment v. South Coast Air Quality Management Dist.* (2010) 48 Cal.4th 310, 328.)

To fulfill its information disclosure function, "an EIR must delineate environmental conditions prevailing absent the project, defining a baseline against which predicted effects can be described and quantified." (*Smart Rail, supra,* 57 Cal.4th at p. 447; see *County of Amador v. El Dorado County Water Agency* (1999) 76 Cal.App.4th 931, 953 [without an adequate baseline description, "analysis of impacts, mitigation measures and project alternatives becomes impossible"]; Guidelines, § 15125, subd. (a).)[16] If the description of the environmental setting " 'is inaccurate, incomplete or

16 Guidelines section 15125, subdivision (a), provides: "An EIR must include a description of the physical environmental conditions in the vicinity of the project, as they exist at the time the notice of preparation is published, or if no notice of preparation is published, at the time environmental analysis is commenced, from both a local and

misleading, the EIR does not comply with CEQA. [Citation.] "Without accurate and complete information pertaining to the setting of the project and surrounding uses, it cannot be found that the [EIR] adequately investigated and discussed the environmental impacts of the development project." ' " (*Clover Valley Foundation v. City of Rocklin* (2011) 197 Cal.App.4th 200, 219.)

In this case, for TACs exposures, the record shows there was available data from monitoring stations and mandatory reports with which SANDAG could have developed a reasoned estimate of the region's existing TACs exposures. Likewise, for sensitive receptors, the record shows SANDAG has data showing current population and land use patterns and current transportation infrastructure from which it could have developed a reasoned estimate of the number and location of sensitive receptors adjacent to highways and heavily traveled roadways.

The fact more precise information may be available during the next tier of environmental review does not excuse SANDAG from providing what information it reasonably can now. (Guidelines, § 15144.) Moreover, if known impacts are not analyzed and addressed in a program EIR, they may potentially escape analysis in a later tier EIR. (§ 21166; *Citizens Against Airport Pollution v. City of San Jose, supra,* 227 Cal.App.4th at pp. 807-808; *Concerned Dublin Citizens v. City of Dublin, supra,* 214 Cal.App.4th at p. 1320; *Citizens for Responsible Equitable Environmental Development v. City of San Diego, supra,* 196 Cal.App.4th at pp. 531-532; *Fort Mojave Indian Tribe v.*

---

regional perspective. This environmental setting will normally constitute the baseline physical conditions by which a lead agency determines whether an impact is significant."

Department of Health Services, supra, 38 Cal.App.4th at p. 1605.) We, therefore, conclude there is not substantial evidence to support SANDAG's determination it could not reasonably provide additional baseline information in the EIR about TACs exposures and the location of sensitive receptors. The error is prejudicial because it precluded informed public participation and decisionmaking. (§ 21005, subd. (a); *City of Maywood, supra,* 208 Cal.App.4th at p. 386.)

3

Both the People and Cleveland contend the EIR's analysis of air quality impacts fails to comply with CEQA because it fails to correlate the transportation plan's adverse air quality impacts to resulting adverse health impacts. SANDAG again contends its disclosure efforts are adequate for the program level of environmental review and producing additional information at this level is infeasible. As with the parties' other contention, this contention is predominantly factual and our review is for substantial evidence. (*Vineyard, supra,* 40 Cal.4th at p. 435.)

"Guidelines section 15126.2, subdivision (a) requires an EIR to discuss, inter alia, 'health and safety problems caused by the physical changes' that the proposed project will precipitate." (*Bakersfield Citizens for Local Control v. City of Bakersfield* (2004) 124 Cal.App.4th 1184, 1219 (*Bakersfield Citizens*).) Accordingly, an EIR must identify and analyze the adverse health impacts likely to result from the project's air quality impacts. (*Id.,* at p. 1220; *Berkeley Keep Jets Over the Bay Com. v. Board of Port Comrs., supra,* 91 Cal.App.4th at pp. 1367-1371.)

Here, the EIR identified in a general manner the adverse health impacts that might result from the transportation plan's air quality impacts. However, the EIR failed to correlate the additional tons of annual transportation plan-related emissions to anticipated adverse health impacts from the emissions. Although the public and decision makers might infer from the EIR the transportation plan will make air quality and human health worse, at least in some respects for some people, this is not sufficient information to understand the adverse impact. (*Bakersfield Citizens, supra*, 124 Cal.App.4th at p. 1220 [EIR analysis of air quality impacts deficient where public would have no idea of the health consequences of increased air pollution].)

While SANDAG contends it is not feasible to provide more definite information at this juncture, we have not located nor has SANDAG identified any evidence in the record supporting this contention. Instead, SANDAG impermissibly relies solely on its own bald assertions of infeasibility contained in the EIR. (*City of Maywood, supra*, 208 Cal.App.4th at p. 385 [an EIR must contain facts and analysis, not just the agency's bare conclusions].) Certainly, we recognize there are limitations to the precision of a program-level analysis. SANDAG is nonetheless obliged to disclose what it reasonably can about the correlation, it has not done so, and there is not substantial evidence showing it could not do so. The error is prejudicial because it precluded informed public

participation and decisionmaking.[17] (§ 21005, subd. (a); *City of Maywood*, *supra*, at p. 386.)

4

a

To mitigate the transportation plan's air quality impacts, the EIR identified the following mitigation measures:

1. Local jurisdictions should incorporate into their land use decisions certain measures recommended by the California Attorney General for reducing greenhouse gas emissions.

2. At the next tier of environmental review, SANDAG will and other implementing agencies should incorporate certain dust control measures into project specifications for transportation network improvements.

3. At the next tier of environmental review, SANDAG will and other implementing agencies should require any heavy duty off-road vehicles used to construct transportation network improvements to utilize all feasible measures to reduce specified emissions to a less than significant level.

4. At the next tier of environmental review, SANDAG will and other implementing agencies should evaluate potential impacts from carbon monoxide, PM_{10}

---

17 Given this conclusion and its bases, we need not decide the People's conditional motion for judicial notice of examples of correlative information contained in comparable EIRs from other jurisdictions.

and $PM_{2.5}$ emissions and their health risks and, if required, add one or more recommended mitigation measures to reduce the emissions.

The EIR further concluded these were the only mitigation measures available at the program-level of environmental review.

b

Both the People and Cleveland contend these measures, except for the second, violate CEQA because they improperly defer mitigation of the transportation plan's significant air quality impacts. SANDAG once more counters these measures are adequate for the program level of environmental review.

This issue, like the issue involving the mitigation of greenhouse gas emissions impacts, is at least partially moot given our conclusion in parts III.C.2 & 3, *ante*, as the additional analysis necessary to correct the noted deficiencies will likely require revisions to related sections of the EIR, including the discussion of mitigation measures. (*Communities for a Better Environment v. City of Richmond*, *supra*, 184 Cal.App.4th at p. 91.) However, we briefly address the People's and Cleveland's contentions. As these contentions are predominantly factual, our review is for substantial evidence. (*Vineyard*, *supra*, 40 Cal.4th at p. 435.)

"An EIR shall describe feasible measures which could minimize significant adverse impacts. (Guidelines, § 15126.4, subd. (a)(1).) An EIR may not defer the formulation of mitigation measures to a future time, but mitigation measures may specify performance standards which would mitigate the project's significant effects and may be accomplished in more than one specified way. (*Id.*, subd. (a)(1)(B).)

"Thus, ' " 'for [the] kinds of impacts for which mitigation is known to be feasible, but where practical considerations prohibit devising such measures early in the planning process (e.g., at the general plan amendment or rezone stage), the agency can commit itself to eventually devising measures that will satisfy specific performance criteria articulated at the time of project approval. Where future action to carry a project forward is contingent on devising means to satisfy such criteria, the agency should be able to rely on its commitment as evidence that significant impacts will in fact be mitigated.' " ' [Citation.] Conversely, ' "[i]mpermissible deferral of mitigation measures occurs when an EIR puts off analysis or orders a report without either setting standards or demonstrating how the impact can be mitigated in the manner described in the EIR." ' " (*Preserve Wild Santee v. City of Santee* (2012) 210 Cal.App.4th 260, 280-281.)

In this case, with one exception, the EIR defers the analysis of appropriate mitigation measures. It also fails to set performance standards and commit SANDAG to complying with them. Although SANDAG contends no other mitigation is feasible at the program level of environmental review, we have not located nor has SANDAG pointed to any evidence in the record supporting this contention. Accordingly, we conclude there is not substantial evidence to support SANDAG's determination the EIR adequately addressed mitigation for the transportation plan's air quality impacts. The error is prejudicial because it precluded informed public participation and decisionmaking. (§ 21005, subd. (a); *City of Maywood*, *supra*, 208 Cal.App.4th at p. 386.)

D

Agricultural Impacts

1

The EIR evaluated the transportation plan's agricultural impacts under two significance thresholds. Under the first threshold, the EIR evaluated the impacts to land designated prime farmland, unique farmland or farmland of statewide significance under the California Resources Agency's Farmland Mapping and Monitoring Program.[18] The EIR concluded implementation of the transportation plan would result in the conversion of 3,485.09 acres of such farmland by 2050.

Under the second threshold, the EIR evaluated impacts to all land with existing agricultural uses regardless of classification, lands subject to Williamson Act contracts, and lands designated under the California Farmland Conservancy Program Act.[19] The EIR concluded implementation of the transportation plan would result in the conversion

---

18 According to the EIR, the Farmland Mapping and Monitoring Program is used to identify agricultural resources of 10-acres or more. "Farmlands are classified according to soil factors, including available water holding capacity, temperature regime, acidity, depth to the water table, electrical conductivity, flooding potential, erosion hazard, permeability, rock content, and rooting depth. The best quality land is identified as Prime Farmland and Farmland of Statewide Importance."

19 According to the EIR, "the Williamson Act [Gov. Code, § 51200 et seq.] enables local governments to enter into contracts with private landowners for the purpose of restricting specific parcels of land to agricultural or related open space use. In return, landowners receive property tax assessments that are much lower than normal because they are based upon farming and open space uses as opposed to full market value."

The California Farmland Conservancy Program Act (§ 10200 et seq.) encourages "the long-term, private stewardship of agricultural lands through the voluntary use of agricultural conservation easements."

of 7,023.07 acres of such land by 2050. The conclusion was based on data from the Farmland Mapping and Monitoring Program augmented with data from SANDAG's own geographic information system.

2

a

Cleveland contends the EIR violates CEQA by understating the transportation plan's growth-induced impacts on agricultural lands. As this contention is predominantly factual, our review is for substantial evidence. (*Vineyard*, *supra*, 40 Cal.4th at p. 435.)

As we have previously indicated, when reviewing the adequacy of an EIR's disclosures, we are chiefly concerned with whether the EIR reasonably fulfills its function of facilitating informed decisionmaking. An analysis which understates the severity of a project's impacts "impedes meaningful public discussion and skews the decisionmaker's perspective concerning the environmental consequences of the project, the necessity for mitigation measures, and the appropriateness of the project approval." (*Citizens to Pres. the Ojai v. County of Ventura* (1985) 176 Cal.App.3d 421, 431.)

In this case, both of the data sets used to analyze the transportation plan's agricultural impacts have important limitations. The Farmland Mapping and Monitoring Program does not capture information for farmland under 10 acres. In addition, according to SANDAG, its own geographic information system's inventory of agricultural land may not include any agricultural lands that went into production after the mid-1990s. The combined effect of these limitations is that there is not substantial evidence to show the EIR's analysis accounted for impacts to farmland of less than 10

acres put into production within the last 20 years. The error necessarily prejudiced informed public participation and decisionmaking because 68 percent of the farmland in the County is between one and nine acres, with the average farm size being four acres. (§ 21005, subd. (a); *City of Maywood*, *supra*, 208 Cal.App.4th at p. 386.)

While SANDAG correctly points out CEQA permits the use of data from the Farmland Mapping and Monitoring Program to analyze a project's agricultural impacts (Guidelines, Exhibit G), CEQA does not mandate the use of such data nor does it insulate an EIR from further scrutiny if the EIR relies on the data. Moreover, because the transportation plan included the sustainable communities strategy, SANDAG was required by statute to "gather and consider the best practically available scientific information regarding resource areas and farmland in the region . . . ." (Gov. Code, § 65080, subd. (b)(2)(B)(v).) By choosing a methodology with known data gaps, SANDAG produced unreliable estimates of the amount of existing farmland and, consequently, unreliable estimates of the transportation plan's impacts to existing farmland. Accordingly, SANDAG failed to comply with its statutory obligation as well as CEQA's information disclosure requirements.

b

Finally, in addition to Cleveland's general contention that the EIR understated the transportation plan's agricultural impacts, Cleveland raises two specific contentions: (1) the EIR failed to disclose and analyze the transportation plan's impacts to small farms; and (2) the EIR's discussion of impacts to agricultural land from growth inaccurately assumed land converted to a rural residential designation would remain farmland.

SANDAG counters Cleveland is precluded under section 21177, subdivision (a), from raising these two specific contentions because Cleveland never exhausted its administrative remedies as to them.[20] Except to the extent the specific contentions are subsumed within the general contention, we agree.

"A CEQA challenge is not preserved 'unless the alleged grounds for noncompliance with [CEQA] were presented to the public agency orally or in writing by any person during the public comment period provided by this division or prior to the close of the public hearing . . . .' [Citation.] 'Exhaustion of administrative remedies is a jurisdictional prerequisite to maintenance of a CEQA action.' [Citation.]

" 'To advance the exhaustion doctrine's purpose "[t]he 'exact issue' must have been presented to the administrative agency . . . ." [Citation.] While " 'less specificity is required to preserve an issue for appeal in an administrative proceeding than in a judicial proceeding' because, . . . parties in such proceedings generally are not represented by counsel . . . ' [citation]" [citation], "generalized environmental comments at public hearings," "relatively . . . bland and general references to environmental matters" [citation], or "isolated and unelaborated comment[s]" [citation] will not suffice. The same is true for " '[g]eneral objections to project approval . . . .' [Citations.]" [Citation.]

---

20 Section 21177, subdivision (a), provides: "An action or proceeding shall not be brought pursuant to Section 21167 unless the alleged grounds for noncompliance with this division were presented to the public agency orally or in writing by any person during the public comment period provided by this division or prior to the close of the public hearing on the project before the issuance of the notice of determination."

" '[T]he objections must be sufficiently specific so that the agency has the opportunity to evaluate and respond to them.' " ' [Citation.]

" ' "The petitioner bears the burden of demonstrating that the issues raised in the judicial proceeding were first raised at the administrative level. [Citation.]" [Citation.] An appellate court employs a de novo standard of review when determining whether the exhaustion of administrative remedies doctrine applies.' " (*Citizens for Responsible Equitable Environmental Development v. City of San Diego*, *supra*, 196 Cal.App.4th at p. 527.)

Cleveland has not met its burden in this case. Before SANDAG approved the EIR, Cleveland submitted a letter commenting on the EIR's analysis of agricultural impacts from growth as follows: "[T]he [EIR] states that approximately 10,500[21] acres of agricultural land will be impacted due to regional growth and land use change by the year 2050. [Citations.] The [EIR] also acknowledges that its regional growth projections are based on current planning assumptions for San Diego County and the jurisdictions therein. [Citation.] However, the EIR for the County's current General Plan update, which by definition reflects current planning assumptions (as of 2011), shows that the General Plan expects *55,963* acres of agricultural land to convert to non-agricultural uses by the year 2030. [Citation.] Even though they account for conditions expected to exist 20 years sooner, these impacts are more than five times greater than the impacts identified in the [transportation plan's EIR].

---

21 This figure apparently represents the combined total of the impacts identified under both significance thresholds (see part III.D.1, *ante*).

"It is not clear how the [EIR] could use current planning assumptions for growth and determine that there will be only 10,500 acres of agricultural land impacted, when the current plans on which it bases its assumptions assume there will be more than five times as many acres impacted. SANDAG must explain if there is a basis for this discrepancy. Without any such explanation, the [EIR] appears to severely underestimate the amount of agricultural land that will be impacted, in contravention of CEQA. [¶] In sum, the [EIR's] failure to accurately account for impacts to agricultural land renders it inadequate as a matter of law."

Even read liberally, Cleveland's comment letter did not fairly apprise SANDAG that Cleveland had specific concerns about the EIR's handling of impacts to small farms and lands redesignated rural residential. Instead, Cleveland's comment letter focused on the discrepancy between SANDAG's estimate of overall growth-induced impacts and the County's estimate of overall growth-induced impacts. Cleveland cites to no other place in the record where any other person or organization raised specific concerns about the EIR's handling of impacts to small farms and lands designated rural residential. Consequently, Cleveland has not demonstrated exhaustion of administrative remedies as to these concerns.

DISPOSITION

The matter is remanded to the superior court with directions to modify the judgment and writ of mandate to incorporate our decision on the cross-appeals. The judgment is affirmed as so modified. The People and Cleveland are awarded their appeal and cross-appeal costs.

MCCONNELL, P. J.

I CONCUR:

IRION, J.

BENKE, J., Dissenting.

My colleagues and I have vastly different views on the extent to which this court can and should control environmental review of the planning decisions of a regional transportation agency such as the San Diego Association of Governments (SANDAG). Where the majority, as a result of the alleged inadequacy of the environmental impact report's (EIR) analysis of greenhouse gas (GHG) impacts, would strike down the EIR implementing SANDAG's regional transportation plan (RTP) calling for investment of about $214 billion over the next several decades in the San Diego region, I would not. Where the majority purports to enforce the California Environmental Quality Act (CEQA) and its Guidelines,[1] I believe my colleagues weaken and confuse the law. Thus, although I conclude that substantial evidence supports the finding SANDAG's GHG impacts analysis is CEQA-compliant, I preface that substantial evidence analysis with the following observations and concerns.

In order to understand the full impact of my colleagues' decision regarding the adequacy of SANDAG's assessment of the GHG impacts of the project, it is first necessary to define a "threshold of significance." CEQA requires "[a]ll public agencies . . . adopt by ordinance, resolution, rule, or regulation, objectives, criteria, and procedures for the evaluation of projects and the preparation of environmental impact reports." (Pub. Resources Code, § 21082.)[2] Such "objectives, criteria, and procedures" are also known

---

1 Citations to "Guidelines" refer to California Code of Regulations, title 14, section 15000 et seq., which are the guidelines for the application of CEQA. (Cal. Code Regs., tit. 14, §§ 15000, 15001.)

2 All further statutory citations refer to the Public Resources Code unless otherwise indicated.

as "thresholds of significance" and are used by an agency as a benchmark in determining the significance of environmental effects of a project. (Guidelines, § 15064.7, subd. (a).) A threshold of significance for GHG impacts *may* be accompanied by a plan to achieve the reduction or mitigation of GHG emissions, but the plan *must* be adopted through a public review process. (Guidelines, § 15064.4, subd. (b)(3).)

Executive Order No. S-3-05, signed in 2005 by then Governor Arnold Schwarzenegger (Executive Order), does not unilaterally qualify as a threshold of significance. To reach this conclusion, one need go no further than our Supreme Court's opinion of *Professional Engineers in California Government v. Schwarzenegger* (2010) 50 Cal.4th 989 (*Professional Engineers*). In *Professional Engineers*, the court concluded that an executive order, which attempted to implement a mandatory furlough program during our state's fiscal crisis, had no foundation in the state constitution or existing statutes. In particular, the court noted "the Governor fails to cite any judicial decision or other supporting authority holding or suggesting that the power under the California Constitution to establish or revise the terms and conditions of state employment, even in a fiscal emergency, resides in the Governor (or any other executive officer or entity) rather than in the Legislature. To the contrary, the following is well established: (1) Under the California Constitution it is *the Legislature*, rather than the Governor, that generally possesses the ultimate authority to establish or revise the terms and conditions of state employment through legislative enactments, and (2) any authority that the Governor or an executive branch entity . . . is entitled to exercise in this area emanates from the Legislature's delegation of a portion of its legislative authority to such executive officials or entities through statutory enactments." (*Id.* at p. 1015.)

The court in *Professional Engineers* likewise rejected the Governor's argument that his power to impose a mandatory work furlough program through an executive order was supported by statutes, including several specific statutory provisions. Among the factors noted contrary to this position, the court recognized that "the Legislature has demonstrated a special interest in retaining . . . [the] ultimate control over the salary and wages of such employees." (*Professional Engineers*, *supra*, 50 Cal.4th at p. 1024.) The court held that the mandatory furlough program was valid *only* because the Legislature, "*through the exercise of its own legislative prerogative*," independently adopted the program. (*Id.* at p. 1047.)

Similarly, the Executive Order at issue in this case, which includes *statewide* GHG reduction targets for 2020, 2035 and 2050, was at its inception merely a broad policy statement of goals issued by the Governor. Like the order at issue in *Professional Engineers*, it too does not have an identifiable foundation in the constitutional power of the Governor or in statutory law.

The majority cites no judicial decision or other supporting authority holding or even suggesting that the power to establish thresholds of significance, qualitative or quantitative, resides in the Governor rather than in the Legislature. Nor is there any authority supporting the view that the Legislature has delegated to the Governor any power to enact or establish thresholds of significance, including with respect to GHG at issue in this case.

To the contrary, as I discuss, the Legislature has clearly demonstrated it intends to retain ultimate control over the regulation of environmental planning. It has vested in the California Air Resources Board (CARB) the responsibility for coordinating efforts to

attain and maintain ambient air quality standards, to conduct research into the causes of and solution to air pollution, and systematically attack the serious problem caused by motor vehicles. (Health & Saf. Code, § 39003.) It also has limited by statute the ability of courts to add substantive or procedural requirements to CEQA provisions. (Pub. Resources Code, § 21083.)

The majority is either unable or unwilling to expressly declare its position on whether the Executive Order is a threshold of significance as that term is employed in CEQA analysis. I sympathize with their apparent uneasiness. If the majority declares the Executive Order *is* a threshold of significance, it is faced with the reality that the Executive Order simply does not meet the requirements necessary to have attained that status. If it expressly acknowledges that the Executive Order is *not* a threshold of significance, then it must also acknowledge that SANDAG is quite correct that it was not required to employ it as a CEQA measuring stick in assessing compliance.

My colleagues attempt to avoid the dilemma altogether. They offer that the *policy* underlying the Executive Order is of such overarching importance that it *must* be included within the significance factors listed in Guidelines section 15064.4, subdivision (b), and, therefore, SANDAG was *required* to consider that policy in what they euphemistically refer to as a "consistency analysis" involving the GHG impacts of its project and the Executive Order. Because SANDAG failed to provide such a policy analysis in its EIR, my colleagues conclude SANDAG abused its discretion. By this exercise in linguistics, the majority in contravention of *Professional Engineers* has elevated the Executive Order to the status of a threshold of significance without ever having to expressly declare they are doing so. Its action is judicial fiat, pure and simple.

The majority seeks support for its new formulation of the law by noting that important legislation has sprung from the Executive Order, and they offer that the Executive Order will continue to be the springboard for legislative action. Relying on *Professional Engineers*, the majority also concludes the policy underlying the Executive Order has been "ratified" by subsequent legislation. (Maj. opn. *ante*, at p. 14.) If, by this reasoning, the majority implies that subsequent environmental legislation somehow bestowed on the Executive Order a power it did not have, I believe it is mistaken. As *Profession Engineers* recognizes, our Legislature acts independently. As I discuss, the fact that the Legislature has enacted environmental legislation in recognition of the Executive Order's goals does not bestow on the Executive Order any more power than it had before the Legislature acted.

Moreover, although the Legislature has exercised its own independent prerogative by tasking CARB with adopting regional GHG reduction targets for 2020 and 2035, it has not done so for 2050. As I also discuss, the Legislature is currently considering a comprehensive and complex plan for 2050 that tasks the CARB to establish regional targets. It is possible the Legislature may alter the Executive Order's 2050 goals or reject them altogether. Using the majority's own logic, the Legislature has not ratified the Executive Order's qualitative or quantitative goals for 2050.

It is true, of course, that *qualitative* thresholds of significance are acceptable in assessing significance. (See Guidelines, § 15064.7, subd. (a).) However, qualitatively addressing the policy and sciences underlying the Executive Order—if this in fact is what the majority means by a "consistency analysis"—adds little if any meaning to the discussion of the significance of GHG impacts. SANDAG considered in its EIR the

important public policy of GHG emissions reduction in implementing its project. It acknowledged the Executive Order and its goals. It concluded the 2050 goal in that order was not at this time applicable. The purpose of remand is therefore unclear to me if the majority merely requires additional, undefined consideration of the qualitative aspects of the Executive Order.

Quantitatively speaking, as noted, SANDAG in its EIR considered, but did not use, the 2050 GHG reduction targets set forth in the Executive Order. Until the Legislature independently acts and tasks the CARB with adopting regional 2050 GHG emissions reduction targets, SANDAG in my view was not required to consider in its EIR the broad 2050 statewide goals set forth in the Executive Order. (See *Professional Engineers*, *supra*, 50 Cal.4th at p. 1047.)

The majority states that it is not requiring SANDAG's project to "*achieve* the Executive Order's 2050 goal or any other specific numerical goal" in undertaking the now-required "consistency analysis." (Maj. opn. *ante*, at p. 15, fn. 6.) This comes as little surprise, inasmuch as an EIR is merely an "informational document." (See Guidelines, § 15003, subd. (i).)

Nonetheless, whether qualitative or quantitative, it is not clear to me how, in assessing the significance of GHG impacts of the project—including for 2050—a lead agency is supposed to adopt from the Executive Order *regional* GHG emissions reduction targets. The majority appears to answer this question by stating SANDAG can determine its "share" of GHG emissions reduction responsibility from theoretical targets. With respect to SANDAG's share of responsibility, it is important to emphasize what the majority has not acknowledged: SANDAG is responsible only for its "*fair* share" when

assessing significance. Establishing an agency's "*fair* share" is a complex and science-based process. It begins by recognizing that the level of GHG emissions is a statewide problem encompassing a diverse array of emitters. Included in the array is not only transportation but also, for example, land use and development, agriculture, electricity generation, forestry, and industrial sectors. The analysis of GHG impacts thus involves emissions across sectors both within SANDAG's planning discretion (i.e., transportation and land use) and outside SANDAG's planning discretion (i.e., heavy industry). SANDAG is not empowered or equipped to offer and use analyses in statewide sectors over which it has no control.

The point is SANDAG, unlike the CARB, is a *regional* and not a state agency. Without a model addressing *regional* GHG emissions reduction targets between 2035 and 2050, it is impossible for SANDAG in its RTP to conduct a "consistency analysis" for these years of study.

As the lack of substance in the now-required "consistency analysis" attests, there is little to say except that, in the world of GHG emissions, "more of them are bad and less is good." It is a reasonable conclusion here that the SANDAG Board of Directors, comprised of locally elected officials from San Diego County and the 18 cities in the region, are already well aware of this. The EIR in any event recognizes the important policy goal of reducing GHG emissions.

As I discuss, there is legislation currently pending tasking the CARB with setting state and regional targets for 2050. This pending legislation further demonstrates my point that the Legislature has not yet independently adopted the Executive Order's 2050 statewide GHG emissions reduction goals. Once the CARB sets these regional targets,

which incidentally, may be different than the Executive Order's statewide goal, SANDAG and the other 18 metropolitan planning agencies (MPO's) throughout the state can then use them to determine their "*fair* share" of GHG emissions in analyzing the significance of GHG impacts of their projects. I fear the majority's demand that SANDAG "do more" *now* based on mere policy goals and/or theoretical targets, and without providing any guidance as to what more should be done, will in effect require SANDAG to set unilaterally 2050 regional GHG reduction targets in order to try to satisfy, somehow, the majority's "consistency analysis." In doing so, it may take action that ultimately conflicts with requirements set by CARB.

Perhaps the most profound harm arising from the majority's finesse of CEQA is the lasting damage it does to Guidelines section 15064.4. This section gives a lead agency substantial discretion to determine both the amount of GHG emissions from a project and whether such emissions are significant. Subdivision (b) of Guidelines section 15064.4 in particular states that in assessing GHG impacts, the lead agency *should* consider three factors, *among others*. One such factor expressly gives a *lead agency* the discretion to determine the thresholds of significance that should apply to its project in determining significance. (Guidelines, § 15064.4, subd. (b)(2).) To the extent thresholds of significance *other* than the three expressly provided in subdivision (b) apply, that should be a determination made by an agency in the proper exercise of its discretion.

It is apparent to me that identifying and selecting thresholds of significance is not a judicial function. Despite the clear language of Guidelines section 15064.4, subdivision (b) and the obvious intent of that section, the majority asserts a right to determine that a gubernatorial policy statement, which does not qualify as a threshold of significance, is to

be included among the "other factors" and then *orders* SANDAG on remand to develop an undefined "consistency analysis" between the lead agency's plan and the policy statement.

This insinuation of judicial power into the environmental planning process and usurping of legislative prerogative is breathtaking. Now we, the courts, without institutional planning expertise or knowledge, get to tell a lead agency what it must use as a threshold of significance. As a consequence of not being prescient enough to know what a court might select, the EIR's of projects such as this RTP, which, as noted, calls for investment of about $214 billion in the San Diego region over the next few decades, are invalidated and sent back to the lead agency to anticipate what we, the court, might next decide is or has become of such critical policy significance that the agency must use it as a threshold of significance. There is no legal support for our action, which strips lead agencies of the discretion vested in them by the Legislature and reposes that discretion in the courts. To be clear, I do not believe our action expands Guidelines section 15064.4; instead, I believe it destroys the integrity of that section. (See Maj. opn. *ante*, at p. 20, fn. 9.)

The mischief caused by the majority would not be confined to the SANDAG region. The majority would have each of our states' six appellate districts, and multiple divisions within many of them, instructing the 18 MPO's regarding whether a "consistency analysis" is required based on, for example, the Executive Order, and, if so, what it should contain. It does not take much energy to foresee the permutations possible as each MPO receives judicial instruction. Chaos in environmental planning comes to mind.

The Legislature, in its wisdom, has foreseen the kind of damage we do today, and it has taken steps to forbid such judicial interference. First, the Legislature vested one agency, CARB, with creating the targets and metrics in assessing, and ultimately reducing, GHG emissions regionally and statewide. (Health & Saf. Code, § 39003.) Second, it has, in CEQA itself, expressly prevented courts from selecting what "other factors" an agency should consider in assessing significance of GHG impacts.

Indeed, section 21083.1 provides the legislative intent underlying CEQA and the interpretation of its statutes and guidelines by our courts: "It is the intent of the Legislature that courts, consistent with generally accepted rules of statutory interpretation, shall not interpret this division or the state guidelines adopted pursuant to Section 21083 in a manner which imposes procedural or substantive requirements beyond those explicitly stated in this division or in the state guidelines." Judicial imposition of significance thresholds does precisely what the statute prohibits.

As I discuss in more detail *post*, I conclude substantial evidence in the record shows SANDAG made a good faith and reasonable effort to analyze in its EIR the GHG impacts of its project. In its 39-page GHG impacts analysis, SANDAG, as noted, analyzed the targets set by the CARB for 2020 and 2035 under three thresholds of significance, in compliance with Guidelines section 15064.4. I thus would *reverse* the trial court's order finding SANDAG's GHG impacts analysis of the project was inadequate, including because SANDAG did not address the 2050 GHG *statewide* reduction goals set forth in the Executive Order.

As to the cross-appeal, because the trial court declined to reach those issues and because the majority in any event is remanding the matter with respect to the EIR's

treatment of GHG impacts and mitigation measures of the project, I would defer the issues raised in the cross-appeal to the trial court for consideration in the first instance. I do, however, note that our instructions on remand include what appears to be a directive that SANDAG consider further analysis of mass transportation. This directive, coupled with the vague requirement of a "consistency analysis," leaves me with an uncomfortable feeling that some might believe that, in sending this case back, we are *sub rosa* directing SANDAG to shift the emphasis in its plan to mass transportation. If that is a direction in which we inadvertently venture, I would only comment that it is not a journey we are empowered or equipped to undertake.

DISCUSSION

I

GHG Impacts

A. *Regulation of GHG by the CARB*

On June 1, 2005, at the United Nations World Environment Day in San Francisco, Governor Schwarzenegger signed the Executive Order in front of hundreds of international leaders. The Governor told his invited guests, which included mayors from more than 70 cities from around the world, that the "debate" over global warming from GHG emissions was "over." (Marshall, *Schwarzenegger Issues Plan to Reduce Greenhouse Gases* (June 2, 2005) N.Y. Times <http://www.nytimes.com/2005/06/02/national/02arnold.html?_r=0> [as of November 2014].)

The Executive Order established the following *statewide* reduction targets for greenhouse gas emissions: by 2010, to 2000 levels; by 2020, to 1990 levels; and by 2050, to 80 percent below 1990 levels. It also directed the California Environmental Protection

Agency (Cal-EPA) to develop strategies to meet these targets. In response, the "Climate Action Team," comprised of representatives from various agencies and commissions including the Cal-EPA and the CARB, was created. (See *Rialto Citizens for Responsible Growth v. City of Rialto* (2012) 208 Cal.App.4th 899, 938; see also Comment, *Quantifying an Uncertain Future: The Demands of the California Environmental Quality Act and the Challenge of Climate Change Analysis* (2012) McGeorge L.Rev. 1065, 1068-1069.)

Although the Executive Order provided the "power" for its issuance was derived from "the Constitution and statutes of the State of California," that order did *not* identify any article, section and/or statute as the source of this alleged authority. In any event, as noted, I do not believe our Constitution, including article V, vested the Governor with the authority to singlehandedly issue and enforce the Executive Order. (See, i.e., *Professional Engineers*, *supra*, 50 Cal.4th at p. 1015 [rejecting the argument the governor had the unilateral authority to implement a mandatory furlough program].) I also do not believe that our Legislature expressly granted that authority to the Governor. (See *id.* at p. 1000.) Therefore, I believe the GHG statewide emission reduction targets set forth in the Executive Order are nothing more than mere policy recommendations unless and until our Legislature independently acts to adopt such targets, which, as I explain, it has done for 2020 and 2035, but not for 2050. (See *ibid.*)

The Executive Order was by no means the first attempt in our state to address GHG emissions. In 2002, our Legislature passed a law regulating GHG vehicle emissions. (See Stats. 2002, ch. 200, enacting Assem. Bill No. 1493 (2001-2002 Reg. Sess.) (AB 1493).) Under this law, the CARB was required to develop and adopt, by

January 1, 2005, "regulations that achieve the maximum feasible and cost-effective reduction of greenhouse gas emissions from motor vehicles." (Health & Saf. Code, § 43018.5, subd. (a).) In enacting this law, our Legislature noted that the "control and reduction of emissions of greenhouse gases are critical to slow the effects of global warming." (Stats. 2002, ch. 200, § 1(c).) Thus, AB 1493 shows that our state policy of reducing GHG emissions did *not* originate with the 2005 Executive Order, as the majority appears to suggest, but rather was in existence before the Executive Order was issued.[3]

The California Global Warming Solutions Act of 2006 (Health & Saf. Code, § 38500 et seq., added by Stats. 2006, ch. 488, § 1, enacting Assem. Bill No. 32 (AB 32)) implemented the 2020 reduction target set forth in the Executive Order. (See Health & Saf. Code, § 38550; see also *Rialto Citizens for Responsible Growth v. City of Rialto*, *supra*, 208 Cal.App.4th at p. 939.) AB 32 directed the CARB to develop a "scoping plan . . . for achieving the maximum technologically feasible and cost-effective reductions in greenhouse gas emissions from sources or categories of sources of greenhouse gases . . . ." (Health & Saf. Code, § 38561, subd. (a); see Health & Saf. Code, § 38562, subd. (a) [requiring the CARB to "adopt greenhouse gas emission limits and emission reduction measures by regulation . . . to become operative beginning on January 1, 2012"]; see also *Association of Irritated Residents v. State Air Resources Bd.* (2012) 206 Cal.App.4th 1487, 1490 [noting AB 32 designated the CARB as '"the state agency

---

3 Our Legislature as early as 1975 tasked the CARB with the responsibility of "coordinating efforts to attain and maintain ambient air quality standards, to conduct research into the causes of and solution to air pollution, and to systematically attack the serious problem caused by motor vehicles, which is the major source of air pollution in many areas of the state." (Health & Saf. Code, § 39003.)

charged with monitoring and regulating sources of emissions of greenhouse gases that cause global warming in order to reduce emissions of greenhouse gases' . . . and imposes numerous directives and timelines on the [CARB]"].)

To assist an agency in its analysis of GHG emissions in CEQA review, our Legislature in 2007 enacted, among other provisions, section 21083.05 (added by Stats. 2007, ch. 185, § 1, enacting Sen. Bill No. 97 (SB 97)).[4] SB 97 directed the Office of Planning and Research (OPR) to prepare and submit to the Natural Resources Agency (NRA) "guidelines for the mitigation of greenhouse gas emissions or the effects of greenhouse gas emissions . . . including, but not limited to, effects associated with transportation or energy consumption." (Former § 21083.05, subd. (a).) SB 97 further provided that the OPR and NRA "shall periodically update the guidelines to incorporate new information or criteria" established by the CARB pursuant to AB 32. (*Id.*, subd. (c).)

The NRA adopted regulations on the significance of GHG emissions for CEQA, which were then incorporated into the CEQA Guidelines including, as perhaps most relevant here, Guidelines section 15064.4, discussed *post*.[5]

In 2008, our Legislature passed the Sustainable Communities and Climate Protection Act of 2008 (Sen. Bill No. 375 (2007-2008 Reg. Sess.)). As the majority recognizes, SB 375 supports the state's climate action goals to reduce GHG emissions through coordinated transportation and land use planning. Under SB 375, the CARB—

---

4 SB 97 was amended effective January 1, 2013. (Stats. 2012, ch. 548, § 5.)

5 "In interpreting CEQA, we accord the Guidelines great weight except where they are clearly unauthorized or erroneous." (*Vineyard Area Citizens for Responsible Growth, Inc. v. City of Rancho Cordova* (2007) 40 Cal.4th 412, 428, fn. 5.)

once again—was directed to provide each region by no later than September 30, 2010 with GHG emission "reduction targets for the automobile and light truck sector for 2020 and 2035, respectively." (Gov. Code, § 65080, subd. (b)(2)(A).) Once these targets were established by the CARB, each of the state's MPO's was required to prepare under Government Code former section 65080, subdivision (b)(2) a "sustainable communities strategy" (SCS) as part of the MPO's RTP. (See Gov. Code, former § 65080, subd. (b)(2).)[6]

In developing the SCS, SB 375 required each MPO to "conduct at least two informational meetings . . . within the region for members of the board of supervisors and city councils" on the SCS. (Gov. Code, § 65080, subd. (b)(2)(E).) The purpose of the meetings was to "discuss the [SCS] . . . , including the key land use and planning assumptions to the members of the board of supervisors and the city council members in that county and to solicit and consider their input and recommendations." The SCS, if and when implemented, would allow the MPO to reach the GHG reduction targets established by the CARB. If those targets were unmet, the MPO would be required to prepare an alternative planning strategy to the SCS. (Gov. Code, § 65080, subd. (b)(2)(E).)

As *the* agency responsible for "target-setting" GHG emissions reductions, the CARB in 2010 created reduction targets for SANDAG's MPO region for 2020 and 2035.

---

6 Government Code section 65080 was amended effective January 1, 2010 (Stats. 2009, ch. 354, § 1) and again effective January 1, 2011 (Stats. 2010, ch. 328, § 95). The requirement of an SCS as part of an MPO's RTP remains in the current version of Government Code section 65080, subdivision (b).

SANDAG used these targets in addressing in its EIR the GHG impacts of the project. However, as SANDAG properly recognized in its EIR impact analysis, the CARB has not yet set 2050 GHG emissions reduction targets for the MPO's. As noted and as I discuss, there is legislation currently pending, Assembly Bill No. 2050 (AB 2050), that would require the CARB to do so.[7]

Thus, our Legislature has recognized the strong public policy of GHG emissions reductions in our state and has fully occupied this enormously complex field by delegating the "target-setting responsibility" of such reductions to the CARB through a series of comprehensive legislative enactments, including in AB 32, SB 97 and SB 375.[8]

---

7 According to a recent summary prepared by the Senate Appropriations Committee, AB 2050 would amend SB 32 by requiring "the California Air Resources Board (CARB) to develop greenhouse gas (GHG) emissions reductions goals for 2050, including intermediate goals, and to perform a number of analyses of the strategies that would be required to reach those goals" for purposes of the next scoping plan update. (Sen. Appropriations. Com., analysis of Assem. Bill No. 2050 (2013-2014 Reg. Sess.) p. 1.)

8 This list is not exhaustive. For example, in 2010 legislation was enacted requiring the Department of Transportation to update the federally mandated California Transportation Plan (CTP) by December 31, 2015 and every five years thereafter. (Gov. Code, §§ 65070, subd. (a) & 65071.) The CTP requires identification of a "statewide integrated multimodal transportation system" that includes among other requirements the incorporation of all SCS and/or alternate planning strategies required by SB 375. (Gov. Code, § 65072.2) "In developing the [CTP] . . . , the department shall address how the state will achieve maximum feasible emissions reductions in order to attain a statewide reduction of [GHG] emissions to 1990 levels by 2020 as required by [AB 32] and 80 percent below 1990 levels by 2050." (*Ibid.*) The CTP must include: "(a) A policy element that describes the state's transportation policies and system performance objectives. These policies and objectives shall be consistent with legislative intent described in Sections 14000, 14000.5, 14000.6, and 65088. [¶] (b) A strategies element that shall incorporate the broad system concepts and strategies synthesized from the adopted regional transportation plans prepared pursuant to Section 65080. The California Transportation Plan shall not be project specific. [¶] (c) A recommendation element that includes economic forecasts and recommendations to the Legislature and the Governor to

The CARB in response has then set reduction targets for each of the 18 MPO's in our state.

Against this backdrop, I disagree with the majority's conclusion that SANDAG acted unreasonably in refusing to engage in a "consistency analysis" using the Executive Order as a CEQA measuring stick when accessing the GHG impacts of its regional project. (See *Professional Engineers, supra*, 50 Cal.4th at p. 1000.) Instead, in my view, the record contains more than sufficient evidence showing SANDAG acted in good faith and properly exercised its broad discretion under Guidelines section 15064.4 in assessing the significance of GHG impacts of the project.

---

achieve the plan's broad system concepts, strategies, and performance objectives." (*Id.*, § 65072.) The Legislature in the CTP directly (*id.*, § 14000.6, subd. (b)) and indirectly (*id.*, § 65072.2) referenced the Executive Order and its goal of reducing GHG emissions to 80 percent of 1990 levels by 2050. However, as noted, the Legislature has not yet tasked the CARB to set 2050 GHG regional reduction targets for the MPO's.

B. *Guidelines Section 15064.4*[9]

As noted, CEQA requires that public agencies "adopt by ordinance, resolution, rule, or regulation" criteria for the evaluation of a project and the preparation of an EIR that are consistent with the statutory provisions of CEQA and its Guidelines. (§ 21082.)

Section 21083, subdivision (a) directs the OPR to "prepare and develop proposed guidelines" for implementation by a public agency. Subdivision (b) of that statute states the "guidelines shall specifically include criteria for public agencies to follow in determining whether or not a proposed project may have a 'significant effect on the environment.'" As noted *ante*, section 21083.5 was added by SB 97 to require the OPR to

---

9 Guideline section 15064.4 provides: "(a) The determination of the significance of greenhouse gas emissions calls for a careful judgment by the lead agency consistent with the provisions in section 15064. A lead agency should make a good-faith effort, based to the extent possible on scientific and factual data, to describe, calculate or estimate the amount of greenhouse gas emissions resulting from a project. A lead agency shall have discretion to determine, in the context of a particular project, whether to: [¶] (1) Use a model or methodology to quantify greenhouse gas emissions resulting from a project, and which model or methodology to use. The lead agency has discretion to select the model or methodology it considers most appropriate provided it supports its decision with substantial evidence. The lead agency should explain the limitations of the particular model or methodology selected for use; and/or [¶] (2) Rely on a qualitative analysis or performance based standards. [¶] (b) A lead agency should consider the following factors, among others, when assessing the significance of impacts from greenhouse gas emissions on the environment: [¶] (1) The extent to which the project may increase or reduce greenhouse gas emissions as compared to the existing environmental setting; [¶] (2) Whether the project emissions exceed a threshold of significance that the lead agency determines applies to the project. [¶] (3) The extent to which the project complies with regulations or requirements adopted to implement a statewide, regional, or local plan for the reduction or mitigation of greenhouse gas emissions. Such requirements must be adopted by the relevant public agency through a public review process and must reduce or mitigate the project's incremental contribution of greenhouse gas emissions. If there is substantial evidence that the possible effects of a particular project are still cumulatively considerable notwithstanding compliance with the adopted regulations or requirements, an EIR must be prepared for the project."

prepare specific guidelines dealing with CEQA review of GHG.

Adopted after passage of SB 97, Guidelines section 15064.4, subdivision (a) requires a lead agency to make a "good-faith effort" to determine the GHG emissions of a project. In making this determination, a lead agency has the discretion to "[u]se a model or methodology to quantify greenhouse gas emissions resulting from a project, and which model or methodology to use" (Guidelines, § 15064.4, subd. (a)(1)) and/or to "[r]ely on a qualitative analysis or performance based standards" (*id.*, subd. (a)(2)). After choosing a methodology and selecting significance thresholds, the lead agency next is required under Guidelines section 15064.4 to assess the "significance of impacts" of GHG emissions. (*Id.*, subd. (b).)

In assessing the significance of GHG impacts of a given project, Guidelines section 15064.4 states a lead agency "should" consider among others the following factors: (1) the extent to which the project may increase or reduce GHG "as compared to the existing environmental setting"; (2) whether the project's GHG emissions "exceed a threshold of significance that the *lead agency determines* applies to the project"; and (3) the extent to which the project "complies with regulations or requirements adopted to implement a statewide, regional, or local plan for the reduction or mitigation" of GHG. (Guidelines, § 15064.4, subd. (b)(1), (2) & (3), italics added.) Subdivision (b)(3) of Guidelines section 15064.4 further provides that "[s]uch requirements must be adopted by the relevant public agency through a public review process and must reduce or mitigate the project's incremental contribution of greenhouse gas emissions."

Guidelines section 15064.4 thus "'confirms that lead agencies retain the discretion to determine the significance of greenhouse gas emissions and should "make a good-faith

effort, based to the extent possible on scientific and factual data, to describe, calculate or estimate the amount of [GHG] emissions resulting from a project." [Citation.]' [Citations.]" (*Citizens Against Airport Pollution v. City of San Jose* (2014) 227 Cal.App.4th 788, 807.)

I therefore disagree with the majority's interpretation of Guidelines section 15064.4: although subdivision (b) of this section clearly states the factors listed in subdivisions (1), (2) and (3) are not exhaustive, that does not ipso facto mean the courts may require an agency to consider additional "factors" (i.e., the Executive Order) in evaluating the GHG impacts of a project, as the majority has done here. In my view, the majority's reading of Guidelines section 15064.4 usurps the broad discretion afforded an agency in analyzing significance and improperly puts courts in charge of determining whether benchmarks other than those expressly provided in subdivisions (1), (2) and (3) must be considered by an agency when undertaking such an analysis.

Here, as I have noted, the EIR used three separate GHG analyses utilizing two of the specific significance criteria authorized by Guidelines section 15064.4. GHG-1, the first analysis, is an "existing conditions" baseline analysis authorized by subdivision (b)(1) of Guidelines section 15064.4.[10] Under this analysis, any increase of GHG emissions over existing conditions (i.e., 2010) was deemed to be a significant impact.

---

10 I note the existing environmental setting "normally constitute[s] the baseline physical conditions by which a lead agency determines whether an impact is significant." (Guidelines, § 15125, subd. (a); see *Neighbors for Smart Rail v. Exposition Metro Line Construction Authority* (2013) 57 Cal.4th 439, 445 [holding that "[w]hile an agency has the discretion under some circumstances to omit environmental analysis of impacts on existing conditions and instead use only a baseline of projected future conditions, existing conditions 'will normally constitute the baseline physical conditions by which a lead agency determines whether an impact is significant'"].)

The GHG-1 analysis concluded that, although regional GHG emissions would decrease under the project from existing levels until after 2020, they would increase above existing levels by 2035 and increase still further by 2050, largely as a result of population increase and development. The EIR therefore determined the GHG impacts in 2020 would be a less than significant impact but would be significant in 2035 and 2050.

The second analysis, GHG-2, used the GHG reduction targets set forth in SB 375 as a significance criteria. GHG-2 used a narrower range of GHG emissions than GHG-1. GHG-2's approach, in my view, was also fully consistent with Guidelines section 15064.4.

Under SB 375, as I have noted, the CARB prepared regional GHG emission reduction targets, compared to 2005 emissions, for cars and light trucks for 2020 and 2035 for each of the state's MPO's. In response, each of the MPO's, including SANDAG, prepared an SCS as part of its RTP to "reduce GHGs by better aligning transportation, land use, and housing. For SANDAG, the targets are to reduce per capita CO_2 emissions 7 percent below 2005 levels by 2020 and 13 percent below 2005 levels by 2035. Because CARB has not developed a target for 2050, no analysis is provided for that year."

Using this significance criteria, the EIR concluded the project would have less than a significant impact because the project met SB 375's goals, as set by the CARB, for lowered per capital vehicle-related GHG emissions in 2020 and 2035.

The third GHG impact analysis, GHG-3, analyzed whether regional GHG emissions (from both transportation and land use/growth) would conflict with (1) the scoping plan adopted by the CARB pursuant to AB 32, which plan functions as a roadmap to achieve GHG reductions in our state, and (2) SANDAG's own adopted

Climate Action Strategy (CAS), which was created in 2010 under a partnership with the California Energy Commission "as a guide for SANDAG and local governments and policymakers in addressing climate change."

Because the scoping plan time horizon was limited to 2020, the EIR's analysis of whether or not the project under GHG-3 would have a significant impact with respect to GHG was limited to 2020, and no analysis was presented for 2035 and 2050. Although recognizing 2035 and 2050 emission reduction targets for GHG's were established in the Executive Order, the EIR in my view properly concluded the order was not a "'plan"' adopted through a public review process as required in subdivision (b)(3) of Guidelines section 15064.4. The EIR, however, analyzed transportation and land use/growth in 2035 and 2050 expected as a result of implementation of the project, with respect to the CAS.

The EIR analysis concluded that with respect to transportation, the estimated emissions from transportation in 2020 would be less than required by AB 32 and would constitute a less than significant impact under this threshold. The EIR also concluded that the project would not impede the CAS and its policy of promoting the reduction of vehicle miles traveled and minimization of GHG in transportation, inasmuch as the project also sought to reduce GHG emissions in transportation through a series of projects. Therefore, for transportation, the EIR found the implementation of the project would constitute a less than significant impact under the CAS threshold for 2020, 2035 and 2050.

With respect to land use/growth, the EIR analysis concluded in GHG-3 that emissions of GHG in 2020 were expected to exceed the scoping plan reduction goals. However, it noted several other measures included in the scoping plan were not yet

adopted or implemented, including "cap-and-trade," and, therefore, were not included in the GHG reduction calculations. Because the RTP was itself consistent with its role in the overall scoping plan strategy, SANDAG concluded for land use/growth that for 2020 the impact would be less than significant under this threshold. The EIR further provided for 2020, 2035 and 2050, implementation of the project would not impede the CAS but in fact would promote it and the goals of increasing energy efficiency and reducing energy consumption and, therefore, would constitute a less than significant impact.

C. *Substantial Evidence Supports the Finding SANDAG's Assessment of Significance of GHG Impacts in its EIR Satisfied CEQA*

Unlike my colleagues, I do not believe SANDAG's failure to discuss the project's consistency with the Executive Order shows a lack of a "good-faith effort" to assess in the EIR the GHG impacts of the project.[11] Rather, in my view, there is abundant evidence in the record showing that SANDAG made a "good-faith effort, based to the extent possible on scientific and factual data, to describe, calculate or estimate the amount of greenhouse gas emissions [in the SANDAG MPO region] resulting from [the] project" (Guidelines, § 15064.4, subd. (a)); and that it properly assessed the significance of these emissions under applicable thresholds (*id.*, subd. (b)), including those adopted by the CARB (through enabling legislation) for 2020 and 2035. (See *Citizens for Responsible Equitable Environmental Development v. City of Chula Vista* (2011) 197 Cal.App.4th 327, 335-336 (*City of Chula Vista*).)

---

11 In finding an alleged lack of evidence in the record of a reasonable, good-faith effort by SANDAG to assess the GHG impacts, the majority, in my view, is in effect applying an independent standard of review, and its contention otherwise is one of form over substance. (Maj. opn. *ante*, at p. 14.)

Moreover, the record also contains substantial evidence showing SANDAG properly exercised its discretion when it decided not to use the Executive Order's 2050 statewide emission reduction target as a CEQA measuring stick for its regional plan. *North Coast Rivers Alliance v. Marin Municipal Water Dist. Board of Directors* (2013) 216 Cal.App.4th 614 (*North Coast*) informs my view on this issue.

There, the petitioners contended an EIR for a project to build a sea-water desalination plant approved by a local water district was deficient because, among other reasons, it contained an inadequate analysis of GHG emissions. Although the trial court rejected this argument, it nonetheless found the EIR lacked substantial evidence to support the water district's conclusion the plant's GHG emissions were not cumulatively considerable. (*North Coast*, *supra*, 216 Cal.App.4th at p. 650.)

In reversing, the court concluded the EIR's use of AB 32, and its requirement that the CARB "'adopt regulations that would require the reporting and verification of statewide GHG emissions and limit statewide GHG emissions to 1990 levels by 2020,'" was acceptable as a threshold of significance, inasmuch as the EIR properly noted "no CEQA thresholds of significance have been established for GHG[]." (*North Coast*, *supra*, 216 Cal.App.4th at p. 651.) The court also concluded the EIR used as a threshold a program voluntarily adopted by Marin County, which the water district joined, where GHG emissions would be reduced to 15 percent below 1990 levels by 2020. (*Ibid.*)

The *North Coast* court then reviewed the EIR in light of these thresholds, which focused primarily on energy consumption for plant operations. (*North Coast*, *supra*, 216 Cal.App.4th at p. 652.) In concluding the EIR's analysis "more than satisfied the requirements of CEQA" (*id.* at p. 652), the court recognized that the petitioners'

disagreement with the district's significance conclusion for GHG impacts was insufficient under CEQA because a """reviewing court 'may not set aside an agency's approval of an EIR on the ground that an opposite conclusion would have been equally or more reasonable,' for, on factual questions, [the court's] 'task is not to weigh conflicting evidence and determine who has the better argument.""" (*Id.* at p. 653.)

Similarly, this court in *City of Chula Vista* rejected the petitioner's contention the lead agency (i.e., the city) was required to use three other well-recognized potential thresholds of significance, instead of the goals set forth in AB 32, in analyzing the GHG impacts of a store replacement project. Citing to then-newly enacted Guidelines section 15064.4, this court concluded that this regulation "confirms that lead agencies retain the discretion to determine the significance of greenhouse gas emissions." (*City of Chula Vista*, *supra*, 197 Cal.App.4th at p. 336.) This court also concluded the lead agency "properly exercised its discretion to utilize compliance with [AB 32] as the threshold" and, as such, *rejected* the petitioner' contention the lead agency erred by not applying different thresholds. (*Ibid.*; see *Citizens Against Airport Pollution v. City of San Jose*, *supra*, 227 Cal.App.4th at p. 807 [recognizing that Guidelines, § 15064.4 gives a lead agency discretion to determine the significance of GHG emissions based to the extent possible on available scientific and factual data].)

North Coast and *City of Chula Vista*, in my view, provide guidance in the instant case and support the conclusion that SANDAG properly exercised its discretion under Guidelines section 15064.4, subdivision (b)(1), (2) and (3), including when it used the regional target numbers established by the CARB (developed in response to AB 32 and SB 375) in analyzing the impacts of GHG of the project. (See *Citizens for a Sustainable*

Treasure Island v. City and County of San Francisco (2014) 227 Cal.App.4th 1036, 1060-1061 [noting the "core principle" that an EIR is not required to engage in "speculative analysis," and, thus, a lead agency is not required to "'forsee[] the unforeseeable,'" "predict[] the unpredictable or quantify[] the unquantifiable"] (*Treasure Island*).) *North Coast* and *City of Chula Vista* also support the conclusion that, subject to the requirements of Guidelines section 15064.4, lead agencies and not the courts have the discretion to determine the benchmarks to be used for determining the GHG impacts of a project.

Indeed, as I previously noted, there is legislation currently pending, Assembly Bill No. 2050 (AB 2050), that among other purposes would delegate to the CARB the authority to set specific GHG emission reduction targets for the MPO's, including in the SANDAG region, but in this instance, the targets would be for 2050. Regardless of whether AB 2050 ultimately passes, the bill is significant because it shows our Legislature has not yet acted to set 2050 reduction targets (through the CARB). AB 2050 also demonstrates, yet again, the intent of the Legislature to fully occupy the field of regulating GHG emissions in our state. I believe the majority ignores this intent by requiring SANDAG, based on a strained interpretation of Guidelines section 15064.4, to do a "consistency analysis" using the Executive Order as a CEQA measuring stick. I also believe doing so has far-reaching, negative consequences.

By imposing a requirement on SANDAG that does not exist under CEQA, including in the applicable GHG Guidelines, the majority is contravening section 21083.1, as I have already discussed. In addition, as I have noted, the regulation of GHG emissions is better left to our Legislature and government agencies like the CARB in

what is clearly an area that "involves numerous highly technical and novel scientific, technical and economic issues" that will span many decades. (*Association of Irritated Residents v. State Air Resources Bd.*, *supra*, 206 Cal.App.4th at pp. 1502, 1505 [noting the CARB has been "assigned the responsibility of designating and overseeing the implementation of measures" to achieve the "challenging" goals of reducing GHG emissions in our state].)

The complexity of the issues addressed by SANDAG's RTP, the first of its kind to be approved in this state, cannot be overstated. The sheer volume of the record in this case pays homage to the difficult issues facing a lead agency like SANDAG in preparing a RTP with an SCS component, where transportation planning and land use are linked to regional GHG emissions reduction goals for the next several decades. In contrast, judges "have neither the resources nor scientific expertise to engage in such analysis." (*Laurel Heights Improvement Assn. v. Regents of University of California* (1988) 47 Cal.3d 376, 393.)

Until our Legislature directs the CARB to set regional goals for 2050, I do not believe SANDAG was required to use the Executive Order and/or its 2050 GHG statewide reduction goal as a threshold to assess the significance of the GHG impacts of the project. (See *Treasure Island*, *supra*, 227 Cal.App.4th at p. 1054 [refusing to "fault" an EIR for a project to redevelop a former naval station into a new, mixed-use community because there were many project features that were subject to future revision, and, thus, the EIR "cannot be faulted for not providing detail that, due to the nature of the [p]roject, simply does not now exist"].)

Finally, the majority in my view is unnecessarily interfering with SANDAG's program EIR and tiering, which frustrates the goal of good planning: "Where a lead agency is using the tiering process in connection with an EIR for a large-scale planning approval, such as a general plan or component thereof . . . , the development of detailed, site-specific information may not be feasible but can be deferred, in many instances, until such time as the lead agency prepares a future environmental document in connection with a project of a more limited geographic scale, as long as deferral does not prevent adequate identification of significant effects of the planning approval at hand." (Guidelines, § 15152, subd. (c).)

Our high court in *In re Bay-Delta etc.* (2008) 43 Cal.4th 1143 rejected a challenge to a program EIR on the basis it lacked sufficient detail regarding water sources to implement a project to restore the ecological health and improve the management of the Bay-Delta region. In so doing, the court noted that the Bay-Delta project was a "broad, general, multiobjective, policy-setting, geographically dispersed" plan (*id.* at p 1171); that at the first-tier program level, the "environmental effects of obtaining water from potential sources may be analyzed in general terms, without the level of detail appropriate for second-tier, site-specific review" (*id.* at p. 1169); that the advantage of a program EIR is it allows a lead agency "'to consider broad policy alternatives and program wide mitigation measures at an early time when the agency has greater flexibility to deal with basic problems or cumulative impacts'" (*ibid.*, citing Guidelines, § 15168, subd. (b)(4)); and that because the Bay-Delta project "is to be implemented over a 30-year period[,] . . . [i]t is therefore impracticable to foresee with certainty specific sources of water and their impacts" (*id.* at p. 1172).

Much like the Bay-Delta project, the project here is a "broad, general, multiobjective, policy-setting" plan. (See *In re Bay-Delta etc., supra*, 43 Cal.4th at p. 1171.) As such, I believe substantial evidence in the record shows SANDAG in its EIR engaged in a "good-faith effort" to analyze the GHG impacts of the project for purposes of the first-tier stage of what is clearly a long-term planning process that will be implemented over decades, "with the understanding that additional detail will be forthcoming when specific second-tier projects are under consideration." (See *id.* at p. 1172; see also *Rio Vista Farm Bureau Center v. County of Solano* (1992) 5 Cal.App.4th 351, 372 [upholding program EIR against a challenge it was vague and insufficiently described potential future facilities of a county's hazardous waste management plan because the plan, much like SANDAG's project at issue here, served only as an "assessment and overview, with any separate future projects, when identified, to be accompanied by additional EIR's"].)

According to SANDAG, implementation of the project will involve "literally hundreds of individual freeway, highway, local road, public transit, bikeway and other transportation projects, as well as ongoing development of various mitigation, planning and transportation management programs." In addition, many of these projects will occur 10, 20 or 30 years into the future and will be carried out by others including local governments and/or agencies, where baseline conditions may have substantially changed and after the project itself will have gone through multiple mandatory updates on a four-year cycle as currently required under Government Code section 65080, subdivision (d).

Because most, if not all, of these individual future transportation projects and/or land use decisions will be subject to its own project-level review under CEQA, and

because, in any event, SANDAG's EIR considered the public policy of GHG emission reduction and the CARB has not yet established 2050 GHG reduction target numbers for the SANDAG MPO region, I believe there is absolutely no reason to send the EIR back to the trial court for further consideration of GHG impacts utilizing the Executive Order as a threshold. Rather, I believe this is a waste of precious resources and will amount to "endless rounds of revision and recirculation of EIR's" that the Legislature did not intend. (See *Laurel Heights Improvement Assn. v. Regents of University of California* (1993) 6 Cal.4th 1112, 1132; see also Guidelines, § 15151 [stating that the "sufficiency of an EIR is to be reviewed in the light of what is reasonably feasible" and that "courts have looked not for perfection but for adequacy, completeness, and a good faith effort at full disclosure" in analyzing the adequacy of an EIR]; *Treasure Island, supra*, 227 Cal.App.4th at p. 1061 [noting it "has long been recognized that premature attempts to evaluate effects that are uncertain to occur or whose severity cannot reliably be measured is 'a needlessly wasteful drain of the public fisc'"].)

In sum, I conclude there is substantial evidence in the record showing SANDAG acted reasonably and in good faith when it addressed the GHG impacts of its project and properly exercised its discretion under Guidelines section 15064.4. I thus would reverse the trial court order finding SANDAG's GHG impacts analysis insufficient under CEQA.

II

Mitigation Measures

Initially, because I conclude the EIR adequately addressed the GHG impacts of the project, unlike the majority I do not deem moot (or partially moot) (Maj. opn. *ante*, at p. 23) SANDAG's contention that the EIR also adequately addressed mitigation measures

for the project's significant GHG impacts. Also unlike the majority, I conclude the EIR adequately considered reasonable mitigation measures for GHG impacts.

A. *Additional Background*

As noted, the EIR under the "existing conditions" baseline, GHG-1, concluded that the GHG impacts in 2020 would be a less than significant impact but would be significant in 2035 and 2050. Based on this analysis, the EIR proposed three mitigation measures to reduce impacts related to GHG emissions to less than significant levels.

The first mitigation measure, GHG-A, provided: "SANDAG shall update future Regional Comprehensive Plans and Regional Transportation Plans/Sustainable Community Plans to incorporate polices and measures that lead to reduced GHG emissions. Such policies and measures may be derived from the General Plans, local jurisdictions' Climate Action Plans, and other adopted policies and plans of its member agencies that include GHG mitigation and adaptation measures or other sources."

The second, GHG-B, encouraged the "San Diego region cities and the County government" to "adopt and implement Climate Actions Plans" (CAP's) and other climate strategies by: a) quantifying GHG emissions, "both existing and projected over a specified time period, resulting from activities within their respective jurisdictions"; b) establishing a "level . . . below which the contribution to GHG emissions from activities covered by the plan would not be cumulatively considerable"; c) identifying and analyzing GHG emissions "resulting for specific actions . . . anticipated within their respective jurisdictions"; d) specifying measures, "including performance standards, that . . . if implemented on a project-by-project basis, would collectively achieve the specified emissions level"; e) establishing a mechanism to monitor the "progress toward achieving

that level" of specified emissions and requiring an amendment if such levels are not achieved; and f) adopting such plans "in a public process following environmental review."

GHG-B further provided that, when appropriate, CAP's should "incorporate planning and land use measures from the California Attorney General's latest list of example policies to address climate change at both the plan and project level." At the plan level, GHG-B identified various policies to be considered and, if appropriate, implemented, from the website of the California Attorney General providing examples to address climate change, including "[s]mart growth, jobs/housing balance, transit-oriented development, and infill development through land use designations, incentives and fees, zoning, and public-private partnerships"; "[c]reate transit, bicycle, and pedestrian connections through planning, funding, development requirements, incentives and regional cooperation, and create disincentives for auto use"; [and] "[e]nergy and water-efficient buildings and landscaping through ordinances, development fees . . . and other implementing tools."

GHG-B also identified project-specific mitigation measures available on the website that, if appropriate, should be implemented at the plan level in a CAP's planning and land use measures, including adopting a "comprehensive parking policy" that encourages use of alternate transportation and discourages use of private vehicles; building or funding a "major transit stop within or near development"; providing public transit incentives, such as free or low-cost monthly transit passes to the public; incorporating bicycle lanes and routes into new development; and requiring facilities and amenities for non-motorized transportation, such as secure bicycle parking.

SANDAG in connection with GHG-B stated it would assist local governments in preparing CAP's and other climate strategies plans through implementation of its own CAS, which, as noted, was created in 2010 "as a guide for SANDAG and local governments and policymakers in addressing climate change." The CAS "provides a toolbox of land use, transportation, and related policy measures and investments that help implement the 2050 RTP/SCS [i.e., the project] through reducing GHG emissions. Policy measures also are identified for buildings and energy use, protecting transportation and energy infrastructure from climate impacts, and to help SANDAG and local jurisdictions reduce GHGs from their operations."

The third mitigation measure discussed in the EIR, GHG-C, provided SANDAG and local governments should require "Best Available Control Technology" (BACT) in constructing and operating projects.

SANDAG also considered additional mitigation measures that were found to be infeasible. One such measure was requiring all vehicles in the San Diego region to be either zero-emission vehicles or to be powered by renewable energy. SANDAG found this measure infeasible because of the "rate of turnover of vehicles on the roadway" and because of the limited number of such vehicles available. Another measure found to be infeasible was requiring all future construction to be net-zero energy use. Although renewable energy is available and is an option for a portion of a project's energy needs, SANDAG concluded it was infeasible for all projects to have net-zero emissions (i.e., hospitals).

Finally, SANDAG also found infeasible the requirement that all future construction activity include only "retrofitted equipment." Because certain equipment

does not have "retrofit components," SANDAG concluded this mitigation measure was infeasible.

SANDAG in the EIR noted that implementation of mitigation measures GHG-A through GHG-C "would reduce GHG emissions through adoption of measures and policies that encourage GHG emissions reduction in regional plans, adoption of Climate Action Plans by member agencies, and using BACT during construction and operation of implemented projects." Because of the growth in population, housing, and employment, the EIR concluded implementation of the project "would result in an increase in GHG emissions" and, as such, even with the mitigation measures, GHG-1, the existing conditions baseline, "would remain a significant and unavoidable impact in 2035 and 2050."

B. *Governing Law and Analysis*

It is axiomatic that an EIR must describe feasible measures that could minimize significant adverse impacts. (Guidelines, § 15126.4, subd. (a)(1).) Feasible means "capable of being accomplished in a successful manner within a reasonable period of time, taking into account economic, environmental, legal, social, and technological factors." (*Id.*, § 15364.)

However, a lead agency may find that "particular economic, social, or other considerations make the alternatives and mitigation measures infeasible and that particular project benefits outweigh the adverse environmental effects. (Pub. Resources Code, § 21081, subds. (a)(3), (b); Guidelines, § 15091, subd. (a)(3).) Specifically, an agency cannot approve a project that will have significant environmental effects unless it finds as to each significant effect, based on substantial evidence in the administrative

record, that (1) mitigation measures required in or incorporated into the project will avoid or substantially lessen the significant effect; (2) those measures are within the jurisdiction of another public agency and have been adopted, or can and should be adopted, by that agency; or (3) specific economic, legal, social, technological, or other considerations make the mitigation measures or alternatives identified in the EIR infeasible, and specific overriding economic, legal, social, technological, or other benefits outweigh the significant environmental effects. (Pub. Resources Code, §§ 21081, 21081.5; Guidelines, § 15091, subds. (a), (b).)" (*Federation of Hillside & Canyon Assns. v. City of Los Angeles* (2004) 126 Cal.App.4th 1180, 1198; see *South County Citizens for Smart Growth v. County of Nevada* (2013) 221 Cal.App.4th 316, 336 [noting that "'CEQA requires the appropriate public agency "to find, based on substantial evidence, that the mitigation measures are 'required in, or incorporated into, the project'; or that the measures are the responsibility of another agency and have been, or can and should be, adopted by the other agency; or that mitigation is infeasible and overriding considerations outweigh the significant environmental effects"'"].)

Claims concerning the feasibility or effectiveness of mitigation measures are reviewed for substantial evidence, which is defined as "'enough relevant information and reasonable inferences from this information that a fair argument can be made to support a conclusion, even though other conclusions might also be reached.'" (*Mira Mar Mobile Community v. City of Oceanside* (2004) 119 Cal.App.4th 477, 486.) In reviewing an agency's decision for substantial evidence, courts "'must indulge all reasonable inferences from the evidence that would support the agency's determinations and resolve all conflicts in the evidence in favor of the agency's decision.'" (*California Native Plant*

Society v. City of Santa Cruz (2009) 177 Cal.App.4th 957, 985.) This standard of review flows from the fact that an "agency has the discretion to resolve factual issues and to make policy decisions." (*Save Our Peninsula Committee v. Monterey County Bd. of Supervisors* (2001) 87 Cal.App.4th 99, 120.)

""As with all substantial evidence challenges, an appellant challenging an EIR for insufficient evidence must lay out the evidence favorable to the other side and show why it is lacking. Failure to do so is fatal. A reviewing court will not independently review the record to make up for appellant's failure to carry his [or her] burden."" (*Pfeiffer v. City of Sunnyvale City Council* (2011) 200 Cal.App.4th 1552, 1572.)

Here, I conclude petitioners have not met their burden of showing the mitigation measures for GHG emissions described by SANDAG in its program EIR were inadequate. As noted, the EIR discussed three separate mitigation measures in connection with impact analysis GHG-1. Each such measure complies with Guidelines section 15126.4, subdivision (c)(5), which was adopted in response to SB 97 and which provides the GHG mitigation measures proposed in connection with adoption of a long-range plan, such as the instant project, "may include the identification of specific measures that may be implemented on a project-by-project basis."[12]

---

12 Subdivision (c) of Guideline section 15126.4 provides in part: "[L]ead agencies shall consider feasible means, supported by substantial evidence and subject to monitoring or reporting, of mitigating the significant effects of greenhouse gas emissions. Measures to mitigate the significant effects of greenhouse gas emissions may include, among others: [¶] (1) Measures in an existing plan or mitigation program for the reduction of emissions that are required as part of the lead agency's decision; [¶] (2) Reductions in emissions resulting from a project through implementation of project features, project design, or other measures, such as those described in Appendix F; [¶] (3) Off-site measures, including offsets that are not otherwise required, to mitigate a project's emissions; [¶] (4) Measures that sequester greenhouse gases; [¶] (5) In the case of the

Moreover, the record shows SANDAG considered additional mitigation measures to reduce GHG emissions and found them infeasible. (See *Clover Valley Foundation v. City of Rocklin* (2011) 197 Cal.App.4th 200, 245 [noting that CEQA does not require "an EIR to explain why certain mitigation measures are infeasible"]; see also C*herry Valley Pass Acres & Neighbors v. City of Beaumont* (2010) 190 Cal.App.4th 316, 351 [noting CEQA does not require an EIR to analyze in detail mitigation measures deemed infeasible].)

At the conclusion of the CEQA review process, the record shows SANDAG adopted both the mitigation measures within its power to implement and a mitigation monitoring program (MMRP) for compliance. (See §§ 21081 & 21081.6.) The mitigation measures and MMRP confirm SANDAG's commitment to implementing GHG mitigation measures described in the EIR.

I do not agree with petitioners that the mitigation measures were insufficiently unenforceable because, particularly with respect to GHG-A and GHG-B, they depended on the cooperation of multiple other agencies. As noted, CEQA allows a lead agency to approve or carry out a project with potential adverse impacts if "[c]hanges or alterations have been . . . incorporated into[] the project" and "[t]hose changes or alterations are within the responsibility and jurisdiction of another public agency and have been, or can and should be, adopted by that other agency." (§ 21081, subd. (a)(1) & (2).)

---

adoption of a plan, such as a general plan, long range development plan, or plans for the reduction of greenhouse gas emissions, mitigation may include the identification of specific measures that may be implemented on a project-by-project basis. Mitigation may also include the incorporation of specific measures or policies found in an adopted ordinance or regulation that reduces the cumulative effect of emissions."

Finally, because SANDAG in my view satisfied its initial burden to consider a range of reasonable mitigation measures in its EIR, I would conclude the burden then switched to petitioners to establish from the record what petitioners describe as other "effective" mitigation measures that allegedly were omitted from consideration in the EIR and to show, again from the record, that such "effective" measures 1) were not only legally feasible but also suitable for discussion in a program EIR involving a project incorporating a broad range of planning measures and policies over the next several decades, *and* 2) would avoid or substantially lessen the project's GHG impacts. (See *San Diego Citizenry Group v. County of San Diego* (2013) 219 Cal.App.4th 1, 14-17 [rejecting the petitioners' contention that unspecified, additional mitigation measures should have been considered in "meaningful detail" in an EIR and noting the general rule that "CEQA does not . . . require discussion of every mitigation measure the agency rejected as infeasible"].) I would conclude petitioners have not met, and cannot meet, this burden in this case. (See *id.* at p. 17 [noting that "[f]easibility under CEQA encompasses desirability to the extent that desirability is based on a reasonable balancing of the relevant economic, environmental, social, and technological factors"].)[13]

BENKE, J.

---

13 Because the trial court never reached the issues raised in the cross-appeal and because the majority in any event is remanding the matter with respect to the EIR's treatment of GHG impacts and mitigation measures of the project, as I have noted, I would defer the issues raised in the cross-appeal to the trial court for consideration. Nonetheless, I feel compelled to state my objection to the majority's conclusion that SANDAG failed to consider a reasonable range of project alternatives.

Executive Order No. S-3-05 (2005) ..... 1 *et passim*

Executive Order No. B-30-15 (2015) 51, 52

STATEMENT OF THE ISSUE

"Must the environmental impact report for a regional transportation plan include an analysis of the plan's consistency with the greenhouse gas emission reduction goals reflected in Executive Order No. S-3-05 to comply with the California Environmental Quality Act (Pub. Resources Code, § 21000 et seq.)?"

SHORT ANSWER TO STATEMENT OF THE ISSUE

To preserve our existing environment and reduce the risk of dangerous climate change, science instructs that we must continually and substantially reduce our greenhouse gas emissions through midcentury. The objective of climate stabilization is now firmly embedded in state law and policy, including the State's foundational climate law, the Global Warming Solutions Act of 2006, commonly referred to as AB 32 (Health & Saf. Code, § 38500 et seq.).

Where the proposed update to a 40-year regional transportation plan shows near-term reductions in greenhouse gas emissions, but the reductions are not projected to continue over the longer-term, the lead agency must make a good faith, reasonable effort to analyze and discuss in its Environmental Impact Report whether the proposed project may conflict or interfere with the State's climate stabilization objectives, or explain why it cannot conduct such an analysis. To be clear, in the present case, this requirement arises not from any executive order, but from CEQA's requirement that a public agency exercise its careful judgment in light of the available facts and science and disclose all that it reasonably can about a project's short- and long-term environmental effects, including whether the project may undermine well-established, long-term environmental goals.

INTRODUCTION

Appellants, the San Diego Association of Governments (SANDAG) and its Board, contend this case presents a thicket of thorny questions on such things as the proper standard of review, deference to agency decision making, separation of powers and the effect of executive orders, and interpretation of the CEQA Guidelines as applied to greenhouse-gas related impacts. But this case turns on a simpler and more fundamental question: Whether SANDAG in its Environmental Impact Report for the 2050 Regional Transportation Plan and Sustainable Communities Strategy (2050 Plan) could decline to consider the State's long-term climate stabilization objectives, and the science that underlies those objectives, and still produce a document that serves the basic informational purposes of CEQA. As both the trial court and Court of Appeal held, it could not.

In enacting CEQA, the Legislature determined "that the long-term protection of the environment, consistent with the provision of a decent home and suitable living environment for every Californian, shall be the guiding criterion in public decisions." (Pub. Resources Code, § 21001, subd. (d).)[1] This end is served by requiring an Environmental Impact Report for any project that may have a significant effect on the environment. In the seminal *Laurel Heights* decision, this court described the EIR as the "heart of CEQA" and an "environmental 'alarm bell' whose purpose it is to alert the public and its responsible officials to environmental changes before they have reached ecological points of no return." (*Laurel Heights Improvement Assn. v. Regents of University of California* (1988) 47 Cal.3d 376, 392 [internal quotations omitted].) The public agency's charge in preparing an EIR thus is to make a reasonable, good faith effort to disclose all that it reasonably can about the project's significant

[1] All cites are to the Public Resources Code unless otherwise noted.

environmental effects. The agency is required to present the hard questions about the project's potential impacts, and to endeavor to answer those questions in light of available facts and science, and with short- and long-term environmental objectives in mind. When the agency meets its CEQA obligations, the EIR serves the law's purposes by fostering informed public discussion and ensuring governmental accountability. In those circumstances, though a challenger may view the document as imperfect, or the agency's decision as unwise, the EIR and the agency's decision to approve the project are legally sufficient and must stand as an exercise of the lead agency's considerable discretion.

This same deference cannot apply where, as in this case, the agency declines to present or attempt to answer the hard environmental questions. In 2011, SANDAG, the Metropolitan Planning Organization for the 4,200-plus square mile San Diego region, prepared an EIR for its 2050 Plan, a planning and expenditure document that, in SANDAG's words, will serve as the region's transportation system "blueprint" for the next 40 years. As the Attorney General noted in her comments on the EIR, while the 2050 Plan may result in near-term reductions in greenhouse gases, projected per capita and total greenhouse gas emissions begin to *rise* after 2020. In light of climate science and the State's well-established policy to continually and substantially reduce greenhouse gas emissions through midcentury in order to achieve climate stabilization, the relevant question is, what is the environmental significance of the region's post-2020 rising emissions trajectory? Should the public and decision makers be concerned? Can current and future actions bend the curve downward, or are the decisions being made today irreversibly committing the region, and the State, to increasing emissions?

SANDAG's response, then and now, is that neither the Legislature nor the California Resources Agency has specifically directed SANDAG, in

carrying out its duties under CEQA, to consider the State's long-term statewide emissions reduction target—80 percent below 1990 emissions level by 2050—that is set out in Executive Order S-3-05 (2005). In the absence of such a directive, SANDAG argues, it was free to ignore these questions. It is irrelevant, however, that Executive Order No. S-3-05 is not directed at SANDAG. CEQA itself, apart from this executive order, requires SANDAG as the lead agency to exercise its own careful judgment, based to the extent possible on scientific and factual data, to determine whether the greenhouse gas emissions resulting from its regional transportation plan will be significant over the longer term, and to produce a document that allows for public discussion and fully informed decision making.

SANDAG failed to meet its obligation. The 2050 Plan EIR disclosed, without any meaningful analysis or discussion, that greenhouse gas emissions would be higher in 2050 than in 2010, but moved quickly to minimize rather than highlight any concerns that might be raised by the longer-term increase. The EIR asserted, for example, that in the year 2020, the 2050 Plan will not conflict with the Air Resources Board's Scoping Plan—the framework document setting out how the State will meet the 2020 statewide greenhouse gas emissions limit established by the Global Warming Solutions Act of 2006. The EIR failed to note, however, that the 2020 target is not an environmental end in itself, but rather an interim step towards achieving substantial longer-term emissions reductions and climate stabilization. The resulting EIR was not only incomplete—it was misleading. In the words of the Court of Appeal, the EIR made it "falsely appear as if the transportation plan is furthering state climate policy when, in fact, the trajectory of the transportation plan's post-2020 [greenhouse gas] emissions directly contravenes it." (Opinion (Nov. 24, 2014) (Opn.) 19.)

This court need not—and should not—prescribe precisely how SANDAG must account for the environmental objective of long-term climate stabilization in making its significance determination. A lead agency has considerable discretion in this regard. Contrary to SANDAG's assertions, the People do not argue that CEQA requires SANDAG to engage in a strict "consistency" analysis, under which any failure of its regional transportation plan to follow in lockstep the statewide reductions described in the Scoping Plan and Executive Order would render the project's greenhouse gas impacts necessarily significant. SANDAG could comply with CEQA by, for example, discussing whether the 2050 Plan's projected increases in greenhouse gas emissions and vehicle miles traveled over the longer-term may interfere with or make it more difficult to achieve the continual and substantial statewide emissions reductions required to meet the State's longer-term climate objectives. Indeed, that appears to be the approach that SANDAG is taking in the currently circulating draft EIR for the 2050 Plan's required four-year update. Had SANDAG included in the 2011 EIR the discussion of significance for the project's greenhouse gas-related impacts that is contained in its current draft EIR, the People likely would not be before this court on this particular issue. Since SANDAG in its opening brief contends that it is not legally required to provide this information to the public and decision makers, there is still a need for this court to settle the question of SANDAG's obligations under CEQA, which could otherwise evade judicial review due to the relatively short amendment cycle for regional transportation plans.

The court should hold that where a regional transportation plan—a large-scale, long-term infrastructure and land use planning project—may commit a region to substantial greenhouse gas emissions for decades to come, the lead agency in its EIR must disclose not only the project's near-term emissions, but also whether early trends are sustainable over the

project's lifespan. If the project's near-term emissions reductions are not expected to continue, the lead agency should make a reasonable effort to analyze and discuss whether the project may conflict or interfere with the State's long-term climate stabilization objectives, or explain why it cannot, supporting its explanation with substantial evidence. The court should hold that SANDAG abused its discretion in determining that, for the 2050 Plan, it had no legal obligation under CEQA to consider the environmental objective of climate stabilization. It should further affirm the judgment of the Court of Appeal that SANDAG's error was prejudicial, provide that SANDAG must decertify the deficient 2011 EIR, and remand the case for further proceedings and the issuance of a writ consistent with this court's opinion.

STATEMENT OF THE CASE

I. SANDAG'S REGIONAL TRANSPORTATION PLANNING OBLIGATIONS

SANDAG is a Metropolitan Planning Organization, one of 18 regional transportation planning entities across the State. (See Administrative Record (AR) 8a:2065, 218:17688-17689.)[2] The area under SANDAG's jurisdiction encompasses the County of San Diego and the region's 18 cities and covers more than 4,200 square miles. (AR 8a:1998, 2142.) By law, SANDAG is required to prepare a regional transportation plan and to update it every four years. (Pub. Util. Code, §§ 120300, 132050, 132051; Gov. Code, § 65080 et seq.; 23 U.S.C. § 134; see also AR 8a:2065 [EIR].) "The purpose of the [regional transportation plan] is to establish regional goals, identify present and future needs, deficiencies and

[2] See also the website for the Institute for Local Government at <http://www.ca-ilg.org/post/californias-18-metropolitan-planning-organizations> [as of July 6, 2015].

constraints, analyze potential solutions, estimate available funding, and propose investments." (AR 218:17690 [Regional Transportation Plan Guidelines].) The 2050 Plan is a planning and transportation expenditure document that, in SANDAG's words, "is the blueprint for a regional transportation system, serving existing and projected residents and workers within the San Diego region . . . over the next 40 years." (AR 8a:1997 [EIR]; see also *id.* at 1998, 2066; *Edna Valley Assn. v. San Luis Obispo County and Cities APCC* (1977) 67 Cal.App.3d 444, 447-448.)

The Sustainable Communities Strategy Law, SB 375, enacted in September 2008, requires SANDAG and other regional transportation planning entities throughout California to incorporate a "Sustainable Communities Strategy" in each region's regional transportation plan. (Gov. Code, § 65080, subd. (b)(2).) Its purpose is to "align regional transportation, housing, and land use plans to reduce the amount of vehicle miles traveled to attain the regional GHG [greenhouse gas] reduction target[s]" set by the Air Resources Board. (AR 8a:2071 [EIR].)[3]

SANDAG began the process for the required 2011 update to its 2050 Regional Transportation Plan and Sustainable Communities Strategy in 2008, and released the draft 2050 Plan in April 2011. (See Appellants' Opening Brief (AOB) 12-13.)

II. THE CEQA PROCESS FOR THE 2011 UPDATE TO SANDAG'S 2050 PLAN

Because a regional transportation plan is a project undertaken by a public agency that may have significant effects on the environment, CEQA requires the Metropolitan Planning Organization as "lead agency" to prepare an Environmental Impact Report. (*Edna Valley*, *supra*, 67

[3] SB 375 and the targets set for the SANDAG region are discussed in greater detail at p. 20, below.

Cal.App.3d at pp. 448-449.) The purpose of an EIR is to identify for the public (through the EIR process) and agency decision makers (presented with a final EIR, including staff's responses to public comments) the project's "significant" environmental effects, and to determine whether there are feasible alternatives, design changes, or mitigation measures that could reduce or eliminate those effects. (§§ 21002, 21002.1, subd. (a), (b), 21061.) If the identified impacts cannot be reduced to less-than-significant levels, the lead agency may still approve the project, but its decision makers must make specific findings that alternatives and further mitigation are not feasible and that other "overriding" benefits—which may include economic and social benefits—outweigh the project's environmental harm. (§§ 21002.1, subd. (c), 21081.)

SANDAG released its draft EIR for the 2050 Plan in June 2011. (AR 7:227.) The Attorney General on behalf of the People, among a number of other entities, individuals, and organizations, commented on the draft EIR. (AR 8b:3763 [EIR Appendix G, Responses to Comments].) Both the Attorney General and the Governor's Office of Planning and Research expressed concern that while the draft EIR stated that the Plan meets the per capita emissions reduction targets set under SB 375 targets, the Plan's per capita emissions from passenger vehicles appear to rise after 2020, which would appear to run counter to SB 375's purposes. (AR 311:25643 [Attorney General's comment letter]; *id.* at 308:25004-25005 [OPR's comment letter].) The Attorney General's comment letter noted, among other things, that the draft EIR showed that the Plan's near-term greenhouse gas-related benefits did not appear to be sustainable beyond 2020. (AR 311:25641-25642.) The Attorney General advised that under these circumstances, in order to fully inform the public and decision makers of the Plan's greenhouse gas-related impacts, SANDAG must evaluate the project over the longer term in relationship to the "overarching

environmental objective" of climate stabilization, which requires continual and substantial emissions reductions through midcentury. (AR 311:25640-25641.) The Attorney General cited relevant climate science, the objectives of the Global Warming Solutions Act of 2006 and its implementing Scoping Plan, and Executive Order No. S-3-05, which sets science-based declining statewide greenhouse gas emissions reduction targets, including a target of reducing total emissions to 80 percent below 1990 levels by the year 2050. (AR 311:25640-25643; see also AR 319:27049-27050 [Executive Order].)

SANDAG declined to consider the Plan's longer-term emissions as they relate to the objective of climate stabilization, stating that "the Legislature declined to include the Executive Order's aspirational 2050 goal in AB 32[,]" and that the Executive Order is not specifically identified in the CEQA Guidelines [Cal. Code Regs., tit. 14, § 15000 et seq.], and is not directly binding on SANDAG as a regional entity. (AR 8b:4430-4433 [response to Attorney General's comments].)

On October 28, 2011, SANDAG conducted a public hearing on the proposed 2050 Plan and Final EIR. (AR 186:12709-13 [Board of Directors meeting minutes].) On that day, the SANDAG Board of Directors adopted resolutions certifying the Final EIR and approving the 2050 Plan, adopting a statement of overriding considerations, and adopting the 2050 Plan. (AR 186:12713.)[4] The same day, SANDAG also filed a Notice of Determination for the Final EIR and the 2050 Plan. (AR 1:2-3.)

[4] A "statement of overriding considerations" reflects "the ultimate balancing of competing public objectives when the agency decides to approve a project that will cause one or more significant effects on the environment." (CEQA Guidelines, § 15021, subd. (d).)

III. THE ENSUING CEQA LITIGATION AND LOWER COURT DECISIONS

In November 2011, Cleveland National Forest Foundation and Center for Biological Diversity filed a petition for writ of mandate and complaint for injunctive relief alleging numerous violations of CEQA (CNFF case). (JA {2} 14-42.) At the same time, CREED-21 and the Affordable Housing Coalition of San Diego County filed a separate action challenging the EIR. (JA {1} 1-13.) In January 2012, the Sierra Club joined the CNFF case. (JA {25}151-189.)

The Attorney General on behalf of the People moved to intervene in the CNFF case (see Gov. Code, §§ 12600, subd. (b), 12606), and the trial court granted the People's application two days later, on January 25, 2012. (JA {22} 102-137, {29} 198-199.) The cases subsequently were consolidated and briefed. (JA {34} 251; JA {38} 264-274.)

Following oral argument, the trial court issued its ruling (JA {75} 1046-59) and on December 20, 2012, its judgment and peremptory writ of mandate. (JA {88} 1132-34; JA {89} 1135-37.)

The trial court held that "the EIR is impermissibly dismissive" of Executive Order No. S-03-05 given that the order's midcentury greenhouse gas goal is official state policy, is integral to the Air Resources Board's AB 32 Scoping Plan, and was "designed to address an environmental objective that is highly relevant under CEQA (climate stabilization)." (JA {75} 1056-57.) The trial court concluded that the EIR's failure to discuss the increase in total emissions from 2020 through 2050 in light of "the statewide policy of reducing same during the same three decades (2020-2050) constitutes a legally defective failure of the EIR to provide the SANDAG decision makers (and thus the public) with adequate information about the environmental impacts of the [2050 Plan]." (*Id.* at 1057.) The trial court did not reach any other issues presented, such as whether the EIR

adequately disclosed and analyzed the Plan's impacts on public health from particulate matter pollution. (*Id.* at 1058.)

On December 26, 2012, SANDAG timely appealed the trial court's judgment. (JA {92} 1140-1141.) The People, CNFF, and CREED-21 filed cross-appeals on the issues that the trial court did not reach. (JA {95} 1161-1163; JA {96} 1164-1168.)

The Court of Appeal issued its opinion on November 24, 2014, as modified on denial of rehearing on December 16, 2014, concluding that "the EIR failed to comply with CEQA in all identified respects." (Opn. 3.) For purposes of the current appeal, only the court's decision as it relates to the adequacy of the 2050 Plan's disclosure and analysis of greenhouse gas emissions is relevant, and on that issue, the decision was split. The majority held that SANDAG "prejudicially abused its discretion by omitting from the EIR an analysis of the transportation plan's consistency with the state climate policy, reflected in the Executive Order, of continual greenhouse gas emissions reductions." (Opn. 20.) The majority concluded that "[t]he omission was prejudicial because it precluded informed decisionmaking and public participation." (Opn. 15.)

Justice Benke dissented, opining that the majority overstepped its judicial review function by effectively mandating how SANDAG must determine the significance of the 2050 Plan's greenhouse gas emissions. (See, e.g., Dis. Opn. 4, 8.)

SANDAG timely filed a petition for review on January 6, 2015, which this court granted on March 11, 2015 on the single issue set out above.

BACKGROUND: THE SCIENCE, LAW, AND POLICY OF CLIMATE CHANGE

Climate change is caused by emissions of greenhouse gases on the planet's surface from actions such as the burning of fossil fuels. (AR 8a:2553-2554 [EIR], 311:25640 [Attorney General's comment letter].)[5] Greenhouse gases reach the atmosphere, where they accumulate and persist. (*Ibid*.) Higher concentrations of atmospheric greenhouse gases in turn lead to disruptions of our environment and climate, including increases in global average temperatures. (AR 8a:2553-2554.) California already is experiencing the effects of climate change, which include longer fire seasons, longer and more frequent heat waves, rising sea levels, and reductions in the Sierra snowpack, a substantial source of the State's water. (AR 311:25640, 320(5):27870.) The harms resulting from climate change fall especially hard on our most vulnerable residents—"the urban poor, the elderly, children, traditional societies, agricultural workers and rural populations." (AR 311:25640.)

The 2050 Plan EIR, the lower courts' decisions, and the briefs in this case discuss the relationship of a number of greenhouse gas- and climate-related statues, regulations, and policy documents to SANDAG's obligations under CEQA. The People briefly summarize these authorities, and the climate science that underlies them, for the court's convenience.

---

[5] The Attorney General's comment letter discusses the causes and effects of climate change and provides citations to authoritative sources. (AR 311:25640-25641.) Since SANDAG does not dispute the mechanism of climate change or its serious, adverse effects, the People in this brief provide only an abbreviated discussion of these topics. For the court's reference, the Intergovernmental Panel on Climate Change's 2007 "Frequently Asked Questions" document, cited in the Attorney General's comment letter, is a concise and authoritative summary, and is available at https://www.ipcc.ch/pdf/assessment-report/ar4/wg1/ar4-wg1-faqs.pdf.

A. Executive Order No. S-03-05 (2005)

Responding to California's particular vulnerability to climate change, in 2005, Governor Schwarzenegger issued Executive Order No. S-3-05. The Executive Order sets out an overarching framework to guide California's climate efforts. It provides in relevant part "[t]hat the following greenhouse gas emission reduction targets are hereby established for California: by 2010, reduce GHG emissions to 2000 levels; by 2020, reduce GHG emissions to 1990 levels; [and] by 2050, reduce GHG emissions to 80 percent below 1990 levels . . . ."

As SANDAG acknowledges in its opening brief, the Executive Order's targets are "based on studies estimating that stabilization of atmospheric CO_2[-equivalent] levels at approximately 450 parts per million (ppm) would stabilize [average] global temperature levels at approximately 2 degrees [Celsius] above pre-industrial levels." (AOB 7.) More specifically, they are grounded in work by the Intergovernmental Panel on Climate Change (IPCC), the leading international scientific body for the assessment of climate change, which acts under the auspices of the United Nations. As SANDAG noted in its EIR, the IPCC constructed a number of possible future global greenhouse gas "emission trajectories" to understand what must be done "to stabilize global temperatures and climate change impacts." (AR 8a:2553-2554 [EIR].)[6] The "IPCC concluded that a stabilization of GHGs at 400 to 450 parts per million (ppm) CO_2 [carbon dioxide] equivalent concentration is required to keep global mean warming

---

[6] See IPCC 4th Assessment Report (2007), <https://www.ipcc.ch/publications_and_data/ar4/syr/en/mains5-4.html#table-5-1> [July 6, 2015]; see also IPCC 5th Assessment Report (2014) <http://www.ipcc.ch/pdf/assessment-report/ar5/wg3/ipcc_wg3_ar5_summary-for-policymakers.pdf> [as of July 6, 2015] at pp. 12-13.

below 3.6º F (2º Celsius), which is assumed to be necessary to avoid dangerous climate change." (AR 8a:2553-54 [EIR].) Stabilization at these levels would require that global emissions peak sometime in the 2000-2015 period and show a substantial reduction by 2050.[7] Achieving stabilization will require greater reductions in annual emissions from developed countries. (See, e.g., AR 216:17623 [SANDAG's Climate Action Strategy].)[8]

As SANDAG observes in its opening brief, meeting the greenhouse gas emissions targets described in the Executive Order "could avoid more extreme climate change scenarios." (AOB 7.)

B. The Global Warming Solutions Act (AB 32) (2006) and the AB 32 Scoping Plan (2008)

The Legislature followed Executive Order No. S-03-5 with the Global Warming Solutions Act of 2006, commonly known as AB 32. (Health & Saf. Code, § 38500 et seq.) AB 32 mandates that by 2020, California must reduce its total statewide annual greenhouse gas emissions to the level they were in 1990. (*Id.*, §§ 38550, 38551.) The Legislature stated its further intent that "the statewide greenhouse gas emissions limit continue in existence and be used to maintain and continue reductions of greenhouse gases beyond 2020." (*Id.*, § 38551, subd. (b).)[9] The 2020 emissions limit

---

[7] See previous footnote.

[8] See, also, e.g., Union of Concerned Scientists, *Avoiding Dangerous Climate Change, A Target for U.S. Emissions Reductions* (2007), available at http://www.usclimatenetwork.org/resource-database/WEB%20emissions-target-fact-sheet.pdf [as of July 6, 2015], recommending that the U.S. reduce emissions by at least 80 percent below 2000 levels by 2050.

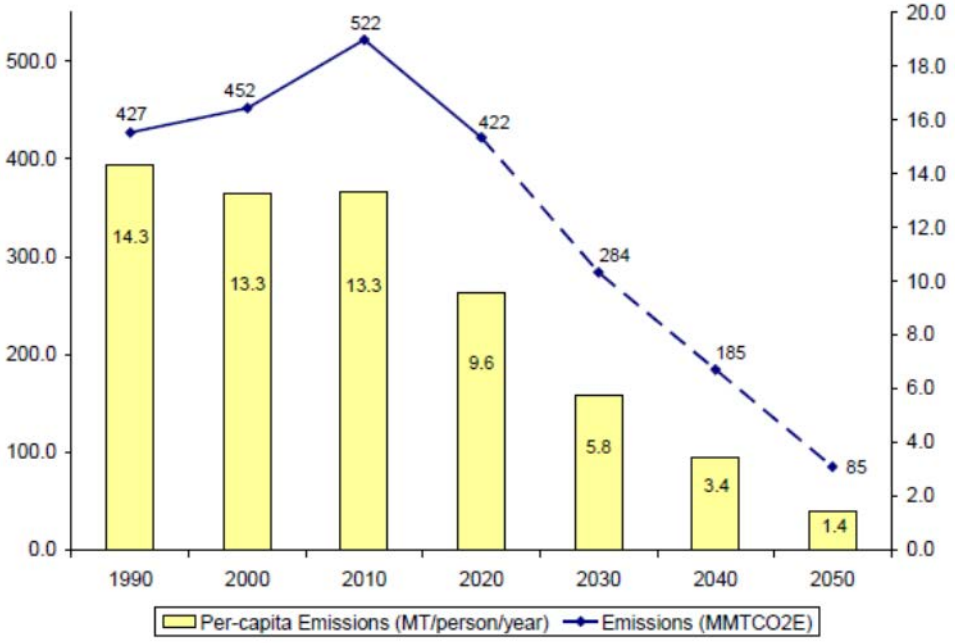
[9] SANDAG asserts that "AB 32 did not ratify the Executive Order[.]" (AOB 42.) While this statement is beside the point, the People (continued…)

is not an end in itself, but "is but a step towards achieving" the "longer-term climate goal" described in Executive Order No. S-3-05. (*Assn. of Irritated Residents v. California Air Resources Bd.* (2012) 206 Cal.App.4th 1487, 1496, citing the Executive Order].)

AB 32 requires the Air Resources Board to develop a framework plan—the Scoping Plan—outlining how California will achieve the required 2020 greenhouse gas limit through such things as direct emission regulations, "market-based compliance mechanisms," incentives, and voluntary actions. (Health & Saf. Code, § 38561.) The Air Resources Board completed the initial AB 32 Scoping Plan in 2008. (AR 320(5):27842.) In the Scoping Plan, the Air Resources Board observed that "[g]etting to the 2020 goal is not the end of the State's effort." (AR 320(5):27848; see also Health & Saf. Code, § 38551, subds. (b), (c).) "The 2020 goal was established to be an aggressive, but achievable, mid-term target, and the 2050 greenhouse gas emissions reduction goal represents the level scientists believe is necessary to reach levels that will stabilize climate." (AR 320(5):27864 [Scoping Plan]; see also 311:25641 [Attorney General's comment letter].) The Attorney General's comment letter on the 2050 Plan draft EIR attached a chart from the Scoping Plan that describes changes in the State's total and per capita emissions over time—California's "emissions trajectory"—necessary to achieve the State's climate stabilization objective:

(…continued)
note that it is also wrong. The Legislature in fact did sanction the science and policy reflected in Executive Order No. S-3-05. (See, e.g., Health & Saf. Code, §§ 38501, subd. (i), 38551.)

Figure 6: Emissions Trajectory Toward 2050



(AR 311:25645.)[10]

In the Scoping Plan, the Air Resources Board noted the important role of better land use and transportation planning, and the need to begin action in the near term. Looking beyond 2020, "it will be necessary to significantly change California's current land use and transportation planning policies. Although these changes will take time, getting started now will help put California on course to cut statewide greenhouse gas emissions by 80 percent in 2050 as called for by Governor Schwarzenegger." (AR 320(5):27858-27859; see also *id.* at 320(5):27879-27880.)

---

[10] During this litigation, the Air Resources Board approved the first update to the Scoping Plan on May 22, 2014. (See <http://www.arb.ca.gov/cc/scopingplan/document/updatedscopingplan2013.htm> [as of July 6, 2015].) The updated Scoping Plan contains a similar figure at p. 33.

C. Legislation Directing Amendments to the CEQA Guidelines to Address Greenhouse Gas Emissions (2007) and Resulting Amendments (2010)

From its outset, CEQA has required that "the long-term protection of the environment" must be "the guiding criterion in public decisions." (§ 21001, subd. (d); see Stats. 1970, ch. 1433, p. 2781.) While concerns about human-caused climate change were not yet part of the regular public discourse in 1970, the statute was written to address environmental problems as they might arise. The statute's description of "tipping points" is prescient:

> The capacity of the environment is limited, and it is the intent of the Legislature that the government of the state take immediate steps to identify any critical thresholds for the health and safety of the people of the state and take all coordinated actions necessary to prevent such thresholds being reached.

(§ 21000, subd. (d), added by Stats. 1970, ch. 1433, p. 2780; see also AR 216:17623 [SANDAG's Climate Action Strategy, noting risk of climate change tipping points].)[11]

Public agencies are guided in their compliance by the CEQA Guidelines, contained at California Code of Regulations, title 14, sections 15000 et seq.[12] The CEQA Guidelines "include criteria for public agencies to follow in determining whether or not a proposed project may have a 'significant effect on the environment'"—the triggering condition for an

---

[11] For the court's reference, the People have provided the original version of CEQA—a succinct four pages—as enacted in September 1970 (Stats. 1970, ch. 1433, pp. 2780-2783). (People's Motion for Judicial Notice, People's Decl., Ex. 2.)

[12] "In interpreting CEQA, [the courts] accord the Guidelines great weight except where they are clearly unauthorized or erroneous." (*Vineyard Area Citizens for Responsible Growth, Inc. v. City of Rancho Cordova* (2007) 40 Cal.4th 412, 428, fn. 5.)

EIR. (§ 21083, subd. (b).) As greenhouse gases and climate change began to be discussed more routinely in CEQA comment letters and CEQA documents, there was a perceived need for the CEQA Guidelines to offer guidance that was more specific to this issue. In August 2007, with the passage of Senate Bill 97, the Legislature added section 21083.05, which directed the Governor's Office of Planning and Research to prepare and the Resources Agency to adopt "guidelines for the mitigation of greenhouse gas emissions or the effects of greenhouse gas emissions as required by this division, including, but not limited to, effects associated with transportation or energy consumption . . . ." (Stats. 2007, ch. 185, § 1 [SB 97].)

Amendments to the CEQA Guidelines became effective in March 2010.[13] Included in the amendments is new section 15064.4, entitled "Determining the Significance of Impacts from Greenhouse Gas Emissions." The provision includes a non-exclusive list of three "factors" that a lead agency should consider: whether the project increases emissions over existing conditions; whether the project's emissions exceed a "threshold of significance" the lead agency determines should apply to the project; and the extent to which the project complies with requirements in a plan to reduce greenhouse gas emissions. (CEQA Guidelines, § 15064.4, subd. (b)(1).)[14] It further instructs that "[t]he determination of the significance of greenhouse gas emissions calls for a careful judgment by the lead agency consistent with the provisions in section 15064[,]" the pre-existing and generally applicable provision outlining a lead agency's obligations in determining significance. (CEQA Guidelines, § 15064.4,

[13] Section 21083.05 was amended in 2012 to reflect that the guidelines had been issued. (Stats. 2012, ch. 548, § 5 [AB 2669].)

[14] The concept of "thresholds" is discussed at p. 42, below. (See also CEQA Guidelines, § 15064.7.)

subd. (a).) The SB 97 amendments "add[ed] no additional substantive requirements; rather, the Guidelines merely assist lead agencies in complying with CEQA's existing requirements." (AR 319:25828 [Final Statement of Reasons (FSOR)].) The provision incorporates by reference the general provision addressing significance determinations and reiterates the obligation of the agency to consider "scientific and factual data" and to make a "good-faith effort." (§§ 15064.4, subd. (a), 15064, subd. (b).)

D. SANDAG's Climate Action Strategy (2010)

In March 2010, SANDAG issued its own "Climate Action Strategy" to serve as a "guide to help policymakers address climate change as they make decisions to meet the needs of our growing population, maintain and enhance our quality of life, and promote economic stability." (AR 216:17618.) The document sets out "theoretical emissions reduction[ ]" targets for total regional greenhouse emissions through 2050 on a declining trajectory. (*Id.* at p. 17628 [Figure 3-1].) In its Climate Action Strategy, SANDAG observed that the Executive Order's 2050 reduction goal is based on climate science and "is used as the long-term driver for state climate change policy development." (*Id.* at p. 17627.) Meeting "the long-term goal of reducing statewide greenhouse gas emissions to 80 percent below the 1990 level by the year 2050 will require fundamental changes in policy, technology, and behavior." (*Id.* at p. 17628.) The Strategy states that "[b]y 2030, the region must have met and gone below the 1990 level and be well on its way to doing its share for achieving the 2050 greenhouse gas reduction level." (*Id.* at p. 17629.)

SANDAG's Climate Action Strategy notes that on-road transportation is the single largest source of greenhouse gas emissions in the region. (AR 216:17641.) Thus, "reductions in total miles vehicles travel are needed to help achieve the goals of AB 32." (*Id.* at p. 17644.) Further, "[t]he

Scoping Plan and other studies in a growing body of evidence strongly suggest that the trend of vehicle miles traveled growth needs to be slowed, stopped, and soon reversed in order to successfully lower greenhouse gas emissions from the on[-]road transportation sector." (*Ibid.*)

E. The Sustainable Communities Strategies Law (2008) and SANDAG's Regional Targets (2010)

As noted above, the Sustainable Communities Strategy Law, SB 375, enacted in September 2008, requires SANDAG and other regional transportation planning entities to incorporate a Sustainable Communities Strategy in each regional transportation plan. The Sustainable Communities Strategy must demonstrate how the region would achieve greenhouse emissions reductions targets established by the Air Resources Board for emissions from passenger vehicles (cars and light-duty trucks). (Gov. Code, § 65080, subd. (b)(2); AR 8a:2080 [EIR]; see also AR 218:17776 [2010 California Regional Transportation Plan Guidelines].) In September 2010, the Air Resources Board established declining SB 375 greenhouse gas emissions targets for the SANDAG region, which require a 7 percent per capita emissions reduction by 2020, and a 13 percent per capita reduction by 2035, measured against emissions in 2005. (AR 8a:2076.) The Strategy's purpose is to align regional transportation, housing, and land use plans to reduce vehicle miles traveled and thereby meet regional SB 375 targets. (AR 8a:2071 [EIR]; AR 218:17776 [2010 Regional Transportation Plan Guidelines].) While a regional planning entity such as SANDAG cannot require that cities and counties amend their general plans, it can create incentives for change, by, for example, "[p]rovid[ing] funds and technical assistance to local agencies" to implement regional planning. (AR 218:17912 [2010 Regional Transportation Plan Guidelines].)

STANDARD OF REVIEW

This "[C]ourt's review of the administrative record for legal error and substantial evidence in a CEQA case, as in other mandamus cases, is the same as the trial court's: the appellate court reviews the agency's action, not the trial court's decision; in that sense appellate judicial review under CEQA is de novo." (*Vineyard Area Citizens for Responsible Growth, Inc. v. City of Rancho Cordova* (2007) 40 Cal.4th 412, 427.) Courts review an agency's action under CEQA for a prejudicial abuse of discretion. (Pub. Resources Code, § 21168.5; *Berkeley Hillside Preservation v. City of Berkeley* (2015) 60 Cal.4th 1086, 1109.) An agency abuses its discretion if it either commits legal error or fails to support its fact-based determinations with substantial evidence in the record. (*Berkeley Hillside*, *supra*, 60 Cal.4th at p. 1109-1110; *Vineyard*, *supra*, 40 Cal.4th at p. 427.)

As this court noted in *Vineyard*, "a reviewing court must adjust its scrutiny to the nature of the alleged defect," depending on whether the claimed error falls "predominately" into the factual or legal category. (*Vineyard*, *supra*, 40 Cal.4th at p. 435.) A court independently determines "whether the agency has employed the correct procedures, 'scrupulously enforc[ing] all legislatively mandated CEQA requirements[.]'" (*Id.*, quoting *Citizens of Goleta Valley v. Bd. of Supervisors* (1990) 52 Cal.3d 553, 564.) Similarly, where an agency's determination is not based on disputed facts, but rather on a disputed question of law, review is de novo. (*City of Marina v. Bd. of Trustees of the California State University* (2006) 39 Cal.4th 341, 355-356 [rejecting agency's determination that it lacked power to mitigate off-site impacts "based on [agency's] erroneous legal assumptions"].) In contrast, a court "accord[s] greater deference to the agency's substantive factual conclusions." (*Vineyard*, *supra*, 40 Cal.4th at p. 435.) An agency's factual findings will be upheld where they are supported by substantial evidence, "even though other conclusions might be

reached." (*Laurel Heights*, *supra*, 47 Cal.3d at p. 422.) "Substantial evidence . . . include[s] facts, reasonable assumptions predicated upon facts, and expert opinion supported by facts." (CEQA Guidelines, § 15384, subd. (b).) It does not, however, include "[a]rgument, speculation, unsubstantiated opinion or narrative, [or] evidence which is clearly erroneous or inaccurate . . . ." (*Id.*, subd. (a).)

In this case, SANDAG's stated reason for refusing to disclose and analyze whether the 2050 Plan's projected longer-term emissions are in line or instead may interfere with climate stabilization is the asserted lack of a legal mandate. (AR 8b:3766-3770 [Master Response #2], 4430-4433 [response to Attorney General's comments].) Because SANDAG's justification is predominantly legal, it is reviewed de novo. But even if SANDAG's justification is considered to be in part factual—because of the EIR's summary assertion that "SANDAG's role in achieving th[e] [2050] target is uncertain and likely small" (see AR 8b:3769)—it must fail as unsupported by the law or by any substantial evidence in the record.

ARGUMENT

I. SUMMARY OF ARGUMENT

As a lead agency under CEQA, SANDAG has a duty to discuss whether the failure of its large-scale, long-term infrastructure and planning project to continue early reductions in greenhouse gas emissions over the longer term would conflict or interfere with the State's climate stabilization objectives. The duty does not arise from Executive Order No. S-3-05, but from CEQA itself. CEQA obliges SANDAG to prepare an EIR that puts a project's significant environmental problems squarely before the public and decision makers, thereby allowing for informed public discussion and governmental accountability. Under CEQA, SANDAG has a duty to consider whether the 2050 Plan may disadvantage long-term environmental

goals. And, of particular import in considering climate change, it must consider the relevant science and data, exercising its own judgment and discretion, and making a good faith effort to disclose all that it reasonably can about the 2050 Plan's impact in the short and long term. SANDAG's flat refusal to consider climate stabilization policy and science resulted in a document that was not only incomplete, but prejudicially misleading.

In response, SANDAG appeals first to the substantial discretion afforded to lead agencies under CEQA. Courts do defer to agencies whose EIRs highlight difficult environmental issues presented by a project and endeavor to confront and address those issues. Deference is not appropriate, however, where an agency instead minimizes an issue and effectively disclaims its responsibility to engage. SANDAG also argues that it "scrupulously" complied with CEQA Guidelines section 15064.4, which provides guidance on determining the significance of a project's greenhouse gas emissions. But that provision is not a rote check list ensuring compliance. It sets out three *non-exclusive* factors that agencies should consider in evaluating the significance of a project's greenhouse gas emissions, and incorporates the general proposition that there is no single, "ironclad" definition of significance. Accordingly, an agency must always exercise its judgment and consider other factors where required to meet CEQA's purposes. Where the very authorities on which SANDAG relies—including the Sustainable Communities Strategy Law and its declining targets, and the AB 32 Scoping Plan—are intended to create an emissions reduction path that continues beyond the year 2020, the Plan's upswing in emissions at the 2020 mark required additional discussion and analysis. SANDAG further suggests that a reader could have constructed an analysis of the 2050 Plan's relationship to climate stabilization by engaging in some arithmetic and pulling together scattered references to the Executive Order. An examination of the record citations provided by SANDAG shows the

futility of any such effort, and, in any event, it is SANDAG's job to disclose and explain—not the public's job to divine—the project's significant impacts.

SANDAG's counsel's statements about the purported difficulty of considering climate stabilization science and policy are irrelevant, as SANDAG's contemporaneous justification for omitting this analysis was a legal one. Moreover, the currently circulating draft EIR for the 2050 Plan's 2015 update establishes that SANDAG can in fact take climate stabilization into account in determining whether its long-term regional transportation plan will have significant impacts. Any question whether the pending process for the current update of the 2050 Plan will satisfy CEQA is outside the scope of this appeal. But, as discussed below, the current approach appears to have triggered a more robust exploration in the EIR of greenhouse gas-related mitigation and alternatives, which undoubtedly will be discussed and debated in the ensuing public process, and will better ensure governmental accountability for SANDAG's ultimate decision.

This court should make clear that SANDAG erred as a matter of law in determining that, for this large-scale, long-term transportation infrastructure and land use planning project, it had no legal obligation under CEQA to consider the science and state policy of long-term climate stabilization. It should further affirm the judgment of the Court of Appeal that SANDAG's error was prejudicial, provide that SANDAG must decertify its deficient 2011 EIR, and remand the case for further proceedings consistent with this court's opinion.

II. SUMMARY OF THE 2050 PLAN EIR

A. Project Description

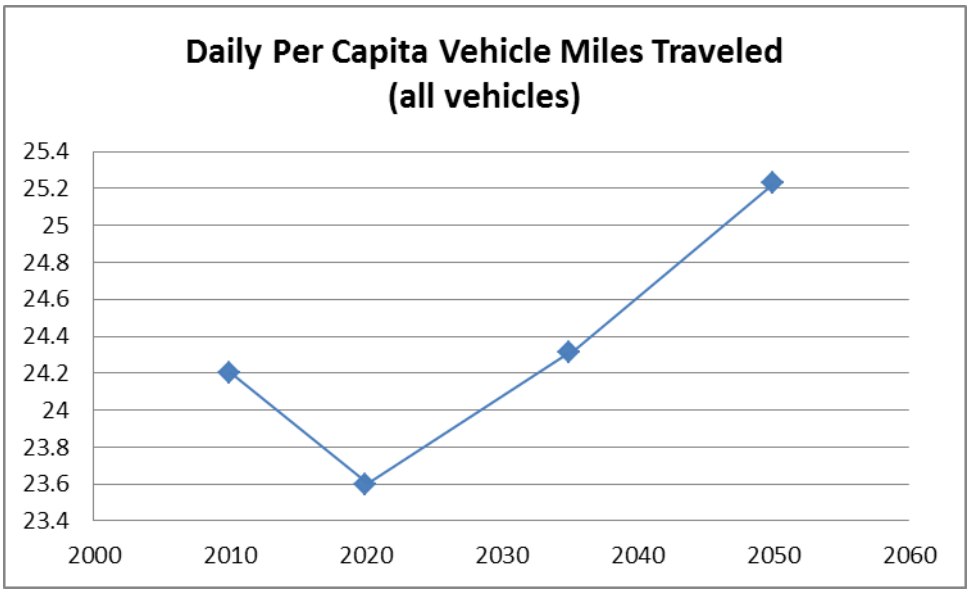
SANDAG's 2050 Plan, while it includes transit projects, places a significant emphasis on highway widening through 2020. (See, e.g., AR 8a:2583 [EIR].) Additional highway widening projects are scheduled to be in place by 2035. (AR 8a:2586 [EIR].) The 2050 Plan contemplates the construction of projects that will expand or extend hundreds of miles of freeways in the San Diego region. (See, e.g., AR 8a:2116-21 [EIR]; see also AR 190b:14214, 14217 [RTP].)

Changes in land use follow these highway expansions. While, according to the EIR, land use patterns, types, and areas of development will be substantially the same in 2020 (AR 8a:2582), "the 2035 land use pattern would generally involve additional residential development in areas that were previously undeveloped open space or at some time in agricultural use . . . ." (AR 8a:2585; see also AR 190a:13156 [Sustainable Communities Strategy].) After 2035, "growth would continue in more eastern locations of the region[,]" which are currently less developed, and "by 2050, spaced rural residential development would have expanded . . . into areas with very minimal development at present." (AR 8a:2587; see also AR 190a:13156 [noting future development patterns will "likely result in an increased demand for driving"].)

B. Disclosure and Analysis of the 2050 Plan's Greenhouse Gas Emissions

In the San Diego region, transportation is responsible for nearly 50 percent of greenhouse gas emissions. (See AR 8a:2556-57 [Tables 4.8-4 (land use emissions) and 4.8-5 (transportation emissions)].) The total amount of driving expected under the 2050 Plan, termed "vehicle miles traveled" or VMT, will increase by more than 50 percent over the life of the

Plan. (AR 8b:4436 [EIR].) The expected increase in driving is not due solely to increases in population in the San Diego area; under the 2050 Plan, people will drive more on a per capita basis in 2050 than they did in 2010. (AR 8b:4435 [Table 3].) In 2010, daily per capita vehicle miles traveled for all vehicle types was 24.2 miles per day. By 2020, the average under the Plan is projected to dip down to 23.6 miles per day, but by 2035, it is above the 2010 average at 24.3 miles, and by 2050, it has risen to 25.2 miles. (AR 8b:4435 [Table 3]; see also 8b:3753, 3755, 3757.)[15] While this is *not* illustrated in the EIR, the People have plotted the trend below:

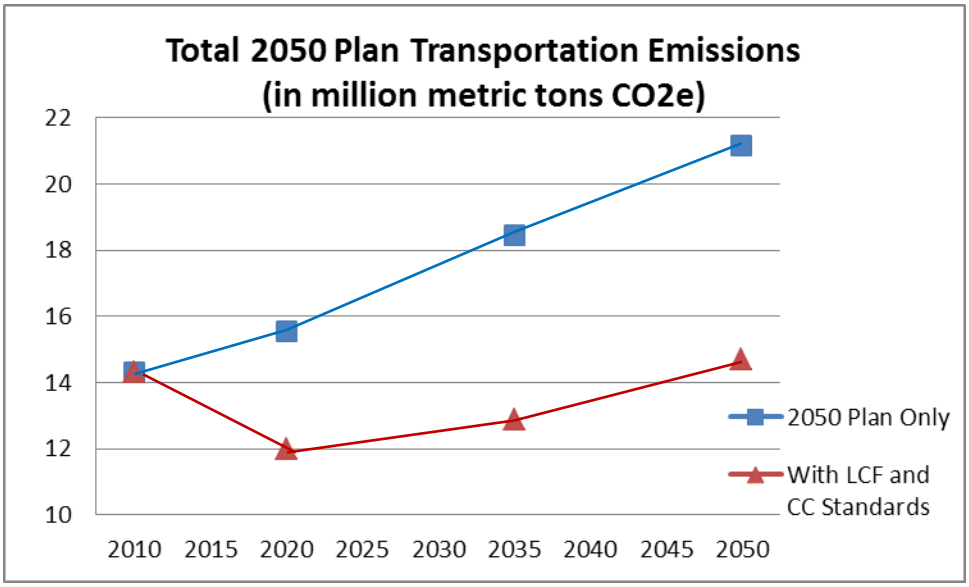


The 2050 Plan's near-term reductions in per capita vehicle miles traveled thus do not appear to be sustainable in the longer term.

Greenhouse gas emissions under the 2050 Plan reflect these driving patterns. There is a steady climb in transportation-related greenhouse gas

[15] Per capita vehicle miles traveled for SB 375 vehicles only—cars and light-duty trucks—follow this same pattern. (AR 8b:4435 [Table 3].)

emissions over the life of the project.[16] After taking into account the effect of state laws requiring reductions in the carbon content of fuel and increased fuel efficiency—the Low Carbon Fuel and "Clean Car" standards—the region's transportation emissions dip a bit below existing levels by 2020, but begin to climb thereafter, exceeding their 2010 starting point by 2050.[17] While these greenhouse gas emissions data are *not* graphed in the EIR, the People illustrate them below so that the upward trend in emissions over the longer term can be seen clearly.[18]



C. Significance Determination

In the 2011 EIR for the 2050 Plan, SANDAG employs three separate "significance criteria" and, under each, makes a determination of significance for discrete future years. (AR 8a:2567 [listing the criteria].)

---

[16] AR 8a:2557, 2572, 2575, 2577 [Tables 4.8-5, 4.8-8, 4.8-10, 4.8-12].

[17] *Ibid.*

[18] In million metric tons carbon dioxide equivalent.

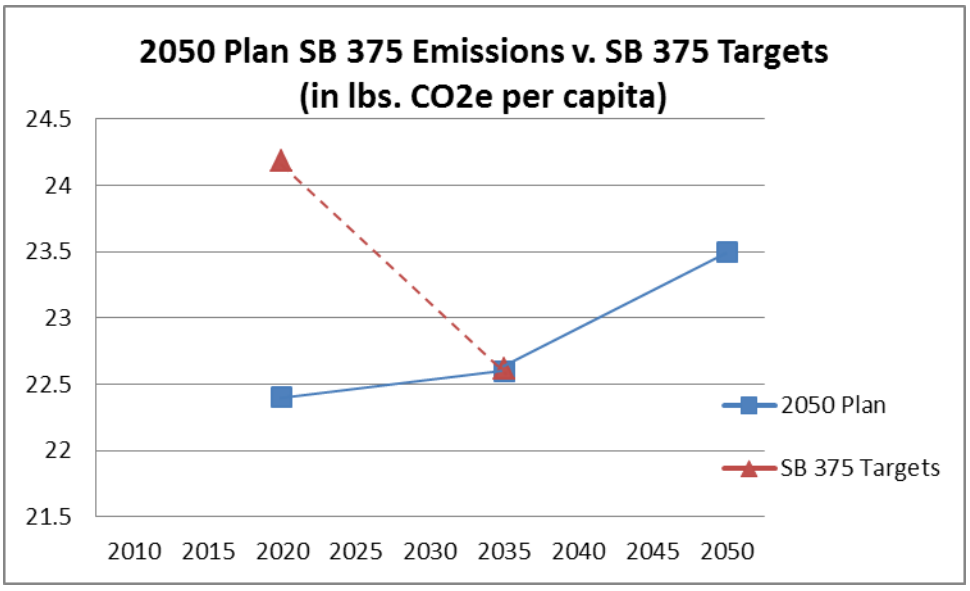
Before discussing these criteria, the People briefly summarize the role of the significance determination in CEQA, for the court's convenience.

The lead agency's determination of whether a proposed project's effects on the environment are significant—viewed in isolation or in light of other past, present, and future projects—plays a "critical role in the CEQA process." (CEQA Guidelines, § 15064, subd. (a); see also § 15064, subd. (h)(1) [discussing significance determination for cumulative effects].) The determination controls the nature of the environmental document, if any, that the agency must prepare. If the project is subject to CEQA and may have a significant effect on the environment, an Environmental Impact Report instead of a more summary Negative Declaration is required. (*No Oil, Inc. v. City of Los Angeles* (1974) 13 Cal.3d 68, 83-85; § 21151.) The EIR in turn must identify and focus on the project's significant environmental effects. (See, e.g., *Friends of Sierra Madre v. City of Sierra Madre* (2001) 25 Cal.4th 165, 184-185; § 21061.) "If the EIR identifies significant effects on the environment the lead agency may not approve the project unless it finds that changes have been made in the project to avoid these effects, or, if the mitigation measures or alternatives identified in the EIR are not feasible, there are overriding benefits that outweigh the impact on the environment." (*Id.* at p. 185, citing § 21081.)

SANDAG employs three separate "significance criteria" and, under each, makes a determination of significance for discrete future years. (AR 8a:2567 [listing the criteria].) The EIR first considers whether the Plan's total emissions would increase over 2010 levels. The EIR summarily states that the Plan's impact will be less than significant in the year 2020 because (with the help of the Low Carbon Fuel and Clean Car regulations) annual emissions are below 2010 levels in that year. (AR 8a:2571-2572.) Without placing these emissions into any meaningful context, the EIR summarily

concludes that the impacts are "significant and unavoidable" in 2035 and 2050 because gross annual emissions will be above 2010 levels in these discrete years. (AR 8a:2027; see AR 8a:2567-2578, 3092, 3095-3096.)

SANDAG's other significance analyses suggest to the reader that, even with the rising trend in total emissions, the region will be doing its part to address climate change. The EIR states that the 2050 Plan's impacts will be less than significant in 2020 and 2035 because the Plan will meet the SB 375 targets. (AR 8a:2030, 2578-2581, 3092, 3094-3095.) The EIR does not highlight that, while the Plan complies with the letter of SB 375 by meeting or exceeding the discrete targets for 2020 and 2035, per capita emissions from SB 375 vehicles (cars and light-duty trucks) begin to *rise* after 2020. (AR 8b:4435 [response to Attorney General's comments, table 2].) Again, while this data is not plotted in the EIR, the People present it in graphic form so that the trend is clear:



Nor does the EIR disclose that the California Air Resources Board staff found the increase in per capita emissions to be "unexpected" given the "expectation that the benefits of an SCS [Sustainable Communities Strategy] would increase with time given the nature of land use patterns and

transportation systems." (SANDAG's Supplement to the Administrative Record (AR Supp.) 344:30143.) Staff observed that the Air Resources Board "set regional targets with that expectation." (*Ibid.*) The EIR contains no analysis or determination of significance for any year beyond 2035 under this criterion, on the ground that SB 375 has no post-2035 targets. (AR 8a:2581, 3096.)

Finally, the EIR purports to examine whether the 2050 Plan's greenhouse gas impacts are significant in light of the potential for the Plan to conflict with the AB 32 Scoping Plan (examined for year 2020 only) and SANDAG's own Climate Action Strategy. (AR 8a:2030; 2581-2588.) In analyzing the potential for the 2050 Plan to conflict with the Scoping Plan, the EIR concludes that the 2050 Plan's land use and transportation greenhouse gas emissions are less than significant in 2020. The EIR supports this assertion by stating summarily that the 2050 Plan "encourages its jurisdictions to align with the Scoping Plan" and that, taking into account the effect of the Low Carbon Fuel and Clean Car regulations, transportation emissions will more than 15 percent below 2005 levels in 2020. (AR 8a:2583, 2583-84; see 320(5):27887.) The EIR states that SANDAG has no obligation to look beyond 2020 in applying this criterion because "[t]he Scoping Plan does not have targets established beyond 2020[.]" (AR 8a:2586.)

Similarly, in analyzing compliance with SANDAG's own Climate Action Strategy, the EIR summarily asserts that the 2050 Plan "would not impede" the Strategy because the 2050 Plan "encourage[es] compact development" and "promotes reduced VMT[.]" (AR 8a:2585-86, 2588.) The EIR does not acknowledge that SANDAG's own Climate Action Strategy observes that "[b]y 2030, the region must have met and gone below the 1990 level and be well on its way to doing its share for achieving the 2050 greenhouse gas reduction level." (AR 216:17629.)

D. Response to Comments Requesting Consideration of Climate Stabilization

The Attorney General, on behalf of the People, and other commenters requested that SANDAG, in discussing and determining significance, take into account the long-term, downward emissions trajectory necessary to achieve climate stabilization, as set out in the Executive Order and the Scoping Plan, which appeared to be inconsistent with the 2050 Plan's emissions trajectory over the longer term. (See, e.g., AR 311:25640-25642 [Attorney General's comment letter].) SANDAG did not find that such an analysis was infeasible or would be misleading under the circumstances. In responding to the Attorney General's comments, SANDAG acknowledged that "the Executive Order target for 2050 can inform CEQA analysis . . . ." (AR 8b:4432.) SANDAG, however, "chose not to" include any such analysis, emphasizing its discretion to select "thresholds of significance" and stating that the Executive Order was "not an adopted GHG [greenhouse gas] reduction plan within the meaning of CEQA Guidelines[.]" (*Ibid*.) It further opined that "SANDAG plays no formal role in implementing the Executive Order, as an executive order has no binding legal effect on agencies and personnel outside of the Governor's chain of command." (AR 8b:4433; see also 8b:3768-3770, 8a:2581-2582.) SANDAG also asserted—in a single sentence and without supporting evidence—that "SANDAG's role in achieving" the 2050 "target is uncertain and likely small." (AR 8b:3769.)

III. CEQA REQUIRES SANDAG TO CONSIDER THE SCIENCE AND POLICY OF CLIMATE STABILIZATION IN DETERMINING THE SIGNIFICANCE OF THE 2050 PLAN'S GREENHOUSE GAS EMISSIONS

The purposes of the Environmental Impact Report—the "heart of CEQA"—and the responsibilities that the EIR's preparation place on a lead agency bear repeating. "Its purpose is to inform the public and its

responsible officials of the environmental consequences of their decisions *before* they are made. Thus, the EIR 'protects not only the environment but also informed self-government.'" (*Citizens of Goleta Valley v. Bd. of Supervisors* (1990) 52 Cal.3d 553, 564 [italics in *Goleta*], quoting *Laurel Heights, supra*, 47 Cal.3d at p. 392.) "Because the EIR must be certified or rejected by public officials, it is a document of accountability." (*Laurel Heights*, *supra*, 47 Cal.3d at p. 392.)

SANDAG justifies limiting the information it provided to the public and decision makers about the 2050 Plan's longer-term greenhouse gas-related impacts on the ground that Executive Order No. S-3-05 is not directly binding on SANDAG as a regional entity and does not purport to require any action by SANDAG. (See AOB 4, 7, 23, 38-42.) That argument is beside the point. The People have never contended that this particular executive order by its own force imposes any obligation on SANDAG. Rather, fundamental CEQA requirements—to consider long-term environmental objectives, and to account for the science relevant to those objectives—combine to require SANDAG to make a good faith effort to disclose and analyze the 2050 Plan's long-term emissions in light of the objective of climate stabilization.[19]

[19] In theory, SANDAG could meet these requirements without specifically citing the Executive Order—provided it addresses the underlying science and state climate policy, as required by CEQA.

From the outset, the Legislature has made clear that CEQA requires lead agencies to look at the long-term impacts of the projects they approve or undertake directly. The concern for the longer term is seen in the statements of the Legislature's intent, which include the finding that "[t]he maintenance of a quality environment for the people of this state now *and in the future* is a matter of statewide concern." (§ 21000, subd. (a) [italics added].) Further, the Legislature declared through CEQA that it is "the policy of the state to[,]" among other things:

> Develop and maintain a high-quality environment now *and in the future* . . . .;
>
> [P]reserve for *future generations* representations of all plant and animal communities . . . .; and
>
> Ensure that *the long-term protection of the environment*, consistent with the provision of a decent home and suitable living environment for every Californian, shall be the *guiding criterion* in public decisions.

(§ 21001, subds. (a), (c), (d) [italics added].)

These concepts are reflected in the CEQA Guidelines, which provide that a lead agency may not focus only on the short term, but must also consider a project's long-term environmental impacts, and whether the project will work "to the disadvantage of long-term environmental goals" (CEQA Guidelines, § 15065, subd. (a)(2); see also *id.* at § 15126.2, subds. (a), (c).) And there is no suggestion that an agency can elect to truncate its analysis before the end of a project's acknowledged lifespan. (See, e.g., CEQA Guidelines, §§ 15003, subd. (h) [lead agency "must consider the whole of an action"]; 15216 ["[a]ll phases of a project must be considered"].) Further, as the CEQA Guidelines provide, in general, and in the specific context of climate change, "[t]he determination of whether a project may have a significant effect on the environment calls for careful

judgment on the part of the public agency involved, based to the extent possible on *scientific and factual data*." (CEQA Guidelines, §§ 15064, subd. (b) [italics added]; 15064.4, subd. (a) [stating that determination of significance of greenhouse gas-related impacts is made consistent with the provisions of section 15064].) These obligations are, of course, governed by CEQA's rule of reason—that lead agencies must make a reasonable, good-faith effort at full disclosure in their EIRs. (See, e.g., CEQA Guidelines, § 15003, subd. (i) [content of EIR]; see also *id.* at §§ 15151 [standards for adequacy of EIR], 15144 [forecasting], 15204 [adequacy of EIR determined by what is "reasonably feasible"].)

SANDAG thus must make a reasonable, good faith effort to consider the need to continually and substantially reduce emissions though midcentury not merely because certain targets are set out in Executive Order No. S-3-05, but because a declining emissions trajectory is scientifically relevant to achieving the objective of long-term climate stabilization. Moreover, the objective of reducing emissions to achieve climate stabilization is now firmly embedded in state law and policy, including AB 32, the AB 32 Scoping Plan, and SB 375. (See discussion at pp. 14-20, above.) As SANDAG noted in its Climate Action Strategy, the 2050 target of 80 percent below 1990 levels "is used as the long-term driver for state climate change policy development." (AR 216:17627.)

The public and decision makers were thus entitled to know whether the 2050 Plan, by making long-term planning decisions and authorizing the funding and construction of durable transportation infrastructure will lock the region into increased vehicle miles traveled and greenhouse gas emissions. They were entitled to this information before any decision was made, as such increases could cancel out improvements in vehicle and fuel efficiency and other statewide efforts, and make it difficult or impossible to bend the region's and the State's emissions curve downward over the

longer term. (See AR 216:17642 [SANDAG's Climate Action Strategy, noting that "continued growth in the rate of driving would likely cancel out" fuel and vehicle improvements]; see also CEQA Guidelines, § 15126.2, subd. (d) [EIR should address significant irreversible environmental changes, "such as highway improvement which provides access to a previously inaccessible area" and would "generally commit future generations to similar uses"].) SANDAG's failure to provide this information was error.

IV. THE 2050 PLAN EIR'S FAILURE TO CONSIDER CLIMATE SCIENCE AND POLICY WAS PREJUDICIAL

CEQA does not require perfection. "Insubstantial or merely technical omissions [from an EIR] are not grounds for relief." (*Neighbors for Smart Rail v. Exposition Metro Line Construction* (2013) 57 Cal.4th 439, 463.) On the other hand, a lead agency commits a prejudicial abuse of discretion where, among other things, it "'fail[s] to include relevant information [that] precludes informed decisionmaking and informed public participation, thereby thwarting the statutory goals of the EIR process.'" (*Ibid.* [brackets added], quoting *Kings County Farm Bur. v. City of Hanford* (1990) 221 Cal.App.3d 692, 712.) Where an EIR fails to "contain sufficient detail to help ensure the integrity of the process of decisionmaking" its fails in its central purpose—to "preclud[e] stubborn problems or serious criticism from being swept under the rug." (*Kings County Farm Bur.*, *supra*, 221 Cal.App.3d at p. 733, citing *Concerned Citizens of Costa Mesa, Inc. v. 32nd Dist. Agricultural Assn.* (1986) 42 Cal.3d 929, 935; see also CEQA Guidelines, § 15151.)

Here, the EIR's failure to analyze the longer-term effects of the land use and transportation decisions made in the initial decades of the 2050 Plan on the ability to achieve the State's climate stabilization objectives was not a mere technical omission. As noted, the EIR emphasized the

Plan's technical compliance with SB 375's discrete 2020 and 2035 greenhouse gas emission targets (AR 8a:2579, 2581)—without considering the upward incline of the region's emissions between those years. Further, it asserted that the Plan will "not impede" and will "assist" and "align with" the Scoping Plan (AR 8a:2582-2585) and SANDAG's Climate Action Strategy (AR 8a:2585-2588)—even though both documents acknowledge that nearer-term targets are interim steps towards achieving a midcentury stabilization goal. (See AR 320(5):27977 [Scoping Plan], 216:17628-17629 [Climate Action Strategy]; see also *Assn. of Irritated Residents*, *supra*, 206 Cal.App.4th at p. 1496.) As the Court of Appeal observed, the net effect of the EIR's approach to determining the significance of the 2050 Plan's greenhouse gas emissions was affirmatively misleading, obscuring the full impact of the Plan's effect on climate change, and undermining SANDAG's accountability for the decision ultimately made. (Opn. 19.) A document that "mislead[s] the public as to the reality of the impacts and subvert[s] full consideration of the actual environmental impacts" is "at direct odds with CEQA's intent." (*Communities for a Better Environment v. South Coast Air Quality Management Dist.* (2010) 48 Cal.4th 310, 322 [internal quotation omitted].)

SANDAG asserts that had the 2011 EIR included an analysis of the Executive Order and the science and policy that underlie it, this "would not have altered the conclusion that impacts would be significant and unavoidable in 2035 and 2050" under the gross emissions significance criterion. (AOB 2.) This is also beside the point. The agency's obligation is not simply to make determinations, but to show its "analytic route," which allows for full public discussion and "informed decision making." (*Vineyard*, *supra*, 40 Cal.4th at p. 445, internal quotations omitted; see also *Berkeley Keep Jets Over the Bay v. Bd. of Port Comrs.* (2001) 91 Cal.App.4th 1344, 1371 [holding that agency may not avoid "explor[ing]

the significant environmental effects created by the project" by labeling the effects significant and unavoidable].)

The practical effect of including in the significance analysis some discussion of whether SANDAG's Regional Transportation Plan is generally consistent, or instead may interfere, with the State's long-term climate stabilization objectives can be seen in the currently circulating draft EIR for the next update to the 2050 Plan. SANDAG has now chosen to approach the question of long-term climate significance by plotting the 2050 Plan's emissions over the project's full lifespan and comparing that emission trajectory to the statewide objectives, while correctly noting that "there is no requirement that the SANDAG region's emissions be reduced by the same percentage ('equal share') as the statewide percentage in order for the State to achieve the AB 32 target[.]" (See People's Motion for Judicial Notice, People's Decl., Ex. 1, p. 34.) This approach places squarely before the public and decision makers the greenhouse gas-related impacts of the 2050 Plan viewed over the longer term. It may trigger substantial discussion about the efficacy of SANDAG's proposed project design features and mitigation measures—many of which are new to this draft EIR—and whether other alternatives might meet the project objectives with fewer impacts. While the question whether SANDAG's current process will satisfy CEQA is outside the scope of this appeal, the new approach to determining the significance of the 2050 Plan's long-term greenhouse gas emissions would appear to foster accountability as CEQA intends and requires. The same cannot be said of the deficient 2011 EIR.

V. SANDAG'S ADDITIONAL ARGUMENTS DO NOT EXCUSE THE 2050 PLAN EIR'S SUBSTANTIAL DEFICIENCIES

A. Deference to Agency Discretion Does Not Sanction a Document that Minimizes a Project's Environmental Effects

SANDAG attempts to defend the contents of the 2011 EIR with general appeals to agency discretion. It notes that "lead agencies have discretion to design EIRs . . . ." (AOB 3.) "[S]electing analytical criteria for assessing greenhouse gas emission impacts involves agency discretion, informed by relevant technical and scientific understanding." (AOB 21.) And courts have "upheld the discretion afforded to lead agencies by Guidelines section 15064[,]" and to choose "significance criteria to evaluate greenhouse gas emissions" and "how to analyze the significance of greenhouse gas emissions." (AOB 33, 34.) All of these statements are true, as far as they go. But SANDAG further asserts that "[b]ecause SANDAG 'properly exercised its discretion' under CEQA, its EIR fulfilled its function as an informational document and should be upheld." (AOB 23, quoting Dis. Opn. at p. 24-30.) This is where SANDAG errs. A lead agency has no discretion to produce an environmental document that obscures, rather than highlights, the difficult environmental questions and tradeoffs posed by a proposed project. CEQA requires that an EIR, regardless of the significance criteria used by the lead agency, be "prepared with a sufficient degree of analysis to provide decision makers with information which enables them to make a decision which intelligently takes account of environmental consequences." (CEQA Guidelines, § 15151.)

As the trial court recognized, the record here establishes that SANDAG's treatment of the science and state policy related to long-term climate stabilization, as reflected in the Executive Order, was improperly

"dismissive." (JA {75} 1056.) While a lead agency has substantial discretion that will not be lightly disturbed by the courts when it is exercised, that protection does not extend where the lead agency refuses to engage in the hard questions presented by the project before it.

Similarly, SANDAG contends that it "is entitled to the 'safe harbor' provided by Public Resources Code section 21083.1" because it has complied with "all of CEQA's and the Guidelines' explicit requirements[.]" (AOB 28, citing *Berkeley Hillside, supra,* 60 Cal.4th at p. 1107.) Section 21083.1 "directs courts 'not [to] interpret [the CEQA statutes] or the state guidelines adopted pursuant to Section 21083 in a manner which imposes procedural or substantive requirements beyond those explicitly stated in [CEQA] or in the state guidelines.'" (*Id.* at p. 1107, quoting § 21083.1 [brackets in *Berkeley Hillside*; italics omitted].) One purpose of section 21083.1 is to provide a "'safe harbor'" to local entities" that "'comply with the explicit requirements of the law.'" (*Ibid.*, quoting Assem. Com. on Natural Resources, Analysis of Sen. Bill No. 722 (1993-1994 Reg. Sess.) July 12, 1993, p. 2.)

The People agree that if SANDAG had actually exercised its careful judgment in determining significance, making a good faith effort to account for climate science and the State's policy to work toward long-term climate stabilization, and supported its analysis and conclusion with substantial evidence, then there would be no legal basis to require more. But the concept of a safe harbor has no application where a lead agency "disclaims [its] power and duty" under CEQA "based on erroneous legal assumptions . . . ." (See *City of Marina*, *supra*, 39 Cal.4th at p. 365 [holding that university trustees abused their discretion in refusing to take action to mitigate off-site impacts based on erroneous legal assumptions].) That is the situation here.

B. The 2009 Amendments to the CEQA Guidelines Did Not Excuse Lead Agencies From Exercising Careful Judgment and Making Their Best Efforts in Determining Significance

SANDAG contends that it "scrupulously followed" section 15064.4 of the CEQA Guidelines because it employed significance criteria described in that provision and because the Resources Agency could have, but did not, specifically list the Executive Order in section 15064.4 as relevant to determining the significance of a project's greenhouse gas emissions. (AOB 30; see also *id.* 22, 24-29.)[20] In essence, SANDAG characterizes section 15064.4 as a rote exercise: if a lead agency checks certain boxes, it is excused from considering whether, in the specific context of the project before it, some additional discussion of climate science and California's policy to work toward climate stabilization is relevant and necessary to a fully informed significance determination. This reading of section 15064.4 is unsupported.

The preamble language of section 15064.4 stresses that while it is intended to provide guidance to lead agencies, the agency remains responsible for conducting an adequate analysis and preparing an adequate informational document. The provision directs agencies to exercise their own "careful judgment" in making the significance determination. (CEQA Guideline, § 15064.4, subd. (a).) In its statement of reasons for adopting this provision, the Resources Agency explained that the provision "reflects the existing CEQA principle that there is no iron-clad definition of

[20] SANDAG devotes several pages to discussing the legal effect of executive orders generally. (AOB 39-41.) That discussion misses the mark, as the People do not contend that Executive Order No. S-3-05 is the source of the legal requirement to consider the State's long-term climate objectives. (See p. 32, above.) Whether or not the Governor, through an executive order, could impose such requirements is therefore not at issue in this case.

'significance'" and that, "[a]ccordingly, lead agencies must use their best efforts to investigate and disclose all that they reasonably can regarding a project's potential adverse impacts." (AR 319:25846; see also CEQA Guidelines, § 15144; *Bozung v. Local Agency Formation Com.* (1975) 13 Cal.3d 263, 279, fn. 21.) Further, the part of section 15064.4 on which SANDAG relies—subdivision (b)—expressly is written as a non-exclusive list of considerations relevant to the significance determination. As the Resources Agency explained in the supporting Statement of Reasons, "while subdivision (b) provides a list of factors that should be considered by public agencies in determining the significance of a project's GHG emissions, other factors can and should be considered as appropriate." (AR 319:25850.)

Moreover, the listed factors themselves reflect the need for the agency to exercise judgment and best efforts in order to meet CEQA's public disclosure and informational purposes. Section 15064.4, subdivision (b)(2), states that an agency should consider "[w]hether the project emissions exceed a threshold of significance that the lead agency determines applies to the project."[21] SANDAG's consideration of whether the 2050 Plan would "[c]onflict with SB 375 GHG emission reduction targets" appears to fall into this category. (AR 8a:2567; see AOB 27.)[22] But the fact that the 2050 Plan technically complies with the discrete per capita greenhouse gas emission targets for passenger vehicles in the years 2020 and 2035 does not

[21] To clarify, the Resources Agency does not develop and adopt thresholds of significance for use by local and regional governments. (See AOB 25 [erroneously referring to "thresholds adopted by the Resources Agency under SB 97"]; CEQA Guidelines, § 15064.7, subd. (a); AR 319:25851 [SB 97 FSOR].)

[22] SANDAG states that SB 375 may also constitute a greenhouse gas emissions reduction "plan" as defined in section 15064.4, subdivision (b)(3). (AOB 27.)

automatically end SANDAG's inquiry. A threshold is in essence a working presumption of significance—"an identifiable quantitative, qualitative or performance level of a particular environmental effect, non-compliance with which means the effect will *normally* be determined to be significant by the agency and compliance with which means the effect *normally* will be determined to be less than significant." (CEQA Guidelines, § 15064.7, subd. (a) [italics added].) While compliance with laws and regulations, including those designed to meet environmental objectives, may be highly relevant to determining significance (see *Communities for a Better Environment v. California Resources Agency* (2002) 103 Cal.App.4th 98, 112-114, disapproved on other grounds in *Berkeley Hillside*, *supra*, 60 Cal.4th at p. 1109, fn. 3), such compliance, standing alone, cannot always support a conclusion that the project's impacts will be less than significant. (*Ibid.*, see also, e.g., *Protect the Historic Amador Waterways v. Amador Water Agency* (2004) 116 Cal.App.4th 1099, 1108-1111 [reduction in stream flow may be a significant environmental effect despite water pipeline project's compliance with environmental requirements]; *Californians for Alternatives to Toxics v. Dept. of Food & Agriculture* (2005) 136 Cal.App.4th 1, 16 [lead agency's sole reliance on state agency's registration of pesticides and its regulatory program was inadequate to address environmental concerns of CEQA].) Here, where per capita emissions from cars and light trucks *rise* between 2020 and 2035, contrary to SB 375's objective of declining emissions (see AR Supp. 344:30143 [Air Resources Board staff report]), SANDAG had an obligation to go beyond a recitation of the 2050 Plan's compliance with a SB 375-based threshold.

Similarly, section 15064.4, subdivision (b)(3) states that an agency should consider "[t]he extent to which the project complies with regulations or requirements adopted to implement a statewide, regional, or local plan for the reduction or mitigation of greenhouse gas emissions." In its EIR,

however, SANDAG identified only those discrete, shorter term objectives and policies set out in the Scoping Plan and its Climate Action Strategy that, in SANDAG's view, the 2050 Plan would not impede.[23] A project's ostensible short-term consistency with specific aspects of climate policies or plans does not excuse the agency from determining whether that apparent consistency dissipates when viewed over the longer term. This is particularly true where the very authorities and documents on which SANDAG relies—the region's SB 375 targets, the AB 32 Scoping Plan, and SANDAG's own Climate Action Strategy—are grounded in the need to continually reduce emissions over the long term to achieve climate stabilization. (See, e.g., AR Supp. 344:30143 [SB 375 staff report]; AR 320(5):379977, 27848 [Scoping Plan]; *Assn. of Irritated Residents*, *supra*, 206 Cal.App.4th at p. 1496 [noting that 2020 limit is an interim goal]; AR 216:17627-17628, 17644 [Climate Action Strategy]; see also Opn. 21, fn. 11 [questioning SANDAG's conclusion that the 2050 Plan will not conflict with SANDAG's Climate Action Strategy].) As section 15064.4, subdivision (b)(3) itself states, an agency's analysis is not at an end where

[23] SANDAG contends that its discussion of whether the 2050 Plan "conflicts with" the 2008 Scoping Plan for the year 2020 or with SANDAG's own 2010 Climate Action Strategy follows the letter of CEQA Guidelines section 15064.4, subdivision (b)(3). (AOB 27-28; see AR 8a:2567, 2581-2588.) It is not clear that the Scoping Plan, as applied to SANDAG, or SANDAG's Climate Action Strategy, are the types of binding regulatory plans contemplated by section 15064.4, subdivision (b)(3). (See AR 319: 25852-26853 [SB 97 FSOR]; see also CEQA Guidelines, § 15183.5, subd. (b).) Still, an approach to determining significance that considers statewide, regional, or local climate policies and objectives is a reasonable and accepted approach fully consistent with the CEQA Guidelines. (See, e.g., CEQA Guidelines, §§ 15064, 15064.4, 15065.) And, in the circumstances of this case, discussion and consideration of the Scoping Plan and SANDAG's Climate Action Strategy are integral to a fully informed public process and decision.

"there is substantial evidence that the possible effects of a particular project are still cumulatively considerable notwithstanding compliance with the adopted regulations or requirements . . . ." (CEQA Guidelines, § 15064.4, subd. (b)(3); see also *id.*, § 15064, subd. (h)(3) [general provision authorizing lead agency to rely on plans that address cumulative environmental impacts in making significance determination].)

SANDAG's other arguments related to CEQA Guidelines section 15064.4 must be rejected. SANDAG states that the fact that section 15064.4 does not mention the Executive Order reflects an intent to exclude it. SANDAG points to Public Resources Code section 21083.05, which, while it provides that the Guidelines must be updated periodically to incorporate either new information or criteria established by the State Air Resources Board pursuant to Division 25.5 (AB 32) "does not require the Guidelines to include information or criteria from the [Executive] Order specifically or from the Governor generally." (AOB 24.) SANDAG's observation, while correct, is once again beside the point. The section is designed to ensure that the Guidelines continue to reflect evolving science and any regulations or requirements adopted by the Air Resources Board that could assist lead agencies in carrying out their CEQA obligations. (See AR 319:25836, 25917, 25930 [SB 97 FSOR].) Section 21083.05 cannot be read to suggest that the Legislature considered the science and state policy concerning climate stabilization to be irrelevant under CEQA.

SANDAG also states that "[t]hrough Guidelines section 15064.4, subdivision (b)(3), the Resources Agency implicitly rejected use of the Executive Order's broad, statewide targets as being technically sound for CEQA analysis." (AOB 31.) It is true that the section does not mention the Executive Order. Neither does it mention the Global Warming Solutions

Act (AB 32), the AB 32 Scoping Plan, or the Sustainable Communities Strategy law (SB 375).[24] Of necessity, there are numerous factors and considerations that may be relevant to a particular project that are not expressly listed in this provision. The Resources Agency did not attempt in section 15064.4 to set out an exhaustive list of considerations that could be relevant in analyzing the impacts for the wide variety of projects undertaken or permitted by the wide variety of entities that are lead agencies under CEQA.

And SANDAG's suggestion that the California Air Resources Board has "rejected use of the Executive Order" in conducting a significance determination under CEQA is wrong. (AOB 31-32.) To clarify, the Air Resources Board does not promulgate CEQA regulations that apply generally to lead agencies or set thresholds of significance. That is not in the Air Resources Board's mandate. In 2008, Air Resources Board staff commenced a project that was intended to lead to Board-issued recommendations to local governments for greenhouse gas emissions thresholds they might choose to adopt for use in considering a limited subset of projects, specifically, "industrial, residential, and commercial projects." (AR 320(3):27789 [2008 Preliminary Draft Staff Proposal].) This project ended without a formal recommendation by staff to the Air Resources Board, and without Board action. The preliminary staff report cited by SANDAG is thus of little assistance in determining SANDAG's obligations under CEQA. Moreover, contrary to SANDAG's assertions,

[24] The People note, however, that the Resources Agency in its Statement of Reasons cited the Executive Order and AB 32, and the findings they contain, for the proposition that "the Governor, Legislature and private sector have concluded that action to reduce greenhouse gas emissions is necessary and beneficial for the State." (AR 319:25834 [SB 97 FSOR].)

the preliminary staff report does cite the scientific basis of the declining emissions trajectory in the Executive Order (AR 320(3):27791-27792), and provides that its 2050 target may in some circumstances be relevant to determining significance (*id.* at 27799).

C. The EIR's Disclosure of 2050 Gross Emissions and Bare Mention of the Executive Order Are Not a Substitute for Good Faith, Reasoned Analysis

SANDAG suggests that the EIR was sufficiently forthcoming about long-term climate impacts because (1) the EIR provided that "greenhouse gas impacts for 2035 and 2050 would be significant, as emissions would increase due to regional population, housing, and employment growth" (AOB 2; *id.* at 26-27, 46); (2) a careful reader could figure out that the 2050 Plan was perhaps not wholly consistent with the State's 2050 emission reduction objectives (AOB 46-47); and (3) the EIR "did not neglect discussion of the Executive Order or its role in state climate strategy" (AOB 47). These arguments do not withstand scrutiny.

"[S]imply labeling the impact 'significant' without accompanying *analysis*" violates "the environmental assessment requirements of CEQA." (*Berkeley Keep Jets, supra*, 91 Cal.App.4th at p. 1371 [italics added].) SANDAG thus cannot rely on a "significant and unavoidable" determination to skip over the required step of explaining how and why the impact is significant. Moreover, quantification of greenhouse gas emissions in the context of this project is not an end in itself, but should serve to "inform[] the qualitative factors" in section 15064.4. (AR 319:25847 [SB 97 FSOR].) The effect of SANDAG's failure to put this long-term project's emissions into a long-term environmental context was to undermine the importance of the EIR's determination that the Plan's 2035 and 2050 gross emissions were significant. Any concern that might be engendered in the public or decision makers about the 2050 Plan's

increases in emissions over time is quickly assuaged by the EIR's discussion and findings under the two other significance criteria. The EIR assures the public and decision makers that the 2050 Plan complies with SB 375's emissions reduction targets and greenhouse gas reduction plans, and that the 2050 Plan's impacts under these apparently more informative standards are less than significant. (AR 8a:2030, 2567-2588.) And, as the Court of Appeal noted, the end result is misleading.

SANDAG's argument that a reader of the EIR could have constructed an analysis of whether the 2050 Plan's emissions are consistent or instead might interfere with the State's long-term climate stabilization objectives is wrong on two counts. This is not a matter of mere "arithmetic" (see AOB at p. 46) but requires some considered discussion, at least as detailed and as analytical as what SANDAG provided in examining whether the 2050 Plan conflicted with the 2008 Scoping Plan and its Climate Action Strategy. (See AR 8a:2581-2588.) Moreover, "[t]he data in an EIR must not only be sufficient in quantity, it must be presented in a manner calculated to adequately inform the public and decision makers . . . ." (*Vineyard*, *supra*, 40 Cal.4th at p. 442.) "[I]nformation scattered here and there in EIR appendices or a report buried in an appendix, is not a substitute for a good faith reasoned analysis." (*Ibid.*, internal quotations omitted.)

Finally, SANDAG's assertion that the EIR discussed the Executive Order "at length" is not supported by its record citations. (AOB 47.) At the pages cited, the EIR:

- Includes a one-sentence summary of the Executive Order among other instances of state action related to climate change (AR 8a:2651);

- States that SANDAG will not consider whether the 2050 Plan would conflict with the AB 32 Scoping Plan for any year beyond 2020, and that while Executive Order No. S-3-05 "sets a goal that statewide GHG emissions be reduced to 80 percent below

1990 levels by 2050," it "does not constitute a 'plan' for GHG reduction, and no state plan has been adopted to achieve the 2050 goal" (AR 8a:2581-2582);

- Opines that, for example, "[t]he Legislature declined to include the Executive Order's aspirational 2050 goal in AB 32" and that "SB 375 legislative findings do not mention achievement of the ambitious 2050 EO S-3-05 GHG emissions reductions target" (AR 8b:3766-3768 [master response to comment]; see also 8b:4436 [response to Attorney General's comments]);

- States that "SANDAG chose not to use the 2050 EO [Executive Order] emissions reduction target as a threshold of significance because the EO is not an adopted GHG reduction plan within the meaning of" CEQA Guidelines, § 15064.4, subd. (b)(2), and because "there is no legal requirement to use it as a threshold of significance" (AR 8b:3768-3770); and

- Summarily asserts, as an additional reason that it will not consider the longer-term reduction target, that "SANDAG's role in achieving this target is uncertain and likely small." (AR 8b:3769.)

On the last point, not only is the statement not supported by any citation or discussion, it misses the point of a cumulative impact analysis. As the 2008 Scoping Plan stated, "[i]n order to achieve the deep cuts in greenhouse gas emissions we will need beyond 2020 it will be necessary to significantly change California's current land use and transportation planning policies." (AR 320(5):27858.) The relevant question is not whether the SANDAG region is a relatively small contributor of greenhouse gases as judged against the scale of the problem, or whether SANDAG can "singlehandedly meet the Executive Order's long-term greenhouse gas reduction goals" (AOB 47), but whether the region's non-trivial and long-term contribution is cumulatively considerable given the state of the climate and the State's long-term climate stabilization objectives. (See *Kings County Farm Bur., supra*, 221 Cal.App.3d at p. 718

["relevant question to be addressed in the EIR is not the relative amount of [pollution] emitted by the project when compared with preexisting emissions" but whether project's "emissions should be considered significant in light of the serious nature" of the air pollution problems in the air basin]; see also *Massachusetts v. EPA* (2007) 549 U.S. 497, 524 [observing that "[a]gencies, like legislatures, do not generally resolve massive problems in one fell swoop"].)

In addition, SANDAG cites a SANDAG staff memorandum dated October 28, 2011, the day the EIR was certified and approved by SANDAG. (AOB 47.) The report informed the SANDAG Board that the Executive Order's 2050 target, if applied directly to SANDAG, would require the region's total emissions to be 5.02 million metric tons in 2050, and that the EIR identified total emissions in that year to be 33.65 million metric tons. (AR 14:4514.) This disclosure, if made earlier in the EIR process, could have formed part of a larger, informative discussion about the project's impacts, serving as a counterpoint to the assertions of compliance with applicable greenhouse gas emissions reductions plans. But this post-EIR document came too late and was too summary to serve any useful purpose in the CEQA process.

D. SANDAG's Post Hoc Attempts to Justify its Refusal to Consider the Science and State Policy Concerning Long-Term Climate Stabilization Should Be Rejected

As noted, SANDAG's contemporaneous justifications for refusing to consider the science and state policy concerning long-term climate stabilization were legal ones. Before this court, SANDAG attempts to assert additional justifications for its truncated analysis. Those reasons are not persuasive. SANDAG's assertions that the Resources Agency and the California Air Resources Board "rejected" any use of the Executive Order in determining significance as not "technically or legally sound"

mischaracterize the relevant documents, as discussed above. (AOB 31-32; see discussion above at pp. 44-45.) And while SANDAG is correct that the California Air Pollution Control Officers Association (CAPCOA), in its 2008 white paper, "CEQA and Climate Change," suggested that it may not be appropriate simply to apply the Executive Order's statewide 2050 target to sub-parts of the state or to individual development projects (AOB 32; see AR 319:26322, 26324-26325), CAPCOA did not suggest that the State's long-term climate stabilization objectives are irrelevant to the significance determination. (See, e.g., AR 319:26292 [stating that "[t]he first approach [explored in the white paper] is grounded in statute (AB 32) and executive order (EO S-3-05)"].)

SANDAG also asserts that "[i]t would be practically impossible for agencies to be accountable for accomplishing the Order's statewide goal for 2050 when the state has not figured out how to allocate that responsibility among its regions and the various emitters in those regions" and that discussing the Executive Order would be "speculative and potentially misleading . . . ." (AOB 36; see also *id.* at 23, 37-38, 47.) This assumes that the only way to consider climate science and long-term climate policy is to adopt the Executive Order's 2050 statewide reduction target as a regional target. But the People have never so argued. The point is that consideration of the need to reduce statewide greenhouse gas emissions over the longer term can inform that analysis, serving as a counterweight to assertions that the 2050 Plan complies with SB 375 and purportedly does not conflict with the Scoping Plan in 2020. (See AR 8b:4432 [SANDAG acknowledging that 2050 target "can inform the CEQA analysis"].)

More fundamentally, SANDAG never relied on any discussion of the Executive Order by the Resources Agency, Air Resources Board staff, or CAPCOA in declining to consider the science and the State's long-term climate objectives. SANDAG's cites are to the these entities' documents,

not to its own analysis, or anything in the EIR that purports to rely on these documents. (See AOB 31-32, 47.) And SANDAG never contended in the EIR that accounting for the longer term was impossible or would result in a misleading document, but only that neither the Legislature nor the Resources Agency had expressly directed such an analysis. SANDAG's counsel's post hoc attempts to shore up the 2011 EIR should be rejected as contrary to CEQA's purposes. As this court has explained, "[t]he audience to whom an EIR must communicate is not the reviewing court but the public and the government officials deciding on the project." (*Vineyard*, *supra*, 40 Cal.4th at p. 443.) A lead agency's arguments in its briefs are

> irrelevant, because the public and decision makers did not have the briefs available at the time the project was reviewed and approved. The question is therefore not whether the project's significant environmental effects *can* be clearly explained, but whether they *were*.

(*Ibid.*, italics in original) The 2050 Plan EIR, like the EIR at issue in *Vineyard*, "fails that test." (See *ibid.* [declining to supplement deficient EIR with counsel's arguments].)

If the court is nevertheless inclined to consider SANDAG's extra-record assertions that the requested analysis is impossible or ill-advised, the People ask the court to take judicial notice of the fact that SANDAG, in the draft EIR for its current 2050 Plan update, has added the following query to its list of "significance criteria": Whether the proposed Plan would be "[b]e inconsistent with the State's ability to achieve the Executive Order [Nos.] B-30-15 and S-3-05 goals of reducing California's GHG emissions to 40 percent below 1990 levels by 2030 and 80 percent below 1990 levels by 2050." (People's Decl., Ex. 1, p. 20; see also *id.* at p. 34.) This not only marks progress, but establishes that a remand to the agency, requiring it to make a good faith effort to disclose and analyze the impacts of the 2050 Plan in the context of state policy relating to long-term climate change will

assist in serving the public disclosure and informed decision making purposes of CEQA.

VI. THIS COURT SHOULD REMAND THE MATTER AND ALLOW SANDAG TO REMEDY THE 2011 ENVIRONMENTAL IMPACT REPORT'S DEFICIENCIES IN THE COURSE OF THE PENDING 2050 PLAN UPDATE

In the nearly four years since the Attorney General submitted her comment letter to SANDAG, science, law, and policy related to climate change have continued to evolve. The International Panel on Climate Change has issued another report informing the public and policy makers of the need for decisive action.[25] The Air Resources Board adopted an updated Scoping Plan.[26] The Governor recently issued a new Executive Order (No. B-30-15) setting a statewide 2030 emissions target marking the State's path toward 2050.[27] The state Senate is considering updates to AB 32 to guide the Air Resources Board in setting post-2020 targets.[28] And SANDAG, as it is required to do every four years, has moved on to its next regional transportation plan update and is circulating a new draft EIR for an updated 2050 Plan. (See SANDAG's regional transportation plan webpage at http://sandiegoforward.org/regionalplan.)

The fact that SANDAG is voluntarily analyzing long-term climate stabilization in the draft EIR for its pending 2050 Plan update does not

---

render this case moot. As evidenced by SANDAG's opening brief, there remains a substantial need for this court to clarify for SANDAG, and potentially for other regional planning entities, that in the circumstances of a large-scale infrastructure and planning project with substantial long-term greenhouse gas emissions, a lead agency has a responsibility under CEQA either to address the science and state policy relating to long-term climate stabilization or explain why it cannot, supporting any such explanation with substantial evidence. The question presented in this case might otherwise evade review, given the relatively short period between regional transportation plan updates. (See *California Charter Schools Assn. v. Los Angeles Unified School Dist.* (2015) 60 Cal.4th 1221, 1233-1234 [case relating to allocation of facilities to charter schools for past school year not moot where issue is "likely to recur yet evade review because of the relatively short duration of the academic year"].)

In light of these developments and the time that has elapsed, rather than requiring SANDAG to revise or supplement the 2011 EIR to correct the deficiencies identified in this litigation, it would appear to be most efficient to focus the remedy on the pending EIR process—a result that is not precluded by CEQA's remedy provisions. (See § 21168.9, subd. (a).) Accordingly, the People request that SANDAG be ordered, in the course of preparing the pending 2050 Plan EIR, to take the corrective actions identified by this court should the People prevail, and, in addition, the specific corrective actions identified by the Court of Appeal (see Opn. at pp. 26-27 [greenhouse gas-related mitigation], 30 [project alternatives], 41 [air quality impacts and mitigation], 44 [agricultural impacts]).[29]

[29] The trial court did not order that specific activities approved under the 2050 Plan be suspended, and the People do not request any change to that aspect of the remedy.

CONCLUSION

The People respectfully request that the court hold that SANDAG abused its discretion in determining that in the EIR for the 2050 Plan—a large-scale, long-term transportation infrastructure and land use planning project—SANDAG had no obligation under CEQA to consider the science and state policy of long-term climate stabilization. It should further affirm the decision of the Court of Appeal that SANDAG's error was prejudicial, provide that SANDAG must decertify the deficient 2011 EIR, and remand the case for further proceedings consistent with this court's opinion.

SUPERIOR COURT OF THE STATE OF CALIFORNIA
FOR THE COUNTY OF SAN DIEGO

CLEVELAND NAT'L FOREST FOUNDATION, et al.,

Petitioners,

v.

SAN DIEGO ASS'N OF GOVERNMENTS,

Respondent;

And CONSOLIDATED CASE and COMPLAINT IN INTERVENTION BY the ATTORNEY GENERAL OF CALIFORNIA

Case No. 2011-00101593

RULING ON PETITIONS FOR WRIT OF MANDATE

Judge: Timothy B. Taylor
Dept.: 72

Hearing: November 30, 2012

1. Overview and Procedural History.

In this CEQA case, the petitioners and the Attorney General claim SANDAG abused its discretion when it decided to certify an EIR and adopt a Regional Transportation Plan (RTP) which for the first time included a "Sustainable Communities Strategy" (SCS) ostensibly designed to meet a greenhouse gas emission reduction target as required by Senate Bill 375, Stats. 2008, Ch. 728. The parties agree this is the first RTP in California to be adopted following the 2008 legislation [AR2075; AR 04465], but they fundamentally disagree about the reach and requirements of that statute as it interfaces with the requirements of CEQA. No court has heretofore interpreted SB 375; the RTP/SCS at issue is meant to provide a blueprint for transportation planning for the next

40 years; and entities like SANDAG up and down the State are looking for guidance from this case regarding how to implement SB 375 in the context of an EIR. Thus, this court is but a way station in the life of this case, which is clearly headed for appellate review regardless of the outcome at the trial level. The case arises against a backdrop of intense scientific and political debate over what one counsel referred to as the signal issue of our time: global climate change.

Petitioners Cleveland Nat'l Forest Foundation ("Cleveland") and the Center for Biological Diversity ("CBD") filed the petition on November 28, 2011. The case was assigned to Judge Hayes, but Cleveland challenged her and the case was reassigned. Petitioners CREED-21 and the Affordable Housing Coalition ("AHC") filed a substantially similar petition, also on November 28, 2011 (ROA 42). This case, No. 2011-00101660, was initially assigned to another department, but the parties later stipulated to (and the court ordered) consolidation with the low-numbered case (ROA 41).

Cleveland and CBD filed an amended petition on 1/23/12, adding the Sierra Club as a petitioner (ROA 17). The AG sought and obtained leave to intervene on 1/25/12, and filed her petition in intervention the same day on behalf of the People (ROA 22-25).

At a CMC on 2/24/12, the parties advised the court that the Administrative Record in this case exceeds 10,000 pages in length (as it turned out, it is over 30,000 pages). In light of this, the court adopted a party-proposed briefing schedule, granted relief from brief page limits imposed by the Rules of Court, and set the matter for a merits hearing (ROA 38). SANDAG subsequently filed answers to both the Cleveland/CBD/Sierra Club amended petition and the CREED-21/AHC petition (ROA 48, 49). SANDAG also filed its answer to the AG's petition in intervention.

The Administrative Record, which is contained on a CD, was lodged on June 27 (ROA 53), having been certified by SANDAG on May 3 (ROA 45). Joint excerpts are contained in two binders, which were lodged 10/25/12. On November 19, the parties lodged a "Corrected Joint Appendix" (ROA 80); but by this time, the court had done the lion's share of its review using the joint excerpts lodged in October.

The briefing has been extensive, and as will be explained below, might have been even more extensive. On June 27, the AG filed an opening brief, an amended opening brief, and (a few days later) an errata to the amended opening brief (ROA 52, 56). Also on June 27, CREED-21/AHC filed their opening brief (ROA 54), and Cleveland/CBD/Sierra Club filed their opening brief (ROA 55). This was a total of 81 pages of briefing (not counting the AG's amendments and corrections). On Sept. 10, SANDAG filed its responsive briefs: one in response to the AG's amended brief (ROA 62), and a second in response to the Cleveland and CREED-21 briefs (ROA 61). This was a total of 95 pages of briefing.

On September 25, 2012, the court had the unpleasant experience of denying several requests for leave to file *amicus* briefs. ROA 68. Respondents recruited several *amici*

who spent time and energy preparing extensive briefs. See ROA 59, 64. The parties and the proposed *amici* appeared on September 25 to ask the court to allow the filing of these briefs, and to set a briefing schedule for joinders and responses thereto. The court was constrained to exercise its discretion to deny all such requests; it explained its decision in two ways. First, the court is aware of its limited role here: to ensure a complete record, and to provide the parties with a timely decision so that the case may proceed promptly to appellate review. The court was concerned that allowing *amicus* briefing, joinders and responses would retard rather than advance the latter goal (particularly given that the trial court's decision will not affect the others statewide with an interest in this topic, but rather only the parties – and then only for the limited period between the decision set forth below and the issuing of a learned opinion from the 4th DCA, Div. 1).

Second, and in a related vein, the court noted that Brobdingnagian budget cuts recently suffered by the Judicial Branch have caused the San Diego Superior Court to lay off hundreds of staff, stop providing court reporters in civil cases, restrict office hours, and, most recently, close a county-wide total of seven civil independent calendar courtrooms (with a consequent re-distribution of the caseload among the "surviving" departments). Again, the court was concerned that 100+ pages of additional briefing (on top of the lengthy party/intervenor briefs) could not be properly addressed by the court in a timely fashion, given these harsh fiscal and workload realities. Fortunately, the work done by *amici* will not have been wasted; they remain free to polish their briefs in light of this court's decision and seek leave to file them as the case proceeds to review before courts with broader authority.

Finally, reply briefing was filed by the AG on October 12; petitioners filed their consolidated reply that same day (ROA 72, 73). This was an additional 50 pages of briefing. The court has reviewed the opening, opposition and reply briefing, as well as the Administrative Record and the Supplement thereto filed October 22 (ROA 74).

The court notes that the briefing was accompanied by lodgments of non-California authorities. The court asks the parties to forebear from routinely lodging copies of federal or foreign authorities in the future. These are ordinarily available to the court on Westlaw. Counsel are encouraged to review the Summer 2011 amendments to CRC 3.1113(i) in this regard. The former rule made such lodgments mandatory; the current rule permits judicial discretion in this area. The court will advise counsel if it needs a lodgment of a non-California authority. Many trees will be saved if counsel will honor this request. Also, recent budget cuts imposed on the court make the clerk time for the handling of these lodgments quite problematic.

On November 16, 2012, the court published a lengthy tentative ruling. The court did so early, in order to facilitate counsel's preparation in light of the intervening Thanksgiving holiday. The court entertained well-prepared and very thoughtful argument on November 30 from Mr. Seymour on behalf of SANDAG, Mr. Selmi on behalf of petitioners, and by Mr. Patterson and Ms. Durbin on behalf of the AG. Petitioners and the AG used a Powerpoint presentation, which the court marked as Ex. 1 to the hearing for record purposes. Following argument, the court took the matter under submission. The court

now renders its decision. Record references below are to the excerpts lodged by the parties in October, except where stated. The court notes that, near the end of her comments during the 1 hour 45 minute hearing, Ms. Durbin requested a Statement of Decision. This is not required, as there was no "trial" of this matter as contemplated by CCP section 632. There was no testimony or cross examination; the matter proceeded, as most if not all CEQA cases do, in the manner of a complex motion argument. The court hopes that the following discussion will be deemed by the parties and the reviewing court to be an adequate specification of the grounds for non-compliance as required by Pub. Res. Code section 21005(c), and an adequate setting forth of the court's decision and the reasons therefor.

2. Overview of the CEQA Process.

A. The Court's Role in CEQA Cases.

In *Mira Mar Mobile Community v. City of Oceanside,* 119 Cal.App.4th 477, 486 (2004) (*Mira Mar Mobile Community*), the court explained that "[i]n a mandate proceeding to review an agency's decision for compliance with CEQA, [courts] review the administrative record *de novo* [citation], focusing on the adequacy and completeness of the EIR and whether it reflects a good faith effort at full disclosure. [Citation.] [The court's] role is to determine whether the challenged EIR is sufficient as an information document, not whether its ultimate conclusions are correct. [Citation.]" An EIR is presumed adequate. Pub. Res. Code § 21167.3, subd. (a).

Courts review an agency's action under CEQA for a prejudicial abuse of discretion. Pub. Res. Code § 21168.5. "Abuse of discretion is established if the agency has not proceeded in a manner required by law or if the determination or decision is not supported by substantial evidence." *Id.;* see *Mira Mar Mobile Community, supra,* 119 Cal.App.4th at 486; *County of San Diego v. Grossmont-Cuyamaca Community College Dist.* ("*Grossmont*"), 141 Cal. App. 4th 86, 96 (2006)(same).

In defining the term "substantial evidence," the CEQA Guidelines state: " 'Substantial evidence' ... means enough relevant information and reasonable inferences from this information that a fair argument can be made to support a conclusion, even though other conclusions might also be reached. Whether a fair argument can be made ... is to be determined by examining the whole record before the lead agency. Argument, speculation, unsubstantiated opinion[,] narrative [or] evidence which is clearly erroneous or inaccurate ... does not constitute substantial evidence." CEQA Guidelines, § 15384(a). "In applying the substantial evidence standard, [courts] resolve all reasonable doubts in favor of the administrative finding and decision. [Citation.]" *Mira Mar Mobile Community, supra,* 119 Cal.App.4th at 486; *Grossmont, supra,* 141 Cal. App. 4th at 96.

Although the lead agency's factual determinations are subject to the foregoing deferential rules of review, questions of interpretation or application of the requirements of CEQA are matters of law. While judges may not substitute their judgment for that of the decision

makers, they must ensure strict compliance with the procedures and mandates of the statute. *Grossmont, supra*, 141 Cal. App. 4th at 96.

B. The Three Steps of CEQA.

CEQA establishes "a three-tiered process to ensure that public agencies inform their decisions with environmental considerations." *Banker's Hill, et al v. City of San Diego*, 139 Cal. App. 4th 249, 257 (2006)("*Banker's Hill*"); see also CEQA Guidelines, § 15002(k)(describing three-step process).

First Step in the CEQA Process.

The first step "is jurisdictional, requiring that an agency conduct a preliminary review in order to determine whether CEQA applies to a proposed activity." *Banker's Hill, supra,* 139 Cal. App. 4th at 257; see also Guidelines, § 15060. The Guidelines give the agency 30 days to conduct this preliminary review. (Guidelines, § 15060.) The agency must first determine if the activity in question amounts to a "project." *Muzzy Ranch Co. v. Solano County Airport Land Use Com.* (2007) 41 Cal.4th 372, 380. "A CEQA ...project falls into one of three categories of activity which may cause either a direct physical change in the environment, or a reasonably foreseeable indirect physical change in the environment (§ 21065.)" *Sunset Sky Ranch Pilots Assn. v. County of Sacramento* (2009) 47 Cal.4th 902, 907.

As part of the preliminary review, the public agency must also determine the application of any statutory exemptions or categorical exemptions that would exempt the proposed project from further review under CEQA. See Guidelines, § 15282 (listing statutory exemptions); Guidelines, §§ 15300–15333 (listing 33 classes of categorical exemptions). The categorical exemptions are contained in the Guidelines and are formulated by the Secretary under authority conferred by CEQA section 21084(a). If, as a result of preliminary review, "the agency finds the project is exempt from CEQA under any of the stated exemptions, no further environmental review is necessary. The agency may prepare and file a notice of exemption, citing the relevant section of the Guidelines and including a brief 'statement of reasons to support the finding.' " *Banker's Hill, supra*, 139 Cal.App.4th at 258, citing Guidelines, §§ 15061(d), 15062(a)(3).

Second Step in the CEQA Process.

If the project does not fall within an exemption, the agency proceeds to the second step of the process and conducts an initial study to determine if the project *may* have a significant effect on the environment. (Guidelines, § 15063.) If, based on the initial study, the public agency determines that "there is substantial evidence, in light of the whole record ... that the project may have a significant effect on the environment, an environmental impact report [(EIR)] shall be prepared." [CEQA, § 21080(d).] On the other hand, if the initial study demonstrates that the project "would not have a significant effect on the environment," either because "[t]here is no substantial evidence, in light of whole record" to that effect or the revisions to the project would avoid such an effect, the

agency makes a "negative declaration," briefly describing the basis for its conclusion. (CEQA, § 21080(c)(1); see Guidelines, § 15063(b)(2); *Banker's Hill, supra*, 139 Cal.App.4th at 259.)

The Guidelines and case law further define the standard that an agency uses to determine whether to issue a negative declaration. "[I]f a lead agency is presented with a *fair argument* that a project may have a significant effect on the environment, the lead agency shall prepare an EIR even though it may also be presented with other substantial evidence that the project will not have a significant effect." (Guidelines, § 15064(f)(1), italics added.) This formulation of the standard for determining whether to issue a negative declaration is often referred to as the "fair argument" standard. See *Laurel Heights Improvement Assn. v. Regents of University of California,* 6 Cal.4th 1112, 1134–1135 (1993). Under the fair argument standard, a project "may" have a significant effect whenever there is a "reasonable possibility" that a significant effect will occur. *No Oil v. City of Los Angeles*, 13 Cal.3d 68, 83-84 (1974). Substantial evidence, for purposes of the fair argument standard, includes "fact, a reasonable assumption predicated upon fact, or expert opinion supported by fact." § 21080, subd. (e)(1). Substantial evidence is not argument, speculation, unsubstantiated opinion or narrative, evidence that is clearly inaccurate or erroneous, or evidence of social or economic impacts unrelated to physical impacts on the environment. § 21080, subd. (e)(2).

If the initial study reveals no substantial evidence that the project may have a significant environmental effect, the agency may adopt a negative declaration. Pub. Res. Code § 21080, subd. (c)(2); Guidelines, § 15070, subd. (b); *Grand Terrace, supra,* 160 Cal.App.4th at 1331; *Save the Plastic Bag Coalition v. City of Manhattan Beach*, 52 Cal. 4th 155, 175 (2011)(holding common sense is part of the substantial evidence analysis). "Alternatively, if there is no substantial evidence of any net significant environmental effect in light of revisions in the project that would mitigate any potentially significant effects, the agency may adopt [an MND]. [Citation.] [An MND] is one in which '(1) the proposed conditions "avoid the effects or mitigate the effects to a point where *clearly* no significant effect on the environment would occur, *and* (2) there is *no substantial evidence* in light of the whole record before the public agency that the project, as revised, may have a significant effect on the environment." (§ 21064.5 . . . .)' [Citations.]" *Grand Terrace, supra,* at 1331-1332. The MND allows the project to go forward subject to the mitigating measures. Pub. Res. Code §§ 21064.5, 21080, subd. (c); see *Grand Terrace, supra,* 160 Cal. App. 4th at 1331.

Third Step in the CEQA Process.

If no negative declaration is issued, the preparation of an EIR is the third and final step in the CEQA process. *Banker's Hill, supra*, 139 Cal. App. 4th at 259; Guidelines, §§ 15063(b)(1), 15080; CEQA, §§ 21100, 21151.

C. The Environmental Impact Report.

Central to CEQA is the EIR, which has as its purpose informing the public and government officials of the environmental consequences of decisions before they are made. [Citation.] "An EIR must be prepared on any 'project' a local agency intends to approve or carry out which 'may have a significant effect on the environment.' Pub. Res. Code §§ 21100, 21151; Guidelines, § 15002, subd. (f)(1). The term 'project' is broadly defined and includes any activities which have a potential for resulting in a physical change in the environment, directly or ultimately. Pub Res. Code § 21065; Guidelines, §§ 15002, subd. (d), 15378, subd. (a); [Citation].) The definition encompasses a wide spectrum, ranging from the adoption of a general plan, which is by its nature tentative and subject to change, to activities with a more immediate impact, such as the issuance of a conditional use permit for a site-specific development proposal." *CREED v. City of San Diego*, 134 Cal. App. 4th 598, 604 (2005).

"To accommodate this diversity, the Guidelines describe several types of EIR's, which may be tailored to different situations. The most common is the project EIR, which examines the environmental impacts of a specific development project. (Guidelines, § 15161.) A quite different type is the program EIR, which 'may be prepared on a series of actions that can be characterized as one large project and are related either: (1) Geographically, (2) As logical parts in the chain of contemplated actions, (3) In connection with issuance of rules, regulations, plans, or other general criteria to govern the conduct of a continuing program, or (4) As individual activities carried out under the same authorizing statutory or regulatory authority and having generally similar environmental effects which can be mitigated in similar ways.'" Guidelines, § 15168, subd. (a); *CREED, supra*, 134 Cal. App. 4th at 605. As the court held in *CREED*, a program EIR may serve as the EIR for a subsequently proposed project only to the extent it contemplates and adequately analyzes the potential environmental impacts of the project. *CREED, supra,* 134 Cal. App. 4th at 615.

The EIR at issue in this case is of the latter variety, a program EIR. Cleveland/CBD/ Sierra Club accuse SANDAG of attempting to use the "programmatic" nature of the EIR as an invalid attempt to excuse it from fully analyzing the health impacts of the RTP. [ROA 55 at 15] The AG joins in this criticism. [ROA 52 at 29]

Under CEQA, an EIR is presumed adequate (Pub. Resources Code, § 21167.3), and the plaintiff in a CEQA action has the burden of proving otherwise. (*Preserve Wild Santee v. City of Santee*, 210 Cal. App. 4th 260, 275 (4th DCA Div. 1 Oct. 19, 2012, internal quotation marks omitted), quoting *Concerned Citizens of South Central L.A. v. Los Angeles Unified School Dist.* (1994) 24 Cal.App.4th 826, 836.) Courts review an agency's determinations and decisions for abuse of discretion. An agency abuses its discretion when it fails to proceed in a manner required by law or there is not substantial evidence to support its determination or decision. [§§ 21168, 21168.5; *Vineyard Area Citizens for Responsible Growth, Inc. v. City of Rancho Cordova* (2007) 40 Cal.4th 412, 426-427 (2007) ("*Vineyard*")]. "Judicial review of these two types of error differs significantly: While [courts] determine de novo whether the agency has employed the correct procedures, 'scrupulously enforc[ing] all legislatively mandated CEQA

requirements' [citation], [courts] accord greater deference to the agency's substantive factual conclusions." (*Vineyard, supra*, 40 Cal. 4th at 435.)

Consequently, in reviewing an EIR for CEQA compliance, courts adjust "scrutiny to the nature of the alleged defect, depending on whether the claim is predominantly one of improper procedure or a dispute over the facts." (*Vineyard, supra*, 40 Cal.4th at 435.) For example, where a petitioner claims an agency failed to include required information in its environmental analysis, the court's task is to determine whether the agency failed to proceed in the manner prescribed by CEQA. Conversely, where a petitioner challenges an agency's conclusion that a project's adverse environmental effects are adequately mitigated, courts review the agency's conclusion for substantial evidence. (*Vineyard, supra*, 40 Cal. 4th at 435.)

4. Issues Raised in This Case.

SANDAG is a council of local governments, and is one of 18 Metropolitan Planning Organizations ("MPO") in California. Each MPO is charged under law with the development of the region's RTP, which must be updated every four years. SANDAG began its work in April of 2010, released drafts of the RTP/SCS for public comment on 4/22/11, and released the draft EIR for public comment on June 7, 2011 [AR225-1580]. Petitioners and the AG's office criticized the drafts. [AR4430, 12696-12699, 17972-75, 18053-55] The final EIR was released on October 18, 2011 [AR1969-3401], and was certified after a public hearing on October 28, 2011. Inasmuch as the petitions were filed on November 28, there is no issue in this case regarding the timeliness of the legal challenges to the EIR. Nor are any issues raised by SANDAG with regard to exhaustion of administrative remedies or standing.

There is substantial overlap in the attacks on the EIR leveled by petitioners and the AG. Both sets of petitioners assert that the EIR fails to adequately analyze air quality impacts [ROA 54 at 3-6; ROA 55 at 12-20]. The AG joins in this assertion [ROA 52 at 7-29]. Both petitioners add that the EIR failed to analyze a reasonable range of alternatives [ROA 54 at 6; ROA 55 at 38].

CREED-21/AHC's brief focuses on the failure of the EIR to properly analyze air quality impacts in two specific areas: greenhouse gas emissions and sensitive receptors [ROA 54 at 4-6]. The Cleveland/CBD/Sierra Club brief carefully analyzes the deficiencies of the EIR in relation to greenhouse gas emissions (ROA 55 at part III), while the AG provides extensive discussion on both sensitive receptors and greenhouse gas emissions [ROA 52 at 14-18 and 22-29]. The Cleveland/CBD/Sierra Club brief raises several other issues which neither the AG nor CREED-21/AHC discuss in any detail (mass transit ridership, agricultural land, growth-inducing impacts, parking management, etc.).

5. Ruling.

The court finds that the real focal point of this controversy is whether the EIR is in conformance with a series of state policies enunciated by the legislative and executive branches since 2005 relating to greenhouse gases. Governor Schwarzenegger issued, in

2005, Executive Order S-03-05, which for the first time set a state goal of reducing greenhouse gas emissions. This Executive Order gave rise to the Global Warming Solutions Act of 2006 (AB 32), which is codified at H&S Code section 38500 *et seq.* Section 38550 provides:

"By January 1, 2008, the [Air Resources Board] shall, after one or more public workshops, with public notice, and an opportunity for all interested parties to comment, determine what the statewide greenhouse gas emissions level was in 1990, and approve in a public hearing, a statewide greenhouse gas emissions limit that is equivalent to that level, to be achieved by 2020. In order to ensure the most accurate determination feasible, the state board shall evaluate the best available scientific, technological, and economic information on greenhouse gas emissions to determine the 1990 level of greenhouse gas emissions."

It is undisputed that the ARB has established greenhouse gas targets for the SANDAG region for 2020 and 2035.

In 2008, the Legislature passed SB 375, which amended both the Public Resources Code and the Government Code in several respects. In section 1 of the statute, the Legislature found and declared:

"(a) The transportation sector contributes over 40 percent of the greenhouse gas emissions in the State of California; automobiles and light trucks alone contribute almost 30 percent. The transportation sector is the single largest contributor of greenhouse gases of any sector.

(b) In 2006, the Legislature passed and the Governor signed Assembly Bill 32 (Chapter 488 of the Statutes of 2006; hereafter AB 32), which requires the State of California to reduce its greenhouse gas emissions to 1990 levels no later than 2020. According to the State Air Resources Board, in 1990 greenhouse gas emissions from automobiles and light trucks were 108 million metric tons, but by 2004 these emissions had increased to 135 million metric tons.

(c) Greenhouse gas emissions from automobiles and light trucks can be substantially reduced by new vehicle technology and by the increased use of low carbon fuel. However, even taking these measures into account, it will be necessary to achieve significant additional greenhouse gas reductions from changed land use patterns and improved transportation. Without improved land use and transportation policy, California will not be able to achieve the goals of AB 32.

(d) In addition, automobiles and light trucks account for 50 percent of air pollution in California and 70 percent of its consumption of petroleum. Changes in land use and transportation policy, based upon established modeling methodology, will provide significant assistance to California's goals to implement the federal and state Clean Air Acts and to reduce its dependence on petroleum.

(e) Current federal law requires regional transportation planning agencies to include a land use allocation in the regional transportation plan. Some regions have engaged in a regional "blueprint" process to prepare the land use allocation. This process has been open and transparent. The Legislature intends, by this act, to build upon that successful process by requiring metropolitan planning organizations to develop and incorporate a sustainable communities strategy which will be the land use allocation in the regional transportation plan.

(f) The California Environmental Quality Act (CEQA) is California's premier environmental statute. New provisions of CEQA should be enacted so that the statute encourages developers to submit applications and local governments to make land use decisions that will help the state achieve its climate goals under AB 32, assist in the achievement of state and federal air quality standards, and increase petroleum conservation.

(g) Current planning models and analytical techniques used for making transportation infrastructure decisions and for air quality planning should be able to assess the effects of policy choices, such as residential development patterns, expanded transit service and accessibility, the walkability of communities, and the use of economic incentives and disincentives.

(h) The California Transportation Commission has developed guidelines for travel demand models used in the development of regional transportation plans. This act assures the commission's continued oversight of the guidelines, as the commission may update them as needed from time to time.

(i) California local governments need a sustainable source of funding to be able to accommodate patterns of growth consistent with the state's climate, air quality, and energy conservation goals."

Section 4 of SB 375 added Government Code section 65080, which provides, in relevant part:

"(a) **Each transportation planning agency** designated under Section 29532 or 29532.1 **shall prepare and adopt a regional transportation plan directed at achieving a coordinated and balanced regional transportation system**, including, but not limited to, mass transportation, highway, railroad, maritime, bicycle, pedestrian, goods movement, and aviation facilities and services. The plan shall be action-oriented and pragmatic, considering both the short-term and long-term future, and shall present clear, concise policy guidance to local and state officials. The regional transportation plan shall consider factors specified in Section 134 of Title 23 of the United States Code. Each transportation planning agency shall consider and incorporate, as appropriate, the transportation plans of cities, counties, districts, private organizations, and state and federal agencies.

(b) The regional transportation plan shall be an internally consistent document and shall include all of the following:

(1) A policy element that describes the transportation issues in the region, identifies and quantifies regional needs, and describes the desired short-range and long-range transportation goals, and pragmatic objective and policy statements. The objective and policy statements shall be consistent with the funding estimates of the financial element. The policy element of transportation planning agencies with populations that exceed 200,000 persons may quantify a set of indicators including, but not limited to, all of the following:
(A) Measures of mobility and traffic congestion, including, but not limited to, daily vehicle hours of delay per capita and vehicle miles traveled per capita.
(B) Measures of road and bridge maintenance and rehabilitation needs, including, but not limited to, roadway pavement and bridge conditions.
(C) Measures of means of travel, including, but not limited to, percentage share of all trips (work and nonwork) made by all of the following:
(i) Single occupant vehicle.
(ii) Multiple occupant vehicle or carpool.
(iii) Public transit including commuter rail and intercity rail.
(iv) Walking.
(v) Bicycling.
(D) Measures of safety and security, including, but not limited to, total injuries and fatalities assigned to each of the modes set forth in subparagraph (C).
(E) Measures of equity and accessibility, including, but not limited to, percentage of the population served by frequent and reliable public transit, with a breakdown by income bracket, and percentage of all jobs accessible by frequent and reliable public transit service, with a breakdown by income bracket.
(F) The requirements of this section may be met utilizing existing sources of information. No additional traffic counts, household surveys, or other sources of data shall be required.

(2) A sustainable communities strategy prepared by each metropolitan planning organization as follows:
(A) No later than September 30, 2010, the State Air Resources Board shall provide each affected region with greenhouse gas emission reduction targets for the automobile and light truck sector for 2020 and 2035, respectively.

***

(B) **Each metropolitan planning organization shall prepare a sustainable communities strategy**, subject to the requirements of Part 450 of Title 23 of, and Part 93 of Title 40 of, the Code of Federal Regulations, including the requirement to utilize the most recent planning assumptions considering local general plans and other factors. The sustainable communities strategy shall (i) identify the general location of uses, residential densities, and building intensities within the region, (ii) identify areas within the region sufficient to house all the population of the region, including all economic segments of the population, over

the course of the planning period of the regional transportation plan taking into account net migration into the region, population growth, household formation and employment growth, (iii) identify areas within the region sufficient to house an eight-year projection of the regional housing need for the region pursuant to Section 65584, (iv) identify a transportation network to service the transportation needs of the region, (v) gather and consider the best practically available scientific information regarding resource areas and farmland in the region as defined in subdivisions (a) and (b) of Section 65080.01, (vi) consider the state housing goals specified in Sections 65580 and 65581, (vii) **set forth a forecasted development pattern for the region, which, when integrated with the transportation network, and other transportation measures and policies, will reduce the greenhouse gas emissions from automobiles and light trucks to achieve, if there is a feasible way to do so, the greenhouse gas emission reduction targets approved by the state board,** and (viii) allow the regional transportation plan to comply with Section 176 of the federal Clean Air Act (42 U.S.C. Sec. 7506).

Section 14 of SB 375, among other revisions, amended Pub. Res. Code section 21155.3 to provide as follows:

"(a) The legislative body of a local jurisdiction may adopt traffic mitigation measures that would apply to transit priority projects. These measures shall be adopted or amended after a public hearing and may include requirements for the installation of traffic control improvements, street or road improvements, and contributions to road improvement or transit funds, transit passes for future residents, or other measures that will avoid or mitigate the traffic impacts of those transit priority projects.

(b)(1) A transit priority project that is seeking a discretionary approval is not required to comply with any additional mitigation measures required by paragraph (1) or (2) of subdivision (a) of Section 21081, for the traffic impacts of that project on intersections, streets, highways, freeways, or mass transit, if the local jurisdiction issuing that discretionary approval has adopted traffic mitigation measures in accordance with this section.
(2) Paragraph (1) does not restrict the authority of a local jurisdiction to adopt feasible mitigation measures with respect to the effects of a project on public health or on pedestrian or bicycle safety.

(c) The legislative body shall review its traffic mitigation measures and update them as needed at least every five years."

As already noted, the centerpiece of this case is the parties' fundamental disagreement over implementation of these statutory requirements within the framework of CEQA. In all the statutory quotations immediately above, **bold type** has been added by the court.

The court agrees with the points made in section III of the Cleveland brief (ROA 55), part II of the AG's brief (ROA 52), and pp. 4-5 of the CREED-21 brief (ROA 54) regarding the inadequate treatment of greenhouse gas emissions in the EIR. This failure is not, as SANDAG would have it, merely a debate over "editorial control" of the EIR (ROA 62 at 32:24). Rather, the issue is whether the EIR fails to carry out its role as an informational document to inform the public about the choices made by its leaders. The court finds that this failure is manifest in several ways.

First, although SANDAG acknowledges SB 375 mandates a "sharper focus on reducing GHG emissions" (AR 13091, Excerpt Tab 190), the EIR is impermissibly dismissive of Executive Order S-03-05. SANDAG argues that the Executive Order does not constitute a 'plan' for GHG reduction, and no state plan has been adopted to achieve the 2050 goal. [ROA 62 at 34] The EIR therefore does not find the RTP/SCS's failure to meet the Executive Order's goals to be a significant impact. This position fails to recognize that Executive Order S-3-05 is an official policy of the State of California, established by a

gubernatorial order in 2005, and not withdrawn or modified by a subsequent (and predecessor) governor. Quite obviously it was designed to address an environmental objective that is highly relevant under CEQA (climate stabilization). See AR 17622 (Excerpt Tab 216). SANDAG thus cannot simply ignore it. This is particularly true in a setting in which hundreds of thousands of people in the communities served by SANDAG live in low-lying areas near the coast, and are thus susceptible to rising sea levels associated with global climate change. The court in *Association of Irritated Residents v. State Air Resources Board*, 206 Cal. App. 4th 1487, 1492-93 (2012), recognized the importance of the Executive Order in upholding the ARB's Scoping Plan. The court agrees with petitioners that the failure of the EIR to cogently address the inconsistency between the dramatic increase in overall GHG emissions after 2020 contemplated by the RTP/SCS and the statewide policy of reducing same during the same three decades (2020-2050) constitutes a legally defective failure of the EIR to provide the SANDAG decision makers (and thus the public) with adequate information about the environmental impacts of the SCS/RTP. Moreover, as was pointed out in oral argument, having chosen to develop a plan for 15 years beyond that which was required under law, SANDAG was obligated to discuss impacts beyond the 2020 horizon. The ARB's scoping plan adopts the Executive Order, and SANDAG failed to extend the analysis to 2050.

Second, SANDAG's response has been to "kick the can down the road" and defer to "local jurisdictions." See, e.g. AR 31-0064, 32-0065, 33-0066, 34-0067, 35-0068, 117-0090, 118-0091 (Excerpts Vol. 1, Tab 3); 4.8-36, 0790 (Excerpts Tab 7); AR G-63-64, 03825-3826 (Excerpts Tab 8B); AR 27734 and 8A:2588 (Nov. 19 Appx.). This theme is repeated in SANDAG's brief at page 38 (arguing mitigation is the responsibility of other agencies). This perverts the regional planning function of SANDAG, ignores the purse string control SANDAG has over TransNet funds, and more importantly conflicts with Govt. Code section 65080(b)(2)(B) quoted above. As the AG argues, it is certainly feasible for SANDAG to agree to fund local climate action plans, yet the EIR does not adopt or even adequately discuss this form of mitigation (AR 2588, Excerpt Tab 8A). And as argued by petitioners in their consolidated reply brief, "encouraging" an optional local plan that "should" incorporate regional policies falls well short of a legally enforceable mitigation commitment with teeth. This is what the CEQA Guidelines require at subsections 15126.4(a)(1)(B), (a)(2) and (c)(5) in a setting in which SANDAG controls the funding for at least some of the projects contemplated by the SCS/RTP. Contrary to SANDAG's assertion (Oppo. at 38:21), it does have the legal power -- indeed, the obligation – to see to it that TransNet funds are spent in a manner consistent with the law. SANDAG conceded (even embraced) this at the November 30 hearing.

Resolution No. 2012-09, adopted by SANDAG, finds that the RTP/SCS "achieves the regional greenhouse gas reduction targets established by CARB" (AR 239-0219, Excerpts Tab 4) when in fact it either does not (AR 118-0091-92, Excerpts Tab 3; AR 4.8-21-23, 0775-0777, Excerpts Tab 7; AR 4.8-15-17, 02567-2569, 2578, Excerpts Tab 8A; AR08242-8245, Excerpts Tab 111) or does so based on questionable inputs [AR 30143, 30187 *et seq.* (Supp. filed 10/22/12); compare AR 14550 (Excerpt Tab 190). The shortcomings of the **EIR** in this regard (for petitioners do not contend, nor does the court

find, that SB 375 was violated) were called to SANDAG's attention as evidenced by what it called "Master Response # 20-23," discussed at AR G-55, 03817 *et seq*. (Excerpts Tab 8B); see also AR 19685 (Excerpts Tab 296); AR 25640 *ff* (Excerpts Tab 311). SANDAG erroneously and peremptorily states in response to these comments that the "upward trajectory" in per capita GHG emissions "does not present an SB 375 or CEQA compliance issue." AR G-59. CEQA requires further discussion, not a one sentence dismissal. Nor is the court convinced that SANDAG may avoid examination of GHG reduction due to "modeling constraints." AR G-68, 003830 (Master Response #23).

In light of the foregoing, the court finds that the petitioners and intervenor have overcome the presumption of validity and have established a prejudicial abuse of discretion. The court does not reach this conclusion lightly, as it is evident from section 9.0 of the EIR that it involved thousands of hours of effort by numerous talented professionals. No doubt the EIR is a satisfactory informational document in many respects; being the first in the state to tackle something as important to future generations as reduction of greenhouse gases in a regional transportation setting carried some risk, and the court, after reviewing the Administrative Record independently, finds that the EIR is inconsistent with state law as described above. Thus, it is the court's duty under *Vineyard, supra*, to sustain the positions advanced by petitioners and the petitioner in intervention.

Had they been permitted to file briefs, *amici* would no doubt have argued that the court's interpretation of CEQA's interface with Executive Order S-03-05 and the statutory scheme of SB 375 (which the Legislative Counsel's Digest filed with Secretary of State September 30, 2008 concedes is an "unfunded mandate") will retard growth, harm California's efforts to attract jobs and create economic activity, and slow down the state's recovery from the recession. All of this may very well be true, but these are arguments properly presented to the political branches of the government which adopted the Executive Order and enacted SB 375 in the first place.

Because the court finds it can resolve the case solely on the inadequate treatment in the EIR of the greenhouse gas emission issue, it finds that it need not address the other issues raised by the parties. *Compare Natter v. Palm Desert Rent Review Comm'n.*, 190 Cal. App. 3d 994, 1001 (1987); *Young v. Three for One Oil Royalties*, 1 Cal. 2d 639, 647-648 (1934).

Let a writ of mandate issue forthwith, directing respondent SANDAG to set aside its October 28, 2011certification of the EIR for the RTP/SCS. Counsel for petitioners is directed to forthwith submit same to the court for signature.

IT IS SO ORDERED.

Dated: December 3, 2012

TIMOTHY B. TAYLOR
Judge of the Superior Court

SUPERIOR COURT OF CALIFORNIA, COUNTY OF SAN DIEGO

Central
330 West Broadway
San Diego, CA 92101

SHORT TITLE: Cleveland National Forest Foundation vs. San Diego Association of Governments [IMAGED]

CLERK'S CERTIFICATE OF SERVICE BY MAIL	CASE NUMBER: **37-2011-00101593-CU-TT-CTL**

I certify that I am not a party to this cause. I certify that a true copy of the Ruling on Petitions for Writ of Mandate dated December 3, 2012 was mailed following standard court practices in a sealed envelope with postage fully prepaid, addressed as indicated below. The mailing and this certification occurred at San Diego, California, on 12/03/2012.

NEHRP (National Earthquake Hazards Reduction Program) Recommended Seismic Provisions

for New Buildings and Other Structures (FEMA P-750)

2009 Edition

Prepared for the Federal Emergency Management Agency of the
U.S. Department of Homeland Security
By the Building Seismic Safety Council of the
National Institute of Building Sciences

BUILDING SEISMIC SAFETY COUNCIL
A council of the National Institute of Building Sciences
Washington, D.C.
2009

NOTICE: Any opinions, findings, conclusions, or recommendations expressed in this publication do not necessarily reflect the views of the Federal Emergency Management Agency. Additionally, neither FEMA nor any of its employees make any warranty, expressed or implied, nor assume any legal liability or responsibility for the accuracy, completeness, or usefulness of any information, product, or process included in this publication.

The **Building Seismic Safety Council** (BSSC) was established in 1979 under the auspices of the National Institute of Building Sciences as a forum-based mechanism for dealing with the complex regulatory, technical, social, and economic issues involved in developing and promulgating building earthquake hazard mitigation regulatory provisions that are national in scope. By bringing together in the BSSC all of the needed expertise and all relevant public and private interests, it was believed that issues related to the seismic safety of the built environment could be resolved and jurisdictional problems overcome through authoritative guidance and assistance backed by a broad consensus.

The BSSC is an independent, voluntary membership body representing a wide variety of building community interests. Its fundamental purpose is to enhance public safety by providing a national forum that fosters improved seismic safety provisions for use by the building community in the planning, design, construction, regulation, and utilization of buildings.

This report was prepared under Contract HSFEHQ-04-C-0465 between the Federal Emergency Management Agency and the National Institute of Building Sciences.

For further information on Building Seismic Safety Council activities and products, see the Council's website (www.bssconline.org) or contact the Building Seismic Safety Council, National Institute of Building Sciences, 1090 Vermont, Avenue, N.W., Suite 700, Washington, D.C. 20005; phone 202-289-7800; fax 202-289-1092; e-mail bssc@nibs.org.

Copies of this report on CD Rom may be obtained from the FEMA Publication Distribution Facility at 1-800-480-2520. Limited paper copies also will be available. The report can also be downloaded in pdf form from the BSSC website at www.bssconline.org .

The National Institute of Building Sciences and its Building Seismic Safety Council caution users of this *Provisions* document to be alert to patent and copyright concerns especially when applying prescriptive requirements.

FOREWORD

One of the goals of the Federal Emergency Management Agency (FEMA) and the National Earthquake Hazards Reduction Program (NEHRP) is to encourage design and building practices that address the earthquake hazard and minimize the resulting risk of damage and injury. Publication of the 2009 edition of the *NEHRP Recommended Seismic Provisions for New Buildings and Other Structures* (FEMA P-750) reaffirms FEMA's ongoing support of efforts to achieve this goal. First published in 1985, the 2009 edition of the *Provisions* marks the seventh in a series of updates to the document and several complementary publications. FEMA is proud to have sponsored this project conducted by the Building Seismic Safety Council (BSSC) of National Institute of Building Sciences (NIBS) and continues to encourage the widespread dissemination and voluntary use of this state-of-art consensus resource document.

In contrast to the earlier editions of the *Provisions* which resulted from three-year update projects, the 2009 edition is the first resulting from a five-year update effort that allowed the BSSC's Provisions Update Committee (PUC) to make some major changes in both the substance and the format of the *Provisions* document. The most significant change involves the adoption by reference of the national consensus design loads standard, ASCE/SEI 7-05, *Minimum Design Loads for Buildings and Other Structures*, including the related consensus standards referenced therein and Supplements 1 and 2. Part 1 of this document includes consensus-approved modifications of the seismic requirements in the standard. Among these modifications is the adoption of new seismic design maps based on seismic hazard maps issued in 2008 by the U.S. Geological Survey (USGS) along with some design-related adjustments. Another major change has been made to the accompanying Commentary, previously issued as a separate volume but now included as Part 2 of the 2009 *Provisions.* The content of the Commentary has been completely rewritten to provide users with an up-to-date, user friendly explanation of how to design using the *Provisions* and the reference standard. Part 3 of the 2009 *Provisions* consists of a series of resource papers intended to clarify aspects of the *Provisions,* stimulate consideration of and feedback from the design community on new seismic design concepts and procedures, and/or encourage the development and adoption of new requirements in ASCE/SEI 7 and the standards referenced therein. Thus, the 2009 *Provisions* serves as a national resource intended for use by both design professionals and the standards- and codes-development community in fostering development of a built environment designed and constructed to protect building occupants from loss of life and serious injury and to reduce the total losses from future earthquakes.

FEMA wishes to express its deepest gratitude for the significant efforts of the over 200 volunteer experts as well as the BSSC Board of Direction, member organizations, consultants, and staff who made the 2009 *NEHRP Recommended Seismic Provisions* possible. Americans unfortunate enough to experience the earthquakes that will inevitably occur in the future will owe much, perhaps even their lives, to the contributions and dedication of these individuals. Without the expertise and efforts of these men and women, this document and all it represents with respect to earthquake risk mitigation would not have been possible.

Federal Emergency Management Agency

PREFACE and ACKNOWLEDGEMENTS

Since its creation in 1979, the National Earthquake Hazard Reduction Program (NEHRP) has provided a framework for efforts to reduce the risk from earthquakes. The Building Seismic Safety Council (BSSC) is extremely proud to have been selected by the Federal Emergency Management Agency (FEMA) to play a role under NEHRP in improving the seismic resistance of the built environment. Further, the BSSC is pleased to mark the occasion of its thirtieth anniversary with delivery to FEMA of the consensus-approved 2009 *NEHRP Recommended Seismic Provisions for New Buildings and Other Structures*, the eighth edition of this landmark publication. The *Provisions* has evolved over the past three decades into a widely available, trusted, state-of-the-art seismic design resource document with requirements that have been adapted for use in the nation's model building codes and standards.

Work on the 2009 *Provisions* began in September 2004 when the National Institute of Building Sciences, the BSSC's parent organization, entered into a contract with FEMA for initiation of the 2009 *Provisions* update effort. Based on input from the BSSC member organization representatives and alternate representatives and the BSSC Board of Direction, individuals to serve on the 2009 Provisions Update Committee (PUC) and its Technical Subcommittees (TSs) and ad hoc Issue Teams were identified. The PUC and its TSs and ITs were fully established in 2005 as was a Seismic Design Procedures Review Group (SDPRG) charged to assess ongoing work by the U.S. Geological Survey (USGS) to update its seismic hazard maps. It is the collective efforts and expertise of the national experts serving on these groups that is reflected in the 2009 *Provisions*.

In recognition of the fact that the codes and standards arena now operates differently than it did in the past, the format of 2009 *Provisions* has been changed to focus more on exploration of new technologies and procedures and less on format and editorial changes. To this end, the national consensus design loads standard, *Minimum Design Loads for Building and Other Structures*, ASCE/SEI 7-05 (including Supplements 1 and 2), has been adopted as the primary reference standard of the *Provisions*. Areas of the standard in need of modification also were identified and proposals to do so were prepared and voted on by the membership. These modifications appear in Part 1 of this document and, together with ASCE/SEI 7-05 and the references cited therein, constitute the 2009 *Provisions*. (A summary of the results of the member organization ballots and comment resolution process is available from the BSSC upon written request and will be posted on the BSSC website at www.bssconline.org.)

A major effort also was made to rewrite the commentary to the *Provisions*. Until now, the commentary was published as a separate volume accompanying the *Provisions* and tended to explain the development of the existing requirements. For 2009, the commentary appears in Part 2 of this *Provisions* document and explains how to apply the *Provisions* requirements as articulated in ASCE/SEI 7-05 and the references cited therein. (Note that the Part 1 modifications to the standard are accompanied by their own commentary text.)

Part 3 of this volume is a collection of resource papers. Included are substantive proposals on topics that require further consideration by and feedback from the seismic design community before they become *Provisions* requirements as well as papers that clarify some aspects of the *Provisions* requirements. In addition, three of the appendices from the 2003 *Provisions* are still considered to include information of interest and they also are included in Part 3.

As in the past, the 2009 *Provisions* would not have been possible without the expertise, dedication, and countless hours of effort of the more than 200 dedicated volunteers who participated in the update process. The American people benefit immeasurably from their commitment to improving the seismic-resistance of the nation's buildings. A list of all those who participated in the 2009 *Provisions* update project is included as the Appendix

of this volume, but a few individuals and groups deserve special recognition. As Chairman of the BSSC Board of Direction, it is my pleasure to express heartfelt appreciation to:

- The members of the BSSC Provisions Update Committee, especially to PUC Chair Ronald Hamburger;
- The members of the Seismic Design Procedures Review Group, especially Chair Charles Kircher and Nicolas Luco of the USGS;
- FEMA Project Officers Michael Mahoney and Mai Tong and FEMA Subject Matter Expert Robert Hanson;
- Michael Valley who worked with the update committees to draft the Part 2 commentary to the 2009 *Provisions*;
- The representatives of the BSSC member organizations who devoted considerable time and attention to the four individual rounds of balloting that were required to produce the 2009 *Provisions* document; and
- The BSSC staff who work tirelessly behind the scenes to support all the update groups and who bring the finished product forward for acceptance.

Finally, I wish to thank the members of the BSSC Board of Direction who recognize the importance of this effort and provided sage advice throughout the update. We are all proud of the 2009 *NEHRP Recommended Seismic Provisions* and it is my pleasure to introduce them.

David Bonneville
Chairman, BSSC Board of Direction

APPENDIX, Participants in the BSSC 2009 *Provisions* Update Project....373

2009 *NEHRP RECOMMENDED SEISMIC PROVISIONS FOR NEW BUILDINGS AND OTHER STRUCTURES:*

PART 1, PROVISIONS

Work on this 2009 edition of the NEHRP (National Earthquake Hazards Reduction Program) Recommended Seismic Provisions for New Buildings and Other Structures began in September 2004 when the National Institute of Building Sciences, the parent organization of the Building Seismic Safety Council (BSSC), entered into a contract with Federal Emergency Management Agency (FEMA) for initiation of the 2009 Provisions update effort. During 2005, the BSSC member organization representatives and alternate representatives and the BSSC Board of Direction were asked to identify individuals to serve on the 2009 Provisions Update Committee (PUC) and its Technical Subcommittees (TSs) and to suggest topics for concentrated study by ad hoc Issue Teams.

The 2009 PUC and its eight Technical Subcommittees (TS) then were established to address document composition and management; design criteria and analysis and advanced technologies; mapping, foundations, and geotechnical considerations; concrete structures; masonry structures; steel and composite steel and concrete structures; wood structures; nonstructural components and nonbuilding structures. Three Issue Teams (ITs) also were established to focus on performance criteria, design parameters, and foundation design requirements. Further, given ongoing work by the U.S. Geological Survey (USGS) to update its seismic hazard maps, a Seismic Design Procedures Review Group (SDPRG) was established to consider the emerging maps and to re-examine the existing design maps and procedures that were introduced in the 1997 edition of the Provisions and that remained essentially unchanged for the 2000 and 2003 editions of the Provisions.

Work already done and decisions made prior to initiation of the 2009 Provisions update project recognized that the codes and standards arena has changed over the past decade and that those changes called for a refocusing of the Provisions on exploration of new technologies and procedures and less consideration of format and editorial changes. To this end, the initial efforts of the 2009 PUC and its TSs focused on adoption of the national load standard, Minimum Design Loads for Building and Other Structures, ASCE/SEI 7-05 (including Supplements No. 1 and No. 2), as the primary reference standard of the Provisions and the identification of parts of the 2003 Provisions that should be maintained as modifications to the standard or otherwise revised to reflect new knowledge and experience data. The result of this effort was a vote by the BSSC member organizations to adopt ASCE/SEI 7-05 by reference and for it to serve as the base document for the update cycle. Three modifications to standard, originally appendices to various chapters of the 2003 Provisions, had been deemed needed by the PUC and TSs and were approved as part of this vote by the membership for inclusion in the 2009 Provisions. As the update cycle progressed, additional modifications to the standard were prepared and voted on by the membership in three separate ballots. All these modifications appear in Part 1 of this document and, together with ASCE/SEI 7-05 and the references cited therein, constitute the 2009 Provisions. (A summary of the results of the member organization ballots and comment resolution process is available from the BSSC upon written request and will be posted on the BSSC website at www.bssconline.org.)

A major effort also was made to rewrite the commentary to the Provisions. Until now, the commentary was published in a separate volume and tended to explain the development of the requirements. For 2009, the commentary appears in Part 2 of this Provisions volume and explains how to apply the Provisions requirements as articulated in ASCE/SEI 7-05 and the references cited therein. (Note that the Part 1 modifications to the standard are accompanied by appropriate commentary text included in Part 1.)

Part 3 of this Provisions volume introduces new procedures or provisions not currently contained in the referenced standards for consideration and experimental use by the design community, researchers, and standards- and code-development organizations and feedback from these users is encouraged. Part 3 also presents individual summaries of ongoing committee work that awaits additional research before being submitted to the BSSC membership for consensus

approval and provides useful guidance on the application of Part 1 requirements, either as a discussion of an overall approach or as a detailed procedure.

1.1 INTENT

The *NEHRP Recommended Seismic Provisions for New Buildings and Other Structures* presents the minimum recommended requirements necessary for the design and construction of new buildings and other structures to resist earthquake ground motions throughout the United States. The intent of these provisions is to provide reasonable assurance of seismic performance that will:

1. Avoid serious injury and life loss,
2. Avoid loss of function in critical facilities, and
3. Minimize structural and nonstructural repair costs where practical to do so.

These objectives are addressed by seeking to avoid structural collapse in very rare, extreme ground shaking and by seeking to provide reasonable control of damage to structural and nonstructural systems that could lead to injury and economic or functionality losses for more moderate and frequent ground shaking. These design requirements include minimum lateral strength and stiffness for structural systems and guidance for anchoring, bracing, and accommodation of structural drift for nonstructural systems.

Occupancy Category III or IV structures intended to provide enhanced safety and functionality are required to have more strength than Occupancy Category I or II structures in an effort to reduce damage to the structural system. Allowable drifts are reduced to control damage to building components connected to multiple floor levels. Nonstructural system performance is enhanced by strengthening the anchorage and bracing requirements, and important equipment must be shown to be functional after being shaken.

The degree to which these goals can be achieved depends on a number of factors including structural framing type, building configuration, materials, as-built details, and overall quality of design. In addition, large uncertainties as to the intensity and duration of shaking and the possibility of unfavorable response of a small subset of buildings or other structures may prevent full realization of the intent.

1.2 REFERENCE DOCUMENT

Design for seismic resistance of structural elements including foundation elements and nonstructural components shall conform to the requirements of ASCE/SEI 7-05, *Minimum Design Loads for Buildings and Other Structures,* including Supplements No. 1 and No. 2 (referred to hereinafter as ASCE/SEI 7-05), as modified herein.[1]

COMMENTARY TO SECTIONS 1.1 AND 1.2

The primary intent of the *NEHRP Recommended Seismic Provisions for New Buildings and Other Structures* is to prevent, for typical buildings and structures, serious injury and life loss caused by damage from earthquake ground shaking. Most earthquake injuries and deaths are caused by structural collapse; therefore, the major thrust of the *Provisions* is to prevent collapse for very rare, intense ground motion, termed the maximum considered earthquake (MCE) ground motion.[2] The intent remains the same in the 2009 *Provisions*; however, the prevention of collapse is redefined in terms of risk-targeted maximum considered earthquake (MCE_R) ground motions. This change is explained fully in the commentary to the Part 1 modification to ASCE/SEI 7-05 Section 11.2.

Falling exterior walls and cladding and falling interior ceilings, light fixtures, pipes, equipment, and other nonstructural components also cause deaths and injuries. The *Provisions* minimizes this risk using requirements for anchoring and bracing nonstructural components, although this level of protection generally is aimed at ground motions less severe than the MCE_R ground motion. This anchoring and bracing of nonstructural systems coupled with reasonable limitations on differential movement between floors (i.e., story drift limits) also serve to control damage that may be costly to repair or that would result in lengthy building closures, particularly for moderate shaking levels.

[1] Supplement No. 2 of the standard is available for download at http://content.seinstitute.org/files/pdf/SupplementNo2ofthe2005Editionof ASCE7.pdf.

[2] The derivation of MCE ground motion was described in detail in Commentary Appendix A of the 2003 *NEHRP Recommended Provisions* (FEMA 450-2), and this appendix, "Development of Maximum Considered Earthquake Ground Motion Maps Figures 3.3-1 through 3.3-14," can be downloaded from http://www.nibs.org/index.php/bssc/publications/fema450nehrp2003/.

Stricter story drift limits can further limit damage to components connected to more than one floor (e.g., walls, cladding and stairways) but, at the same time, can create higher acceleration levels in the building that could increase damage to nonstructural components braced or anchored to a single floor (e.g., ceilings, light fixtures, and pipes). Achieving an optimum balance between the cost and performance of the structural system and the effect of structural stiffness on performance of the nonstructural systems is impossible using the prescriptive rules of a building code, particularly given the variety of structural systems used in the United States.

Buildings deemed to have higher importance due to hazardous contents or critical occupancy are assigned to higher Occupancy Categories (see ASCE/SEI 7-05 Table 1-1). The damage level in these buildings is intended to be reduced by decreasing nonlinear demand using an importance factor, *I*, to reduce the response modification coefficient, *R*. The resulting increased strength will reduce structural damage, or increase reliability of acceptable performance, for a given level of shaking. Some authorities having jurisdiction subject the design and construction of such buildings to a higher level of scrutiny.

The performance of critical occupancy structures in past earthquakes indicates that the increase in the importance factor controls structural damage in moderate shaking. In strong shaking associated with the design level of two-thirds the maximum considered earthquake or higher, the values of *I* have not been well tested for their effect on either functionality for critical buildings or increased reliability of life safety protection for high occupancy buildings.

The importance factor also increases the design anchorage and bracing load for nonstructural systems, which should increase the reliability of their staying in place and, thus, remaining undamaged. In addition, certain critical equipment must remain operable after strong shaking. Experience data show that some nonstructural components will remain functional if they stay in position, but other components will require testing to show that they will function following strong shaking. The emphasis to date has been on the seismic qualification of individual components. However, the nonstructural systems of many buildings are, in reality, complex networks that can be shut down by a single failure. For example, a break in a pressurized pipe can flood part or all of a building forcing it to close, and failure of the anchorage (or internal workings) of a battery, day tank, fuel lines, muffler, or main engine can shut down an emergency generator. Therefore, the special regulations for seismic protection of nonstructural systems represent a rational approach to achieving performance appropriate for the various occupancies, but experience data to confirm their adequacy are lacking.

When the hazard definition for design was changed from motion with a 2 percent chance of exceedance in 50 years to the 1 percent chance of collapse in 50 years, the primary intended performance was retained. The design basis ground motion is still two-thirds of the risk-targeted maximum considered earthquake (MCE_R) ground motion. The increase in the importance factor is intended to ensure a lower probability of collapse for the performance of higher occupancy and critical buildings.

The *Provisions* requirements are not intended to prevent damage due to earth slides (such as those that occurred in Anchorage, Alaska) or tsunami (such as occurred in Hilo, Hawaii, and the Indian Ocean). They provide only for required resistance to earthquake ground shaking without significant settlement, slides, subsidence, or faulting in the immediate vicinity of the structure. In most cases, practical engineering solutions are available to resist other potential earthquake hazards, but they must be developed on a case-by-case basis.

Although the *Provisions* sets the minimum performance goals described in Section 1.1, earthquake performance of buildings and other structures is highly variable. The characteristics of the shaking itself are highly uncertain and even different sets of motions defined to qualify as maximum considered earthquake ground motions can result in significantly different responses. Additional uncertainty is created by the wide variety of systems and configurations allowed under the regulations as well as by the various interpretations and implementation practices of individual designers. Thus, a small percentage of buildings designed to the requirements of the *Provisions* may not meet the performance intent when exposed to earthquake ground motions. The commentary the *Tentative Provisions for the Development of Seismic Regulations for Buildings* (Applied Technology Council, 1978), upon which the first edition of the *NEHRP Recommended Provisions* (1985) was based, suggested a less than 1 percent chance of collapse in a 50-year period for a building designed using the tentative requirements. More recent studies (e.g., *Quantification of Building Seismic Performance Factors*, FEMA P-695, 2009) suggest a 10 percent chance of collapse with shaking at the maximum considered earthquake level, which is roughly equivalent to the 1978 estimations.

1.3 MODIFICATIONS TO ASCE/SEI 7-05

With only a few exceptions (such as the changes to Table 12.2-1 shown in underline and strikeout), modifications are presented as replacements for existing sections of ASCE/SEI 7-05 or as new sections to be added to the standard. Commentary, if any, to the modifications that appear in the remainder of this part of the 2009 Provisions is presented at the end of each chapter of modifications. Commentary to the seismic chapters (Chapters 11 through 22) of the unmodified reference document itself, ASCE/SEI 7-05, is presented in Part 2 of the 2009 Provisions.

Modifications to Chapter 11, Seismic Design Criteria

Replace with the following:

SECTION 11.1.2, SCOPE

11.1.2 Scope. Every structure, and portion thereof, including nonstructural components, shall be designed and constructed to resist the effects of earthquake motions as prescribed by the seismic requirements of this standard. Certain nonbuilding structures, as described in Chapter 15, are also within the scope and shall be designed and constructed in accordance with the requirements for Chapter 15. Requirements concerning alterations, additions, and change of use are set forth in Appendix 11B. Existing structures and alterations to existing structures need only comply with the seismic requirements of this standard where required by Appendix 11B. The following structures are exempt from the seismic requirements of this standard:

1. Detached one- and two-family dwellings that are located where the mapped, short period, spectral response acceleration parameter, S_S, is less than 0.4 or where the Seismic Design Category determined in accordance with Section 11.6 is A, B or C.
2. Dwellings of wood-frame construction satisfying the limitations of and constructed in accordance with the *International Residential Code*.
3. Buildings of wood-frame construction satisfying the limitations of and constructed in accordance with Section 2308 of the *International Building Code*.
4. Agricultural storage structures that are intended only for incidental human occupancy.
5. Structures that require special consideration of their response characteristics and environment that are not addressed in Chapter 15 and for which other regulations provide seismic criteria, such as vehicular bridges, electrical transmission towers, hydraulic structures, buried utility lines and their appurtenances, and nuclear reactors.

SECTION 11.2, DEFINITIONS

Change the definition for "Maximum Considered Earthquake (MCE) Ground Motion" to:

RISK-TARGETED MAXIMUM CONSIDERED EARTHQUAKE (MCE_R) GROUND MOTION: The most severe earthquake effects considered by this standard as defined in Section 11.4.

Add the following new definition:

MAXIMUM CONSIDERED EARTHQUAKE GEOMETRIC MEAN PEAK GROUND ACCELERATION (PGA_M): The most severe earthquake effects considered for liquefaction as defined in Section 11.8.

SECTION 11.3, NOTATION

Add the following:

C_R	=	risk coefficient; see Section 21.2.1.1
C_{RS}	=	mapped value of the risk coefficient at short periods as defined by Figure 22-3
C_{R1}	=	mapped value of the risk coefficient at a period of 1 second as defined by Figure 22-4
S_{SD}	=	mapped deterministic, 5 percent damped, spectral response acceleration parameter at short periods as defined in Section 11.4.1
S_{SUH}	=	mapped uniform-hazard, 5 percent damped, spectral response acceleration parameter at short periods as defined in Section 11.4.1

S_{1D} = mapped deterministic, 5 percent damped, spectral response acceleration parameter at a period of 1 second as defined in Section 11.4.1

S_{1UH} = mapped uniform-hazard, 5 percent damped, spectral response acceleration parameter at a period of 1 second as defined in Section 11.4.1

Revise the following to read as indicated:

S_S = 5 percent damped, spectral response acceleration parameter at short periods as defined in Section 11.4.3

S_1 = spectral response acceleration parameter at a period of 1 second as defined in Section 11.4.3

S_{aM} = the site-specific MCE_R spectral response acceleration at any period

S_{MS} = the MCE_R, 5 percent damped, spectral response acceleration parameter at short periods adjusted for target risk and site-class effects as defined in Section 11.4.3

S_{M1} = the MCE_R, 5 percent damped, spectral response acceleration parameter at a period of 1 second adjusted for target risk and site-class effects as defined in Section 11.4.3

SECTION 11.4, SEISMIC GROUND MOTION

Replace with the following:

11.4 SEISMIC GROUND MOTION VALUES[3]

11.4.1 Mapped Acceleration Parameters and Risk Coefficients. The parameters S_{SUH} , S_{1UH}, S_{SD}, and S_{1D} shall be determined from the 0.2- and 1-second spectral response accelerations shown on Figures 22-1 and 22-2 and Figures 22-5 through 22-6, respectively, and the risk coefficients C_{RS} and C_{R1} shall be determined from Figures 22-3 and 22-4, respectively.

11.4.2 Site Class. Based on the site soil properties, the site shall be classified as either Site Class A, B, C, D, E, or F in accordance with Chapter 20. Where the soil properties are not known in sufficient detail to determine the Site Class, Site Class D shall be used unless the authority having jurisdiction or geotechnical data determines Site Class E or F soils are present at the site.

11.4.3 Site Coefficients, Risk Coefficients, and Risk-targeted Maximum Considered Earthquake (MCE_R) Spectral Response Acceleration Parameters. The spectral response acceleration for short periods (S_S), adjusted for the target risk of collapse, shall be determined as the lesser value of Equations 11.4-1 and 11.4-2:

$$S_S = C_{RS}\, S_{SUH} \qquad (11.4\text{-}1)$$

$$S_S = S_{SD} \qquad (11.4\text{-}2)$$

and the spectral response acceleration at a period of 1 second (S_1), adjusted for the target risk of collapse, shall be determined as the lesser value of Equations 11.4-3 and 11.4-4:

$$S_1 = C_{R1}\, S_{1UH} \qquad (11.4\text{-}3)$$

$$S_1 = S_{1D} \qquad (11.4\text{-}4)$$

where

S_{SD} = mapped deterministic, 5 percent damped, spectral response acceleration parameter at short periods as defined in Section 11.4.1

S_{SUH} = mapped uniform-hazard, 5 percent damped, spectral response acceleration parameter at short periods as defined in Section 11.4.1

C_{RS} = mapped value of the risk coefficient at short periods as defined in Section 11.4.1

S_{1D} = mapped deterministic, 5 percent damped, spectral response acceleration parameter at a period of 1 second as defined in Section 11.4.1

[3] To utilize the U.S. Geological Survey's seismic design map web application to obtain ground motion values, visit http://earthquake.usgs.gov/designmaps/usapp. Also see the USGS introduction to the web application included on the CD that accompanies this volume.

S_{1UH} = mapped uniform-hazard, 5 percent damped, spectral response acceleration parameter at a period of 1 second as defined in Section 11.4.1

C_{R1} = mapped value of the risk coefficient at a period of 1 second as defined in Section 11.4.1

The MCE_R spectral response acceleration for short periods (S_{MS}) and at 1 second (S_{M1}), adjusted for Site Class effects and the target risk of collapse, shall be determined by Equations 11.4-5 and 11.4-6, respectively.

$$S_{MS} = F_a S_s \quad (11.4\text{-}5)$$

$$S_{M1} = F_v S_1 \quad (11.4\text{-}6)$$

where site coefficients F_a and F_v are defined in Tables 11.4-1 and 11.4-2, respectively. When the simplified design procedure of Section 12.14 is used, the value F_a shall be determined in accordance with Section 12.14.8.1, and the values of F_v, S_1, S_{MS}, and S_{M1} need not be determined. Where S_1 is less than or equal to 0.04 and S_S is less than or equal to 0.15, the structure is permitted to be assigned to Seismic Design Category A and is only required to comply with Section 11.7.

Table 11.4-1 Site Coefficient, F_a

Site Class	Spectral Response Acceleration Parameter at Short Period				
	$S_S \le 0.25$	$S_S = 0.5$	$S_S = 0.75$	$S_S = 1.0$	$S_S \ge 1.25$
A	0.8	0.8	0.8	0.8	0.8
B	1.0	1.0	1.0	1.0	1.0
C	1.2	1.2	1.1	1.0	1.0
D	1.6	1.4	1.2	1.1	1.0
E	2.5	1.7	1.2	0.9	0.9
F	See Section 11.4.7				

Note: Use straight-line interpolation for intermediate values of S_S.

Table 11.4-2 Site Coefficient, F_v

Site Class	Spectral Response Acceleration Parameter at 1-second Period				
	$S_1 \le 0.1$	$S_1 = 0.2$	$S_1 = 0.3$	$S_1 = 0.4$	$S_1 \ge 0.5$
A	0.8	0.8	0.8	0.8	0.8
B	1.0	1.0	1.0	1.0	1.0
C	1.7	1.6	1.5	1.4	1.3
D	2.4	2.0	1.8	1.6	1.5
E	3.5	3.2	2.8	2.4	2.4
F	See Section 11.4.7				

Note: Use straight-line interpolation for intermediate values of S_1.

11.4.4 Design Spectral Acceleration Parameters. Design earthquake spectral response acceleration parameter at short periods, S_{DS}, and at a 1-second period, S_{D1}, shall be determined from Equations 11.4-7 and 11.4-8, respectively. Where the alternate simplified design procedure of Section 12.14 is used, the value of S_{DS} shall be determined in accordance with Section 12.14.8.1, and the value of S_{D1} need not be determined:

$$S_{DS} = \frac{2}{3} S_{MS} \quad (11.4\text{-}7)$$

$$S_{D1} = \frac{2}{3} S_{M1} \quad (11.4\text{-}8)$$

11.4.5 Design Response Spectrum. Where a design response spectrum is required by this standard and site-specific ground motion procedures are not used, the design response spectrum curve shall be developed as indicated in Figure 11.4-1 and as follows:

1. For periods less than T_0, the design spectral response acceleration, S_a, shall be taken as given by Equation 11.4-9:

$$S_a = S_{DS}\left(0.4 + 0.6\frac{T}{T_0}\right) \quad (11.4\text{-}9)$$

2. For periods greater than or equal to T_0 and less than or equal to T_S, the design spectral response acceleration, S_a, shall be taken equal to S_{DS}.

3. For periods greater than T_S, and less than or equal to T_L, the design spectral response acceleration, S_a, shall be taken as given by Equation 11.4-10:

$$S_a = \frac{S_{D1}}{T} \tag{11.4-10}$$

4. For periods greater than T_L, S_a shall be taken as given by Equation 11.4-11:

$$S_a = \frac{S_{D1} T_L}{T^2} \tag{11.4-11}$$

where

S_{DS} = the design spectral response acceleration parameter at short periods;
S_{D1} = the design spectral response acceleration parameter at 1-second period;
T = the fundamental period of the structure, seconds;
T_0 = 0.2 S_{D1}/S_{DS};
T_S = S_{D1}/S_{DS}; and
T_L = long-period transition period (seconds) shown in Figure 22-7.

11.4.6 MCE_R Response Spectrum. Where a MCE_R response spectrum is required, it shall be determined by multiplying the design response spectrum by 1.5.

11.4.7 Site-Specific Ground Motion Procedures. The site-specific ground motion procedures set forth in Chapter 21 are permitted to be used to determine ground motions for any structure. A site response analysis shall be performed in accordance with Section 21.1 for structures on Site Class F sites, unless the exception to Section 20.3.1 is applicable. For seismically isolated structures and for structures with damping systems on sites with S_1 greater than or equal to 0.6, a ground motion hazard analysis shall be performed in accordance with Section 21.2.

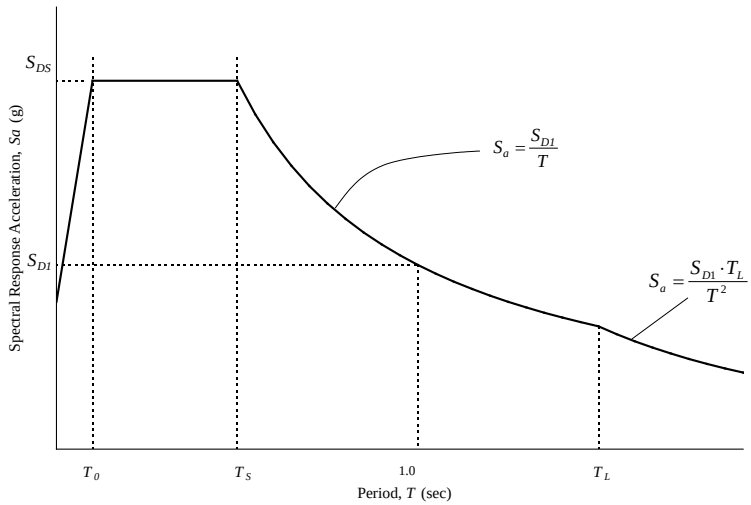

Figure 11.4-1 Design response spectrum.

SECTION 11.8, GEOLOGIC HAZARDS AND GEOTECHNICAL INVESTIGATION

Replace with the following:

11.8 Geologic Hazards and Geotechnical Investigation

11.8.1 Site Limitation for Seismic Design Categories E and F. A structure assigned to Seismic Design Category E or F shall not be located where there is a known potential for an active fault to cause rupture of the ground surface at the structure.

11.8.2 Geotechnical Investigation Report Requirements for Seismic Design Categories C through F. A geotechnical investigation report shall be provided for a structure assigned to Seismic Design Category C, D, E, or F in

accordance with this section. An investigation shall be conducted and a report shall be submitted that shall include an evaluation of the following potential geologic and seismic hazards:

1. Slope instability;
2. Liquefaction;
3. Total and differential settlement; and
4. Surface displacement due to faulting or seismic-induced lateral spreading or lateral flow.

The report shall contain recommendations for appropriate foundation designs or other measures to mitigate the effects of the above hazards.

EXCEPTION: Where deemed appropriate by the authority having jurisdiction, a site-specific geotechnical report is not required when prior evaluations of nearby sites with similar soil conditions provide sufficient direction relative to the proposed construction.

11.8.3 Additional Geotechnical Investigation Report Requirements for Seismic Design Categories D through F. The geotechnical investigation report for a structure assigned to Seismic Design Category D, E, or F shall include:

1. The determination of dynamic seismic lateral earth pressures on basement and retaining walls due to design earthquake ground motions.
2. The potential for liquefaction and soil strength loss evaluated for site peak ground acceleration, earthquake magnitude, and source characteristics consistent with the maximum considered earthquake geometric mean peak ground accelerations. Peak ground acceleration shall be determined based on either: (a) a site-specific study taking into account soil amplification effects as specified in Section 11.4.7 or (b) the peak ground acceleration, PGA_M, from Equation 11.8-1:

$$PGA_M = F_{PGA}\, PGA \qquad (11.8\text{-}1)$$

where

PGA_M = maximum considered earthquake geometric mean peak ground acceleration adjusted for Site Class effects;
PGA = mapped maximum considered earthquake geometric mean peak ground acceleration shown in Figures 22-8 through 22-11; and
F_{PGA} = site coefficient from Table 11.8-1.

3. Assessment of potential consequences of liquefaction and soil strength loss as computed in Item 2, including estimation of total and differential settlement, lateral soil movement, lateral soil loads on foundations, reduction in foundation soil-bearing capacity and lateral soil reaction, soil downdrag and reduction in axial and lateral soil reaction for pile foundations, increases in soil lateral pressures on retaining walls, and flotation of buried structures.
4. Discussion of mitigation measures such as selection of appropriate foundation type and depths, selection of appropriate structural systems to accommodate anticipated displacements and forces, ground stabilization, or any combination of these measures and how they shall be considered in the design of the structure.

Table 11.8-1 Site Coefficient F_{PGA}

Site Class	Mapped MCE Geometric Mean Peak Ground Acceleration, PGA				
	PGA ≤ 0.1	PGA = 0.2	PGA = 0.3	PGA = 0.4	PGA ≥ 0.5
A	0.8	0.8	0.8	0.8	0.8
B	1.0	1.0	1.0	1.0	1.0
C	1.2	1.2	1.1	1.0	1.0
D	1.6	1.4	1.2	1.1	1.0
E	2.5	1.7	1.2	0.9	0.9
F	See Section 11.4.7				

Note: Use straight-line interpolation for intermediate values of PGA.

Commentary to Chapter 11 Modifications

COMMENTARY TO SECTION 11.1.2

C11.1.2 Scope. The scope statement establishes in general terms the applicability of the standard as a base of reference. Certain structures are exempt and need not comply. The reasons for each are described below.

Note that it is not acceptable to use a combination of *International Building Code* (IBC) and *International Residential Code* (IRC) conventional construction provisions. Conventional requirements of either the IBC or the IRC can be combined with engineered design of elements in accordance with IBC engineered design requirements. Elements designed using the IBC engineered design requirements are not exempt from the seismic requirements of ASCE/SEI 7.

Exemption 1 – Detached one- and two-family dwellings in Seismic Design Categories A, B, and C, along with those located where $S_s < 0.4$g, are exempt because they represent low seismic risks.

Exemption 2 – This exemption recognizes that the wood-frame seismic design requirements of the *International Residential Code* (IRC) substantially meet the intent of conventional construction (wood-frame) provisions included in the *NEHRP Recommended Seismic Provisions* through the 2003 Edition.

Exemption 3 – This exemption recognizes that wood-frame seismic design requirements of *International Building Code* (IBC) Section 2308 substantially meet the intent of conventional construction (wood-frame) provisions included in the *NEHRP Recommended Seismic Provisions* through the 2003 Edition.

Exemption 4 – Agricultural storage structures generally are exempt from most code requirements because of the exceptionally low risk to life involved.

Exemption 5 – Bridges, transmission towers, nuclear reactors, and other structures with special configurations and uses are not covered because regulations developed to apply to buildings and building-like structures do not adequately address their design and performance issues.

The standard is not retroactive and usually applies to existing structures only where there is an addition, change of use, or alteration. Minimum acceptable seismic resistance of existing buildings is a policy issue normally set by the authority having jurisdiction. Appendix 11B of the standard contains rules of application for basic conditions. ASCE 31, *Seismic Evaluation of Buildings*, and ASCE 41, *Seismic Rehabilitation of Existing Buildings*, are available for technical guidance but do not contain policy recommendations. The International Code Council includes a chapter in the IBC to control the alteration, repair, addition, and change of occupancy of existing buildings and also maintains the *International Existing Building Code* (IEBC) and an associated commentary.

COMMENTARY TO SECTION 11.2

C11.2 DEFINITIONS

Renaming the maximum considered earthquake (MCE) ground motions as the risk-targeted maximum considered earthquake (MCE_R) ground motions is an editorial change recommended by the BSSC's Provisions Update Committee and accepted by the BSSC's Board. The MCE_R ground motions are based on the 2008 USGS seismic hazard maps and also incorporate three technical changes to ASCE/SEI 7-05:

1. Use of risk-targeted ground motions,
2. Use of maximum direction ground motions, and
3. Use of near-source 84th percentile ground motions.

Reasons for each of the three technical changes are included in the commentary that accompanies the modifications to Chapter 21.

COMMENTARY TO SECTIONS 11.4.3 AND 11.4.4

C11.4.3 Site Coefficients, Risk Coefficients, and Risk-targeted Maximum Considered Earthquake (MCE_R) Spectral Response Acceleration Parameters. The following illustrates the process of developing MCE_R response spectral accelerations using the formulas and maps of Section 11.4.3 and Chapter 22, respectively, and provides a summary of design ground motions for 34 city sites in regions of the United States of greatest seismic risk. Additional information and

references explaining the differences from the MCE ground motions in ASCE/SEI 7-05 are included in the commentary to Chapter 21.

Illustration of the Development of MCE_R Spectral Response Acceleration Using Section 11.4.3 Equations and Chapter 22 Uniform-Hazard, Risk Coefficient, and Deterministic Maps.

The formulas of Section 11.4.3 (and the associated uniform-hazard, risk coefficient, and deterministic maps of Chapter 22) are intended to add transparency to the development of MCE_R ground motions. The development of MCE_R ground motions is explained in Section 21.2 and its commentary as part of the site-specific ground motion procedures for seismic design. As will be illustrated, the formulas (and maps) add transparency by emulating the site-specific procedure. A cost of this transparency is the added complexity of more formulas (and maps). However, a USGS website similar to the USGS Java ground motion parameter calculator automates use of the proposed formulas (and maps): http://earthquake.usgs.gov/designmaps/usapp.

The three steps that the website implements are as follows:

Step 1 – Adjust uniform-hazard ground motions (Site Class B) for target risk of collapse

As illustrated in the top row of Figure C11.4-1, the first step is to obtain the mapped uniform-hazard (2 percent-in-50-years probability of exceedance) spectral response acceleration for short periods (S_{SUH}) from Figure 22-1 and for a period of 1 second (S_{1UH}) from Figure 22-2, and then to multiply these values by the corresponding mapped risk coefficients (C_{RS} and C_{R1}) from Figures 22-3 and 22-4, respectively. This step is expressed in Equations 11.4-1 for the short periods and 11.4-3 for the 1-second period and is consistent with Section 21.2.1 of the site-specific procedure in Chapter 21. The resulting spectral response accelerations, C_{RS}, S_{SUH} and $C_{R1}S_{1UH}$, are referred to as probabilistic ground motions. Figure C11.4-1 illustrates this for the 1-second period only using small maps of the conterminous United States that depict S_{1UH}, C_{R1}, and $C_{R1}S_{1UH}$.

The reasons for using 2 percent-in-50-years (uniform-hazard) spectral response accelerations, which were the basis for the probabilistic portions of the MCE ground motion maps in ASCE/SEI 7-05, are explained in the commentary of the *2003 NEHRP Recommended Provisions*. As explained below in the Chapter 21 commentary, the uniform-hazard maps (Figures 22-1 and 22-2) represent the spectral response acceleration in the maximum direction, which are larger than the *geometric mean* spectral response acceleration maps developed by the USGS by factors of 1.1 for the short periods and 1.3 for the 1-second period. The risk coefficients adjust these uniform-hazard (2 percent-in-50-years) spectral response accelerations to achieve building designs with 1 percent probability of collapse in 50 years (i.e., uniform risk), as explained below in the Chapter 21 commentary.

Step 2 – Take minimum of probabilistic and deterministic ground motions (Site Class B)

As illustrated in the middle row of Figure C11.4-1, the second step in the development of MCE_R ground motions is to obtain the mapped deterministic spectral response acceleration for short periods (S_{SD}) from Figure 22-5 and for a period of 1 second (S_{1D}) from Figure 22-6, and then to take the minimum of each of these values (expressed in Equations 11.4-2 and 11.4-4, respectively) and the corresponding value resulting from Step 1 (i.e., those expressed in Equations 11.4-1 and 11.4-3, respectively). This step is consistent with Sections 21.2.2 ("Deterministic Ground Motions") and 21.2.3 ("Site Specific MCE_R") of the site-specific procedure in Chapter 21. The resulting spectral response accelerations are denoted S_S for the short periods and S_1 for the 1-second period. Figure C11.4-1 illustrates this for the 1-second period only using small maps of the conterminous United States that depict $C_{R1}S_{1UH}$, S_{1D}, and S_1.

The reasons for using the minimum of probabilistic and deterministic spectral response accelerations, which was done previously (but not transparently) in developing the MCE ground motions maps in ASCE/SEI 7-05, are explained in the commentary of the *2003 NEHRP Recommended Provisions*. In brief, deterministic ground motions provide a reasonable and practical upper-bound to design ground motions, but their use implies a somewhat higher level of collapse risk than the 1 percent probability of collapse in 50 years associated with probabilistic (risk-targeted) ground motions. In general, deterministic ground motions govern only at sites near active sources in regions of high seismicity.

As defined in ASCE/SEI 7-05 Section 21.2.2, the deterministic spectral response accelerations (for Site Class B) shall not be taken as lower than 1.5g for the short periods and 0.6g for the 1-second period; hence, the ground motions on the proposed deterministic maps (Figures 22-5 and 22-6) are no lower than these values. Otherwise the ground motions on the proposed deterministic maps are 180 percent (as opposed to 150 percent in ASCE/SEI 7-05) of median spectral response accelerations, for reasons explained below in the section entitled "Deterministic Ground Motions – 84th Percentile." Like the proposed uniform-hazard maps used in Step 1, the proposed deterministic maps represent the spectral response acceleration in the maximum direction.

Step 3 – Adjust Site Class B ground motions for site condition (e.g., Site Class D)

As illustrated in the bottom row of Figure C11.4-1, the third step is to multiply the spectral response accelerations resulting from Step 2 (S_S and S_1) by the corresponding site coefficients (F_a and F_v) from Tables 11.4-1 and 11.4-2, respectively. This step is expressed in Equation 11.4-5 for the short periods and 11.4-6 for the 1-second period, where the resulting ground motions are named risk-targeted maximum considered earthquake (MCE_R) spectral response accelerations and are denoted S_{MS} and S_{M1}, respectively. Figure C11.4-1 illustrates the step for the 1-second period only using a small map of the conterminous United States that depicts S_1, an abbreviated version of Table 11.4-2, and another small map that depicts S_{M1}.

This step is the same as that in ASCE/SEI 7-05 Section 11.4.3, except that the resulting MCE spectral response accelerations (S_{MS} and S_{M1}) have been renamed MCE_R spectral response accelerations.

Figures C11.4-2 and C11.4-3 are maps of the United States and California, respectively, showing values of the MCE_R 1-second spectral response acceleration parameter, S_{M1}, and associated regions of Seismic Design Category, assuming Site Class D conditions. These maps illustrate MCE_R ground motions resulting from the three-step process described above for the 1-second period only.

The design ground motions are 2/3 of these MCE_R ground motions as calculated using Equations 11.4-7 and 11.4-8.

Summary of Design Ground Motions – 34 United States Cities

Example values of the design ground motions that incorporate both USGS updates to uniform-hazard values (and hazard functions), including the new NGA relations, and the three technical changes mentioned above, are shown next. For comparison, values of design ground motions of the current standard (ASCE/SEI 7-05) and, for California sites, values of design ground motions of the 2001 *California Building Code* (CBC) are given. In all cases, example values are based on design ground motions, representative of Site Class D conditions (i.e., default site class).

Table C11.4-1 lists the 34 city sites by region, the county (or counties) and associated populations they represent, and the latitude and longitude of the specific location of the city site. Typically, each city is the largest city of the county or metropolitan statistical area (MSA) of interest. The exception is Los Angeles County which has four city sites due to its large geographical area and associated risk. The specific location (latitude and longitude) of city sites is important for sites in high seismic regions (i.e., near an active source) since ground motions can vary greatly over relatively small distances. Example sites are selected to be coincident with the location of the hazard grid point nearest the center of the city of interest. Hazard grid points are the discrete locations at which the USGS calculates values of probabilistic and deterministic ground motions (and risk coefficients). At the time that these examples were developed, ground motions were available (from the USGS) only for these discrete locations; however, final maps and database tools such as the USGS online ground motion parameter calculator also provide values of ground motions at intermediate locations.

Table C11.4-2 provides values of short-period spectral acceleration, S_{DS}, and Table C11.4-3 provides values of 1-second spectral acceleration, S_{D1}, for each of the 34 city sites of Table C11.4-1. Spectral acceleration values and Seismic Design Category (SDC) are given for both ASCE/SEI 7-05 provisions and changes put forth in these provisions (2009 *Provisions*). For California city sites, these tables also provide the corresponding values of seismic coefficients ($2.5C_a$, at short periods, and, C_v, at 1 second) of the 2001 *California Building Code* (1997 Uniform Building Code or UBC). Weighted mean values of spectral acceleration (and seismic coefficients) are calculated for each region considering the population associated with each city site in Tables 11.4-2 and 11.4-3.

The following observations are made by comparing the design ground motions of these *Provisions* with those of ASCE/SEI 7-05 and the design coefficients of the 2001 *California Building Code* (CBC):

1. On a regional basis, the changes to ASCE/SEI 7-05 put forth in these *Provisions* result in only a slight increase or decrease in design ground motions, on average. Notable exceptions are short-period ground motions in the central and eastern United States (CEUS) for which the changes reduce design values and for certain city sites (e.g., St. Louis, Chicago, and New York) where the changes also lower the Seismic Design Category.
2. In the western region (WUS), the changes to ASCE/SEI 7-05 put forth in these *Provisions* result in a modest increase, or decrease, in design ground motions (plus or minus 10 percent), and generally lower seismic design values from those of 2001 CBC (1997 UBC).
3. For certain city sites (e.g., San Bernardino and San Diego), the changes to ASCE/SEI 7-05 put forth in these *Provisions* result in a substantial increase, or decrease, in design ground motions due primarily to changes in underlying updated USGS hazard functions.

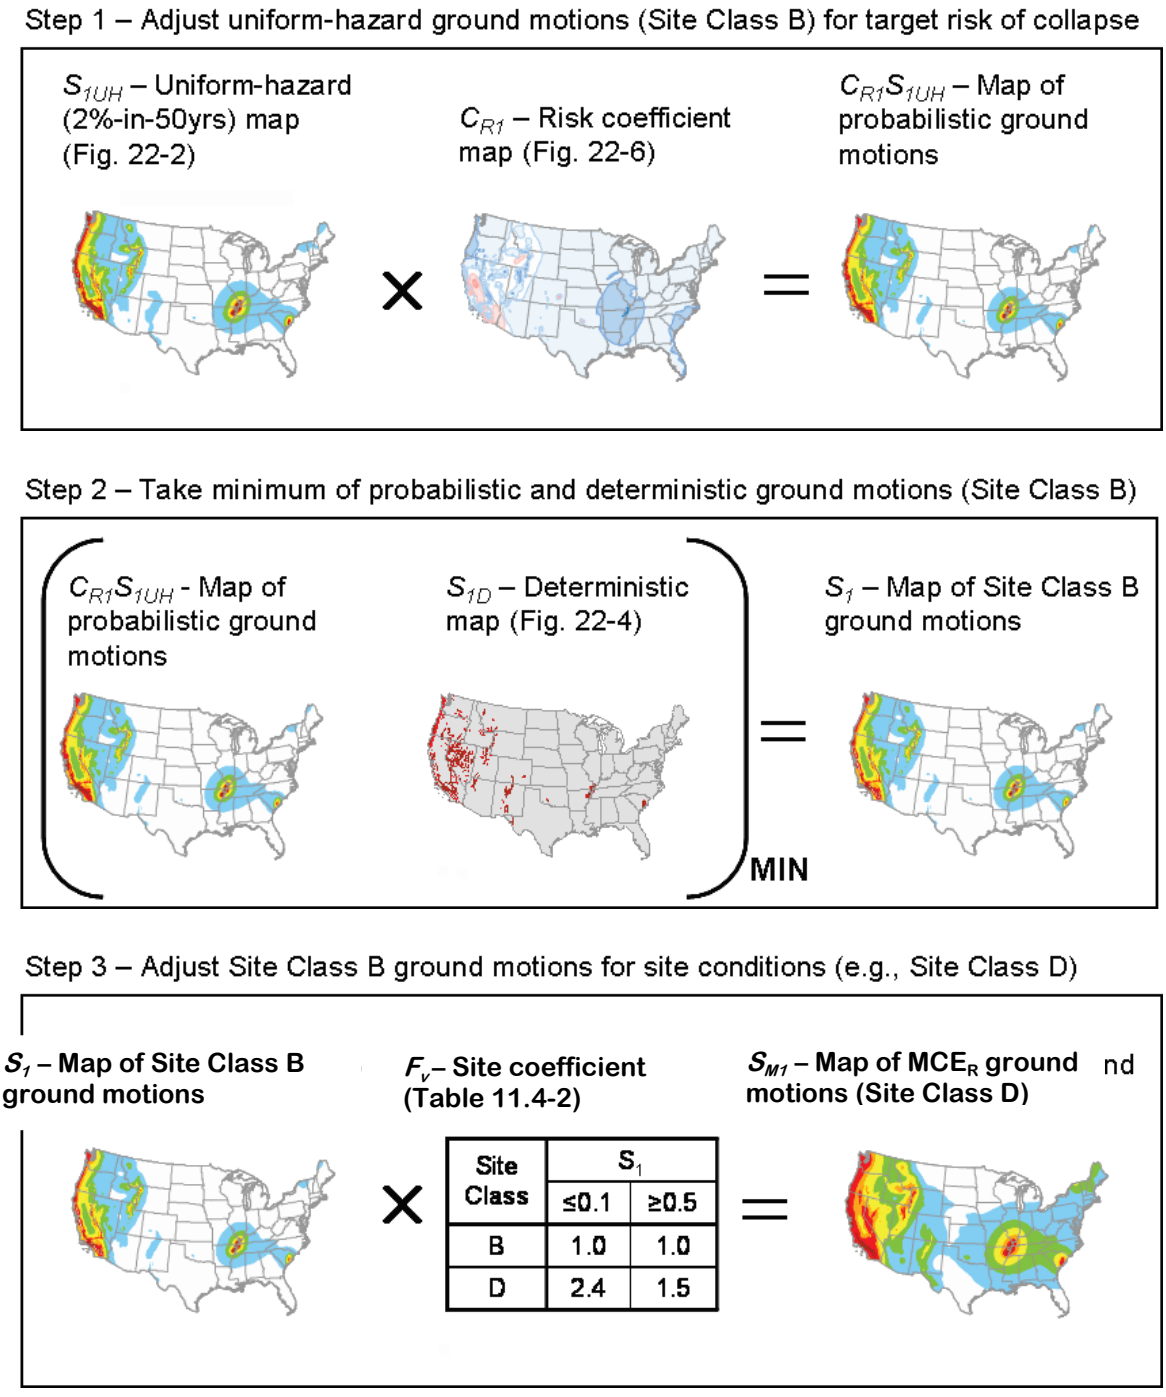

Figure C11.4-1 Illustration of process for developing 1-second MCE_R Site Class D ground motions using formulas of Section 11.4.3 and associated mapped values of ground motions and risk coefficients of Chapter 22.

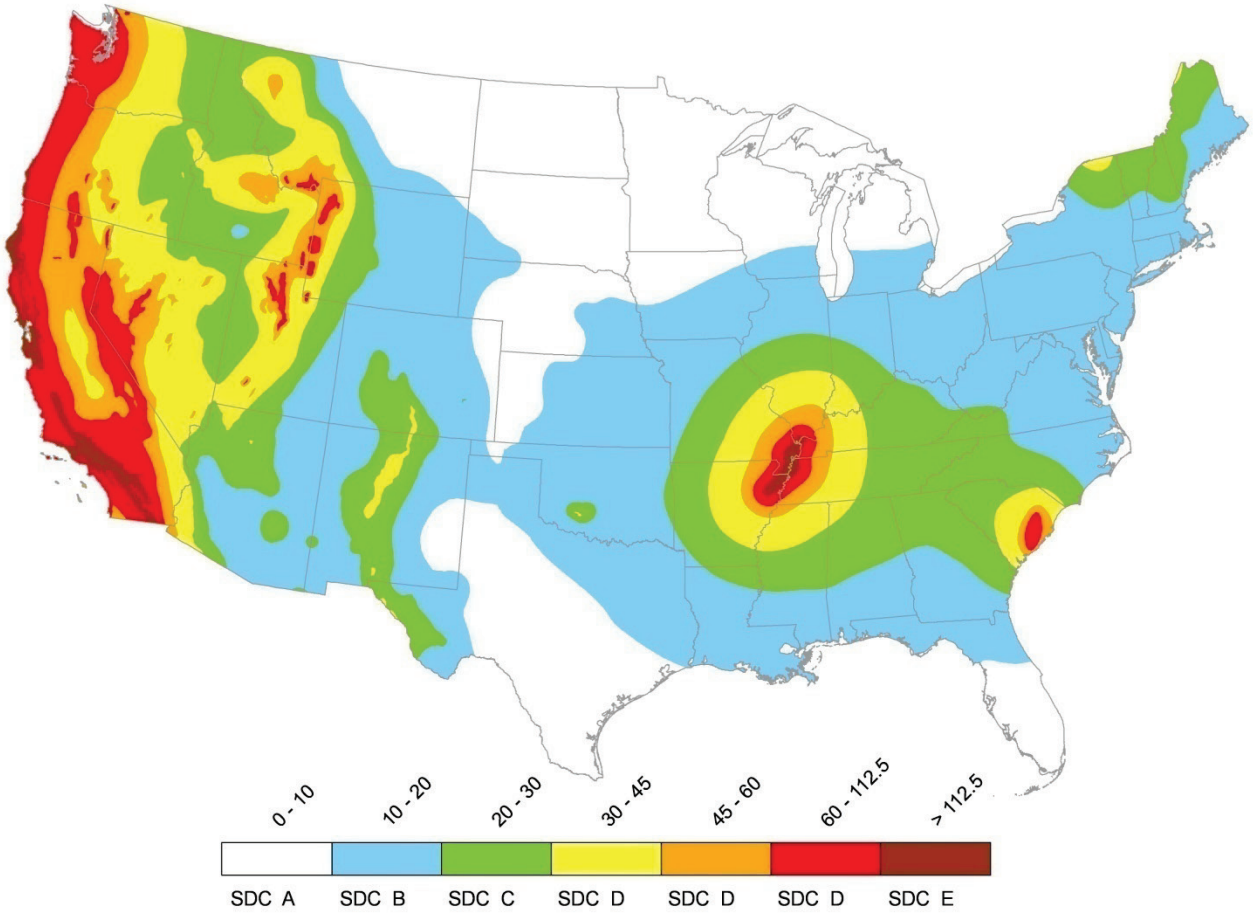

Figure C11.4-2 Map illustrating values of the MCE_R 1-second spectral response acceleration parameter, S_{M1} (%g), and associated regions of Seismic Design Category, assuming Site Class D conditions.

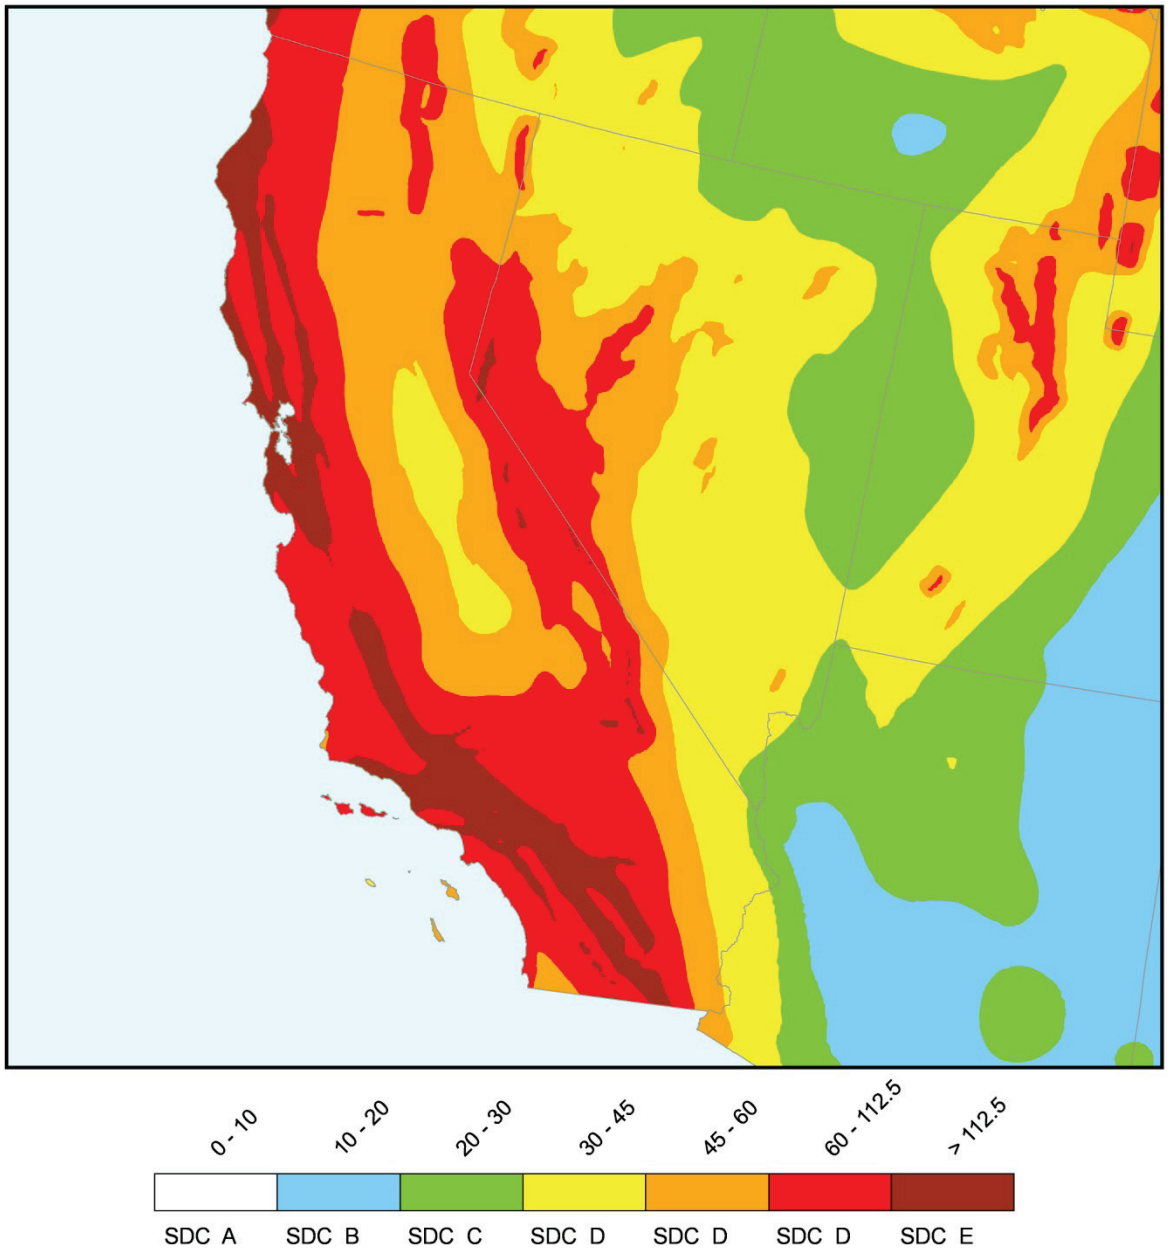

Figure C11.4-3 Map illustrating values of the MCE_R 1-second spectral response acceleration parameter, S_{M1} (%g), and associated regions of Seismic Design Category, assuming Site Class D conditions, for California sites.

COMMENTARY TO SECTION 11.8.3

C11.8.3 Additional Geotechnical Investigation Report Requirements for Seismic Design Categories D through F. The dynamic lateral earth pressure on basement and retaining walls during the period of earthquake ground shaking is considered to be an earthquake load, *E,* for use in design load combinations. This dynamic earth pressure is superimposed on the pre-existing static lateral earth pressure during ground shaking. The pre-existing static lateral earth pressure is considered to be an *H* load.

While the dynamic seismic lateral earth pressures (Item 1) may be determined for design earthquake ground motions, taken as 2/3 of maximum considered earthquake ground motions, the potential for liquefaction and soil strength loss and related consequences (Items 2 and 3) must be evaluated for maximum considered earthquake ground motions because they can be catastrophic to a structure.

Page intentionally left blank.

Modifications to Chapter 12, Seismic Design Requirements for Building Structures

TABLE 12.2-1, DESIGN COEFFICIENTS AND FACTORS FOR SEISMIC-FORCE-RESISTING SYSTEMS

Revise as indicated (substantive changes are shaded, deletions are shown in strikeout, and additions are underlined):

H. STEEL SYSTEMS NOT SPECIFICALLY DETAILED FOR SEISMIC RESISTANCE, EXCLUDING CANTILEVER COLUMN SYSTEMS	14.1	3	3	3	NL	NL	NP	NP	NP

[a]Response modification coefficient, *R*, for use throughout the standard. Note *R* reduces forces to a strength level, not an allowable stress level.
[b]Reflection amplification factor, C_d, for use in Sections 12.8.6, 12.8.7, and 12.9.2
[c]NL = Not Limited and NP = Not Permitted. For metric units use 30.5 m for 100 ft and use 48.8 m for 160 ft. Heights are measured from the base of the structure as defined in Section 11.2.
[d]See Section 12.2.5.4 for a description of building systems limited to buildings with a height of 240 ft (73.2 m) or less.
[e]See Section 12.2.5.4 for building systems limited to buildings with a height of 160 ft (48.8 m) or less.
[f]Ordinary moment frame is permitted to be used in lieu of intermediate moment frame for Seismic Design Categories B or C.
[g]The tabulated value of the overstrength factor, Ω_0, is permitted to be reduced by subtracting one-half for structures with flexible diaphragms, but shall not be taken as less than 2.0 for any structure.
[h]See Sections 12.2.5.6 and 12.2.5.7 for limitations for steel OMFs and IMFs in structures assigned to Seismic Design Category D or E.
[i]See Sections 12.2.5.8 and 12.2.5.9 for limitations for steel OMFs and IMFs in structures assigned to Seismic Design Category F.
[j]Steel ordinary concentrically braced frames are permitted in single-story buildings up to a height of 60 ft (18.3 m) where the dead load of the roof does not exceed 20 psf (0.96 kN/m^2) and in penthouse structures.
[l] Alternatively, the seismic load effect with overstrength, E_m, can be based on the expected strength determined in accordance with AISI S110.
[m] Cold-formed steel – special bolted moment frames shall be limited to one story in height in accordance with AISI S110.

TABLE 12.6-1, PERMITTED ANALYTICAL PROCEDURES

Replace with the following:

Table 12.6-1 Permitted Analytical Procedures

Seismic Design Category	Structural Characteristics	Equivalent Lateral Force Analysis Section 12.8	Modal Response Spectrum Analysis Section 12.9	Seismic Response History Procedures Chapter 16
B, C	All structures	P	P	P
D, E, F	Regular structures not exceeding 160 feet in height and all structures of light frame construction	P	P	P
	Regular structures equal to or exceeding 160 feet in height with $T < 3.5\ T_s$	P	P	P
	Irregular structures not exceeding 160 feet in height and having only horizontal irregularities type 2, 3, 4, or 5 of Table 12.3-1 or vertical irregularities type 4, 5a or 5b of Table 12.3-2	P	P	P
	All other structures	NP	P	P

Note: P – Permitted; NP – Not permitted.

SECTION 12.8.7, P-DELTA LIMIT

Replace with the following:

12.8.7 P-delta Limit. Stability coefficient, θ, as determined for each level of the structure by the following equation, shall not exceed 0.10:

$$\theta = \frac{P_x \Delta I}{V_x h_{sx} C_d} \qquad (12.8\text{-}16)$$

where:

P_x = the total vertical design load at and above Level x. Where calculating the vertical design load for purposes of determining P-delta effects, the individual load factors need not exceed 1.0.
Δ = the design story drift calculated in accordance with Section 12.8.6.
I = the occupancy importance factor determined in accordance with Section 11.5.1.
V_x = the seismic shear force acting between Level x and x - 1.
h_{sx} = the story height below Level x.
C_d = the deflection amplification factor from Table 12.2-1

EXCEPTION: The stability coefficient, θ, shall be permitted to exceed 0.10 if either of the following applies:

1. The resistance to lateral forces is determined to increase continuously in a monotonic nonlinear static (pushover) analysis according to ASCE/SEI 41 Section 3.3.3.3.2 using S_a defined as a MCE_R spectral response acceleration according to the *Provisions* at the effective fundamental period. Modeling and analysis shall conform to ASCE/SEI 41 Section 3.3.3, except that the analysis shall be done for seismic actions occurring simultaneously with the effects of dead load in combination with not less than 25 percent of the required design live loads, reduced as permitted for the area of a single floor. Degradation shall be modeled and P-delta effects shall be included in the analysis. A review of the nonlinear static analysis shall be performed by an independent team having experience in seismic analysis methods and the theory and application of nonlinear seismic analysis and structural behavior under earthquake loading. The review team shall be composed of at least two members including at least one registered design professional.
2. Compliance with the provisions of the nonlinear response history procedure in Chapter 16 is demonstrated.

SECTION 12.11.2.2.1, TRANSFER OF ANCHORAGE FORCES INTO DIAPHRAGM

Replace with the following:

12.11.2.2.1 Transfer of Anchorage Forces into Diaphragm. Diaphragms shall be provided with continuous ties or struts between diaphragm chords to distribute these anchorage forces into the diaphragm.

EXCEPTION: In buildings with diaphragms of light-frame construction, continuous cross-ties are not required provided all of the following are satisfied:

1. The unsupported height of the wall does not exceed 12 feet,
2. Anchorages are spaced no more than 4 feet on center,
3. The length of the diaphragm in the direction parallel to the wall being anchored does not exceed 2.5 times the length of the diaphragm in the orthogonal direction, and
4. The anchorage connection extends far enough into the diaphragm to transfer the anchorage force into the diaphragm.

Diaphragm connections shall be positive, mechanical, or welded. Added chords are permitted to be used to form subdiaphragms to transmit the anchorage forces to the main continuous cross-ties. The maximum length-to-width ratio of the structural subdiaphragm shall be 2.5 to 1. Connections and anchorages capable of resisting the prescribed forces shall be provided between the diaphragm and the attached components. Connections shall extend into the diaphragm a sufficient distance to develop the force transferred into the diaphragm.

SECTION 12.11.2.2.3, WOOD DIAPHRAGMS

Replace with the following:

12.11.2.2.3 Wood Diaphragms. In wood diaphragms, the continuous ties shall be in addition to the diaphragm sheathing.

EXCEPTION: Where continuous cross-ties are not required by Section 12.11.2.2.1 and the anchorage connections extend into the diaphragm a sufficient distance to develop the force transferred into the diaphragm sheathing.

Anchorage shall not be accomplished by use of toenails or nails subject to withdrawal nor shall wood ledgers or framing be used in cross-gain bending or cross-grain tension. The diaphragm sheathing shall not be considered effective as providing the ties or struts required by this section.

SECTION 12.14.7.5.1, TRANSFER OF ANCHORAGE FORCES INTO DIAPHRAGM

Replace with the following:

12.14.7.5.1 Transfer of Anchorage Forces into Diaphragm. Diaphragms shall be provided with continuous ties or struts between diaphragm chords to distribute these anchorage forces into the diaphragm.

EXCEPTION: In buildings with diaphragms of light-framed construction, continuous cross-ties are not required provided all of the following are satisfied:

1. The unsupported height of the wall does not exceed 12 feet,
2. Anchorages are spaced no more than 4 feet on center,
3. The length of the diaphragm in the direction parallel to the wall being anchored does not exceed 2.5 times the length of the diaphragm in the orthogonal direction, and
4. The connection extends far enough into the diaphragm to transfer the anchorage force into the diaphragm.

Added chords are permitted to be used to form subdiaphragms to transmit the anchorage forces to the main continuous cross-ties. The maximum length-to-width ratio of the structural subdiaphragm shall be 2.5 to 1. Connections and anchorages capable of resisting the prescribed forces shall be provided between the diaphragm and the attached components. Connections shall extend into the diaphragm a sufficient distance to develop the force transferred into the diaphragm.

SECTION 12.14.7.5.2, WOOD DIAPHRAGMS

Replace with the following:

12.14.7.5.2 Wood Diaphragms. In wood diaphragms, the continuous ties shall be in addition to the diaphragm sheathing.

EXCEPTION: Where continuous cross-ties are not required by Section 12.14.7.5.1 and the anchorage connections extend into the diaphragm a sufficient distance to develop the force transferred into the diaphragm sheathing.

Anchorage shall not be accomplished by use of toenails or nails subject to withdrawal nor shall wood ledgers or framing be used in cross-gain bending or cross-grain tension. The diaphragm sheathing shall not be considered effective as providing the ties or struts required by this section.

SECTION 12.14.8.1, SEISMIC BASE SHEAR

Revise, in part, to read as follows:

. . . In calculating S_{DS}, S_s shall be in accordance with Section 11.4.3, but need not be taken larger than 1.5.

[Remainder of section stays the same.]

Commentary to Chapter 12 Modifications

COMMENTARY TO SECTION 12.6

C12.6 ANALYSIS SELECTION PROCEDURE

Table 12.6-1 applies only to buildings without seismic isolation (Chapter 17) or passive energy devices (Chapter 18). The four basic procedures addressed in Table 12.6-1 are equivalent lateral force (ELF) analysis (Section 12.8), modal response spectrum (MRS) analysis (Section 12.9), linear response history (LRH) analysis, and nonlinear response history (NRH) analysis. Requirements for performing response history analysis are provided in Chapter 16. Nonlinear static (pushover) analysis is not provided as an "approved" analysis procedure in ASCE/SEI 7-05. The value of $T_s = S_{D1}/S_{DS}$ depends on the site class because S_{DS} and S_{D1} include such effects. When ELF is not allowed, the analysis must be performed using modal response spectrum or response history analysis.

ELF is not allowed for buildings with the listed irregularities because it assumes a gradually varying distribution of mass and stiffness along the height and negligible torsional response. The $3.5T_s$ limit recognizes that higher modes are more significant in taller buildings (Lopez and Cruz, 1996; Chopra, 2007), such that the ELF method may underestimate the design base shear and may not predict correctly the vertical distribution of seismic forces.

Table C12.6-1 demonstrates that $3.5T_s$ generally increases as ground motion intensity increases and as soils become softer. Assuming that the fundamental building period is about 0.1 times the number of stories, the maximum building height for which the ELF applies ranges from about 10 stories for low seismic hazard sites with firm soil to 30 stories for high seismic hazard sites with soft soil. Since this trend was not intended, the modification to Section 12.6 adds a height limit of 160 feet.

Table C12.6-1 Values of $3.5T_S$ for Various Cities and Various Site Classes

Location	S_s (g)	S_1 (g)	$3.5T_s$ (seconds) for Site Class			
			A&B	C	D	E
Denver	0.219	0.057	0.91	1.29	1.37	1.07

COMMENTARY TO SECTION 12.8.7

C12.8.7 P-delta Limit. ASCE/SEI 7-05 allows amplified forces to be used in a linear elastic analysis where the stability coefficient, θ, exceeds 0.10. By comparison, FEMA 350 requires explicit modeling of P-delta effects for steel moment-resisting frames where θ exceeds approximately 0.04. Where the tangent stiffness of the structure may become negative, dynamic displacement demands can increase significantly (Gupta and Krawinkler, 2000). Structures with θ not greater than 0.10 generally are expected to have a positive tangent stiffness, depending on the progression of plastic hinging and strain hardening. The 2009 *Provisions* allows structures to exceed this limit only if a nonlinear static analysis including P-delta effects demonstrates that the tangent stiffness remains positive up to the target displacement computed for the MCE_R or if nonlinear dynamic analysis demonstrates adequate resistance to instability.

The occupancy importance factor, I, is inserted into Equation 12.8-16 to correct an error in ASCE/SEI 7. In this way, the stability coefficient is based on the elastic stiffness of the system.

Modifications to Chapter 13, Seismic Design Requirements for Nonstructural Elements

SECTION 13.6.5.5, ADDITIONAL REQUIREMENTS [FOR COMPONENT SUPPORTS]

Replace Item 6f with the following:

Attachments into concrete utilize anchors that have not been prequalified for seismic applications in accordance with ACI 355.2.

SECTION 13.6.8.2, FIRE PROTECTION SPRINKLER SYSTEMS IN SEISMIC DESIGN CATEGORY C

Replace with the following:

13.6.8.2 Fire Protection Sprinkler Systems. Fire protection sprinkler systems designed and constructed in accordance with NFPA 13 shall be deemed to meet the other requirements of this section.

SECTION 13.6.8.3, FIRE PROTECTION SPRINKLER SYSTEMS IN SEISMIC DESIGN CATEGORIES D THROUGH F

Delete this section and renumber remaining sections.

Commentary to Chapter 13 Modifications

COMMENTARY TO SECTION 13.6.5.5

C13.6.5.5 Additional Requirements [for Component Supports]. As reflected in this section of the standard and in the footnote to Table 13.6-1, vibration isolated equipment with snubbers is subject to amplified loads as a result of dynamic impact.

Use of expansion anchors for non-vibration isolated mechanical equipment rated over 10 hp is prohibited based on experience with older anchor types. The ASCE 7 Seismic Subcommittee is considering a proposal that also would exempt anchors qualified by simulated seismic testing and long-term vibration testing.

The previous language in Item 6f was intended to identify anchor types that would be considered non-ductile. The previous requirement has been superseded by requirements for qualification that include checks for ductility and good performance in earthquake conditions.

COMMENTARY TO SECTION 13.6.8.2

C13.6.8.2 Fire Protection Sprinkler Systems. NFPA 13-2007 applies to Seismic Design Categories C, D, E, and F. The lateral design procedures of NFPA 13-2007 have been revised for consistency with the ASCE/SEI 7-05 design approach while retaining traditional sprinkler system design concepts. Using conservative upper-bound values of the various design parameters, a single lateral force coefficient, C_p, was developed. It is a function of the mapped short period response parameter S_s. Stresses in the pipe and connections are controlled by limiting the maximum reaction at bracing points as a function of pipe diameter.

In Seismic Design Category C, the prescriptive requirements of NFPA 13-2007, using a default lateral force of 50 percent of the weight of the water-filled pipe, provide a conservative design, although application of the NFPA sway bracing calculation may produce a lower design lateral force.

Page intentionally left blank.

Modifications to Chapter 14, Material Specific Seismic Design and Detailing Requirements

SECTION 14.1, STEEL

Replace with the following:

14.1 STEEL

Structures, including foundations, constructed of steel to resist seismic loads shall be designed and detailed in accordance with this standard including the reference documents and additional requirements provided in this section.

14.1.1 Reference Documents. The design, construction, and quality of steel components that resist seismic forces shall conform to the applicable requirements of the following as amended herein:

1. AISC 360
2. AISC 341
3. AISI NAS
4. AISI S110
5. AISI-GP
6. AISI-PM
7. AISI Lateral
8. AISI WSD
9. ASCE 19
10. ASCE 8
11. SJI Tables

14.1.1.1 Modifications to AISC 341-05. The text of AISC 341 shall be modified as indicated in Sections 14.1.1.1.1 and 14.1.1.1.2. Italics are used for text to indicate requirements that differ from AISC 341.

14.1.1.1.1 Replace Section 15.7 with the following:

15.7 Beam-to-Column Connections

Where a brace or gusset plate connects to both members at a beam-to-column connection, the connection shall conform to one of the following:

(1) The connection shall accommodate the required rotation at a minimum story drift of 2.5 percent of the story height or

(2) The connection shall be designed to resist a moment equal to the lesser of the following:

(i) A moment corresponding to $1.1R_yF_yZ$ (LRFD) or $(1.1/1.5)R_yF_yZ$ (ASD), as appropriate, of the beam.

(ii) A moment corresponding to $\Sigma 1.1R_yF_yZ$ (LRFD) or $\Sigma[(1.1/1.5)R_yF_yZ]$ (ASD), as appropriate, of the column.

This moment shall be considered in combination with the required strength of the brace connection and beam connection, including amplified diaphragm collector forces.

1.4.1.1.1.2 Add new Section 16.7 as follows:

16.7 Beam-to-Column Connections

Where a brace or gusset plate connects to both members at a beam-to-column connection, the connection shall conform to one of the following:

(1) The connection shall accommodate the required rotation at a minimum story drift of 2.5 percent of the story height or

(2) The connection shall be designed to resist a moment equal to the lesser of the following:

(i) A moment corresponding to $1.1R_yF_yZ$ (LRFD) or $(1.1/1.5)R_yF_yZ$ (ASD), as appropriate, of the beam.

(ii) A moment corresponding to $\Sigma 1.1R_yF_yZ$ (LRFD) or $\Sigma[(1.1/1.5)R_yF_yZ]$ (ASD), as appropriate, of the column.

This moment shall be considered in combination with the required strength of the brace connection and beam connection, including amplified diaphragm collector forces.

14.1.2 Seismic Design Categories B and C. Steel structures assigned to Seismic Design Category B or C shall be of any construction permitted by the reference documents in Section 14.1.1. An *R* factor as set forth in Table 12.2-1 is permitted where the structure is designed and detailed in accordance with the requirements of AISC 341 for structural steel buildings, AISI S110 for cold-formed steel construction, or AISI Lateral for light-framed cold-formed steel construction. Systems not detailed in accordance with AISC 341, AISI S110, or AISI Lateral shall use the *R* factor designated for "Structural steel systems not specifically detailed for seismic resistance" in Table 12.2-1.

14.1.3 Seismic Design Categories D through F. Steel structures assigned to Seismic Design Category D, E, or F shall be designed and detailed in accordance with AISC 341 for structural steel, AISI S110 for cold-formed steel construction, or AISI Lateral for light-framed cold-formed steel construction.

14.1.4 Cold-formed Steel. The design of cold-formed carbon or low-alloy steel to resist seismic loads shall be in accordance with the requirements of AISI NAS, AISI S110 and the design of cold-formed stainless steel structural members to resist seismic loads shall be in accordance with the requirements of ASCE 8.

14.1.4.1 Modifications to AISI S110 (2007 edition). The text of AISI S110 shall be modified as indicated in Sections 14.1.4.1.1 through 14.1.2.1.5. Italics are used for text within Sections 14.1.4.1.1 through 14.1.2.1.5 to indicate requirements that differ from AISI S110.

14.1.4.1.1 AISI S110, Section D1. Revise Section D1 to read as follows:

D1 Cold-Formed Steel Special Bolted Moment Frames (CFS-SBMF)

Cold-formed steel–special bolted moment frames (CFS-SBMF) systems shall withstand inelastic deformations through friction and bearing at their bolted connections. Beams, columns, and connections shall satisfy the requirements in this section. CFS-SBMF systems shall be limited to one-story structures, no greater than 35 feet in height, without column splices and satisfying the requirements in this section. *The SBMF shall engage all columns supporting the roof or floor above. The single size beam and single size column with the same bolted moment connection detail shall be used for each frame. The frame is to be supported on a level floor or foundation.*

14.1.4.1.2 AISI S110, Section D1.1.1. Revise Section D1.1.1 to read as follows:

D1.1.1 Connection Limitations

Beam-to-column connections in CFS-SBMF systems shall be bolted connections with snug-tight high-strength bolts. The bolt spacing and edge distance shall be in accordance with the limits of AISI S100, Section E3. *The 8-bolt configuration shown in Table D1-1 shall be used. The faying surfaces of the beam and column in the bolted moment connection region shall be free of any lubricants or debris.*

14.1.4.1.3 AISI S110, Section D1.2.1. Revise Section D1.2.1 to read as follows:

D1.2.1 Beam Limitations

In addition to the requirements of Section D1.2.3, beams in CFS-SBMF systems shall be *ASTM A653 Gr. 55 galvanized steel* cold-formed C-sections members with lips, and designed in accordance with Chapter C of AISI S100. *The beam depth shall be between 12 in (305 mm) and 20 in (508 mm).* The flat depth-to-thickness ratio of the web shall not exceed $6.18\sqrt{E/F_y}$.

14.1.4.1.4 AISI S110, Section D1.2.2. Revise Section D1.2.2 to read as follows:

D1.2.2 Column Limitations

In addition to the requirements of D1.2.3, columns in CFS-SBMF systems shall be *ASTM A500 Gr. B* cold-formed hollow structural section (HSS) members *painted with a standard industrial finished surface,* and designed in accordance with Chapter C of AISI S100. *The column depth shall be between 8 in (203 mm) and 12 in (305 mm).* The flat depth-to-thickness ratio shall not exceed $1.40\sqrt{E/F_y}$.

14.1.4.1.5 AISI S110, Section D1.3. Revise Section D1.3 to read as follows:

D1.3 Design Story Drift

Where the applicable building code does not contain design coefficients for CSF-SBMF systems, the provisions of Appendix 1 shall apply. The design story drift shall not exceed *0.03h*, unless approved by authority having jurisdiction. *In no case shall the design story drift exceed 0.05h.*

For structures having a period less than T_S, as defined in the applicable building code, alternate methods of computing Δ shall be permitted, provided such alternate methods are acceptable to the authority having jurisdiction.

[Remainder of Section 14.1 is unchanged.]

SECTION 14.2.2, MODIFICATIONS TO ACI 318

Replace with the following:

14.2.2 Modifications to ACI 318. The text of ACI 318 shall be modified as indicated in Sections 14.2.2.1 through 14.2.2.9. Italics are used for text within Sections 14.2.2.1 through 14.2.2.9 to indicate provisions that differ from ACI 318.

14.2.2.1 Definitions. Add the following definitions to Section 2.2.

DETAILED PLAIN CONCRETE STRUCTURAL WALL: *A wall complying with the requirements of Chapter 22.*

ORDINARY PRECAST STRUCTURAL WALL: *A precast wall complying with the requirements of Chapters 1 through 18.*

WALL PIER*: A wall segment with a horizontal length-to-thickness ratio of at least 2.5, but not exceeding 6, whose clear height is at least two times its horizontal length.*

14.2.2.2 ACI 318, Section 7.10. Modify Section 7.10 by revising Section 7.10.5.6 to read as follows:

7.10.5.6 Where anchor bolts are placed in the top of columns or pedestals, the bolts shall be enclosed by lateral reinforcement that also surrounds at least four vertical bars of the column or pedestal. The lateral reinforcement shall be distributed within 5 in. of the top of the column or pedestal, and shall consist of at least two No.4 or three No.3 bars. *In structures assigned to Seismic Design Categories C, D, E or F, the ties shall have a hook on each free end that complies with 7.1.4.*

14.2.2.3 Scope. Modify Section 21.1.1.3 to read as follows:

21.1.1.3 All members shall satisfy requirements of Chapters 1 to 19 and 22. Structures assigned to SDC B, C, D, E, or F also shall satisfy 21.1.1.4 through 21.1.1.8, as applicable, *except as modified by the requirements of Chapters 14 and 15 of this document.*

14.2.2.4 Intermediate Precast Structural Walls: Modify Section 21.4 by renumbering Section 21.4.3 to Section 21.4.4 and adding new Sections 21.4.3 and 21.4.5, to read as follows*:*

21.4 *Connections that are designed to yield shall be capable of maintaining 80 percent of their design strength at the deformation induced by design displacement, or shall use type 2 mechanical splices.*

21.4.4 *Elements of the connection that are not designed to yield shall develop at least 1.5 S_y.*

21.4.5 *Wall piers not designed as part of a moment frame shall have transverse reinforcement designed to resist the shear forces determined from Section 21.3.3. Spacing of transverse reinforcement shall not exceed 8 in. Transverse reinforcement shall be extended beyond the pier clear height for at least 12 in.*

EXCEPTIONS*: The preceding requirement need not apply in the following situations:*

1. *Wall piers that satisfy Section 21.13.*
2. *Wall piers along a wall line within a story where other shear wall segments provide lateral support to the wall piers and such segments have a total stiffness of at least six times the sum of the in-plane stiffnesses of all the wall piers.*

Wall segments with a horizontal length-to-thickness ratio less than 2.5 shall be designed as columns.

14.2.2.5 Wall Piers and Wall Segments. Modify Section 21.9 by adding a new Section 21.9.10 to read as follows:

21.9.10 Wall Piers and Wall Segments in Special Structural Walls.

21.9.10.1 *Wall piers not designed as a part of a special moment-resisting frame shall have transverse reinforcement designed to satisfy the requirements in Section 21.9.10.2.*

EXCEPTIONS:

1. *Wall piers that satisfy Section 21.13.*
2. *Wall piers along a wall line within a story where other shear wall segments provide lateral support to the wall piers, and such segments have a total stiffness of at least six times the sum of the in-plane stiffnesses of all the wall piers.*

21.9.10.2 *Transverse reinforcement with seismic hooks at both ends shall be designed to resist the shear forces determined from Section 21.6.5.1. Spacing of transverse reinforcement shall not exceed 6 in. (152 mm). Transverse reinforcement shall be extended beyond the pier clear height for at least 12 in. (304 mm).*

21.9.10.3 *Wall segments with a horizontal length-to-thickness ratio less than 2.5 shall be designed as columns.*

14.2.2.6 Special Precast Structural Walls. Modify Section 21.10.2 to read as follows:

21.10.2 Special structural walls constructed using precast concrete shall satisfy all the requirements of Section 21.9 in addition to 21.4 *as modified in Section 14.2.2.7*.

14.2.2.7 Foundations. Modify Section 21.12.1.1 to read as follows:

21.12.1.1 Foundations resisting earthquake-induced forces or transferring earthquake-induced forces between structure and ground shall comply with requirements of Section 21.12 and other applicable code provisions *unless modified by Sections 12.1.5, 12.13 or 14.2 of ASCE/SEI 7-05.*

14.2.2.8 Detailed Plain Concrete Shear Walls. Modify Section 22.6 by adding a new Section 22.6.7 to read:

22.6.7 Detailed Plain Concrete Shear Walls.

22.6.7.1 *Detailed plain concrete shear walls are walls conforming to the requirements for ordinary plain concrete shear walls and 22.6.7.2*

22.6.7.2 *Reinforcement shall be provided as follows:*

a. Vertical reinforcement of at least 0.20 in.^{2} (129 mm^2) in cross-sectional area shall be provided continuously from support to support at each corner, at each side of each opening, and at the ends of walls. The continuous vertical bar required beside an opening is permitted to substitute for the No. 5 bar required by Section 22.6.6.5.

b. Horizontal reinforcement at least 0.20 in.^{2} (129 mm^2) in cross-sectional area shall be provided:

1. *Continuously at structurally connected roof and floor levels and at the top of walls.*
2. *At the bottom of load-bearing walls or in the top of foundations where doweled to the wall*
3. *At a maximum spacing of 120 in. (3048 mm).*

Reinforcement at the top and bottom of openings, where used in determining the maximum spacing specified in Item 3 in the preceding text, shall be continuous in the wall.

14.2.2.9 Strength Requirements for Anchors: Modify Section D.4 by adding a new exception at the end of Section D.4.2.2 to read as follows:

EXCEPTION: *If N_b is determined using Equation D-7, the concrete breakout strength of Section D.4.2 shall be considered satisfied by the design procedure of Sections D.5.2 and D.6.2 without the need for testing regardless of anchor bolt diameter and tensile embedment.*

SECTIONS 14.2.3, ADDITIONAL DETAILING REQUIREMENTS FOR CONCRETE PILES, AND 14.2.3.1, CONCRETE PILE REQUIREMENTS FOR SDC C

Replace with the following:

14.2.3 Additional Detailing Requirements for Concrete Piles. In addition to the foundation requirements set forth in

ACI 318 Sections 12.1.5, 12.13 and 21.12, design, detailing and construction of concrete piles shall conform to the provisions of this section.

14.2.3.1 Concrete Pile Requirements for Seismic Design Category C. Concrete piles in structures assigned to Seismic Design Category C shall comply with the requirements of this section.

14.2.3.1.1 Anchorage of Piles. All concrete piles and concrete filled pipe piles shall be connected to the pile cap by embedding the pile reinforcement in the pile cap for a distance equal to the development length as specified in ACI 318 as modified by Section 14.2.2 of this standard or by the use of field-placed dowels anchored in the concrete pile. For deformed bars, the development length is the full development length for compression or tension, in the case of uplift, without reduction in length for excess area.

Hoops, spirals, and ties shall be terminated with seismic hooks as defined in ACI 318 Section 2.2.

Where a minimum length for reinforcement or the extent of closely spaced confinement reinforcement is specified at the top of the pile, provisions shall be made so that those specified lengths or extents are maintained after pile cut-off.

SECTION 14.2.3.2, CONCRETE PILE REQUIREMENTS FOR SEISMIC DESIGN CATEGORIES D THROUGH F

Replace Sections 14.2.3.2.1 through 14.2.3.2.5 with the following:

14.2.3.2.1 Site Class E or F Soil. Where concrete piles are used in Site Class E or F, they shall have transverse reinforcement in accordance with ACI 318 Sections 21.6.4.2 through 21.6.4.4 within seven pile diameters of the pile cap and the interfaces between strata that are hard or stiff and strata that are liquefiable or are composed of soft to medium stiff clay.

14.2.3.2.2 Nonapplicable ACI 318 Sections for Grade Beam and Piles. ACI 318 Section 21.12.3.3 need not apply where grade beams have the required strength to resist the forces from the load combinations with overstrength factor of Section 12.4.3.2 or 12.14.3.2.2. ACI 318 Section 21.12.4.4(a) need not apply to concrete piles, and Section 21.12.4.4(b) need not apply to precast, prestressed concrete piles.

14.2.3.2.3 Reinforcement for Uncased Concrete Piles (SDC D through F). Reinforcement shall be provided where required by analysis. For uncased cast-in-place drilled or augered concrete piles, a minimum of four longitudinal bars with a minimum longitudinal reinforcement ratio of 0.005 and transverse reinforcement in accordance with ACI 318 Sections 21.6.4.2 through 21.6.4.4 shall be provided throughout the minimum reinforced length of the pile as defined below starting at the top of the pile. The longitudinal reinforcement shall extend beyond the minimum reinforced length of the pile by the tension development length.

The minimum reinforced length of the pile shall be taken as the greater of:

1. One-half of the pile length;
2. A distance of 10 ft (3 m);
3. Three times the pile diameter;
4. The flexural length of the pile which shall be taken as the length of from the bottom of the pile cap to a point where the concrete section cracking moment multiplied by a resistance factor 0.4 exceeds the required factored moment at that point.

In addition, for piles located in Site Class E or F, longitudinal reinforcement and transverse confinement reinforcement, as described above, shall extend the full length of the pile.

Where transverse reinforcement is required, transverse reinforcing ties shall be a minimum of No. 3 bars for up to 20-in.-diameter (300 mm) piles and No.4 bars for piles of larger diameter.

In Site Classes A through D, longitudinal reinforcement and transverse confinement reinforcement, as defined above, shall extend a minimum of seven times the pile diameter above and below the interfaces of soft to medium stiff clay or liquefiable strata except that transverse reinforcing ties not located within the minimum reinforced length shall be permitted to use a transverse spiral reinforcement ratio of not less than one-half of that required in ACI 318 Section 21.6.4.4(a). Spacing of transverse reinforcement not located within the minimum reinforced length is permitted to be increased, but shall not exceed the least of the following:

1. 12 longitudinal bar diameters;

2. One-half the pile diameter;
3. 12 in. (305 mm).

14.2.3.2.4 Reinforcement for Metal-Cased Concrete Piles (SDC D through F). Reinforcement requirements are the same as for uncased concrete piles.

EXCEPTION: Spiral-welded metal-casing of a thickness not less than No. 14 gauge can be considered as providing concrete confinement equivalent to the closed ties or equivalent spirals required in an uncased concrete pile, provided that the metal casing is adequately protected against possible deleterious action due to soil constituents, changing water levels, or other factors indicated by boring records of site conditions.

14.2.3.2.5 Reinforcement for Precast Concrete Piles (SDC D through F). Transverse confinement reinforcement consisting of closed ties or equivalent spirals shall be provided in accordance with ACI 318 Sections 21.6.4.2 through 21.6.4.4 for the full length of the pile.

EXCEPTION: In other than Site Classes E or F, the specified transverse confinement reinforcement shall be provided within three pile diameters below the bottom of the pile cap, but it shall be permitted to use a transverse reinforcing ratio of not less than one-half of that required in ACI 318 Section 21.6.4.4(a) throughout the remainder of the pile length.

[Remainder of Section 14.2.3.2 is unchanged.]

NEW SECTION 14.2.4, ACCEPTANCE CRITERIA FOR SPECIAL PRECAST STRUCTURAL WALLS BASED ON VALIDATION TESTING

Add the following new section:

14.2.4 Acceptance Criteria for Special Precast Structural Walls Based on Validation Testing

14.2.4.1 Notation

Symbols additional to those in ACI 318 Chapter 2 are defined.

E_{max} = maximum lateral resistance of test module determined from test results (forces or moments)

E_n = nominal lateral resistance of test module calculated using specified geometric properties of test members, specified yield strength of reinforcement, specified compressive strength of concrete, a strain compatibility analysis or deformation compatibility analysis for flexural strength and a strength reduction factor ϕ of 1.0

E_{nt} = calculated lateral resistance of test module using the actual geometric properties of test members, the actual strengths of reinforcement, concrete, and coupling devices, obtained by testing per Sections 14.2.4.7.7, 14.2.4.7.8, and 14.2.4.7.9, and a strength reduction factor ϕ of 1.0

θ = drift ratio

β = relative energy dissipation ratio

14.2.4.2 Definitions

Definitions additional to those in ACI 318 Chapter 2 are defined.

14.2.4.2.1 Coupling Elements. Devices or beams connecting adjacent vertical boundaries of structural walls and used to provide stiffness and energy dissipation for the connected assembly greater than the sum of those provided by the connected walls acting as separate units.

14.2.4.2.2 Drift Ratio. Total lateral deformation of the test module divided by the height of the test module.

14.2.4.2.3 Global Toughness. The ability of the entire lateral force resisting system of the prototype structure to maintain structural integrity and continue to carry the required gravity load at the maximum lateral displacements anticipated for the ground motions of the maximum considered earthquake.

14.2.4.2.4 Prototype Structure. The concrete wall structure for which acceptance is sought.

14.2.4.2.5 Relative Energy Dissipation Ratio. Ratio of actual to ideal energy dissipated by test module during reversed cyclic response between given drift ratio limits, expressed as the ratio of the area of the hysteresis loop for that cycle to the area of the circumscribing parallelograms defined by the initial stiffnesses during the first cycle and the peak resistances during the cycle for which the relative energy dissipation ratio is calculated. See Section 14.2.4.9.1.3.

14.2.4.2.5 Test Module. Laboratory specimen representing the critical walls of the prototype structure. See Section 14.2.4.5.

14.2.4.3 Scope and General Requirements

14.2.4.3.1 These provisions define minimum acceptance criteria for new precast structural walls, including coupled precast structural walls, designed for regions of high seismic risk or for structures assigned to high seismic performance or design categories, where acceptance is based on experimental evidence and mathematical analysis.

14.2.4.3.2 These provisions are applicable to precast structural walls, coupled or uncoupled, with height to length, h_w/l_w, ratios equal to or greater than 0.5. These provisions are applicable for either prequalifying precast structural walls for a specific structure or prequalifying a new precast wall type for construction in general.

14.2.4.3.3 Precast structural walls shall be deemed to have a response that is at least equivalent to the response of monolithic structural walls designed in accordance with ACI 318 Sections 21.1 and 21.9, and the corresponding structural walls of the prototype structure shall be deemed acceptable, when all of the conditions in Sections 14.2.4.3.3.1 through 14.2.4.3.3.5 are satisfied.

14.2.4.3.3.1 The prototype structure satisfies all applicable requirements of these provisions and of ACI 318 except Section 21.9.

14.2.4.3.3.2 Tests on wall modules satisfy the conditions in Sections 14.2.4.4 and 14.2.4.9.

14.2.4.3.3.3 The prototype structure is designed using the design procedure substantiated by the testing program.

14.2.4.3.3.4 The prototype structure is designed and analyzed using effective initial properties consistent with those determined in accordance with Section 14.2.4.7.11, and the prototype structure meets the drift limits of these provisions.

14.2.4.3.3.5 The structure as a whole, based on the results of the tests of Section 14.2.4.3.3.2 and analysis, is demonstrated to have adequate global toughness (the ability to retain its structural integrity and support its specified gravity loads) through peak displacements equal to or exceeding the story-drift ratios specified in Section 14.2.4.7.4, 14.2.4.7.5 or 14.2.4.7.6, as appropriate.

14.2.4.4 Design Procedure

14.2.4.4.1 Prior to testing, a design procedure shall be developed for the prototype structure and its walls. That procedure shall account for effects of material non-linearity, including cracking, deformations of members and connections, and reversed cyclic loading. The design procedure shall include the procedures specified in Sections 14.2.4.4.1.1 through 14.2.4.4.1.4 and shall be applicable to all precast structural walls, coupled and uncoupled, of the prototype structure.

14.2.4.4.1.1 Procedures shall be specified for calculating the effective initial stiffness of the precast structural walls, and of coupled structural walls, that are applicable to all the walls of the prototype structure.

14.2.4.4.1.2 Procedures shall be specified for calculating the lateral strength of the precast structural walls, and of coupled structural walls, applicable to all precast walls of the prototype structure.

14.2.4.4.1.3 Procedures shall be specified for designing and detailing the precast structural walls so that they have adequate ductility capacity. These procedures shall cover wall shear strength, sliding shear strength, boundary tie spacing to prevent bar buckling, concrete confinement, reinforcement strain, and any other actions or elements of the wall system that can affect ductility capacity.

14.2.4.4.1.4 Procedures shall be specified for determining that an undesirable mechanism of nonlinear response, such as a story mechanism due to local buckling of the reinforcement or splice failure, or overall instability of the wall, does not occur.

14.2.4.4.2 The design procedure shall be used to design the test modules and shall be documented in the test report.

14.2.4.4.3 The design procedure used to proportion the test specimens shall define the mechanism by which the system resists gravity and earthquake effects and shall establish acceptance values for sustaining that mechanism. Portions of the mechanism that deviate from code requirements shall be contained in the test specimens and shall be tested to determine acceptance values.

14.2.4.5 Test Modules

14.2.4.5.1 At least two modules shall be tested. At least one module shall be tested for each limiting engineering design criteria (shear, axial load and flexure) for each characteristic configuration of precast structural walls, including intersecting structural walls or coupled structural walls. If all the precast walls of the structure have the same

configuration and the same limiting engineering design criterion, then two modules shall be tested. Where intersecting precast wall systems are to be used, the response for the two orthogonal directions shall be tested.

14.2.4.5.2 Where the design requires the use of coupling elements, those elements shall be included as part of the test module.

14.2.4.5.3 Modules shall have a scale large enough to represent the complexities and behavior of the real materials and of the load transfer mechanisms in the prototype walls and their coupling elements, if any. Modules shall have a scale not less than one half and shall be full-scale if the validation testing has not been preceded by an extensive analytical and experimental development program in which critical details of connections are tested at full scale.

14.2.4.5.4 The geometry, reinforcing details, and materials properties of the walls, connections, and coupling elements shall be representative of those to be used in the prototype structure.

14.2.4.5.5 Walls shall be at least two panels high unless the prototype structure is one for which a single panel is to be used for the full height of the wall.

14.2.4.5.6 Where precast walls are to be used for bearing wall structures, as defined in ASCE/SEI 7-05, the test modules shall be subject during lateral loading to an axial load stress representative of that anticipated at the base of the wall in the prototype structure.

14.2.4.5.7 The geometry, reinforcing, and details used to connect the precast walls to the foundation shall replicate those to be used in the prototype structure.

14.2.4.5.8 Foundations used to support the test modules shall have geometric characteristics, and shall be reinforced and supported, so that their deformations and cracking do not affect the performance of the modules in a way that would be different than in the prototype structure.

14.2.4.6 Testing Agency. Testing shall be carried out by an independent testing agency approved by the Authority Having Jurisdiction. The testing agency shall perform its work under the supervision of a registered design professional experienced in seismic structural design.

14.2.4.7 Test Method

14.2.4.7.1 Test modules shall be subjected to a sequence of displacement-controlled cycles representative of the drifts expected under earthquake motions for the prototype structure. If the module consists of coupled walls, approximately equal drifts (within 5 percent of each other) shall be applied to the top of each wall and at each floor level. Cycles shall be to predetermined drift ratios as defined in Sections 14.2.4.7.2 through 14.2.4.7.6.

14.2.4.7.2 Three fully reversed cycles shall be applied at each drift ratio.

14.2.4.7.3 The initial drift ratio shall be within the essentially linear elastic response range for the module. See 14.2.4.7.11. Subsequent drift ratios shall be to values not less than 5/4 times, and not more than 3/2 times, the previous drift ratio.

14.2.4.7.4 For uncoupled walls, testing shall continue with gradually increasing drift ratios until the drift ratio in percent equals or exceeds the larger of : (a) 1.5 times the drift ratio corresponding to the design displacement or (b) the following value:

$$0.80 \le 0.67\left[h_w/l_w\right] + 0.5 \le 2.5 \qquad (14.2.4\text{-}1)$$

where h_w = height of entire wall for prototype structure (in inches) and l_w = length of entire wall in direction of shear force (in inches).

14.2.4.7.5 For coupled walls, h_w/l_w in Equation 14.2.4-1 shall be taken as the smallest value of h_w/l_w for any individual wall of the prototype structure.

14.2.4.7.6 Validation by testing to limiting drift ratios less than those given by Equation 14.2.4-1 shall be acceptable provided testing is conducted in accordance with this document to drift ratios equal or exceeding of those determined for the response to a suite of nonlinear time history analyses conducted in accordance with the 2009 *NEHRP Recommended Seismic Provisions* for risk-targeted maximum considered earthquake ground motions.

14.2.4.7.7 Actual yield strength of steel reinforcement shall be obtained by testing coupons taken from the same reinforcement batch as used in the test module. Two tests, conforming to the ASTM specifications cited in ACI 318 Section 3.8, shall be made for each reinforcement type and size.

14.2.4.7.8 Actual compressive strength of concrete shall be determined by testing of concrete cylinders cured under the same conditions as the test module and tested at the time of testing the module. Testing shall conform to the applicable requirements of ACI 318 Sections 5.6.1 through 5.6.4.

14.2.4.7.9 Where strength and deformation capacity of coupling devices does not depend on reinforcement tested as required in Section 14.2.4.7.7, the effective yield strength and deformation capacity of coupling devices shall be obtained by testing independent of the module testing.

14.2.4.7.10 Data shall be recorded from all tests such that a quantitative interpretation can be made of the performance of the modules. A continuous record shall be made of test module drift ratio versus applied lateral force, and photographs shall be taken that show the condition of the test module at the peak displacement and after each key testing cycle.

14.2.4.7.11 The effective initial stiffness of the test module shall be calculated based on test cycles to a force between $0.6E_{nt}$ and $0.9E_{nt}$, and using the deformation at the strength of $0.75E_{nt}$ to establish the stiffness.

14.2.4.8 Test Report

14.2.4.8.1 The test report shall contain sufficient evidence for an independent evaluation of all test procedures, design assumptions, and the performance of the test modules. As a minimum, all of the information required by Sections 14.2.4.8.1.1 through 14.2.4.8.1.11 shall be provided.

14.2.4.8.1.1 A description shall be provided of the design procedure and theory used to predict test module strength, specifically the test module nominal lateral resistance, E_n, and the test module actual lateral resistance E_{nt}.

14.2.4.8.1.2 Details shall be provided of test module design and construction, including fully dimensioned engineering drawings that show all components of the test specimen.

14.2.4.8.1.3 Details shall be provided of specified material properties used for design, and actual material properties obtained by testing in accordance with Section 14.2.4.7.7.

14.2.4.8.1.4 A description shall be provided of test setup, including fully dimensioned diagrams and photographs.

14.2.4.8.1.5 A description shall be provided of instrumentation, its locations, and its purpose.

14.2.4.8.1.6 A description and graphical presentation shall be provided of applied drift ratio sequence.

14.2.4.8.1.7 A description shall be provided of observed performance, including photographic documentation, of the condition of each test module at key drift ratios including, (as applicable), the ratios corresponding to first flexural cracking or joint opening, first shear cracking, and first crushing of the concrete for both positive and negative loading directions, and any other significant damage events that occur. Photos shall be taken at peak drifts and after the release of load.

14.2.4.8.1.8 A graphical presentation shall be provided of lateral force versus drift ratio response.

14.2.4.8.1.9 A graphical presentation shall be provided of relative energy dissipation ratio versus drift ratio.

14.2.4.8.1.10 A calculation shall be provided of effective initial stiffness for each test module as observed in the test and as determined in accordance with Section 14.2.4.7.11 and a comparison made as to how accurately the design procedure has been able to predict the measured stiffness. The design procedure shall be used to predict the overall structural response and a comparison made as to how accurately that procedure has been able to predict the measured response.

14.2.4.8.1.11 The test date, report date, name of testing agency, report author(s), supervising registered design professional, and test sponsor shall be provided.

14.2.4.9 Test Module Acceptance Criteria

14.2.4.9.1 The test module shall be deemed to have performed satisfactorily when all of the criteria Sections 14.2.4.9.1.1 through 14.2.4.9.1.3 are met for both directions of in-plane response. If any test module fails to pass the validation testing required by these provisions for any test direction, then the wall system has failed the validation testing.

14.2.4.9.1.1 Peak lateral strength obtained shall be at least $0.9E_{nt}$ and not greater than $1.2\ E_{nt}$.

14.2.4.9.1.2 In cycling up to the drift level given by Sections 14.2.4.7.4 through 14.2.4.7.6, fracture of reinforcement or coupling elements, or other significant strength degradation, shall not occur. For a given direction, peak lateral strength during any cycle of testing to increasing displacement shall not be less than 0.8 times E_{max} for that direction.

14.2.4.9.1.3 For cycling at the given drift level for which acceptance is sought in accordance with Section 14.2.4.7.4, 14.2.4.7.5 or 14.2.4.7.6, as applicable, the parameters describing the third complete cycle shall have satisfied the following:

1. The relative energy dissipation ratio shall not be less than 1/8 and
2. The secant stiffness between drift ratios of -1/10 and +1/10 of the maximum applied drift shall not be less than 0.10 times the stiffness for the initial drift ratio specified in Section 14.2.4.7.3.

SECTION 14.4.5, MODIFICATIONS TO CHAPTER 1 OF ACI530/ASCE 5/TMS 402

Add the following new sections:

14.4.5.3 Plain (unreinforced) AAC masonry shear walls shall satisfy the requirements of Section 1.14.2.2.6 of ACI 530/ASCE 5/TMS 402.

14.4.5.4 Ordinary reinforced AAC masonry shear walls shall satisfy the requirements of Section 1.14.2.2.8 of ACI 530/ASCE 5/TMS 402.

Commentary to Chapter 14 Modifications

COMMENTARY TO SECTION 14.1.1

ASCE/SEI 7-05 included two different systems for both eccentrically braced frames (EBF) and buckling restrained braced frames (BRBF). The primary distinction between these two systems was whether or not there were moment resisting beam-column connections within the braced bays. However, testing at the University of California at Berkeley (Uriz and Mahin, 2004) has indicated designs that do not properly account for the stiffness and distribution of forces in braced frame connections may be subject to undesirable performance. This modification to ASCE/SEI 7-05 consolidates the EBF and BRBF building frame systems into a single designation with proper consideration of the beam-column connection demands.

This modification to ASCE/SEI 7-05 and the related changes to AISC 341-05 Sections 15.7 and 16.7 also allow the engineer either to:

1. Provide a fully restrained moment connection meeting the requirements for ordinary moment connections in AISC 341-05 and thereby directly providing a load path to resist the connection force and deformation demands or
2. Provide a connection with the ability to accommodate the potential rotation demands. An example of this would be a configuration tested at Lehigh University (Figure 1 of Fahnestock, et. al. 2006) that effectively formed a pinned condition in the beam just beyond the beam-column-brace connection.

COMMENTARY TO SECTION 14.1.4

C14.1.4 Cold-Formed Steel. This section adopts three standards by direct reference: AISI NAS, *North American Specification for the Design of Cold-Formed Steel Structural Members*, AISI S110, *Standard for Seismic Design of Cold-Formed Steel Structural Systems – Special Bolted Moment Frames*, and ASCE/SEI 8, *Specification for the Design of Cold Formed Stainless Steel Structural Members.*

Each document has specific limits of applicability. AISI NAS applies to the design of structural members that are cold-formed to shape from carbon or low-alloy steel sheet, strip, plate or bar not more than one-inch in thickness (AISI NAS, Section A1.1). Building on the requirements of AISI NAS, AISI S110 has additional special seismic design provisions for a newly designated seismic force resisting system entitled "cold-formed steel – special bolted moment frame (CFS-SBMF)." Finally, ASCE 8 governs the design of structural members that are cold-formed to shape from annealed and cold-rolled sheet, strip, plate, or flat bar stainless steels (ASCE 8, Section 1.1.1). All three documents focus on load-carrying members in buildings; however, allowances are made for applications in nonbuilding structures, if dynamic effects are appropriately considered.

Within AISI NAS and ASCE 8, there are requirements on the general provisions for the applicable types of steel; design of elements, members, structural assemblies, connections and joints; and mandatory testing. In addition, AISI NAS contains a chapter on the design of cold-formed steel structural members and connections undergoing cyclic loading. Both standards contain extensive commentaries for the benefit of the user.

C14.1.4.1.1 CFS-SBMF need to use the same-size beams and same-size columns throughout. In addition, the system needs to engage all primary columns, which support the roof or floor above, and those columns need to be supported on a level floor or foundation.

C14.1.4.1.2 These modifications were made for consistency with the test database.

C14.1.4.1.3 To be consistent with the test database (Uang and Sato, 2007), the limitations on both beam depth, steel grade, and surface treatment are added in Section D1.2.1 of AISI S110.

C14.1.4.1.4 To be consistent with the test database (Uang and Sato, 2007), the limitations on column depth, steel grade, and surface treatment are added in Section D1.2.2 of AISI S110. The width-thickness ratio was reduced based upon further review of the test specimens.

C14.1.4.1.5 AISI S110 is intended primarily for industrial platforms; however, the standard is not limited to these non-building structures and does not prohibit architectural attachments (such as partition walls). Therefore, the 0.05*h* drift limit in Section D1.3 of AISI S110 has been reduced to 0.03*h* to more closely align with the 0.025*h* drift limit of ASCE/SEI 7. The sentence, "In no case shall the design story drift exceed 0.05*h*." was added to ensure an absolute upper bound on the drift limit.

C14.1.4.2 Light-Framed Cold-Formed Construction. This subsection of cold-formed steel relates to light-framed construction, which is defined as a method of construction where the structural assemblies are formed primarily by a system of repetitive wood or cold-formed steel framing members or subassemblies of these members (ASCE/SEI 7, Section 11.2). Not only does this subsection repeat the direct adoptions of AISI NAS and ASCE 8, but it also allows the user to choose from an additional suite of standards that address different aspects of construction, including the following:

1. AISI GP, Standard for Cold-Formed Steel Framing – General Provisions, applies to the design, construction, and installation of structural and non-structural cold-formed steel framing members where the specified minimum base metal thickness is between 18 mils and 118 mils (AISI GP, Section A1).
2. AISI WSD, Standard for Cold-Formed Steel Framing – Wall Stud Design, applies to the design and installation of cold-formed steel studs for both structural and nonstructural walls in buildings (AISI WSD, Section A1).

COMMENTARY TO SECTION 14.2

C14.2 CONCRETE

The section adopts by reference ACI 318 for structural concrete design and construction. In addition, modifications to ACI 318 are made that are needed to coordinate the provisions of that material design standard with the provisions of ASCE/SEI 7. Work is ongoing to better coordinate the provisions of the two documents (ACI 318 and ASCE/SEI 7) such that the provisions in Section 14.2 will be significantly reduced in future editions of ASCE/SEI 7.

C14.2.2.2 ACI 318 Section 7.10. ACI 318 Section 7.10.5.6 prescribes reinforcement details for ties in compression members. Those details are appropriate for SDC A and B structures. This modification prescribes additional details for ties around anchor bolts in structures assigned to SDC C through F.

A wall pier is recognized as a separate category of structural element in this document but not ACI 318.

C14.2.2.3 Scope. This provision describes how the ACI 318 provisions should be interpreted for consistency with the ASCE/SEI 7 provisions.

C14.2.2.4 Intermediate Precast Structural Walls. ACI 318 Section 21.4 imposes requirements on precast walls for moderate seismic risk applications. Ductile behavior is to be ensured by yielding of the steel elements or reinforcement between panels or this provision requires the designer to determine the deformation in the connection corresponding to the earthquake design displacement, and then to check from experimental data that the connection type used can accommodate that deformation without significant strength degradation.

The wall pier requirements of Section 21.4.5 are patterned after the same requirements of Section 14.2.2.4 for wall piers that are part of structures in high seismic design categories. The 2006 Edition of the *International Building Code* restricts yielding to steel reinforcement only because of concern that steel elements in the body of a connection could fracture due to inelastic strain demands.

Several steel element connections have been tested under simulated seismic loading and the adequacy of their load-deformation characteristics and strain capacity have been demonstrated (Schultz and Magana, 1996). One such connection was used in the five-story building test that was part of the PRESSS Phase 3 research. The connection was used to provide

damping and energy dissipation, and demonstrated a very large strain capacity (Nakaki et al., 2001). Since then, several other steel element connections have been developed that can achieve similar results (Banks and Stanton), (Nakaki et al.). In view of these results, it is appropriate to allow yielding in steel elements that have been shown experimentally to have adequate strain capacity to maintain at least 80 percent of their yield force through the full design displacement of the structure.

C14.2.2.5 Wall Piers and Wall Segments. Wall piers are typically segments between openings in walls that are thin in the direction normal to the horizontal length of the wall. In current practice these elements are often not regarded as columns or as part of the structural walls. If not properly reinforced these elements are vulnerable to shear failure and that failure prevents the wall from developing the assumed flexural hinging. Section 21.9.10 is written to reduce the likelihood of a shear failure. Wall segments with a horizontal length-to-thickness ratio less than 2.5 are required to be designed as columns in compliance with Section 21.9 if they are utilized as part of the lateral-force-resisting system, even though the shortest cross-sectional dimension may be less than 12 in. in violation of Section 21.6.1.1. Such wall segments may be designed to comply with Section 21.13 if they are not utilized as part of the lateral-force-resisting system. Wall segments with a horizontal length-to-thickness ratio larger than or equal to 2.5, which do not meet the definition of wall piers (Section 14.2.2.2), must be designed as special structural walls or as portions of special structural walls in full compliance with Section 21.9 or 21.10.

C14.2.2.7 Foundations. The intention is that there should be no conflicts between the provisions of ACI 318 Section 21.12 and ASCE/SEI 7-05 Section 12.1.5, 12.13, or 14.2. However, the additional detailing requirements for concrete piles of Section 14.2.3 can result in conflicts with ACI 318 provisions if the pile in not fully embedded in the soil.

C14.2.2.8 Detailed Plain Concrete Walls. Design requirements for plain masonry walls have existed for many years and the corresponding type of concrete construction is the plain concrete wall. To allow the use of such walls as the lateral-force-resisting system in SDC A and B, this provision requires such walls to contain at least the minimal reinforcement specified in Section 22.6.7.2.

C14.2.2.9 Strength Requirements for Anchors. ACI 318 requires laboratory testing to establish the strength of anchor bolts greater than 2 in. in diameter or exceeding 25 in. in tensile embedment depth. This modification makes the ACI 318 equation giving the basic concrete breakout strength of a single anchor in tension in cracked concrete applicable irrespective of the anchor bolt diameter and tensile embedment depth.

Korean Power Engineering (KPE) has made tension tests on anchors with diameters up to 4.25 in. and embedment depths up to 45 in. and found that the diameter and embedment depth limits of ACI 318 Section D.4.2.2 for the design procedure for anchors in tension (Section D.5.2) can be eliminated. KPE also has conducted shear tests on anchors with diameters up to 3.0 in. and embedment depths as large as 30 in. and found no effect of the embedment depth on shear strength. However, the diameter tests showed that the basic shear breakout strength Equation D-24 needed some modification for the complete elimination of the 2 in. limit to be fully appropriate. Analytical work performed at the University of Stuttgart supports the need for some modification to Equation D-24. Changes consistent with the Korean and Stuttgart findings have already been made to the *FIB Design Guide* for anchors.

COMMENTARY TO SECTION 14.2.3

C14.2.3 Additional Detailing Requirements for Concrete Piles. Chapter 20 of the *PCI Bridge Design Manual* provides detailed information on the structural design of piles and on pile to cap connections for precast prestressed concrete piles. ACI 318 does not contain provisions governing the design and installation of portions of concrete piles, drilled piers, and caissons embedded in ground except for SDC D, E and F structures.

C14.2.3.1.2 Reinforcement for Uncased Concrete Piles (SDC C). The transverse reinforcing requirements in the potential plastic hinge zone of uncased concrete piles in Seismic Design Category C is a selective composite of two ACI 318 requirements. In the potential plastic hinge region of an intermediate moment-resisting concrete frame column, the transverse reinforcement spacing is restricted to the least of: (a) 8 times the diameter of the smallest longitudinal bar, (b) 24 times the diameter of the tie bar, (c) one-half the smallest cross-sectional dimension of the column, and (d) 12 in. Outside of the potential plastic hinge region of a special moment-resisting frame column, the transverse reinforcement spacing is restricted to the smaller of 6 times the diameter of the longitudinal column bars and 6 in.

C14.2.3.1.5 Reinforcement for Precast Nonprestressed Concrete Piles (SDC C). Transverse reinforcement requirements in and outside of the plastic hinge zone of precast nonprestressed piles are clarified. The transverse reinforcement requirement in the potential plastic hinge zone is a composite of two ACI 318 requirements (see Section C14.2.3.1.2). Outside of the potential plastic hinge region, the transverse reinforcement spacing is restricted to sixteen (16) times the longitudinal bar diameter. This should permit the longitudinal bars to reach compression yield before buckling. The maximum 8-in. tie spacing comes from current building code provisions for precast concrete piles.

C14.2.3.1.6 Reinforcement for Precast Prestressed Piles (SDC C). The transverse and longitudinal reinforcing requirements given in ACI 318, Chapter 21, were never intended for slender precast prestressed concrete elements and will result in unbuildable piles. These requirements are based on the *Recommended Practice for Design, Manufacture and Installation of Prestressed Concrete Piling* (PCI Committee on Prestressed Concrete Piling, 1993).

Equation 14.2.4-1, originally from ACI 318, has always been intended to be a lower-bound spiral reinforcement ratio for larger diameter columns. It is independent of the member section properties and can therefore be applied to large or small diameter piles. For cast-in-place concrete piles and precast prestressed concrete piles, the resulting spiral reinforcing ratios from this formula are considered to be sufficient to provide moderate ductility capacities (Fanous et al., 2007).

Full confinement per Equation 14.2.4-1 is required for the upper 20 feet of the pile length where curvatures are large. The amount is relaxed by 50 percent outside of that length in view of lower curvatures and in consideration of confinement provided by the soil.

C14.2.3.2.3 Reinforcement for Uncased Concrete Piles (SDC D through F). The reinforcement requirements for uncased concrete piles are taken from the 2006 IBC requirements, and should be adequate to provide ductility in the potential plastic hinge zones (Fanous et al., 2007).

C14.2.3.2.5 Reinforcement for Precast Concrete Piles (SDC D through F). The transverse reinforcement requirements for precast nonprestressed concrete piles are taken from the 2006 IBC requirements and are should be adequate to provide ductility in the potential plastic hinge zones (Fanous et al., 2007).

C14.2.3.2.6 Reinforcement for Precast-Prestressed Piles (SDC D through F). The reduced amounts of transverse reinforcement specified in this provision compared to those required for column members in ACI 318 are justified by the results of the study by Fanous et al., 2007. The last paragraph of the provision provides minimum transverse reinforcement requirements outside of the zone of prescribed ductile detailing.

COMMENTARY TO SECTION 14.2.4

C14.2.4 Acceptance Criteria for Special Precast Structural Walls Based on Validation Testing

C14.2.4.1 Notation. Symbols additional to those in ACI 318 Chapter 2 are defined:

A_h = area of hysteresis loop.
E_1,E_2 = peak lateral resistance for positive and negative loading, respectively, for third cycle of loading sequence.
f_1 = live load factor defined in Section 14.2.4.2.3.
h_w = height of column of test module, in. or mm.
K, K' = initial stiffness for positive and negative loading, respectively, for first cycle.
θ_1,θ_2 = drift ratios at peak lateral resistance for positive and negative loading, respectively, for third cycle of loading sequence.
$\theta 1', \theta 2'$ = drift ratios for zero lateral load for unloading at stiffness K, K' from peak positive and negative lateral resistance, respectively, for third cycle of loading sequence.
Δ = lateral displacement, in. or mm. See Figures. C14.2.4.2.2-1, C14.2.4.2.2-2, and C14.2.4.2.2-3.
Δ_a = allowable story drift, in. or mm. See Table 12.12-1 of ASCE/SEI 7-05.

C14.2.4.2 Definitions

C14.2.4.2.1 Coupling elements. Coupling elements are connections provided at specific intervals along the vertical boundaries of adjacent structural walls. Coupled structural walls are stiffer and stronger than the same walls acting independently. For cast-in-place construction effective coupling elements are typically coupling beams having small span-to-depth ratios. The inelastic behavior of such beams is normally controlled by their shear strength. For precast construction, effective coupling elements can be precast beams connected to the adjacent structural walls either by post-tensioning, ductile mechanical devices, or grouted-in-place reinforcing bars. The resultant coupled construction can be either emulative of cast-in-place construction or non-emulative (jointed). However, for precast construction coupling beams can also be omitted and mechanical devices used to connect directly the vertical boundaries of adjacent structural walls.

C14.2.4.2.2 Drift ratio. The definition of the drift ratio, θ, is illustrated in Figure C14.2.4.2.2-1 for a three panel wall module. The position of the module at the start of testing, with only its self-weight acting, is indicated by broken lines. The module is set on a horizontal foundation support that is centered at A and is acted on by a lateral force H applied at the top of the wall. The self-weight of the wall is distributed uniformly to the foundation support. However, under lateral loading, that self-weight and any axial gravity load acting at the top of the wall cause overturning moments on the wall that are additional

to the overturning moment Hh_w and can affect deformations. The chord AB of the centroidal axis of the wall is the vertical reference line for drift measurements.

For acceptance testing a lateral force H is applied to the wall through the pin at B. Depending on the geometric and reinforcement characteristics of the module that force can result in the module taking up any one, or a combination, of the deformed shapes indicated by solid lines in Figures C14.2.4.2.2-1, C14.2.4.2.2-2 and C14.2.4.2.2-3.

Figure C14.2.4.2.2-2 illustrates several possible components of the displacement Δ for a wall that is effectively solid while Figure C14.2.4.2.2-3 illustrates two possibly undesirable components of the displacement Δ. Regardless of the mode of deformation of the wall, the lateral force causes the wall at B to displace horizontally by an amount Δ. The drift ratio is the angular rotation of the wall chord with respect to the vertical and for the setup shown equals Δ / h_w where h_w is the wall height and is equal to the distance between the foundation support at A and the load point at B. Where prestressing steel is used in wall members, the stress f_{ps} in the reinforcement at the nominal and the probable lateral resistance shall be calculated in accordance with ACI 318 Section 18.7.

C14.2.4.2.3 Global toughness. These provisions describe acceptance criteria for special precast structural walls based on validation testing. The requirements of Section 21.1.1.8 of ACI 318 concerning toughness cover both to the energy dissipation of the wall system which, for monolithic construction, is affected primarily by local plastic hinging behavior and the toughness of the prototype structure as a whole. The latter is termed "global toughness" in these provisions and is a condition that does not apply to the walls alone. That global toughness requirement can be satisfied only though analysis of the performance of the prototype structure as a whole when the walls perform to the criteria specified in these provisions.

The required gravity load for global toughness evaluations is the value given by these provisions. For conformity with Section 9.2.1 of ACI 318-08, UBC 1997, IBC 2006 and NFPA 5000, the required gravity load is $1.2D + f_1L$ where the seismic force is additive to gravity forces and 0.9D where the seismic force counteracts gravity forces. D is the effect of dead loads, L is the effect of live loads, and f_1 is a factor equal to 0.5 except for garages, areas occupied as places of public assembly, and all areas where the live load is greater than 100 psf (4.79 kN/m^2) where f_1 equals 1.0.

C14.2.4.2.5 Relative energy dissipation ratio. This concept is illustrated in Figure C14.2.4.2.2-1 for the third loading cycle to the limiting drift ratio required by Section 14.2.4.7.4, 14.2.4.7.5 or 14.2.4.7.6, as appropriate.

Figure 14.2.4.2.2-2 illustrates several possible components of the displacement Δ for a wall that is effectively solid while Figure C14.2.4.2.2-3 illustrates two possibly undesirable components of the displacement Δ. Regardless of the mode of deformation of the wall, the lateral force causes the wall at B to displace horizontally by an amount Δ. The drift ratio is the angular rotation of the wall chord with respect to the vertical and for the setup shown equals Δ / h_w where h_w is the wall height and is equal to the distance between the foundation support at A and the load point at B.

Where prestressing steel is used in wall members, the stress f_{ps} in the reinforcement at the nominal and the probable lateral resistance shall be calculated in accordance with Section 18.7 of ACI 318.

C14.2.4.2.3 Global toughness. These provisions describe acceptance criteria for special precast structural walls based on validation testing. The requirements of ACI 318 Section 21.1.1.8 concerning toughness cover both to the energy dissipation of the wall system which, for monolithic construction, is affected primarily by local plastic hinging behavior and the toughness of the prototype structure as a whole. The latter is termed "global toughness" in these provisions and is a condition that does not apply to the walls alone. That global toughness requirement can be satisfied only though analysis of the performance of the prototype structure as a whole when the walls perform to the criteria specified in these provisions.

The required gravity load for global toughness evaluations is the value given by these provisions. For conformity with Section 9.2.1 of ACI 318-08, UBC 1997, IBC 2006 and NFPA 5000, the required gravity load is $1.2D + f_1L$ where the seismic force is additive to gravity forces and 0.9D where the seismic force counteracts gravity forces. D is the effect of dead loads, L is the effect of live loads, and f_1 is a factor equal to 0.5 except for garages, areas occupied as places of public assembly, and all areas where the live load is greater than 100 psf (4.79 kN/m^2) where f_1 equals 1.0.

C14.2.4.2.5 Relative energy dissipation ratio. This concept is illustrated in Figure C14.2.4.2.5 for the third loading cycle to the limiting drift ratio required by Section 14.2.4.7.4, 14.2.4.7.5 or 14.2.4.7.6, as appropriate. For Figure C14.2.4.2.5, it is assumed that the test module has exhibited different initial stiffnesses, K and K', for positive and negative lateral forces and that the peak lateral resistances for the third cycle for the positive and negative loading directions, E_1 and E_2, also differ. The area of the hysteresis loop for the third cycle, A_h, is hatched. The circumscribing figure consists of two parallelograms, ABCD and DFGA. The slopes of the lines AB and DC are the same as the initial stiffness, K, for positive loading and the slopes of the lines DF and GA are the same as the initial stiffness, K', for negative loading. The relative energy dissipation ratio concept is similar to the equivalent damping concept used in Section 17.8.3 of the ASCE/SEI 7-05 for required tests of seismic isolation systems.

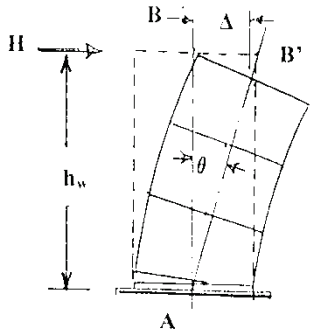

Figure C14.2.4.2.2-1 Definition of drift ratio θ.

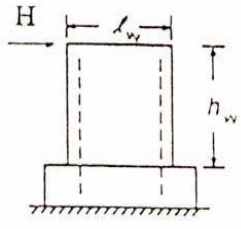
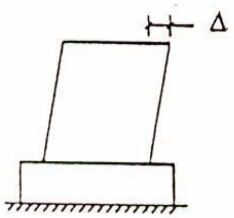
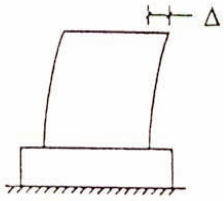


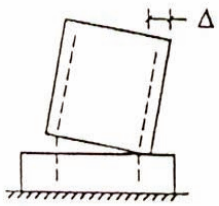
(a) Wall and loading



(c) Deformation due to shear



(b) Deformation due to flexure



(d) Deformation due to extension of reinforcement at foundation to wall interface

Figure C14.2.4.2.2-2 Typical wall deformation components.

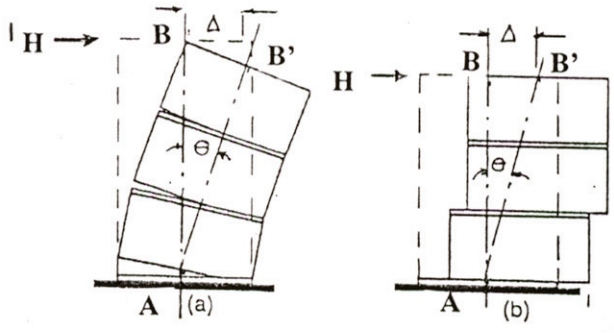


Figure C14.2.4.2.2-3 Undesirable deformations along horizontal joints: (a) excessive gap opening between panels and (b) shear slip.

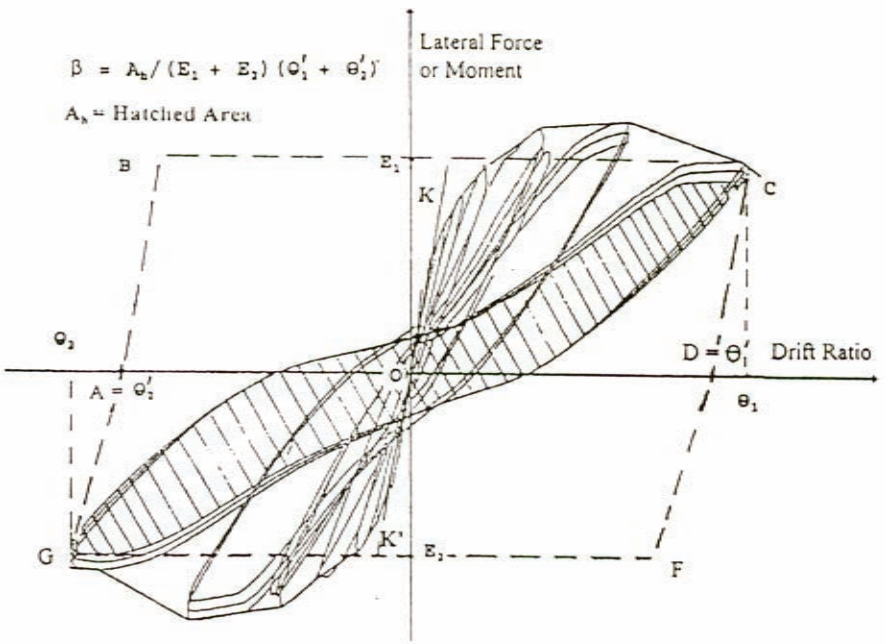

Figure C14.2.4.2.5 Relative energy dissipation ratio.

For a given cycle the relative energy dissipation ratio, β, is the area, A_h, inside the lateral force-drift ratio loop for the module, divided by the area of the effective circumscribing parallelograms ABCD and DFGA. The areas of the parallelograms equal the sum of the absolute values of the lateral force strengths, E_1 and E_2, at the drift ratios θ_1 and θ_2 multiplied by the sum of the absolute values for the drift ratios θ_1' and θ_2'.

C14.2.4.3 Scope and general requirements. While only ACI Committee 318 can determine the requirements necessary for precast walls to meet the provisions of ACI 318 Section 21.1.1.8, ACI 318 Section 1.4 already permits the building official to accept wall systems, other than those explicitly covered by ACI 318 Chapter 21, provided specific tests, load factors, deflection limits, construction procedures and other pertinent requirements have been established for acceptance of such systems consistent with the intent of the code. The purpose of these provisions is to provide a framework that establishes the specific tests, load factors, deflection limits and other pertinent requirements appropriate for acceptance, for regions of high seismic risk or for structures assigned to high seismic performance or design categories, of precast wall systems, including coupled wall systems, not satisfying all the requirements of ACI 318 Chapter 21. For regions of moderate seismic risk or for structures assigned to intermediate seismic performance or design categories, less stringent provisions than those specified here are appropriate.

These provisions assume that the precast wall system to be tested has details differing from those prescribed by ACI 318 Section 21.9 for conventional monolithic reinforced concrete construction. Such walls may, for example, involve the use of precast elements, precast prestressed elements, post-tensioned reinforcement, or combinations of those elements and reinforcement.

For monolithic reinforced concrete walls a fundamental design requirement of ACI 318 Chapter 21 is that walls with h_w/l_w exceeding1.0 be proportioned so that their inelastic response is dominated by flexural action on a critical section located near the base of the wall. That fundamental requirement is retained in these provisions. The reason is that tests on modules, as envisioned in these provisions, cannot be extrapolated with confidence to the performance of panelized walls of proportions differing from those tested for the development of ACI 318 Chapter 21 if the shear-slip displacement pattern of Figure C14.2.4.2.2.3, or the shear deformation response of Figure C14.2.4.2.2.2, governs the response developed in the test on the module. Two other fundamental requirements of ACI 318 Chapter 21 are for ties around heavily strained boundary element reinforcement and the provision of minimum amounts of uniformly distributed horizontal and vertical reinforcement in the web of the wall. Ties around boundary element reinforcement to inhibit its buckling in compression are required where the strain in the extreme compression fiber is expected to exceed some critical value. Minimum amounts of uniformly distributed horizontal and vertical reinforcement over the height and length of the wall are required to restrain the opening of inclined

cracks and allow the development of the drift ratios specified in Sections 14.2.4.7.4, 14.2.4.7.5 and 14.2.4.7.6. Deviations from those tie and distributed reinforcement requirements are possible only if a theory is developed that can substantiate reasons for such deviations and that theory is tested as part of the validation testing.

C14.2.4.3.1. These provisions are not intended for use with existing construction or for use with walls that are designed to conform to all the requirements of ACI 318 Section 21.9. The criteria of these provisions are more stringent than those for walls designed to ACI 318 Section 21.9. Some walls designed to Section 21.9, and having low height to length ratios, may not meet the drift ratio limits of Equation 14.2.4-1 because their behavior may be governed by shear deformations. The height to length ratio of 0.5 is the least value for which Equation 14.2.4-1 is applicable.

C14.2.4.3.3 For acceptance, the results of the tests on each module must satisfy the acceptance criteria of Section 14.2.4.9. In particular, the relative energy dissipation ratio calculated from the measured results for the third cycle between the specified limiting drift ratios must equal or exceed 1/8. For uncoupled walls, relative energy dissipation ratios increase as the drift ratio increases. Tests on slender monolithic walls have shown relative energy dissipation ratios, derived from rotations at the base of the wall, of about 40-45 percent at large drifts. The same result has been reported even where there has been a significant opening in the web of the wall on the compression side. For 0.020 drift ratios and walls with height to length ratios of 4, relative energy dissipation ratios have been computed as 30, 18, 12, and 6 percent, for monolithic reinforced concrete, hybrid reinforced/post-tensioned prestressed concrete with equal flexural strengths provided by the prestressed and deformed bar reinforcement, hybrid reinforced/post-tensioned prestressed concrete with 25 percent of the flexural strength provided by deformed bar reinforcement and 75 percent by the prestressed reinforcement, and post-tensioned prestressed concrete special structural walls, respectively. Thus, for slender precast uncoupled walls of emulative or non-emulative design it is to be anticipated that at least 35 percent of the flexural capacity at the base of the wall needs to be provided by deformed bar reinforcement if the requirement of a relative energy dissipation ratio of 1/8 is to be achieved. However, if more than about 40 percent of the flexural capacity at the base of the wall is provided by deformed bar reinforcement, then the self-centering capability of the wall following a major event is lost and that is one of the prime advantages gained with the use of post-tensioning. For squat walls with height to length ratios between 0.35 and 0.69 the relative energy dissipation has been reported as remaining constant at 23 percent for drifts between that for first diagonal cracking and that for a post-peak capacity of 80 percent of the peak capacity. Thus, regardless of whether the behavior of a wall is controlled by shear or flexural deformations a minimum relative energy dissipation ratio of 1/8 is a realistic requirement.

For coupled wall systems, theoretical studies and tests have demonstrated that the 1/8 relative energy dissipation ratio can be achieved by using central post-tensioning only in the walls and appropriate energy dissipating coupling devices connecting adjacent vertical wall boundaries.

C14.2.4.3.3.4. The ASCE/SEI 7-05 allowable story drift limits are the basis for the drift limits of IBC 2006 and NFPA 5000. Allowable story drifts, Δ_a, are specified in Table 1617.3 of IBC 2006 and likely values are discussed in the Commentary to Section 14.2.4.7.4. The limiting initial drift ratio consistent with Δ_a equals $\Delta_a/\phi C_d h_w$, where ϕ is the strength reduction factor appropriate to the condition, flexure or shear, that controls the design of the test module. For example, for Δ_a/h_w equal to 0.015, the required deflection amplification factor C_d of 5, and ϕ equal to 0.9, the limiting initial drift ratio, corresponding to B in Figure C14.2.4.9.1, is 0.0033. The use of a ϕ value is necessary because the allowable story drifts of the IBC are for the design seismic load effect, E, while the limiting initial drift ratio is at the nominal strength, E_n , which must be greater than E/ϕ. The load-deformation relationship of a wall becomes significantly non-linear before the applied load reaches E_{nt}. While the load at which that non-linearity becomes marked depends on the structural characteristics of the wall, the response of most walls remains linear up to about 75 percent of E_{nt}.

C14.2.4.3.3.5. The criteria of Section 14.2.4.9 are for the test module. In contrast, the criterion of Section 14.2.4.3.3.5 is for the structural system as a whole and can be satisfied only by the philosophy used for the design and analysis of the building as a whole. The criterion adopted here is similar to that described in the last paragraph of R21.1.1 of ACI 318 and the intent is that test results and analyses demonstrate that the structure, after cycling three times through both positive and negative values of the limiting drift ratio specified in Section 14.2.4.7.4, 14.2.4.7.5 or 14.2.4.7.6, as appropriate, is still capable of supporting the gravity load specified as acting on it during the earthquake.

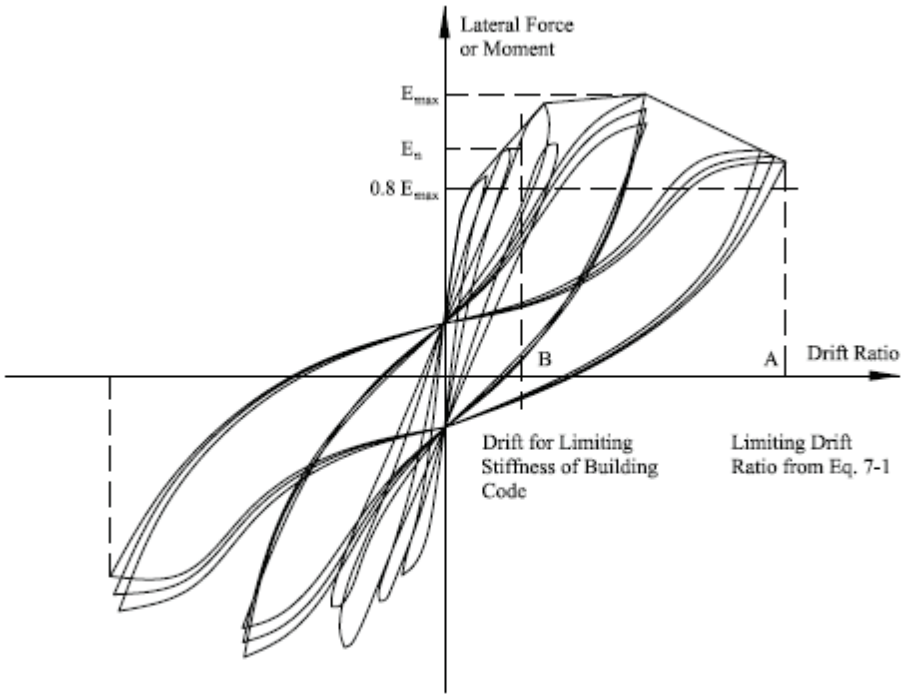

Figure C14.2.4.9.1 Quantities used in evaluating acceptance criteria.

C14.2.4.4 Design Procedure.

C14.2.4.4.1. The test program specified in these provisions is intended to verify an existing design procedure for precast structural walls for a specific structure or for prequalifying a generic type of special precast wall system for construction in general. The test program is not for the purpose of creating basic information on the strength and deformation properties of such systems for design purposes. Thus, the test modules should not fail during the validation testing, a result that is the opposite of what is usually necessary during testing in the development phase for a new or revised design procedure. For a generic precast wall system to be accepted based on these provisions, a rational design procedure is to have been developed prior to this validation testing. The design procedure is to be based on a rational consideration of material properties and force transfer mechanisms, and its development will usually require preliminary and possibly extensive physical testing that is not part of the validation testing. Because special wall systems are likely to respond inelastically during design-level ground shaking, the design procedure must consider wall configuration, equilibrium of forces, compatibility of deformations, the magnitudes of the lateral drifts, reversed cyclic displacements, the relative values of each limiting engineering design criteria (shear, flexure and axial load) and use appropriate constitutive laws for materials that include considerations of effects of cracking, loading reversals and inelasticity.

The effective initial stiffness of the structural walls is important for calculating the fundamental period of the prototype structure. The procedure used to determine the effective initial stiffness of the walls is to be verified from the validation test results as described in Section 14.2.4.7.11.

Provisions Sections 14.2.4.4.1.1 through 14.2.4.4.1.3 state the minimum procedures to be specified in the design procedure prior to the start of testing. The Authority Having Jurisdiction may require that more details be provided in the design procedure than those of Sections 14.2.4.4.1.1 through 14.2.4.4.1.3 prior to the start of testing.

C14.2.4.4.2. The justification for the small number of test modules, specified in Section 14.2.4.5.1 is that a previously developed rational design procedure is being validated by the test results. Thus, the test modules for the experimental program must be designed using the procedure intended for the prototype wall system and strengths must be predicted for the test modules before the validation testing is started.

C14.2.4.5 Test Modules.

C14.2.4.5.1. One module must be tested for each limiting engineering design criterion, such as shear, or axial load and flexure, for each characteristic configuration of walls. Thus, in accordance with Section 14.2.4.4.3 if the test on the module results in a maximum shear stress of $3\sqrt{f_c'}$ then the maximum shear stress that can be used in the prototype is that same value. Each characteristic in-plane configuration of walls, or coupled walls, in the prototype structure must also be tested. Thus, as a minimum for one-way structural walls, two modules with the configuration shown in Figure C14.2.4.2.2-1, and, for one way coupled walls, two modules with the configuration shown in either Figure C14.2.4.5.1(a) or in Figure C14.2.4.5.1(b), must be tested. In addition, if intersecting wall systems are to be used then the response of the wall systems for the two orthogonal directions needs to be tested. For two-way wall systems and coupled wall-frame systems, testing of configurations other than those shown in Figures C14.2.4.2.2-1 and C14.2.4.5.1 may be appropriate when it is difficult to realistically model the likely dominant earthquake deformations using orthogonal direction testing only.

This provision should not be interpreted as implying that only two tests will need to be made to qualify a generic system. During the development of that system it is likely that several more tests will have been made, resulting in progressive refinements of the mathematical model used to describe the likely performance of the generic structural wall system and its construction details. Consequently, only one test of each module type for each limiting engineering design condition, at a specified minimum scale and subjected to specific loading actions, may be required to validate the system. Further, as stated in Section 14.2.4.9.1, if any one of those modules for the generic wall system fails to pass the validation testing required by these provisions, then the generic wall system has failed the validation testing

In most prototype structures, a slab is usually attached to the wall and, as demonstrated by the results of the PRESSS building test, the manner in which the slab is connected to the wall needs to be carefully considered. The connection needs to be adequate to allow the development of story drifts equal to those anticipated in these provisions. However, in conformity with common practice for the sub-assemblage tests used to develop the provisions of Chapter 21of ACI 318, there is no requirement for a slab to be attached to the wall of the test module. The effect of the presence of the slab should be examined in the development program that precedes the validation testing.

C14.2.4.5.3. Test modules need not be as large as the corresponding walls in the prototype structure. The scale of the test modules, however, must be large enough to capture all the complexities associated with the materials of the prototype wall, its geometry and reinforcing details, load transfer mechanisms, and joint locations. For modules involving the use of precast elements, for example, scale effects for load transfer through mechanical connections should be of particular concern. The issue of the scale necessary to capture fully the effects of details on the behavior of the prototype should be examined in the development program that precedes the validation testing.

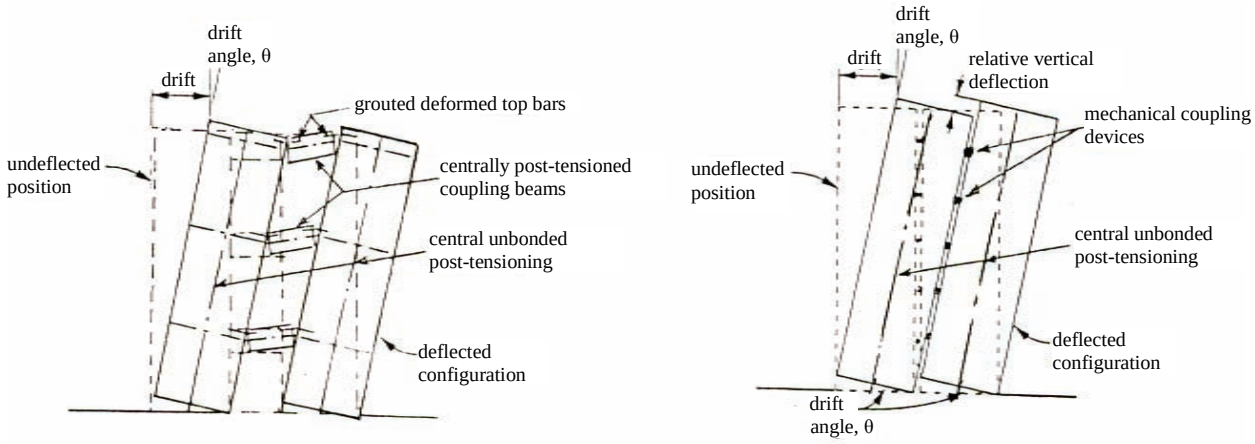

Figure C14.2.4.5.1 (a) Coupled wall test module with coupling beams; (b) Coupled wall test module with vertical mechanical couplers.

C14.2.4.5.4. It is to be expected that for a given generic precast wall structure, such as an unbonded centrally post-tensioned wall constructed using multiple precast or precast pretensioned concrete wall panels, validation testing programs will initially use specific values for the specified strength of the concrete and reinforcement in the walls, the layout of the connections between panels, the location of the post-tensioning, the location of the panel joints, and the design stresses in the wall. Pending the development of an industry standard for the design of such walls, similar to the standard for special hybrid

moment frames, specified concrete strengths, connection layouts, post-tensioning amounts and locations, etc., used for such walls will need to be limited to the values and layouts used in the validation testing programs.

C14.2.4.5.5. For walls constructed using precast or precast/prestressed panels and designed using non-emulative methods, the response under lateral load can change significantly with joint opening (Figure C14.2.4.2.2-2d and Figure C14.2.4.2.2-3a). The number of panels used to construct a wall depends on wall height and design philosophy. If, in the prototype structure, there is a possibility of horizontal joint opening under lateral loading at a location other than the base of the wall, then the consequences of that possibility need to be considered in the development and validation test programs. Joint opening at locations other than the base can be prevented through the use of capacity design procedures.

C14.2.4.5.6. The significance of the magnitude of the gravity load that acts simultaneously with the lateral load needs to be addressed during the validation testing if the development program suggests that effect is significant.

C14.2.4.5.7. Details of the connection of walls to the foundation are critical, particularly for non-emulative wall designs. The deformations that occur at the base of the wall due to plastic hinging or extension of the reinforcing bars or post-tensioning steel crossing the wall to foundation interface, (Figure C14.2.4.2.2-2d), are in part determined by details of the anchorage and the bonding of those reinforcements on either side of the interface. Grout will be normally used to bed panels on the foundation and the characteristics of that grout in terms of materials, strength and thickness, can have a large effect on wall performance. The typical grout pad with a thickness of 1 inch (25 mm) or less can be expected to provide a coefficient of friction of about 0.6 under reversed loadings. Pads with greater thickness and without fiber reinforcement exhibit lesser coefficients of friction. Adequate frictional resistance is essential to preventing undesirable shear-slip deformations of the type shown in Figure C14.2.4.2.2.3(b).

C14.2.4.5.8. The geometry of the foundations need not duplicate that used in the prototype structure. However, the geometric characteristics of the foundations (width, depth and length) need to be large enough that they do not influence the behavior of the test module.

C14.2.4.6 Testing Agency. In accordance with the spirit of the requirements of Sections 1.3.5 and 1.4 of ACI 318, it is important that testing be carried out by a recognized independent testing agency, approved by the agency having jurisdiction and that the testing and reporting be supervised by a registered design professional familiar with the proposed design procedure and experienced in testing and seismic structural design.

C14.2.4.7 Test Method. The test sequence is expressed in terms of drift ratio, and the initial ratio is related to the likely range of linear elastic response for the module. That approach, rather than testing at specific drift ratios of 0.005, 0.010, etc., is specified because, for modules involving prestressed concrete, the likely range of elastic behavior varies with the prestress level.

An example of the test sequence specified in Sections 14.2.4.7.2 through 14.2.4.7.6 is illustrated in Figure C14.2.4.7. The sequence is intended to ensure that displacements are increased gradually in steps that are neither too large nor too small. If steps are too large, the drift capacity of the system may not be determined with sufficient accuracy.

If the steps are too small, the system may be unrealistically softened by loading repetitions, resulting in artificially low maximum lateral resistances and artificially high maximum drifts. Also, when steps are too small, the rate of change of energy stored in the system may be too small compared with the change occurring during a major event. Results, using such small steps, can mask undesirable brittle failure modes that might occur in the inelastic response range during a major event. Because significant diagonal cracking is to be expected in the inelastic range in the web of walls, and in particular in squat walls, the pattern of increasing drifts used in the test sequence can markedly affect diagonal crack response in the post-peak range of behavior.

The drift capacity of a building in a major event is not a single quantity, but depends on how that event shakes the structure. In the forward near field, a single pulse may determine the maximum drift demand, in which case a single large drift demand cycle for the test module would give the best estimation of the drift capacity. More often, however, many small cycles precede the main shock and that is the scenario represented by the specified loading.

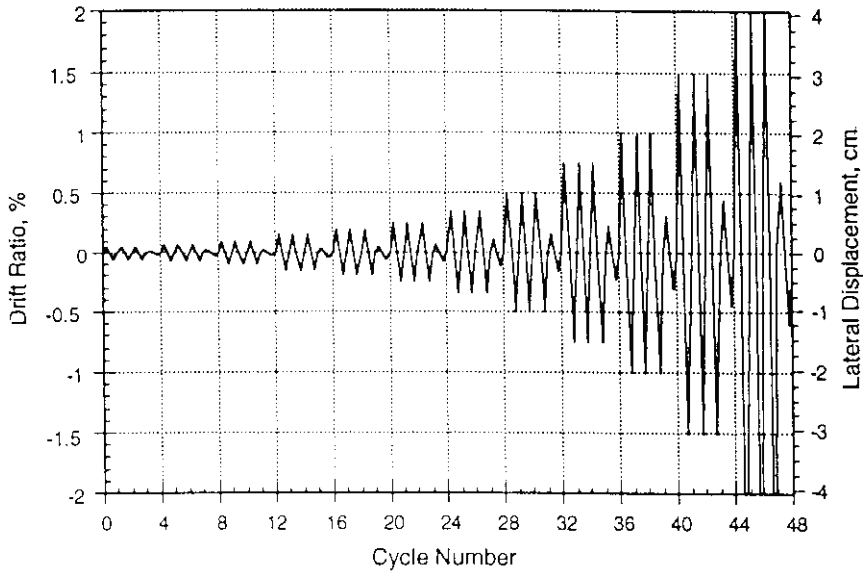

Figure C14.2.4.7 Example of specified test sequence.

There is no requirement for an axial load to be applied to the wall simultaneously with the application of the lateral displacements. In many cases it will be conservative not to apply axial load because, in general, the shear capacity of the wall and the resistance to slip at the base of the wall increase as the axial load on the wall increases. However, as the height of the wall increases and the limiting drift utilized in the design of the wall increases, the likelihood of extreme fiber crushing in compression at maximum drift increases, and the importance of the level of axial load increases. The significance of the level of axial loading should be examined during the development phase.

C14.2.4.7.4 For the response of a structure to the design seismic shear force, building codes (e.g., UBC 97, IBC 2006 or NFPA 5000) or recommended provisions (e.g., ASCE/SEI 7-05 and FEMA 356) specify a maximum allowable drift. However, structures designed to meet that drift limit may experience greater drifts under the design basis earthquake ground motion and are likely to experience greater drifts under the risk-targeted maximum considered earthquake ground motion. In addition to the characteristics of the ground motion, actual drifts will depend on the strength of the structure, its initial elastic stiffness, and the ductility expected for the given lateral load resisting system. Specification of suitable limiting drifts for the test modules requires interpretation and allowance for uncertainties in the assumed ground motions and structural properties.

In IBC 2006, the design seismic shear force applied at the base of a building is related directly to its weight and the design elastic response acceleration, and inversely to a response modification factor, R. That R factor increases with the expected ductility of the lateral force resisting system of the building. Special structural walls satisfying the requirements of Sections 21.1 and 21.9 are assigned an R value of 6 when used in a building frame system and a value of 5 when used in a bearing wall system. They are also assigned allowable story drift ratios that are dependent on the hazard to which the building is exposed. When the design seismic shear force is applied to a building, the building responds inelastically and the resultant computed drifts, (the design story drifts), must be less than a specified allowable drift. Additional guidance is given in FEMA 356 where the deformations for rectangular walls with height to length ratios greater than 2.5, and flanged wall sections with height to length ratios greater than 3.5, are to be assumed to be controlled by flexural actions. When structural walls are part of a building representing a substantial hazard to human life in the event of a failure, the allowable story drift ratio for shear controlled walls is 0.0075 and for flexure controlled walls is a function of the plastic hinge rotation at the base of the wall. For flexure controlled walls values range up to a maximum of about 0.02 for walls with confined boundary elements with low reinforcement ratios and shear stress less than $3\sqrt{f_c'}$.

To compensate for the use of the R value, IBC Section 1617.4.6 requires that the drift determined by an elastic analysis for the code-prescribed seismic forces be multiplied by a deflection amplification factor, C_d ,to determine the design story drift and that the design story drift must be less than the allowable story drift. In building frame systems, structural walls satisfying the requirements of Section 21.9 of ACI 318 are assigned a C_d value of 5. However, research has found that design story drift ratios determined in the foregoing manner may be too low. Drift ratios of 6 times IBC-calculated values, (rather

than 5), are more representative of the upper bounds to expected drift ratios. The value of 6 is also in agreement with the finding that the drift ratio of an inelastic structure is approximately the same as that of an elastic structure with the same initial period. For flexure controlled walls the value of 6/5 times the present IBC limits on calculated drift ratio, would lead to a limit on real drift ratios of up to 0.024.

Duffy et al. reviewed experimental data for shear walls to define post-peak behavior and limiting drift ratios for walls with height to length ratios between 0.25 and 3.5. Seo et al. re-analyzed the data of Duffy et al. together with data from tests conducted subsequent to the analysis of Duffy et al. Duffy et al. established that for squat walls with web reinforcement satisfying ACI 318-02 requirements and height to length ratios between 0.25 and 1.1, there was a significant range of behavior for which drifts were still reliable in the post-peak response region. Typically the post-peak drift increased by 0.005 for a 20 percent degradation in capacity under cyclic loading. For greater values of degradation, drifts were less reliable. That finding has also been confirmed through tests conducted by Hidalgo et al. (2002) on squat walls with effective height to length ratios ranging between 0.35 and 1.0. Values of the drift ratio of the walls at inclined cracking and at peak capacity varied little with web reinforcement. By contrast, drifts in the post-peak range were reliable to a capacity equal to 80 percent of the peak capacity and were 0.005 greater than the drifts at peak capacity provided the walls contained horizontal and vertical web reinforcement equal to 0.25 percent.

From an analysis of the available test data, and from theoretical considerations for a wall rotating flexurally about a plastic hinge at its base, Seo et al. concluded that the limiting drift at peak capacity increased almost linearly with the height to length ratio of the wall. When the additional post peak drift capacity for walls with adequate web reinforcement was added to the drift at peak capacity, the total available drift capacity in percent was given by $1.0 \leq 0.67\,(h_w / l_w) + 0.5 \leq 3.0$ where h_w is the height of the wall, and l_w is the length of the wall.

The data from the tests of Hidalgo et al. (2002) suggest that while that formula is correct for squat walls, the lower limit on drift can be decreased to 0.8 as specified in these provisions and that the use of that formula should be limited to walls with height to length ratios equal to or greater than 0.5. For wall height to length ratios less than 0.5, the behavior is controlled principally by shear deformations (Figure C14.2.4.2.2.2c), and Equation 14.2.4-1 should not be used. The upper value of 0.030 for the drift ratio was somewhat optimistic because the data were for walls with height to length ratios equal to or less than 3.5 and subsequent tests have shown that the upper limit of 2.5, as specified in Equation 14.2.4.1, is a more realistic limit.

C14.2.4.7.5 The design capacity for coupled wall systems must be developed by the drift ratio corresponding to that for the wall with the least h_w/l_w value. However, it is desirable that testing be continued to the drift given by Equation 14.2.4-1 for the wall with the greatest h_w/l_w in order to assess the reserve capacity of the coupled wall system.

C14.2.4.7.6 The drift limits of Equation 14.2.4.1 are representative of the maximum that can be achieved by walls designed to ACI 318. The use of smaller drift limits is appropriate if the designer wishes to use performance measures less than the maximum permitted by ACI 318. Examples are the use of reduced shear stresses so that the likelihood of diagonal cracking of the wall is minimized or reduced compressive stresses in the boundary elements of the wall so that the risk of crushing is reduced. Nonlinear time history analyses for the response to a suite of risk-targeted maximum considered earthquakes (MCE_R) ground motions, rather than 1.5 times a suite of the corresponding design basis earthquake (DBE) ground motions, is required because the drifts for the response to the MCE_R motion can be significantly larger than 1.5 times the drifts for the response to the DBE motions.

C14.2.4.7.10 In many cases, data additional to the minimum specified in Section 14.2.4.7.7 may be useful to confirm both design assumptions and satisfactory response. Such data include relative displacements, rotations, curvatures, and strains.

C14.2.4.8 Test Report. The test report must be sufficiently complete and self-contained for a qualified expert to be satisfied that the tests have been designed and carried out in accordance with these criteria, and that the results satisfy the intent of these provisions. Sections 14.2.4.8.1.1 through 14.2.4.8.1.11 state the minimum evidence to be contained within the test report. The authority having jurisdiction or the registered design professional supervising the testing may require that additional test information be reported.

C14.2.4.9 Test Module Acceptance Criteria.

The requirements of this clause apply to each module of the test program and not to an average of the results of the program. Figure C14.2.4.9.1 illustrates the intent of this clause.

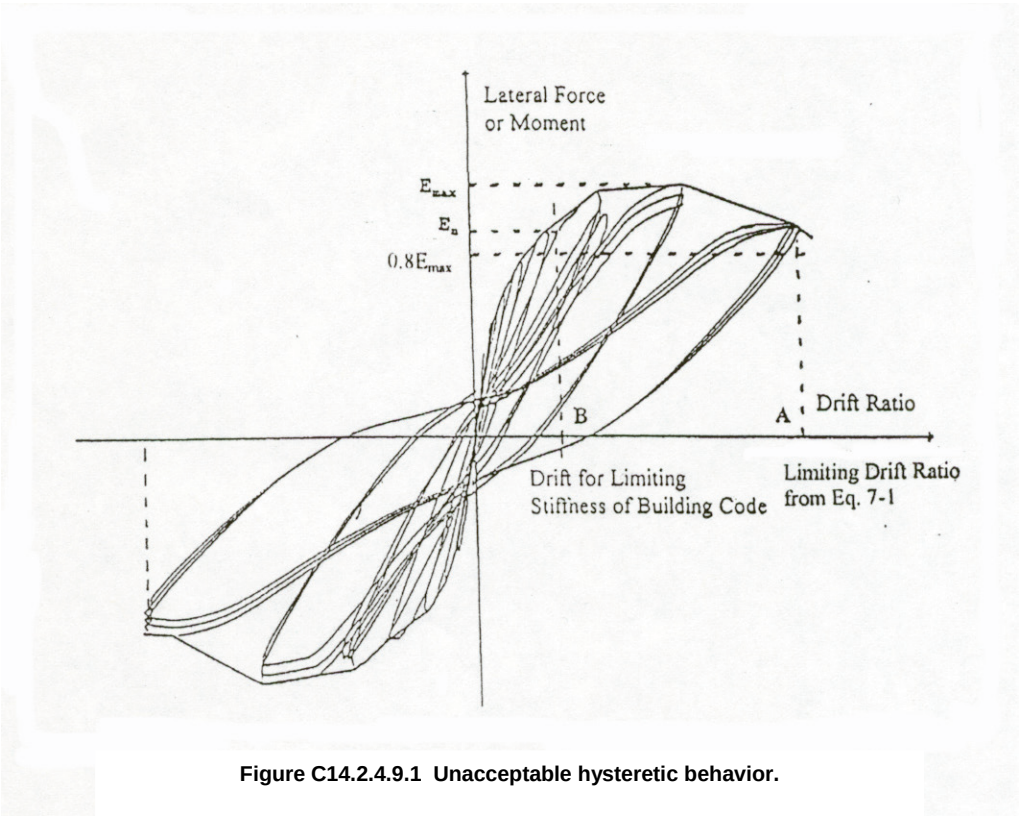

Figure C14.2.4.9.1 Unacceptable hysteretic behavior.

C14.2.4.9.1.1 Where nominal strengths for opposite loading directions differ, as is likely for C-, L- or T- shaped walls, the criterion of Section 14.2.4.9.1.1 applies separately to each direction.

C14.2.4.9.1.2 At high cyclic-drift ratios, strength degradation is inevitable. To limit the level of degradation so that drift ratio demands do not exceed anticipated levels, a maximum strength degradation of $0.20E_{max}$ is specified. Where strengths differ for opposite loading directions, this requirement applies independently to each direction.

C14.2.4.9.1.3. If the relative energy dissipation ratio is less than 1/8, there may be inadequate damping for the building as a whole. Oscillations may continue for some time after an earthquake, producing low-cycle fatigue effects, and displacements may become excessive.

If the stiffness becomes too small around zero drift ratio, the structure will be prone to large displacements for small lateral force changes following a major earthquake. A hysteresis loop for the third cycle between peak drift ratios of 1/10 times the limiting drift ratio given by Equation 14.2.4-1, that has the form shown in Figure C14.2.4.9.1, is acceptable. At zero drift ratio, the stiffnesses for positive and negative loading are about 11 percent of the initial stiffnesses. Those values satisfy Section 14.2.4.9.1. An unacceptable hysteresis loop form would be that shown in Figure C14.2.4.9.1 where the stiffness around zero drift ratio is unacceptably small for both positive and negative loading.

COMMENTARY TO SECTION 14.4.5

C14.4.5 Modifications to Chapter 1 of ACI 530/ASCE 5/TMS 402. The seismic design factors, SDC limits, and height restrictions of these provisions are based on a combination of testing, analysis, underlying consensus standards, experience, and consistency with comparable structural systems.

The testing and analysis, described in Tanner et al. (2005a and b) and Varela et al. (2005b), began in 1999 and were developed as part of an integrated research strategy. This strategy, presented at ICC-ES hearings in 2003 and affirmed in its essence using performance-based methods similar to those in the 90-percent-complete draft of FEMA P-695 (Applied Technology Council, 2008), had as its objective the development of seismic design factors consistent with at most a 10 percent probability of collapse under what was essentially equivalent to the maximum considered earthquake ground motion. That research developed factors of R and C_d equal to 3 with no restrictions on SDC or height. Additional information on that research is presented in American Society of Testing and Materials (2007), Masonry Standards Joint Committee (2005a and b and 2008a and b), The Masonry Society (2007), Tanner et al. (2005a and b), and Varela et al. (2006).

Following the initial presentation of this strategy and its associated proposals in the ICC-ES forum, it was discussed extensively with the BSSC's Provisions Update Committee and other interested parties including the BSSC's Code Resource Support Committee. Those discussions led to a modification of the proposal to R and C_d factors equal to 2, to SDC from A to C, and to height restrictions of 35 ft for SDC C. These values and their associated restrictions are consistent with a probability of failure much lower than 10 percent under what was essentially equivalent to the risk-targeted maximum considered earthquake ground motion (MCE_R).

Structures of autoclaved aerated concrete (AAC) masonry are designed and constructed using U.S. consensus standards including material standards (American Society of Testing and Materials, 2007), design provisions, and mandatory construction requirements (Masonry Standards Joint Committee, 2005a and b and 2008a and b). These U.S. consensus standards are augmented by refereed documents (The Masonry Society, 2007) and the online recommendations of the Autoclaved Aerated Concrete Products Association (http://www.aacpa.org/).

In the United States, AAC masonry buildings built with local approvals, under design rules consistent with the consensus standards, and with heights greater than those permitted by these provisions, have successfully resisted hurricane winds with no damage.

The seismic design factors, SDC limits, and height restrictions of these provisions are consistent (or even more conservative) than those assigned to Ordinary Reinforced Masonry Shear Walls of clay or concrete masonry.

Modifications to Chapter 15, Seismic Design Requirements for Nonbuilding Structures

TABLE 15.4-2, SEISMIC COEFFICIENTS FOR NONBUILDING STRUCTURES NOT SIMILAR TO BUILDINGS

Revise the following items as indicated (deletions in strikeout and additions underlined):

Cast-in-place concrete silos~~, stacks, and chimneys~~ having walls continuous to the foundation	15.6.2	3	1.75	3	NL	NL	NL	NL	NL
All other reinforced masonry structures not similar to buildings	14.4.1	3	2	2.5	NL	NL	NL	50	50
All other nonreinforced masonry structures not similar to buildings	14.4.1	1.25	2	1.5	NL	NL	50	50	50
Concrete chimneys and stacks	15.6.2	2	1.5	1.5	NL	NL	NL	NL	NL
All other steel and reinforced concrete distributed mass cantilever structures not covered herein including ~~stacks, chimneys,~~ silos, and skirt-supported vertical vessels that are not similar to buildings	15.6.2 15.7.10 and 15.7.10.5 a and b.	3	2	2.5	NL	NL	NL	NL	NL

SECTION 15.5.3, STEEL STORAGE RACKS

Replace with the following:

15.5.3 Steel Storage Racks. Steel storage racks supported at or below grade shall be designed in accordance with Section 2.7 of the ANSI/RMI MH 16.1 standard and its force and displacement requirements.

For storage racks supported above grade, the value of V in Section 2.7.2 of ANSI/RMI MH 16.1 shall not be taken less than the value of F_p determined in accordance with Section 13.3.1 of this standard, where R_p is taken equal to R, and a_p is taken equal to 2.5.

Alternatively, in addition to the requirements of Section 15.5.1, steel storage racks shall be designed in accordance with the requirements of Sections 15.5.3.1 through 15.5.3.4

[Sections 15.5.3.1 through 15.5.3.4 are unchanged.]

SECTION 15.6.2, STACKS AND CHIMNEYS

Replace with the following:

15.6.2 Stacks and Chimneys. Stacks and chimneys are permitted to be either lined or unlined and shall be constructed from concrete, steel, or masonry. Steel stacks, concrete stacks, steel chimneys, concrete chimneys, and liners shall be designed to resist seismic lateral forces determined from a substantiated analysis using reference documents. Interaction of the stack or chimney with the liners shall be considered. A minimum separation shall be provided between the liner and chimney equal to C_d times the calculated differential lateral drift.

For concrete chimneys assigned to Seismic Design Category D, E or F, splices for vertical rebar shall be staggered such that no more than 50 percent of the bars are spliced at any elevation. Design and detailing of cross-sections in the regions of breach openings, where the loss of cross-sectional area is greater than 10 percent, shall be performed in one of the following ways:

a. For vertical force, shear force, and bending moment demands along the vertical direction, design the affected cross-section using the overstrength factor of 1.5. The following detailing requirements shall be satisfied:

   i. The region of such overstrength shall extend above and below (except if the opening is at the base) the opening(s) by a distance equal to half of the width of the largest opening in the affected region.

   ii. Appropriate reinforcement development lengths shall be provided beyond the required region of overstrength.

iii. The jamb regions around each opening shall be detailed using the column tie requirements in Section 7.10.5 of ACI 318. Such detailing shall extend for a jamb width of a minimum of two times the wall thickness and for a height of the opening height plus twice the wall thickness above and below the opening, but no less than the development length of the longitudinal bars. The percentage of longitudinal reinforcement in jamb regions shall meet the requirements of Section 10.9 of ACI 318 for compression members.

b. Provided that the cross-sectional moment of inertia in the opening region is at least 70 percent of the same above and below it, it shall be permitted to treat the breach opening region as follows:

i. All detailing requirements listed in Item a. above for the overstrength option shall be followed, in addition to the ones listed below.

ii. Hoop ties in jamb regions shall be detailed as columns of intermediate moment frames using the requirements in Section 21.3.5 of ACI 318. The dimensions for jamb region shall be the same as that required in Item a. above for the overstrength option.

iii. No construction joints within the opening region plus two times the wall thickness above and below the opening.

iv. Ratio of outer diameter to wall thickness shall not exceed 20 within the opening region.

SECTION 15.7.6, GROUND-SUPPORTED STORAGE TANKS FOR LIQUIDS

Add the following exception to the end of Section 15.7.6.1, General:

EXCEPTION: For $T_c > 4$ seconds, S_{ac} may be determined by a site-specific study using one or more of the following methods: (a) the procedures found in Chapter 21, provided such procedures, which rely on ground-motion attenuation equations for computing response spectra, cover the natural period band containing T_c, (b) ground-motion simulation methods employing seismological models of fault rupture and wave propagation, and (c) analysis of representative strong-motion accelerogram data with reliable long-period content extending to periods greater than T_c. However, in no case shall the value of S_{ac} be taken as less than the minimum of:

1. The value determined in accordance with Equation 15.7-11 using 50 percent of the mapped value of T_L from Figure 22-7 or
2. 0.8 times the value determined in accordance with Equation 15.7-11 using the mapped value of T_L from Figure 22-7.

In determining the value of S_{ac}, the value of T_L shall not be less than 4 seconds.

Commentary to Chapter 15 Modifications

COMMENTARY TO SECTION 15.5.3

C15.5.3 Steel Storage Racks. The two approaches to the design of steel storage racks set forth by the standard are intended to produce comparable results. The specific revisions to the RMI specification cited in earlier editions of the *Provisions* and the detailed requirements of the new ANSI/RMI standard reflect the recommendations of FEMA 460, *Seismic Considerations for Steel Storage Racks Located in Areas Accessible to the Public.*

COMMENTARY TO SECTION 15.6.2

C15.6.2 Stacks and Chimneys. The design of stacks and chimneys to resist natural hazards generally is governed by wind design considerations. The exceptions to this general rule involve locations with high seismicity, stacks and chimneys with large elevated masses, and stacks and chimneys with unusual geometries. It is prudent to evaluate the effect of seismic loads in all but those areas with the lowest seismicity. Although not specifically required, it is recommended that the special seismic details required elsewhere in the standard be considered for application to stacks and chimneys.

Concrete chimneys have low ductility, and their seismic behavior is especially critical in the opening regions due to inherent reduction in strength and loss of confinement for vertical reinforcement in the jamb regions around the openings. Spectacular earthquake-induced chimney failures have occurred in recent history (in Turkey in 1999) and have been attributed to strength/detailing problems (Kilic and Sozen, 2003). Therefore, the *R* value of 3 traditionally used in ASCE/SEI 7-05 for

concrete stacks and chimneys is reduced to 2 and detailing requirements for breach openings are added in the 2009 *NEHRP Recommended Seismic Provisions*.

Guyed steel stacks and chimneys are generally lightweight. As a result, the design loads due to natural hazards generally are governed by wind. On occasion, large flares or other elevated masses located near the top may require in-depth seismic analysis. Although it does not specifically address seismic loading, Chapter 6 of Troitsky (1982) provides a methodology appropriate for resolution of the seismic forces defined in the standard.

COMMENTARY TO SECTION 15.7.6.1

C15.7.6.1 General. The response of ground storage tanks to earthquakes is well documented by Housner, Mitchell and Wozniak, Veletsos, and others. Unlike building structures, the structural response of these tanks is influenced strongly by the fluid-structure interaction. Fluid-structure interaction forces are categorized as sloshing (convective) and rigid (impulsive) forces. The proportion of these forces depends on the geometry (height-to-diameter ratio) of the tank. API 650, API 620, AWWA D100, AWWA D110, AWWA D115, and ACI 350.3 provide the data necessary to determine the relative masses and moments for each of these contributions.

The standard requires that these structures be designed in accordance with the prevailing reference documents, except that the height of the sloshing wave, δ_s, must be calculated using Equations 15.7-13. Note that API 650 and AWWA D100 include this requirement in their latest editions.

Equations 15.7-10 and 15.7-11 provide the spectral acceleration of the sloshing liquid for the constant-velocity and constant-displacement regions of the response spectrum, respectively. The 1.5 factor in these equations is an adjustment for 0.5 percent damping. An exception in the use of Equation 15.7-11 was added for the 2009 *NEHRP Recommended Seismic Provisions*. Actual site-specific studies carried out since the introduction of the T_L requirements of ASCE/SEI 7-05 indicate that the mapped values of T_L are extremely conservative. Because a revision of the T_L maps is a time-consuming task that would not be possible during the 2009 *Provisions* update cycle, an exception was added to allow the use of site-specific values that are less than the mapped values with a floor of 4 seconds or one-half the mapped value of T_L. The exception was added under Section 15.7.6 because T_L is a tank issue. Discussion of the site-specific procedures can be found in the Part 2 Commentary for Chapter 22.

Modification to Chapter 16, Seismic Response History Procedures

SECTION 16.1.3.2, THREE-DIMENSIONAL ANALYSIS

Replace with the following:

16.1.3.2 Three-Dimensional Analysis. Where three-dimensional analyses are performed, ground motions shall consist of pairs of appropriate horizontal ground motion acceleration components that shall be selected and scaled from individual recorded events. Appropriate ground motions shall be selected from events having magnitudes, fault distances, and source mechanisms that are consistent with those that control the risk-targeted maximum considered earthquake (MCE_R). Where the required number of recorded ground motion pairs is not available, appropriate simulated ground motion pairs are permitted to be used to make up the total number required. For each pair of horizontal ground motion components, a square root of the sum of squares (SRSS) spectrum shall be constructed by taking the SRSS of the 5-percent-damped response spectra for the scaled components (for direct scaling, an identical scale factor is applied to both components of a pair). Each pair of motions shall be scaled such that for each period between $0.2T$ and $1.5T$, the average of the SRSS spectra from all horizontal component pairs does not fall below the corresponding ordinate of the MCE_R response spectrum determined in accordance with Section 11.4.5 or 11.4.7.

At sites within 5 km of an active fault that controls the hazard, each pair of components shall be rotated to the fault-normal and fault-parallel direction of the causative fault and shall be scaled so that the average of the fault-normal components is not less than the MCE_R response spectrum for each period between $0.2T$ and $1.5T$.

Commentary to Chapter 16 Modification

COMMENTARY TO SECTION 16.1.3.2

C16.1.3.2 Three-dimensional Analyses. One key change to the ground motion design requirements developed by the BSSC's Seismic Design Procedure Review Group (SDPRG) for the 2009 *NEHRP Recommended Seismic Provisions* is the use of maximum direction ground motions. In addition to changing the design values defined in Chapter 11 and used throughout the *Provisions*, implementing maximum direction ground motions affects the previous ground motion scaling rules specified in Section 16.1.3.2. Studies (Maffei and Hashemi, 2008) of 50 ground motions of M6.5-M7.9 earthquakes for both far-field and near-field records and for periods in the range of 0.1 to 3.0 seconds indicate that the maximum direction of ground motion is slightly less than the SRSS of the two components with the SRSS spectrum tending to be approximately 1.16 times the maximum direction spectrum.

For each of the 50 ground motions, the maximum response of a single-degree-of-freedom (SDOF) oscillator (assuming 5-percent damping) was determined for ground motion orientations from 0 to 90 degrees (in one-degree increments) and was compared to the associated SRSS of maximum response. The ratios of the SRSS of maximum response and the maximum amplitude of the response for varying parameters are given in Tables C16.1.3.2-1 through C16.1.3.2-3.

Table C16.1.3.2-1 Ratio of SRSS of Maximum Response to Maximum Amplitude as a Function of SDOF Period

SDoF Period	Number of Data Points	Ratio-Mean	Ratio –Standard Deviation
0.1 sec	50	1.19	0.077
0.3 sec	50	1.16	0.068
1.0 sec	50	1.14	0.067
3.0 sec	50	1.13	0.077
Average	**200**	**1.16**	**0.076**

Table C16.1.3.2-2 Ratio of SRSS of Maximum Response to Maximum Amplitude as a Function of Ground Motion Records

Ground Motion	Number of Data Points	Ratio-Mean	Ratio -Standard Deviation
Far-Field	88	1.16	0.067
Near-Field	112	1.15	0.078
Average	**200**	**1.16**	**0.076**

Table C16.1.3.2-3 Ratio of SRSS of Maximum Response to Maximum Amplitude as a Function of Site Class

Site Class	Number of Data Points	Ratio-Mean	Ratio -Standard Deviation
B	8	1.15	0.066
C	84	1.15	0.072
D	108	1.16	0.073
Average	**200**	**1.16**	**0.076**

The modified scaling requirements simplify phrasing of existing language by replacing 10 percent less than 1.16 times the MCE_R response spectrum with the MCE_R response spectrum, itself, resulting in an effective "1.0" multiplier. This effective multiplier comes from $(0.9)(1.16) \approx 1.0$.

However, for sites within approximately 5 km of an active fault that controls the ground-motion hazard, the near field strong-motion database indicates that the fault-normal (FN) direction is (or is close to) the direction of maximum ground motion for periods around 1.0 second and greater (Huang et al., 2008; Watson-Lamprey and Boore, 2007). In this case, the two horizontal components of a selected record are to be transformed so that one component is the motion in the FN direction and the other component is the motion in the fault-parallel (FP) direction. Scaling so that the average FN component response spectrum is at the level of the MCE_R response spectrum ensures that the FN components will not be underestimated, which would happen if the SRSS rule was applied at short distances. The same scale factor selected for the FN component of a given record is used for the FP component also.

Modifications to Chapter 18, Seismic Design Requirements for Structures with Damping Systems

SECTION 18.3.1, NONLINEAR RESPONSE HISTORY PROCEDURE

Replace with the following:

18.3.1 Nonlinear Response History Procedure. A nonlinear response history (time history) analysis shall utilize a mathematical model of the structure and the damping system as provided in Chapter 16 and this section. The model shall directly account for the nonlinear hysteretic behavior of elements of the structure and the damping devices to determine its response, through methods of numerical integration, to suites of ground motions compatible with the design response spectrum for the site.

The analysis shall be performed in accordance with Chapter 16 together with the requirements of this section. Inherent damping of the structure shall not be taken greater than 5 percent of critical unless test data consistent with levels of deformation at or just below the effective yield displacement of the seismic-force-resisting system support higher values.

If the calculated force in an element of the seismic force-resisting system does not exceed 1.5 times its nominal strength, that element is permitted to be modeled as linear.

18.3.1.1 Damping Device Modeling. Mathematical models of displacement-dependent damping devices shall include the hysteretic behavior of the devices consistent with test data and accounting for all significant changes in strength, stiffness, and hysteretic loop shape. Mathematical models of velocity-dependent damping devices shall include the velocity coefficient consistent with test data. If this coefficient changes with time and/or temperature, such behavior shall be modeled explicitly. The elements of damping devices connecting damper units to the structure shall be included in the model.

Exception: If the properties of the damping devices are expected to change during the duration of the response history analysis, the dynamic response is permitted to be enveloped by the upper and lower limits of device properties. All these limit cases for variable device properties must satisfy the same conditions as if the time dependent behavior of the devices were explicitly modeled.

18.3.1.2 Response Parameters. For each ground motion analyzed, individual response parameters consisting of the maximum value of the individual member forces, member inelastic deformations and story drifts at each story shall be determined. Moreover, for each ground motion used for response history analysis, individual response parameters consisting of the maximum value of the discrete damping device forces, displacements, and velocities, in the case of velocity-dependent devices, shall be determined.

If at least seven ground motions are used for response history analysis, the design values of the damping device forces, displacements, and velocities are permitted to be taken as the average of the values determined by the analyses. If fewer than seven ground motions are used for response history analysis, the design damping device forces, displacements and velocities shall be taken as the maximum value determined by the analyses. A minimum of three ground motions shall be used.

SECTION 18.3.2, NONLINEAR STATIC PROCEDURE

Replace with the following:

18.3.2 Nonlinear Static Procedure. Nonlinear static procedures may be used to construct the lateral force-displacement curve of the seismic-force-resisting system in lieu of the elastoplastic curve assumed in the response spectrum procedure and in the equivalent lateral force procedure. When nonlinear static procedures is used, the nonlinear modeling described Chapter 16 shall be used. The resulting force-displacement curve shall be used in lieu of the assumed effective yield displacement, D_Y, of Equation 18.6-10 to calculate the effective ductility demand under the design earthquake ground motion, μ_D, and under the risk-targeted maximum considered earthquake ground motion, μ_M, in Equations 18.6-8 and 18.6-9, respectively. The value of (R/C_d) shall be taken as 1.0 in Equations 18.4-4, 18.4-5, 18.4-8, and 18.4-9 for the response spectrum procedure, and in Equations 18.5-6, 18.5-7 and 18.5-15 for the equivalent lateral force procedure.

Modification to Chapter 21, Site-Specific Ground Motion Procedures for Seismic Design

SECTION 21.2, GROUND MOTION HAZARD ANALYSIS

Replace Sections 21.2.1 through 21.2.3 with the following:

21.2.1 Probabilistic Ground Motions. The probabilistic spectral response acceleration shall be taken as the spectral response acceleration in the maximum direction of ground motions represented by a 5 percent damped acceleration response spectrum that is expected to achieve a 1 percent probability of collapse within a 50-year period. For the purpose of this provision, ordinates of the probabilistic ground-motion response spectrum shall be determined by either Method 1 of Section 21.2.1.1 or Method 2 of Section 21.2.1.2.

21.2.1.1 Method 1. Ordinates of the probabilistic ground-motion response spectrum shall be determined as the product of the risk coefficient at each spectral response period, C_R, and the spectral response acceleration represented by a 5 percent damped acceleration response spectrum having a 2 percent probability of exceedance within a 50-year period. The value of the risk coefficient, C_R, shall be determined using values of C_{RS} and C_{R1} from Figures 22-3 and 22-4, respectively. At spectral response periods less than or equal to 0.2 second, C_R shall be taken as equal to C_{RS}. At spectral response periods greater than or equal to 1.0 second, C_R shall be taken as equal to C_{R1}. At response spectral periods greater than 0.2 second and less than 1.0 second, C_R shall be based on linear interpolation of C_{RS} and C_{R1}.

21.2.1.2 Method 2. Ordinates of the probabilistic ground-motion response spectrum shall be determined at each spectral response period from the iterative integration of a site-specific hazard curve with a lognormal probability density function representing the collapse fragility (i.e., probability of collapse as a function of spectral response acceleration). At each period, the ordinate of the probabilistic ground-motion response spectrum shall achieve a 1 percent probability of collapse within a 50-year period for a collapse fragility having (i) a 10 percent probability of collapse at said ordinate of the probabilistic ground-motion response spectrum and (ii) a logarithmic standard deviation value of 0.8.

21.2.2 Deterministic Ground Motions. The deterministic spectral response acceleration at each period shall be calculated as the largest 84th percentile 5 percent damped spectral response acceleration in the direction of maximum horizontal response computed at that period for characteristic earthquakes on all known active faults within the region. For the purposes of this standard, the ordinates of the deterministic ground motions response spectrum shall not be taken as lower than the corresponding ordinates of the response spectrum determined in accordance with Figure 21.2-1, where F_a and F_v are determined using Tables 11.4-1 and 11.4-2, respectively, with the value of S_s taken as 1.5 and the value of S_1 taken as 0.6.

21.2.3 Site-Specific MCE_R. The site-specific MCE_R spectral response acceleration at any period, S_{aM}, shall be taken as the lesser of the spectral response accelerations from the probabilistic ground motions of Section 21.2.1 and the deterministic ground motions of Section 21.2.2.

Commentary to the Chapter 21 Modification

C21.2 GROUND MOTION HAZARD ANALYSIS

As explained in the commentary to Chapter 11, the risk-targeted maximum considered earthquake ground motions (MCE_R) in the 2009 *NEHRP Recommended Seismic Provisions* are based on the 2008 USGS seismic hazard maps and also incorporate three technical changes to ASCE/SEI 7-05:

1. Use of risk-targeted ground motions,
2. Use of maximum direction ground motions, and
3. Use of near-source 84th percentile ground motions.

Reasons for use of maximum direction ground motions are explained first in the commentary below, because they apply to both the probabilistic and deterministic ground motions discussed subsequently. Use of risk-targeted and near-source 84th percentile ground motions are discussed in the probabilistic and deterministic ground motions sections below, respectively.

The requirements in the previous editions of the *Provisions* and ASCE/SEI 7 do not define the direction of ground motions used for design. The procedure used to develop the statistical estimate of ground motion results in the geometric mean (geomean) of two orthogonal components of motion at a site. Many engineers find the maximum direction to be a more meaningful parameter for structural design. The basic concept is that a structure is designed to resist the ground motion at its site; the prediction of ground motion is inherently statistical, and the basis for the statistical estimate of the ground motion is rooted in the probability that a structure will actually fail. In general, structures will not have the same resistance in all directions; however, for those structures in which seismic resistance is a significant economic factor, there is a tendency to design to the level required by building codes, with the result that the resistance of the structure is relatively insensitive to the direction of the motion. When one considers such structures subjected to two simultaneous components of ground motion, these structures characteristically fail in the direction of the stronger of the two components. Failure rates of simple buildings in one recent study (low-rise wood buildings in Applied Technology Council, 2008) show this effect: the overall failure rate for three-dimensional analyses was higher than those for two-dimensional analyses for the same set of structures analyzed for the same 22 pairs of ground motions. The specification of maximum direction ground motions reduces the probability of structural failure based upon equivalent static two-dimensional design compared to the use of the geomean based demand, but this reduction has not been quantified at this time. For consistency, revisions have been made to both probabilistic and deterministic ground motion criteria to reflect required use of maximum direction ground motions.

The USGS updates of the uniform-hazard and deterministic ground motion spectral value maps have used the new next generation attenuation (NGA) relations for sites in the western United States (WUS). The new NGA relationships output an average horizontal spectral demand and the dispersion in that demand, where this average is the rotated geomean denoted as GMRotI50 (Boore et al., 2006). GM denotes the geometric mean of two horizontal components, Rot denotes that rotations over all non-redundant angles are considered, I denotes that period-independent rotations are used, and 50 identifies the prediction of median values. The geometric mean of two horizontal components of ground motions is calculated as the square root of the product of the two horizontal response spectral accelerations at each period of interest. As demonstrated by Boore et al. (2006), GMRotI50 is numerically very similar to (i.e., within 3 percent of) the geometric mean of two as-recorded components that was typically the output of older attenuation relationships.

A recent study (Huang et al., 2008a) found that near-source ground motion spectral response accelerations of the new NGA relations are somewhat less than those in the maximum direction of response. This study (2008a, 2008b) focused on large magnitude earthquakes, with moment magnitudes greater than 6.5 and site-to-source distances less than 15 km. For this family of earthquake records, ground motions in the maximum direction of response are about 110 percent of 5 percent damped, short-period spectral response acceleration, and about 130 percent of 5 percent damped, 1-second spectral response acceleration calculated using the new NGA relations (GMRotI50). Table C21.2-1 presents summary results to enable calculation of median and 84th percentile ratios of maximum to geomean spectral demands across the period range of 0 to 4.0 seconds; values of the ratio are assumed to remain constant for periods greater than 4.0 seconds. Values are rounded to the nearest 0.1, which is the appropriate degree of precision. The ratio of 84th percentile (Column 3) to median (Column 2) demands is approximately 1.8 to 1.9. Linear interpolation should be used to establish values of the ratios for periods not listed.

Other regions (e.g., the central and eastern United States) are expected to have similar ratios of maximum direction ground motions to geomean ground motions although the limited number of strong-motion records from the central and eastern United States precludes rigorous evaluation such as that performed by the NGA study (Huang et al., 2008). However, studies by Beyer and Bommer (2006) using a set of 949 earthquake records with much wider ranges of moment magnitude (4.2 to 7.9) and hypocentral distance (5 to 200 km) indicated similar ratios of maximum to geomean response to those of the Huang et al. study on large magnitude, near-fault ground motions. The Beyer and Bommer data set included records from 20+ European earthquakes.

Table C21.2-1 Median and 84th Percentile of the Ratio of Maximum Spectral Demand to Geomean Demand

Period (second)	Median	84th Percentile	Period (second)	Median	84th Percentile
0.0	1.1	2.0	0.5	1.2	2.1
0.1	1.1	2.0	1.0	1.3	2.3
0.2	1.1	2.0	2.0	1.3	2.5
0.3	1.1	2.0	4.0+	1.4	2.7

For consistency of ground motion scaling (against either geomean or maximum direction spectra) in three-dimensional response history analysis of structures, the 2009 *Provisions* has adopted changes related to Section 16.1.3.2 of ASCE/SEI 7-05 such that it enables the scaling of pairs of horizontal ground motion records matching maximum direction spectra (MCE_R or design spectra of maximum direction of response) to be equivalent to that matching the corresponding geomean spectra. Additional explanation of these changes is provided in Section C16.1.3.2.

C21.2.1 Probabilistic Ground Motions. The definition and basis of probabilistic ground motions in these new *Provisions* has changed from that in ASCE/SEI 7-05, from a 2 percent in 50-year hazard level to a 1 percent in 50-year collapse risk target. This change is intended to improve seismic design by achieving a more uniform level of collapse prevention. The change affects the calculation and values of probabilistic ground motions, but not their use in the design process (i.e., 5 percent damped spectral response accelerations are still used). The technical basis of the change can be found in "Risk-Targeted versus Current Seismic Design Maps for the Conterminous United States" (Luco et al., 2007). A summary of the technical basis is provided below.

In the 1997, 2000 and 2003 editions of the *NEHRP Recommended Provisions*, the probabilistic MCE ground motions are defined as those that have a 2 percent probability of being exceeded in 50 years. In other words, the probabilistic MCE ground motions are of uniform hazard, both geographically and across structural vibration periods. It has long been recognized, however, that "it really is the probability of structural failure with resultant casualties that is of concern, and the geographical distribution of that probability is not necessarily the same as the distribution of the probability of exceeding some ground motion" (p. 296 of ATC 3-06, 1978).

The primary reason that the two probabilities are not the same is that there are geographic differences in the shape of the ground motion versus annual frequency of exceedance hazard curves from which uniform-hazard ground motions are read. The commentary of earlier editions of the *Provisions* (post-1997) reports that "because of these differences, questions were raised concerning whether definition of the ground motion based on a constant probability for the entire United States would result in similar levels of seismic safety for all structures" (p. 319 of the 2003 *NEHRP Recommended Provisions Commentary*). The change to risk-targeted ground motions uses the different shapes of hazard curves to adjust the uniform-hazard (2-percent-in-50-years) ground motions such that they are expected to result in a uniform annual frequency of collapse, or risk level, when used in design. The adjustment factors, or risk coefficients, are akin to the ASCE/SEI 43-05 site-specific design factor, which is a function of an approximate slope of the ground motion hazard curve.

The adjustments to the uniform-hazard ground motions are computed by making use of the so-called risk integral (e.g., McGuire, 2004). The risk integral calculates an annual frequency of collapse by coupling the ground motion hazard curve at a location with the expected performance of a structure designed for that location. More precisely, the hazard curves are coupled with the conditional probability of collapse as a function of the ground motion level. Earlier editions of the *Provisions* express the expectation that "if a structure experiences a level of ground motion 1.5 times the design level [i.e., the MCE ground motion], the structure should have a low likelihood of collapse" (p. 320 of the 2003 *NEHRP Provisions Commentary*). This "low likelihood of collapse" has been estimated as 10 percent (Applied Technology Council, 2009) using state-of-the-art incremental dynamic analysis (e.g., Vamvatsikos and Cornell, 2002) of structures designed in accordance with this edition of the *NEHRP Recommended Seismic Provisions* (2009). For the likelihood of collapse under other (than the MCE) ground motion levels, a so-called β-value of 0.8 has been used for the 2009 *Provisions*, based on both the findings of the Applied Technology Council (2009) and other past research. Other β-values ranging from 0.5 to 1.0 have been considered, with little effect on the resulting risk coefficients. The ground motion hazard curves used in the risk integral are from the USGS.

Using more subjective estimates of the conditional probability of collapse as a function of the ground motion level, and early (1976) hazard curves for only four locations, the authors of the resource document on which the *Provisions* are based (Applied Technology Council, 1978) used the risk integral to estimate the annual frequency of collapse of buildings designed for uniform-hazard ground motions (see ATC 3-06, p. 310-311). They found that "the probabilities of failure [i.e., risk levels] were roughly the same for each of the four buildings." In contrast, using contemporary hazard curves and building performance expectations, Luco et al. (2007) have found that the risk levels are systematically lower in the central and eastern United States (CEUS) than in the WUS due to well-documented differences in the shapes of ground motion hazard curves (e.g., Leyendecker et al., 2000). To result in uniform risk levels, adjustments to the uniform-hazard ground motions are needed.

The risk level targeted in these *Provisions* (2009) corresponds (approximately) to 1 percent probability of collapse in 50 years. This target is based on the average of the annual frequencies of collapse across the WUS that are expected to result from (as calculated via the risk integral) design for the probabilistic MCE ground motions in the 2003 *NEHRP Recommended Provisions*. Consequently, the requisite risk coefficients are generally within 15 percent of unity in the WUS (except in the coastal region of Oregon, where they are slightly smaller). In the CEUS, the risk coefficients are generally smaller, again due

to the well-documented differences in shapes of ground motion hazard curves there relative to the WUS. In the New Madrid seismic zone and near Charleston, South Carolina, in particular, the adjustments to the uniform-hazard ground motions are as small as a factor of 0.7. Compared to the underlying uniform-hazard ground motions, the risk coefficients are generally less sensitive to refinements of the ground motion hazard curves (e.g., USGS updates or site-specific analyses), since they depend on the shape but not amplitude of the hazard curves. They vary with the structural vibration period and site class, but not dramatically.

The change to risk-targeted probabilistic ground motions complements improvements to the basis for response modification factors (*R* factors) reflected in FEMA P-695 (Applied Technology Council, 2009) and provides a more rational basis for seismic design methods. As alluded to above, similar risk-based procedures are already being used for design and evaluation of nuclear facilities, as well as offshore structures.

C21.2.2 Deterministic Ground Motions. Deterministic ground motions should account for uncertainties associated with near-fault ground motions, particularly at longer periods, and necessitate a more statistically appropriate estimate of 5 percent damped spectral response accelerations than those based on the 150 percent of the median ground motions used in ASCE/SEI 7-05. The use of 84th percentile ground motions in these *Provisions* (2009) effectively requires increasing median ground motions by 180 percent. The technical basis of this change can be found in Huang et al. (2008a and 2008b). The authors found that 150 percent of the median spectral response accelerations of the new NGA relations (average of the three relations) to be significantly less than 84th percentile ground motions in the maximum direction of response. Near active sources (in the WUS), 84th percentile ground motion in the maximum direction of response is about 200 percent (1.8 x 110 percent) of 5 percent damped, short-period spectral response acceleration, and about 230 percent (1.8 x 130 percent) of 5 percent damped, 1-second spectral response acceleration of the new NGA relations for GMRotI50 (average value of the three NGA relations). Table C21.2-2 summarizes ratios of 84th percentile maximum direction to median geomean-direction response for periods from 0 to 4.0 seconds. Ratios for periods greater than 4.0 seconds are assumed to be the same as the ratio for 4.0 seconds.

Table C21.2-2 Ratios of 84th Percentile to Median Spectral Demands for NGA Relationships

		Period (seconds)					
		0.2	0.5	1.0	2.0	3.0	4.0
β	B-A	0.60	0.61	0.65	0.70	0.70	0.70
	C-B	0.59	0.59	0.62	0.64	0.65	0.65
	C-Y	0.61	0.63	0.63	0.67	0.67	0.70
y_{84} / y_{50}		1.82	1.84	1.89	1.95	1.96	1.98

Modification to Chapter 22, Seismic Ground Motion and Long-period Transition Maps

Replace existing Chapter 22 with the following:

Chapter 22
SEISMIC GROUND MOTION, LONG-PERIOD TRANSITION, RISK COEFFICIENT, AND MCE GEOMEAN PGA MAPS

Contained in this chapter are Figures 22-1 through 22-7, which provide the mapped uniform-hazard ground motion parameters (S_{SUH} and S_{1UH}), the mapped risk coefficients (C_{RS} and C_{R1}), the mapped deterministic ground motion parameters (S_{SD} and S_{1D}), and the mapped long-period transition period (T_L), for use in applying the seismic provisions of ASCE/SEI 7. Also contained in this chapter are Figures 22-8 through 22-11, which provide the mapped maximum considered earthquake geometric mean peak ground accelerations.

These maps were prepared by the United States Geological Survey (USGS) and have been updated for the 2009 edition of the *NEHRP Recommended Seismic Provisions for New Buildings and Other Structures*. Maps for Guam and Tutuila (American Samoa) are not included because uniform-hazard ground motion parameters, deterministic ground motion parameters, and risk coefficients have not yet been developed for those islands. Therefore, like in the 2005 edition of ASCE/SEI 7, the parameters S_S and S_1 defined in Section 11.4.3 shall be, respectively, 1.5 and 0.6 for Guam and 1.0 and 0.4 for Tutuila. The mapped maximum considered earthquake geometric mean peak ground accelerations shall be 0.6 for Guam and 0.4 for Tutuila.

The following is a list of figures contained in this chapter:

Figure 22-1 Uniform-hazard (2% in 50-year) ground motions of 0.2-second spectral response acceleration (5% of critical damping), Site Class B.

Figure 22-2 Uniform-hazard (2% in 50-year) ground motions of 1-second spectral response acceleration (5% of critical damping), Site Class B.

Figure 22-3 Risk coefficient at 0.2-second spectral response period.

Figure 22-4 Risk coefficient at 1-second spectral response period.

Figure 22-5 Deterministic ground motions of 0.2-second spectral response acceleration (5% of critical damping), Site Class B.

Figure 22-6 Deterministic ground motions of 1-second spectral response acceleration (5% of critical damping), Site Class B.

Figure 22-7 Long-period transition period, T_L (seconds).

Figure 22-8 MCE geometric mean PGA, %g, Site Class B for the coterminous United States.

Figure 22-9 MCE geometric mean PGA, %g, Site Class B for Alaska.

Figure 22-10 MCE geometric mean PGA, %g, Site Class B for Hawaii.

Figure 22-11 MCE geometric mean PGA, %g, Site Class B for Puerto Rico and the United States Virgin Islands.

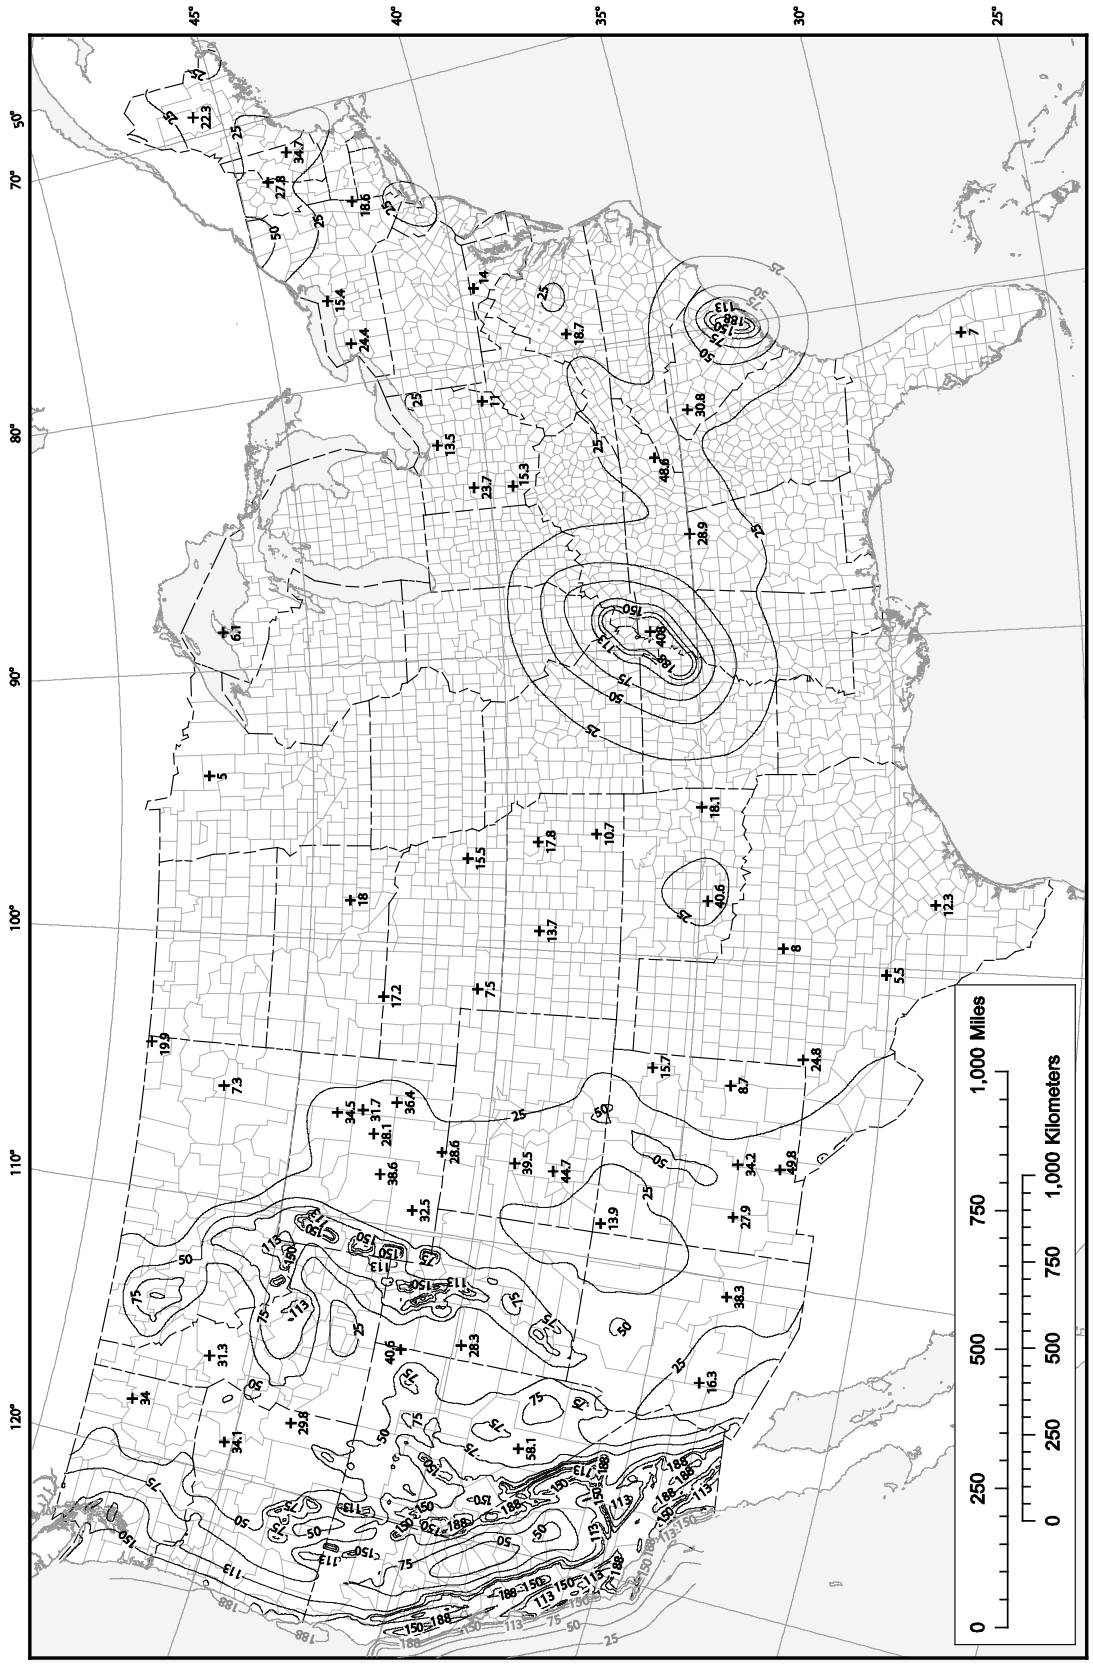

Figure 22-1 Uniform-hazard (2% in 50-Year) ground motions of 0.2-second spectral response Acceleration (5% of critical damping), Site Class B

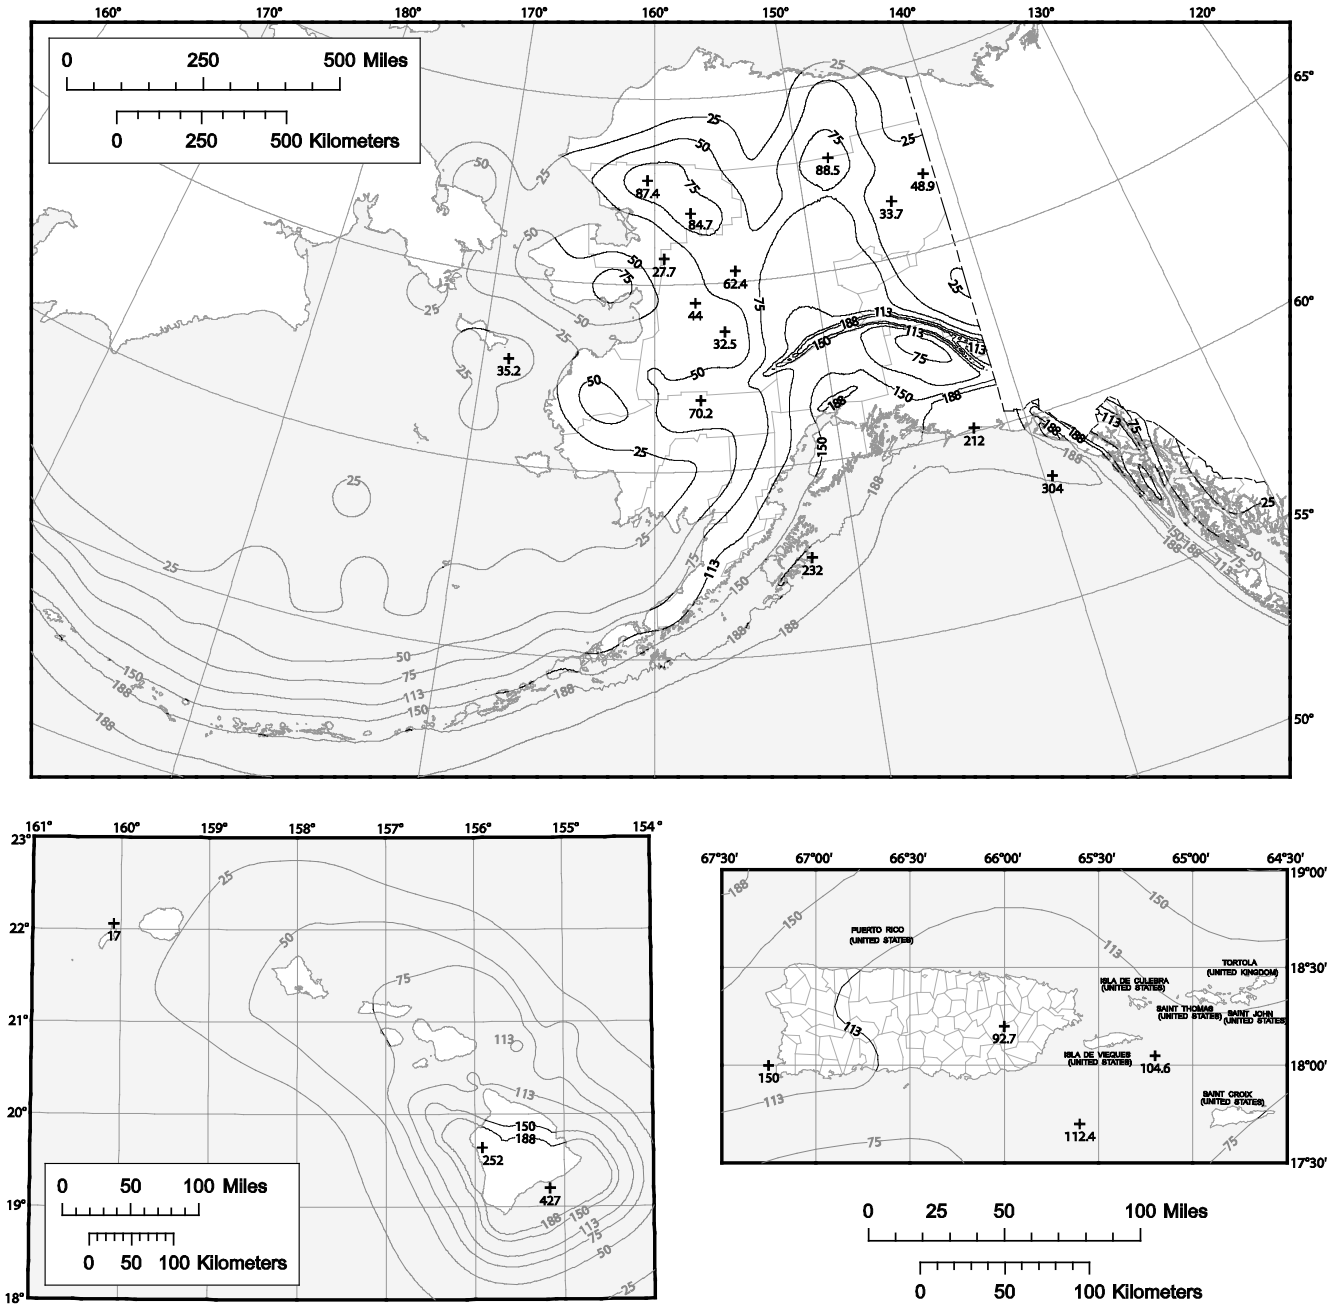

Contours and spot values are in units of %g

Notes:

- Maps prepared by United States Geological Survey (USGS).
- Ground motion values contoured on these maps are for the maximum direction of acceleration. As such, they are different (by a factor of 1.1) from those on the 2008 USGS National Seismic Hazard Maps posted at http://earthquake.usgs.gov/research/hazmaps/.
- Larger, more detailed versions of these maps are not included because it is recommended that the corresponding USGS web tool (http://earthquake.usgs.gov/designmaps/) be used to determine the mapped value for a specified location.

Commentary to New Chapter 22

Chapter 22 Commentary
SEISMIC GROUND MOTION, LONG-PERIOD TRANSITION,
RISK COEFFICIENT, AND MCE GEOMEAN PGA MAPS

The USGS has prepared the four new sets of maps for Chapter 22 of the 2009 *NEHRP Recommended Seismic Provisions*:

1. Maps of uniform-hazard (2 percent in 50-year) ground motions,
2. Maps of the risk coefficients for converting 2 percent in 50-year uniform-hazard ground motions to 1 percent in 50-year risk-targeted probabilistic ground motions,
3. Maps of deterministic ground motions (consistent with site-specific criteria of Section 21.2.2), and maps of peak ground accelerations for the evaluation of the potential for liquefaction and soil strength loss (according to Section 11.8.3).

Because this would have resulted in a substantial increase in the number of maps, the BSSC Provisions Update Committee recommended that the separate maps for regions of the United States and its territories that appeared in ASCE/SEI 7-05 be consolidated (for the uniform-hazard ground motion, risk coefficient, and deterministic ground motion maps), into the single figures in Chapter 22. Thus, the total number of map figures (11) in these *Provisions* (2009) is less than that in ASCE/SEI 7-05 (i.e., 20). Because the consolidated map figures are relatively small and difficult to read, the USGS website that automates use of the maps and formulas will be especially useful (http://earthquake.usgs.gov.designmaps/usapp).

As described in the commentary to Chapter 21 and below, the uniform-hazard and deterministic ground motion maps in Chapter 22 of these *Provisions* (2009) represent response in the maximum direction. The USGS has developed these maps based on "geomean" ground motions (the product of hazard assessment using modern ground motion attenuation functions), adjusted using constant factors that transform geomean response to maximum direction response. The same factors (i.e., 1.1 at short-periods and 1.3 at a period of 1 second) are used for all seismic regions (i.e., both the central and eastern United States or CEUS and the western United States or WUS) and for both probabilistic and deterministic ground motions.

In contrast, the peak ground acceleration maps in Chapter 22 represent geomean ground motions, as described below. Furthermore, the peak ground acceleration maps represent the lesser of uniform-hazard (2 percent in 50-year) and deterministic peak ground accelerations, without consideration of corresponding risk coefficients.

Uniform-Hazard (2 Percent in 50-Year) Ground Motion Maps

The uniform-hazard maps in Chapter 22 of these *Provisions* (2009) are based on the 2008 USGS National Seismic Hazard Maps (http://earthquake.usgs.gov/hazmaps); however, since the ground motion values on the uniform-hazard maps are for the maximum direction of acceleration (as explained above), they are different from the “geomean” USGS maps. The 0.2-second and 1-second spectral response acceleration uniform-hazard maps are different by a factor of 1.1 and 1.3 from the respective USGS maps. Development of the USGS maps is documented in Petersen et al. (2008).

Risk Coefficient Maps

Development of risk coefficients and related work by the USGS is documented by Luco et al. (2007). The risk coefficient maps indicate that, in general, risk-targeted probabilistic ground motions (based on 1 percent in 50-year collapse risk) would moderately decrease the uniform-hazard ground motions (based on 2 percent in 50-year hazard) in high-hazard areas of the CEUS and the coastal region of Oregon (by as much as 30 percent) and either slightly increase or decrease the uniform-hazard ground motions in the WUS and remaining areas of the maps (by less than 15 percent). These changes do not affect calculation of deterministic ground motions, which often govern in high seismic areas.

Deterministic Ground Motion Maps

The deterministic maps in Chapter 22 of the *Provisions* represent the greater of 84th percentile (maximum direction) response and the “water level” values described in the next paragraph. The USGS has developed these maps based on median "geomean" ground motions (the product of hazard assessment using modern ground motion attenuation functions) adjusted using factors that transform median geomean-direction response to 84th percentile maximum-direction response. The same factors (i.e., 1.1 x 1.8 at short-periods and 1.3 x 1.8 at a period of 1 second) are used for all seismic regions (i.e., both the CEUS and WUS regions).

As defined in ASCE/SEI 7-05 Section 21.2.2, the deterministic spectral response accelerations (for Site Class B) shall not be taken as lower than 1.5g for the short periods and 0.6g for the 1-second period; hence, the ground motions on the deterministic maps (Figures 22-3 and 22-4) are no lower than these values. Otherwise the ground motions on the deterministic maps are 180 percent (as opposed 150 percent in ASCE/SEI 7-05) of median spectral response accelerations,

for reasons explained above in the commentary to Chapter 21. Like the uniform-hazard maps described above, the deterministic maps represent the spectral response acceleration in the maximum direction.

Peak Ground Acceleration Maps

Unlike the uniform-hazard and deterministic ground motion maps described above, the peak ground acceleration maps in Chapter 22 of the *Provisions* represent geometric mean ground motions (not response in the maximum direction). Despite representing geometric mean ground motions, the peak ground acceleration maps are different from the 2008 USGS National Seismic Hazard Maps (http://earthquake.usgs.gov/hazmaps) upon which they are based. This is because they represent the lesser of uniform-hazard (2 percent in 50-year hazard) and deterministic peak ground accelerations. Development of the uniform-hazard peak ground accelerations is documented in Petersen et al. (2008). The deterministic peak ground accelerations are calculated as the greater of 180 percent of median ground motions and a water level of 0.6g, Note that risk coefficients are not included in the development of the peak ground acceleration maps, which is why they are referred to as "maximum considered earthquake geometric mean peak ground acceleration" maps without the "risk-targeted" prefix.

New Chapter 23, Vertical Ground Motions for Seismic Design

Add the following new Chapter 23 and renumber the existing ASCE/SEI 7-05 Chapter 23 as Chapter 24:

Chapter 23
VERTICAL GROUND MOTIONS FOR SEISMIC DESIGN

23.1 DESIGN VERTICAL RESPONSE SPECTRUM. Where a design vertical response spectrum is required by these *Provisions* and site-specific procedures are not used, the design vertical response spectral acceleration, S_{av}, (in g – gravity unit) shall be developed as follows:

1. For vertical periods less than or equal to 0.025 second, S_{av} shall be determined in accordance with Equation 23.1-1 as follows:

$$S_{av} = 0.3C_V S_{DS} \quad (23.1\text{-}1)$$

2. For vertical periods greater than 0.025 second and less than or equal to 0.05 second, S_{av} shall be determined in accordance with Equation 23.1-2 as follows:

$$S_{av} = 20C_V S_{DS}(T_V - 0.025) + 0.3C_V S_{DS} \quad (23.1\text{-}2)$$

3. For vertical periods greater than 0.05 second and less than or equal to 0.15 second, S_{av} shall be determined in accordance with Equation 23.1-3 as follows:

$$S_{av} = 0.8C_V S_{DS} \quad (23.1\text{-}3)$$

4. For vertical periods greater than 0.15 second and less than or equal to 2.0 seconds, S_{av} shall be determined in accordance with Equation 23.1-4 as follows:

$$S_{av} = 0.8C_V S_{DS}\left(\frac{0.15}{T_V}\right)^{0.75} \quad (23.1\text{-}4)$$

where C_V is defined in terms of S_S in Table 23.1-1, S_{DS} = the design spectral response acceleration parameter at short periods, and T_V = the vertical period of vibration.

Table 23.1-1 Values of Vertical Coefficient C_V

MCE_R Spectral Response Parameter at Short Periods [a]	Site Class A, B	Site Class C	Site Class D, E, F
$S_S \geq 2.0$	0.9	1.3	1.5
$S_S = 1.0$	0.9	1.1	1.3
$S_S = 0.6$	0.9	1.0	1.1
$S_S = 0.3$	0.8	0.8	0.9
$S_S \leq 0.2$	0.7	0.7	0.7

[a] Use straight-line interpolation for intermediate values of S_S .
