The EIR/EIS states that "former industrial, commercial, and military activities in the region have resulted in soil and groundwater contamination from spills, leaking underground tanks, unlined chemical disposal sites, and inadvertent disposal of chemicals". The EIR/EIS also concludes that "within the CEMEX area, the NMGWM projects that groundwater elevations could decrease and that decrease could incrementally affect groundwater flow directions. If there are nearby inland sites that are remediating contaminated groundwater in the same aquifers and that are located within the radius of influence of the slant wells, then the pumping of the slant wells could potentially interfere with those remediation activities, pulling contaminated groundwater into currently uncontaminated areas and degrading the existing water quality. This would violate the state policy of maintaining the existing water quality. A significant impact would occur if the proposed project created a condition that would violate water quality standards or otherwise degrade water quality." However, the EIR/EIS makes no mention of the contaminants found in the local aquifer. At a minimum, the environmental impacts analysis should 1) identify possible sources of the contaminants, including any known plumes that may migrate toward the slant wells, 2) discuss relevant water quality screening values, 3) analyze the impacts of the contaminants on the source water, and 4) discuss the potential for the contaminants to concentrate in brine, and, if so, any potential adverse impacts to marine life from the brine disposal. Additionally, the Cemex Lapis Sand Plant, which has been in operation since 1906, is a potential source of groundwater contamination that is not addressed in the EIR/EIS.

ERF-12 cont.

ERF-13

The EIR/EIS Table 4.7-1 incorrectly appears to incorrectly identify the Fort Ord Operable Unit 1 as "Closed – Groundwater cleanup completed". According to the State Water Resources Control Board GeoTracker database, Operable Unit 1 (OU1) is the Fritzsche Army Airfield Fire Drill Area site. It originally consisted of a groundwater plume (primarily TCE) and some source area soil contamination (primarily TCE). The soil contamination has been successfully remediated, leaving only the groundwater plume. Since identification of an off-site (outside the former Ft. Ord boundaries) portion of the groundwater plume in 2005, this plume is typically defined as consisting of two parts: the on-site and off-site portions. See, https://geotracker.waterboards.ca.gov/profile_report.asp?global_id=DOD100220600

ERF-14

The EIR/EIS states that "[r]outine backwashing of the pretreatment filters would occur each day. Backwashing the pretreatment filters would require that a chlorine solution (sodium hypochlorite, similar to bleach) be added to the backwash water supply to control bacterial growth on the filters. . . [a]pproximately 0.4 million gallons per day (mgd) of decanted backwash water may be pumped to the Brine Discharge Pipeline, blended with brine produced by the RO system, and discharged to the existing MRWPCA ocean outfall. The volume of sodium hypochloride to be used, its likely concentrations in discharge water and potential adverse impacts to the marine environment are not adequately addressed.

ERF-15

Additional Flaws in the Analysis of Biological Impacts

The EIR/EIS does not disclose that California fully protected species are present in the study area, nor consider the impacts of the Project on these species. The EIR/EIS entirely fails to consider the impacts of the Project on the fully protected California Brown Pelican. Calif. Fish & Game Code §3511. The California Brown Pelican roosts in the Monterey Bay National Marine Sanctuary. Nor does the EIR/EIS disclose that the Pacific right whale, the northern elephant seal (Mirounga angustirostris), and Southern sea otters (Enhydra lutris nereis) are California fully protected mammals. Calif. Fish & Game

ERF-16

Code §4700. The EIR/EIS does not consider whether the Project violates their California fully protected species status. The EIR/EIS also fails to discuss potential impacts to dungeness crab, a species with high ecological and regional economic importance.

There could be unanticipated effects on benthic and pelagic communities in the vicinity of the discharge, or on individual members of protected species that feed, pass through or otherwise spend time in high brine concentration areas near the Facility's outfall. Yet, there is insufficient discussion and support for findings regarding impacts of elevated brine concentrations on these animals and their food sources.

ERF-16 cont.

The EIR/EIS Fails to Adequately Analyze the Potential Adverse Impacts on Snowy Plovers

A portion of the Project will occur on land currently used by the western snowy plover, a threatened species under the federal Endangered Species Act (ESA). Due to significant concerns with the Project detailed in the below comments, we urge the Commission to modify Project approval for the following reasons:

• The Commission has failed to meet its obligations under state and federal law by not analyzing all Project impacts on the plover, including slant well maintenance and operational activities, permanent loss of western snowy plover habitat, beach erosion, sea level rise and cumulative impacts from neighboring property.

• The Project, as currently proposed, will result in the likely take of the threatened western snowy plover, which is an important coastal natural resource. Because mitigation measures are likely insufficient to avoid take of listed species caused by construction and operation of the Project, CalAm needs to prepare a Habitat Conservation Plan (HCP) in support of an application for an Incidental Take Permit to avoid liability under the Endangered Species Act (ESA).

ERF-17

Endangered Species Act

The Endangered Species Act (ESA) affords broad protections to threatened and endangered species. The ESA is "the most comprehensive legislation for the preservation of endangered species ever enacted by any nation."[16] Its fundamental purposes are "to provide a means whereby the ecosystems upon which endangered species and threatened species depend may be conserved [and] to provide a program for the conservation of such endangered species and threatened species . . . ."[17]

To achieve these objectives, the ESA directs the USFWS to determine which species of plants and animals are "threatened" and "endangered" and place them on the list of species afforded protection under the ESA.[18] An "endangered" species is one "in danger of extinction throughout all or a significant portion of its range," and a "threatened" species is "likely to become endangered in the near future throughout all or a significant portion of its range."[19] Once a species is listed, the ESA provides

16 *Tennessee Valley Auth. v. Hill* ("Hill"), 437 U.S. 153, 180 (1978).
17 16 U.S.C. § 1531(b).
18 16 U.S.C. § 1533.
19 *Id*. at §§ 1532(6), (20).

a variety of procedural and substantive protections to ensure not only the species' continued survival, but also its ultimate recovery. The Supreme Court has noted that "Congress has spoken in the plainest words, making it clear that endangered species are to be accorded the highest priorities."[20]

Section 9 of the ESA prohibits any "person" from "taking" or causing take of any member of an endangered species.[21] This take prohibition also applies to threatened species such as the western snowy plover.[22] The term "take" is defined broadly, need not be lethal, and includes to "harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect" or cause another to do so.[23] The USFWS has further defined "harass" to include "an intentional or negligent act or omission which creates the likelihood of injury to wildlife by annoying it to such an extent as to significantly disrupt normal behavioral patterns, including breeding, feeding, or sheltering."[24] In addition, "harm" is defined to "include significant habitat modification or degradation where it actually kills or injures wildlife by significantly impairing essential behavioral patterns, including breeding, feeding or sheltering."[25]

The ESA's legislative history supports "the broadest possible" reading of the prohibition against take.[26] "Take" includes direct as well as indirect harm and need not be purposeful.[27] Present or future harms qualify as take: "an imminent threat of harm . . . falls easily within the broad scope of Congress' definition of 'take.'"[28]

The ESA authorizes private enforcement of the take prohibition through a broad citizen suit provision. "[A]ny person may commence a civil suit on his own behalf to enjoin any person, including . . . any . . . governmental instrumentality or agency . . . who is alleged to be in violation of any provision of [the ESA] . . . ."[29] Citizens may seek to enjoin both present activities that constitute an ongoing take and future activities that are reasonably likely to result in a take.[30] Courts have held that "the language and legislative history of the ESA, as well as applicable case law, support our holding today that a showing of a future injury to an endangered or threatened species is actionable under the ESA [citizen suit provisions]."[31] 50 F.3d at 783. Upon a showing of "imminent threat of injury to wildlife," the injury requirement of the Secretary's definition of "take" and "harm" would be satisfied.[32] The ESA's citizen suit provision also provides for the award of costs of litigation, including reasonable attorney and expert witness' fees.[33]

33 16 U.S.C. § 1540(g)(4).

Under section 10 of the ESA, a non-federal entity such as a developer can avoid potential liability for taking a threatened species by obtaining an incidental take permit.[34] In exchange for permission to "take" a listed species pursuant to an ITP, the permit applicant must commit to implement a plan that "conserv[es]" – *i.e.*, facilitates the recovery of – the species.[35] This plan is called a Habitat Conservation Plan and it must delineate "the impact which will likely result from such taking" and the "steps the applicant will take to minimize and mitigate such impacts . . . ."[36]

Snowy Plover Background

The western snowy plover (*Charadrius nivosus nivosus*) is one of the least numerous shorebirds in North America and the Pacific coast population of the western snowy plover was federally listed as threatened in 1993.[37] Historically, thousands of western snowy plovers nested along the California coast.[38] However, by 1980, the western snowy plover had disappeared from significant parts of its coastal California breeding range, and biologists estimate the breeding population along the coast has now dwindled to less than 1,500 birds.[39]

The population has continued to decline despite publication of the recovery plan and protection under the ESA. Habitat degradation – often from beach-front recreation and development – has caused the western snowy plover's population to decline over the past century.[40] Because western snowy plover habitat consists of unstable sandy shorelines, it is "highly susceptible to degradation by construction of seawalls, breakwaters, jetties, piers, homes, hotels, parking lots, access roads, trails, bike baths, day-use parks, marinas, ferry terminals, recreational facilities, and support services." [41] Unstable coastal habitat also makes western snowy plovers vulnerable to climate change, since sea level rise and erosion decrease their habitat area.[42]

ERF-17 cont.

Insufficient Analysis of Impacts to Snowy Plover

The EIR/EIS insufficiently examines the impacts of the Project on the snowy plover. First, the Project will significantly reduce important western snowy plover habitat along the shoreline of Monterey Bay, including historic nesting and foraging habitat on and immediately adjacent to the Project site.

As the EIR/EIS recognizes, impacts from construction of the nine subsurface slant wells and conversion of the test well to a permanent well "would be significant." EIR/EIS 4.6-129. The nine acre construction footprint for the wells is located within potential nesting habitat and the construction would result in the temporary loss of eight acres and the permanent loss of one acre of potential wintering habitat. In addition, "construction noise and vibration, earthmoving activities, vegetation clearance, and nigh lighting associated with installation of the [wells] . . . could also impact plovers by causing temporary flight of breeding birds, nest abandonment, or nest failure." *Id*. "Human presence and construction noise and activities" would be a significant impact. *Id.* at 4.6-130. In addition to the direct impacts of the Project that reduce western snowy plover habitat, sea level rise and erosion linked to climate change will also contribute to reduction of plover habitat.

The EIR/EIS states that mitigation measures, such as construction during non-breeding season and other avoidance techniques, will reduce impacts to the western snowy plover to below the level of significance. *See* Mitigation Measure 4.6-1d: Protective Measures for Snowy Plover. However, even if this is true for construction activities, the EIR/EIS inadequately evaluates the impacts to plovers during maintenance and operational activities. Because anthropogenic disturbance is the primary threat to the western snowy plover, numerous biologists have concluded that protecting occupied sites from human disturbance and associated domestic animals may be essential to the conservation and recovery of the species.[43] Operational and maintenance activities have the potential to cause significant impacts and must be more closely examined.

ERF-18 cont.

As the EIR/EIS states, continual disturbance of this six-acre slant well site for maintenance purposes "may preclude plovers from nesting in this location in the future." EIR/EIS 4.6-235. "Therefore, this would be a permanent loss of up to 6 acres of western snowy plover habitat." *Id.* However, unlike the discussion of mitigation measures to be adopted for construction activities, the EIR/EIS limits mitigation resulting from maintenance activities to restoration actions beyond the Project site. "Permanent loss of western snowy plover habitat will be compensated, at a minimum ratio of 2:1, or as otherwise negotiated with USFWS, through actions to enhance existing degraded habitat." EIR/EIS 4.6-170. The EIR/EIS does not attempt to analyze mitigation measures that could be taken on-site to reduce take of endangered plovers. Nor is there a discussion on whether enhancement of degraded habitats would fully compensate for the loss of the six acres lost due to Project activities.

In addition, the EIR/EIS fails to examine the operational impacts of the Projects, and the slant wells in particular, to snowy plovers. While the simultaneous operation of the 10 wells pumps "would generate a noise level of approximately 66 dBA at 50 feet," and 57 dBA at 150 feet, the EIR/EIS concludes that the pumps would not impact plovers at the site. However, plovers may be significantly closer than 50 feet away from the well pumps, and the examples the EIR/EIS uses to justify the cumulative impacts are not persuasive. For example, while crashing waves of the Pacific Ocean may register at 57 dBA at 300 feet, and machinery and mining vehicles associated with CEMEX operations register at 85 dBA at 50 feet, and there is noise associated with traffic on Highway 1, the impacts from noise sources may be as much related to proximity as they are decibel level, and there is no analysis in the EIR/EIS which suggests that snowy plovers could tolerate yet another source of anthropogenic noise. Just because the

ERF-19

43 United States Fish and Wildlife Service. 2007. Recovery Plan for the Pacific Coast Population of the Western Snowy Plover *(Charadrius alexandrinus nivosus).* Sacramento, California. xiv + 751. *See also* Brindock KM, MA Colwell. 2011. Habitat Selection by Western Snowy Plovers During the Nonbreeding Season. Journal of Wildlife Management 75(4):786-793.

"noise level from pump operations would be less than the combination of these existing sources" does not mean that pump noises would have no impact – if anything, the cumulative effects of these noise sources in combination with the new pumps may drive plovers away from the site. EIR/EIS 4.6-237. These cumulative effects from the pumps and neighboring properties must be considered in the analysis of noise impacts. Additionally, the EIR/EIS fails to analyze the potential impacts on snowy plovers from the vibrations caused by the well pumps. ERF-19 cont. ERF-20

CalAm Must Prepare a Habitat Conservation Plan

As a result of the activities associated with the slant wells and pumps, the incidental take of snowy plovers is highly likely. To comply with the mandates of the ESA, CalAm must prepare a HCP in support of an application for an Incidental Take Permit (ITP) to avoid liability under the ESA.

Incidental take of a snowy plover is likely to occur as a result of habitat displacement, construction and maintenance activities, and operation noise and vibrations from the well pumps. Not only will the Project permanently and temporarily remove habitat from plover use, but the impacts of the Project in combination with other neighboring uses, in addition to the ongoing threats of sea level rise and beach erosion, will harm the plover and contribute to its population decline. Because "take" is broadly defined to "include significant habitat modification or degradation where it actually kills or injures wildlife by significantly impairing essential behavioral patterns, including breeding, feeding or sheltering," and the mitigation measures proposed are unlikely to bring impacts to a less-than-significant level, resulting in take in the form of harm and harassment, CalAm must fulfill its obligations under the ESA Section 10 and apply for an ITP. 16 U.S.C. § 1539(a)(1)(B). ERF-21

The Analysis of Cumulative Marine Biological Impacts is Flawed.

CEQA Guideline 15130(b)(3) requires an EIR to define the geographic scope of the area affected by the cumulative effect and provide a reasonable explanation for the geographic limitation used.

There is no explanation of why the geographic area (north of Moss landing Harbor south to the northern limits of Sand City) is chosen, nor why the "area within 5 miles of shore" is chosen. EIR/EIS 4.5-67. ERF-22

The EIR/EIS posits a 2 step filter for whether projects are considered as part of the cumulative marine impact analysis: projects (1) within the [unexplained] geographic scope and (2) whose impacts could overlap with those of the Project. This second step - impacts which overlap - is not an approach explained in the EIR/EIS, nor sanctioned by CEQA or NEPA, and therefore appears improper. Further, the EIR/EIS seems to exclude projects characterized as having "very localized construction impacts," without any rationale or explanation why. ERF-23

The EIR/EIS improperly excludes from the cumulative marine impact analysis the City of Sand City Coastal Desalination Project (No. 6) which will utilize four seawater extraction wells. ERF-24

The EIR/EIS also improperly excludes the 90-inch Bay Avenue Outfall Phase I (No. 43) which will discharge and breach the sand bar periodically. ERF-25

In identifying potential cumulative growth-inducing effects, the EIR/EIS states that "[s]everal of the planned future cumulative projects identified in Table 4.1-2 would provide new sources of potable water supply in Monterey County. The Monterey Bay Regional Water Project (DeepWater Desal) (No. 34) would provide water to the City of Salinas as well as parts of Santa Cruz County. If both the MPWSP and DeepWater Desal were approved, water from DeepWater Desal could be used to support growth in other nearby areas such as northern Monterey County." Yet the EIR/EIS improperly excludes from the cumulative marine impact analysis the Peoples' Moss Landing Desal Project. The EIR/EIS states the Peoples' Moss Landing Water Desal Project and the proposed Project "would not both be implemented to serve the same customers." EIR/EIS 4.1-21. The Draft Process Design Report for The People's Moss Landing Water Desal Project does not so limit the People's Desal Project or mention the Monterey Peninsula Water Supply Project. ERF-26

Similarly, the EIR/EIS states that "it is expected that either the DeepWater Desal Project (No. 34) or The Peoples' Moss Landing Desal Project (No. 57), but not both, would be constructed and operated in the reasonably foreseeable future." EIR/EIS 4.5-70. The Draft Process Design Report for The People's Moss Landing Water Desal Project does not support this asserted limitation. It is not certain if multiple desalination sites will or will not be constructed, but because they have also begun their CEQA environmental review processes, they are legitimate and "reasonably foreseeable and probable future" projects that need to be considered. Combined, the impacts from the Cal Am project and these other proposed sites may be "considerable…or…increase other environmental impacts. CEQA Guidelines, § 15355.

In fact, it appears that the EIR/EIS has focused on the DeepWater Desal Project to the exclusion of The Peoples' Moss Landing Desal Project because "the DeepWater Desal is the largest of the other two desal projects and further along in environmental review." EIR/EIS 4.5-67-68. This "larger and farther along" approach for excluding projects from cumulative analysis is not condoned by CEQA or NEPA.

By excluding The People's Moss Landing Water Desal Project, the EIR/EIS has not considered the People's open bay seawater collection and brine discharge in its cumulative marine impact analysis. ERF-27

The EIR/EIS appears to individually consider the other projects (No. 31, 35, 47, and 34) "in the evaluation of the proposed project," but fails to consider the Project **in combination with** all of these projects. For example, the EIR/EIS states that the "test slant well (No. 47) was considered in the evaluation of the proposed project." Separately, the RUWAP Recycled Water Element (No. 35) was considered "in combination with the proposed project," but not in combination with all of the identified projects. ERF-28

In considering the RUWAP Recycled Water Element (No. 35), the EIR/EIS appears to improperly terminate any consideration of whether cumulative impacts would be significant after stating that the "RUWAP Recycled Water Element in combination with the proposed project would be **within the range** analyzed under Impact 4.5-4; that impact was determined to be less than significant." This "within the range" approach contradicts CEQA - which defines cumulative impacts as the change in ERF-29

the environment resulting "from the incremental impact of the project when added to other closely related past, present, and reasonably foreseeable probable future projects. Cumulative impacts can result from individually minor but collectively significant projects taking place over a period of time." CEQA Guideline 15355, subd. (b). Simply because the project specific impacts were insignificant does not mean that the cumulative impacts will be insignificant, nor that the Project impacts will not make a considerable contribution to cumulative impacts.

Further, the EIR/EIS fails to disclose which Impact 4.5-4 "range" it is referring to. The reader does not know if the EIR/EIS is referring to impingement of marine organisms, entrainment, to impingement of fine organic matter, salinity, dissolved oxygen, or some other criteria. This is important information. Salinity effects, for example, are species-specific. Within the Zone of Initial Dilution, the EIR/EIS admits that areas could be unsuitable for spawning of squid as a result of the Project alone. EIR/EIS 4.5-60.

ERF-29 cont.

The EIR/EIS repeatedly avoids consideration of cumulative impacts by improperly relying on findings of Project-specific insignificance determinations. Cumulative impacts can result from individually minor but collectively significant projects taking place over a period of time. CEQA Guideline 15355, subd. (b). Simply because the Project-specific impacts were insignificant does not mean that the cumulative impacts will be insignificant nor that the Project impacts will not make a considerable contribution to cumulative impacts.

ERF-30

The cumulative **construction** impacts discussion is flawed as it only considers the impacts of construction of the Monterey Peninsula Water Supply Project. The cumulative construction impacts discussion is further flawed because while the EIR/EIS acknowledges potential impacts from release of drilling fluids, it does not consider the cumulative impacts from such releases.

ERF-31

In considering the cumulative salinity impacts of the DeepWater Desal project, the EIR/EIS improperly considers only "the two projects," (EIR/EIS p. 4.5-69), not the cumulative impacts of these two projects with all other reasonably foreseeable projects.

ERF-32

The EIR/EIS is flawed as it minimizes the cumulative salinity impacts based on "the distance between the DeepWater Desal proposed outfall and the existing outfall proposed for use by the MPWSP (i.e., 31,511 feet; 9,605 meters) leads to the determination that there is no expectation of the two BMZs [brine mixing zones] reaching each other or intermixing discharge waters." The 2012 Science Advisory Panel technical report prepared for the California Water Resources Control Board, entitled "Management of Brine Discharges to Coastal Waters" explains that "brine mixing zone" may be too myopic a focus and suggests that brine "far field" impacts should also be consider. The paper explains at section 6.1 that

> It is important to understand the distinctions between near field, mixing zones, and other related terms that are often associated with wastewater discharges. These are discussed further in Appendix D. The near field is a hydrodynamic, or physical, concept. It is the region where mixing of the effluent is influenced and affected by

ERF-33

> discharge parameters. The physical processes are primarily entrainment caused by shear between the buoyant jet (either positively or negatively buoyant), an internal hydraulic jump where the plume impacts a boundary (e.g., sea floor) or water surface and transitions to horizontal flow, and entrainment in the horizontally spreading layer. The near field ends where the self-induced turbulence collapses under the influence of the induced density stratification. **The layer then spreads as a density current of some finite thickness.** Ultimately, ambient diffusion due to oceanic turbulence is responsible for most mixing and dilution; this region is known as the far field. **The rate of mixing and dilution in the far field is much slower than in the near field**. A mixing zone is a regulatory concept that will generally encompass most, or all, of the near field.

ERF-33 cont.

Appendix D of that same paper explains that "the mixing zone may not correspond to actual physical mixing processes."

The EIR/EIS Does Not Sufficiently Address the Project's Energy Use or Cumulative Impacts from Greenhouse Gas Emissions

The high energy requirements of desalination contribute to climate change and ocean acidification, using desalination is a tradeoff of a short-term water problem for a long-term climate disruption. Action to address climate change has become ever more urgent with each passing day. The federal government confirmed that 2014 was the hottest year ever recorded. (NASA 2015.) In the National Climate Assessment released by the U.S. Global Change Research Program, experts make clear that "reduc[ing] the risks of some of the worst impacts of climate change" will require "aggressive and sustained greenhouse gas emission reductions" over the course of this century (Melillo, 2014.) California has a mandate under AB 32 to reach 1990 levels of greenhouse gas emissions by the year 2020, equivalent to approximately a 15 percent reduction from a business-as-usual projection. (Health & Saf. Code § 38550.) The state Legislature has found that failure to achieve greenhouse gas reduction would be "detrimental" to the state's economy. (Health & Saf. Code § 38501(b).) Most recently, Governor Brown issued Executive Order B-30-15 establishing that California must reduce greenhouse gas emissions 40 percent below 1990 levels by 2030 to avoid major climate disruptions, resulting in such impacts as increased temperatures and wildfires, and a reduction in snowpack and precipitation levels and water availability.

ERF-34

Although some sources of greenhouse gas emissions may seem minor, climate change is a problem with cumulative impacts and effects. (*Ctr. for Biological Diversity v. Nat'l Highway Traffic Safety Admin.*, (9th Cir. 2008) 538 F.3d 1172, 1217 ("the impact of greenhouse gas emissions on climate change is precisely the kind of cumulative impacts analysis" that agencies must conduct).) One source or one small project may not appear to have a significant effect on climate change, but the combined impacts of many sources can drastically damage California's climate as a whole. Therefore, CEQA and NEPA require that an EIR/EIS fully disclose and analyze a project's greenhouse gas emissions and contribution to climate change and ocean acidification, including both direct and indirect impacts. (CEQA Guidelines, § 15064.)

Desalination facilities are notorious energy hogs. The EIR/EIS notes the facility would result in "long-term high energy consumption of substantial amounts of electricity, including electricity produced from non-renewable resources." The reverse osmosis process to remove the salt from seawater

involves passing the water through a series of filters at very high pressures which, at such a large scale of production, requires an enormous amount of energy. The proposed slant well subsurface intake technology will require even more energy to haul source water into the facility. In both economic and environmental terms, the desalination process is costly.

Although the desalination process would not itself emit greenhouse gases, the high energy use means a high consumption of fossil fuels and extensive environmental impacts associated with their use. The greenhouse gas emissions associated with increased consumption of fossil fuels may actually contribute to water shortages,[44] and thus solidify desalination as only a temporary fix and actually counter-productive in the long-run. The project will produce significant and unavoidable impacts even with mitigation on climate change and emissions.[45]

Energy intensive desalination may make sense to combat water shortages in certain areas of the world, where population already vastly exceeds available water resources because the cost of "the energy and CO2 for desalination [is] comparable to current values obtained from importing water hundreds of miles overland"[46] but this is not the case in Northern California, and is certainly not the case here, where the desalination facility is specifically sized to service future development and population growth.

ERF-34 cont.

CEQA requires that an EIR to discuss cumulative impacts of a project when the project's incremental effect is cumulatively considerable. CEQA Guideline 15130, subd. (a). The EIR/EIS determines that the Project's greenhouse gas effect is cumulatively considerable, but fails to properly discuss the cumulative impacts. This EIR improperly focuses solely on construction and operational impacts of the Project alone - without consideration of the greenhouse gas effect of the Project **in combination with** past, present and reasonably foreseeable project. By definition, the "cumulative impact from several projects is the change in the environment which results from the incremental impact of the project when added to other closely related past, present, and reasonably foreseeable probable future projects." CEQA Guideline 15355, subd. (b).

Further, CEQA requires that the discussion of cumulative impacts reflect the severity of the impacts and their likelihood of occurrence. CEQA Guideline 15130(b). The Draft EIR contains no discussion of the severity of the cumulative greenhouse gas impacts.

The DEIR/DEIS Fails in its Assessment Growth Inducing Impacts

To comply with CEQA, an EIR must discuss the ways in which the proposed project could affect economic or population growth in the vicinity of the project and how the characteristics of the project could result in other activities with adverse impacts to the environment [CEQA Guidelines Section 15126.2(d)].

ERF-35

Specifically, CEQA Guidelines Section 15126.2(d) states that an EIR must:

44 Dickie, Phil, Making Water: Desalination: Option or Distraction for a Thirsty World?, June 2007.
45 Draft Environmental Impact Report for the Monterey Peninsula Water Supply Project, State of California Public Utilities Commission, 2015:4.11-15.
46 Reeb, Carol, Letter to State Water Board Members, April 5, 2012.

> "Discuss the ways in which the proposed project could foster economic or population growth, or the construction of additional housing, either directly or indirectly, in the surrounding environment. Included in this are projects, which would remove obstacles to population growth (a major expansion of a wastewater treatment plant might, for example, allow for more construction in service areas). Increases in the population may tax existing community service facilities, requiring construction of new facilities that could cause significant environmental effects. Also discuss the characteristic of some projects which may encourage and facilitate other activities that could significantly affect the environment, either individually or cumulatively. It must not be assumed that growth in any area is necessarily beneficial, detrimental, or of little significance to the environment"

Economic growth refers to the extent to which a proposed project could cause increased activity in the local or regional economy. Economic and population growth can be induced in a number of ways, including through the elimination of obstacles to growth, or through the stimulation of economic activity. Elimination of obstacles to growth refers to the extent to which a proposed project removes infrastructure limitations or removes regulatory constraints that could result in growth. For example, an increase in the capacity of utility or road infrastructure that is installed as part of the proposed project could allow either new or additional development in the surrounding areas. Increases in the population may tax existing community service facilities, requiring new facilities, the construction of which could cause potentially significant environmental impacts.

This is clearly the case in the Monterey Bay Area, which currently suffers from traffic congestion, overcrowded schools, depleted water basins, urban and industrial stormwater pollution, and overtaxed wastewater treatment and conveyance facilities. In short, the region's infrastructure is inadequate to accommodate current demands. Yet, as proposed, the Facility is designed to produce significantly more water than the current service area demand. The Facility's capacity was specifically designed to include estimated water needs for developing all currently vacant lots of record, and "bounce back" of the area's tourism industry, in addition to a replacement supply. In fact, providing sufficient water supplies to serve existing vacant legal lots of record, and accommodating tourism demand under recovered economic conditions, are stated "fundamental" objectives of the Project. (Goals that are perhaps at odds with another "fundamental" objective of minimizing project costs and associated water rate increases.) As the CEQA Guidelines recognize, development and population growth have numerous primary and secondary environmental impacts that must be analyzed in an EIR, including traffic impacts, air pollution, greenhouse gas emissions, and water pollution. Instead of evaluating these reasonably foreseeable impacts of the project, the EIR/EIS improperly writes off that analysis as an obligation of municipal planning processes.

ERF-35 cont.

In addressing potential cumulative growth-inducing effects, the EIR/EIS identified a number of planned projects that would provide new sources of potable water supply in Monterey County. "The Monterey Bay Regional Water Project (DeepWater Desal) (No. 34) would provide water to the City of Salinas as well as parts of Santa Cruz County. If both the MPWSP and DeepWater Desal were approved, water from DeepWater Desal could be used to support growth in other nearby areas such as northern Monterey County. The RUWAP Desalination Element (No. 31) would serve the Marina Coast Water District's Ord Community with approximately 1,000 afy of potable supply." It concludes that "[g]rowth induced by one or more of these cumulative water supply projects in combination with the proposed project would result in secondary effects of growth in Monterey County that are similar to,

ERF-36

but would likely be more severe and widespread than, those summarized above in Table 6.3-9; these impacts including increased traffic, noise, and air pollution and loss of open space and biological resources." However, none of these, or other likely impacts, are adequately described or analyzed in the EIR/EIS.

ERF-36 cont.

The EIR/EIS Provides Insufficient Analysis of Preferred Alternatives to Desalination

There is general consensus that brine discharge, and entrainment/ impingement from intake systems are serious threats to marine life. These concerns are reflected in California's recently adopted desalination policy. Monterey Bay is a particularly valuable environment, for both ecological and commercial reasons. In 2010, MBNMS, in collaboration with the California Coastal Commission, California Central Coast Regional Water Quality Control Board, and NOAA Fisheries, published Guidelines for Desalination Plants in Monterey Bay National Marine Sanctuary which implement the desalination action plan included in the MBNMS Final Management Plan. Stressing the importance and sensitivity of the Monterey Bay environment, the Guidelines state:

- Desalination should only be considered when other preferable alternatives for meeting water needs, such as increased conservation and wastewater recycling are maximized or otherwise determined not feasible, and it is clear that desalination is a necessary component of the region's water supply portfolio;

- Project proponent should provide a complete evaluation of the need for a desalination plant. This should include a background of the water supply situation and discussion and evaluation of alternatives that have been considered to obtain the necessary volume of water; including the potential to use other economically and environmentally preferable alternatives including increased conservation, brackish water desalination, and wastewater recycling to meet some or all of the water needs of a proposed project;

ERF-37

The EIR/EIS does not adequately consider the New Monterey Peninsula Water Conservation and Rationing Plan, which outlines a target water production goal of 12,002 afy,[47] nearly satisfying the service area demand of 12,270 afy, and fails to adequately evaluate the feasibility of desalination alternatives, such as wastewater and storm water reclamation, watershed restoration, and climate appropriate landscaping.

Thank you for your consideration of these issues.

Sincerely,

Fredric Evenson, for

Re: Draft Environmental Impact Report/Environmental Impact Statement
Monterey Peninsula Water Supply Project

Dear Ms. Borak and Ms. Grimmer:

Fort Ord Rec Users (forU) is a community organization comprised of individuals and groups with a shared vision to preserve and enhance recreational use and the natural habitat of the former Fort Ord. ForU provides the following comments regarding the Draft Environmental Impact Report/Environmental Impact Statement (hereafter DEIR/EIS) issued in January 2017 for the California American Water Company (CalAM) project. ForU respectfully requests these comments be made part of the administrative record for all state and federal proceedings related to this project.

The planned source water for the CalAM Project will be the 180' aquifer of the Salinas Valley Groundwater Basin (SVGB). This source is not seawater, as erroneously represented in the DEIR/EIS. CalAM seeks approval to pump up to 27,000 AFY of brackish water from the 180' aquifer of the SVGB. FORU-1

A. BACKGROUND

It is undisputed that CalAM has no water rights in the SVGB. Among those with water rights in the SVGB is the public water purveyor for the City of Marina and the former Fort Ord, Marina Coast Water District (MCWD).

Governing agencies cannot effectively evaluate feasibility, nor reliably make any finding that harm will not occur, without a full understanding of the existing obligations of those with legal rights to water in the SVGB.

Former Fort Ord land consists of 28,000 acres—equivalent to the square footage of the City and County of San Francisco. The controlling agency for the reuse of Fort Ord, the Fort Ord Reuse Authority (FORA) was created by legislation in 1994 in the Fort Ord Reuse Authority Act (CA Government Code Section 67650 et seq.) The County of Monterey and cities of Marina, Seaside, Del Rey Oaks, Sand City, Salinas, Pacific Grove, Carmel, and Monterey developed and adopted the Fort Ord Reuse Plan in 1997, in cooperation with the United States Army, Marina Coast Water District, University of California, California State University, Monterey Peninsula College, Monterey Unified School District, and Transportation Agency of Monterey County, among other entities. FORU-2

The plan sets forth the addition of 6,160 new homes on the former base, as well as commercial square footage and the growth of California State University, Monterey Bay, whose student population is expected to quadruple to 25,000 in ten years. The total population planned for former Fort Ord is 37,000 persons, on properties primarily within lands belonging to the County of Monterey, Marina, and Seaside.

To understand the scope of this planned growth, note that Marina has a population of about 22,000 and Seaside, 28,000. For the 6,160 dwellings anticipated, only 685 residential permits were issued from 1997–2016. More than 2,000 homes are presently approved and entitled—but unbuilt—within City of Marina's as-yet-undeveloped portion of the former fort. **The demands of this planned growth will be a heavy burden**—and the strain on our severely limited water resources is yet to be felt.

One-hundred percent (100%) of the water source for this Fort Ord growth is the SVGB, and most of the production is required to come from the 180' and 400' aquifers. In 1993, the U.S. Army transferred to the Monterey County Water Resources Agency 6,600 AFY of water from the SVGB, as part of its transfer of Fort Ord land to the civilian sector. (See Agreement No. A-06404 "Agreement Between the United States of America and the Monterey County Water Resources Agency Concerning Annexation of Fort Ord into Zones 2 and 2A of the Monterey County Water Resources Agency.")

The recorded "Annexation Agreement and Groundwater Mitigation Framework for Marina Area Lands" was entered into by land-owning jurisdictions, MCWD, the City of Marina, and Monterey County Water Resources Agency in 1996 and remains an enforceable agreement today. The express purpose of the agreement is to reduce seawater intrusion and protect the groundwater resource and preserve the environment of the Salinas River Groundwater Basin. The agreement sets forth terms and conditions for annexation in the future, however, the pumping limitations on the three aquifers of the SVGB were effective immediately. In particular, this annexation agreement specifies that MCWD is to limit its pumping of the 900' aquifer to a maximum of 1400 AFY for Fort Ord and **the balance of 5,200 AFY is to be sourced from the 180' and 400' aquifers.**

FORU-2 cont.

Of importance to any ruling on this MPWSP are MCWD's rights and needs in the upper aquifers of the SVGB. To meet its water production for the build-out of Fort Ord, MCWD is restricted to the upper aquifers as its source for 5200 of the 6600 AFY. CalAM seeks project approval to pump up to 27,000 AFY from *the same aquifer.*

Through an agreement executed June 7, 2000, and recorded June 23, 2000, the U.S. Army transferred all water rights and water infrastructure to MCWD, which became the water purveyor for the entire 28,000 acres of former Fort Ord. (See Article 5., Water and Sewer Rights, of the "Memorandum of Agreement Between the United States of America, Acting by and Through the Secretary of the Army, United States Department of the Army and the Fort Ord Reuse Authority for the Sale of Portions of the Former Fort Ord Located in Monterey County, California." In 1998, FORA entered into a "Water/Wastewater Facilities Agreement" dated

March 31, 1998, with MCWD. This agreement adopts and affirms the pumping limitations of the above-referenced 1993 and 1996 agreements, to wit:

(a) a maximum of 1400 AFY from the 900' foot aquifer for former Fort Ord land; and

(b) up to 5200 AFY from the 180' and 400' aquifers

to serve all present and future development. These figures are intended to serve current users and those "reasonably expected to use" water in the future with the build-out of Fort Ord.

FORU-2 cont.

These facts are recited because your understanding of the burgeoning population growth and development of the 28,000 acres served by MCWD is critical in considering any approvals for any project that competes for pumping rights in the severely overdrafted SVGB.

B. CALAM IS PUMPING FROM THE SALINAS VALLEY GROUNDWATER BASIN

CalAM is pumping water from the SVGB, not "seawater" as represented.

1. CalAM erroneously represents the MPSWP as "designed to take supply water from the ocean via underground slant-wells that draw water from the earth underneath the ocean." (DEIR/EIS/EIS p. 2–30)

2. All subsurface slant-well pumping by the MPWSP will be from the 180' aquifer of the SVGB—not from "the submerged lands of the Monterey Bay National Marine Sanctuary." (DEIR/EIS p. 3–15)

3. The brackish coastal water of the SVGB is the intended water source of the project. This reality became glaringly obvious when "the slant well clusters were moved farther inland" to address coastal erosion. (DEIR/EIS p. ES–16)

FORU-3

C. CALAM HAS NO WATER RIGHTS IN THE SALINAS VALLEY GROUNDWATER BASIN—THE PROJECT IS NOT FEASIBLE.

CalAM has neither water rights in the SVGB nor a credible legal claim to the supply water for this project. The project must therefore be deemed out of the question.

1. CalAM admits it has no legal right to extract groundwater from the Salinas Valley Groundwater Basin.

FORU-4

2. To establish a feasible claim to water rights, CalAM must prove no other legal user of water is injured. Existing users of the SVGB, including MCWD will be injured if this project is approved. FORU-4 cont.

3. Alternatives exist by which CalAM and the Peninsula may secure water. FORU-5

D. GROUNDWATER FROM SVGB MUST STAY IN THE SVGB UNDER STATE LAW

Parties with legal rights to SVGB water have grave concern as to the adequacy of SVGB aquifers for current and future water demand. This problem is not considered in the environmental review. FORU-6

1. MCWD pumping is to increase from current levels of 3,000–4,000 AFY to 10,000 AFY with the build-out of Fort Ord. Of this total, 5200 AFY must be taken from the 180' and 400' aquifers. MCWD and others with water rights are presently pumping from these aquifers.

2. Water produced by the CalAM project will be exported from the SVGB in defiance of state law. None of the water produced by the MPSWP will serve City of Marina or Fort Ord. FORU-7

E. CALAM FAILS TO PROVE NO HARM

Overpumping of the 180' and 400' SVGB aquifers has increased seawater intrusion over the past 70 years (Monterey County Water Resources Agency Historic Seawater Intrusion Map 12-16-2014). FORU-8

CalAM admits a critical issue is whether implementation of the MPWSP and operation of the slant well will exacerbate seawater intrusion in the SVGB. CalAM has failed to provide credible evidence that its pumping of an additional 27,000 acre feet per year will have any other result than acceleration of seawater intrusion.

F. CALAM FAILS TO DISCLOSE THE DEGREE OF UNCERTAINTY IN ITS MODELING

There is little knowledge of the interconnections between the 180', 400', and 900' aquifers of the SVGB; the risks the project poses to the SVGB are therefore unknown and unpredictable. Yet these aquifers are the sole sources of water for Marina and Fort Ord. FORU-9

Increased pumping will further degrade the quantity and quality of water, making water more expensive to those dependent upon the SVGB, including MCWD customers. CalAM's project modeling lacks baseline data and therefore lacks analytical context. CalAM's failure to follow scientific process is unacceptable. FORU-10

G. CAL AM REJECTS USE OF CREDIBLE TECHNOLOGY THAT CAN REDUCE UNCERTAINTY

CalAM unreasonably rejects use of electrical-resistivity tomography (ERT) for mapping seawater intrusion and the fragile hydrogeology of the SVGB. ERT is readily available, data rich, non-intrusive, and low cost. ERT data can be expected to significantly reduce the degree of uncertainty. Readily attainable imaging is especially critical in the high-risk context of water. CalAM's failure to use ERT amounts to gross negligence in today's technological environment. FORU-11

H. THERE HAVE BEEN NO SUCCESSFUL, COMPLETED SLANT WELLS FOR SUBSURFACE OCEAN DESALINATION ANYWHERE IN WORLD

CPUC has shown poor diligence in its evaluation of technical, legal, and financial challenges. To date, there is no convincing evidence that the project is a viable option for water procurement for the Monterey Peninsula. FORU-12

1. Santa Barbara, Dana Point, and Santa Cruz are among those entities that explored, rejected, or abandoned slant-well technology.

2. Breakdowns and interruptions in the operation of the CalAM test well raise doubts as to the reliability and appropriateness of the technology.

3. There is no consideration or review of test results in the DEIR/EIS. (DEIR/EIS p. 3–15)

4. The uncertainty of a successful slant-well project weighs heavily against the investment of **public** funds, resources, and trust.

FORU-12 cont.

I. CALAM'S PROJECT IS *UNJUST.*

CalAM's source-water facility is within the jurisdiction of a public water agency, MCWD. CalAM's operations will interfere with and harm MCWD's ability to provide water to its 30,000 ratepayers and the anticipated development of Fort Ord at a *reasonable cost*; yet the DEIR/EIS dismisses MCWD's rights and responsibilities in a single line, citing MCWD's potential political interference. Assessment of adverse impacts of a project under CEQA is NOT synonymous with "harm or injury" to water-rights holders. The un-rightful taking of water from the SVGB is injurious to those with water rights and therefore legally sufficient and appropriate for denial of this project.

FORU-13

CalAM's stated purpose is to appropriate water to which it has no right and export it to users on the Monterey Peninsula. A just regional perspective forbids that one water purveyor take unlawfully from another, especially to benefit the wealthy and influential at the expense of the politically weak.

1. CalAM's arrogation of SVGB water will greatly impair and diminish MCWD's ability to provide an affordable, long-term, sustainable water supply for the City of Marina and Fort Ord.

2. The value of homes and businesses in Marina will be further suppressed by the addition of a *third* regional plant within the city's sphere of influence. Marina already shoulders the adverse environmental burdens and stigma of proximity to regional wastewater and waste facilities.

FORU-14

3. The project degrades Marina's coastline and undermines the benefits intended by

FORU-15

the designation of Marina State Beach and Fort Ord Dunes State Park. FORU-15 cont.

4. The project sacrifices the people of Marina's publicly controlled water purveyor, Local Coastal Plan, local vision, and future prospects to the interests of a profit-seeking corporation with a long history on the Monterey Peninsula of aggressive self-dealing. FORU-16

For the foregoing reasons Fort Ord Rec Users request the CPUC deny certification of the Draft Environmental Impact Report/Environmental Impact Statement issued in January 2017 for the California American Water Company (CalAM) project and deny project approval. FORU-17

Respectfully submitted,

Margaret Davis

SUBJECT: DRAFT EIR/EIS FOR THE MONTEREY PENINSULA WATER SUPPLY PROJECT

Dear Staff:

LandWatch Monterey County has reviewed the draft EIR/EIS for the Monterey Peninsula Water Supply Project (MPWSP) and seven (7) alternatives. The MPWSP includes a 9.6 millions gallons/day (mgd) desalination plant combined with Aquifer Storage and Recovery (ASR), PureWater Monterey County and transmission infrastructure. An alternative, which includes a 6.4 mgd desalination plant combined with ASR and the PureWater Monterey County Project (Alternative 5a), was determined to be the environmentally superior project. We have the following specific comments:

1. The DEIR states, "In that the quantity of such fresh water component of the supply water is not currently known, the modeling and the EIR/EIS analysis assess a range of return water between 0 and 12 percent of the source water." (DEIR p. 2-35) Please explain the source of these percentages and why they were selected for analysis. Please also explain how the upper limit of 12% was determined. LWMC-1

2. Table 5.2 (Appendix E2) includes data regarding the amount of return water required for various scenarios. Under a 12% scenario for the CEMEX site for the years 2012 and 2073, total return water is 2,085 acre-feet/year (af/yr). Table 2-4 (DEIR p. 2-18) identifies produced water in excess of demand of between 1,936 af/yr and 2,636 af/yr. Under a 12% scenario for the Potrero Road site for the years 2012 and 2073, total return water is identified as 3,242 af/yr. Thus, under various scenarios, there would be insufficient water to meet demand. Please explain how the MPWSP meets project demand under these conditions. LWMC-2

3. The DEIR states, "The Management Plan indicates that the population of CalAm's entire Monterey District was 99,396 in 2010 and that the combined population of the main system and the Bishop, Hidden Hills, and Ryan Ranch satellite distribution systems, which would also be served by the proposed project, was 95,972." (DEIR p. 2-15) Please explain why the combined population of 95,972 is less than the population of CalAm's entire district. LWMC-3

4. The DEIR states, "The CPUC is not the arbiter of whether CalAm possesses water rights for the project and nothing in this EIR/EIS should be construed as the CPUC's opinion regarding such LWMC-4

rights, except to the extent that the CPUC must determine whether there is a sufficient degree of likelihood that CalAm will possess rights to the water that would supply the desalination plant such that the proposed project can be deemed to be feasible." (DEIR p. 2-30) Please identify the criteria the CPUC will use to determine if the project is feasible. Since the question of whether or not CalAm has water rights will only be resolved until after project approval, please address how water rights will be considered under the criteria.

LWMC-4 cont.

5. The DEIR identifies project greenhouse gas emissions (GHG) emissions total 8,370 metric tons per year as a significant and unavoidable impact (DEIR Table 4.11-5). Preparation of a GHG Emission Reduction Plan is the proposed mitigation measure.

   The deferral of the formulation of that plan, which is not known to be feasible, is not permissible. *Communities for a Better Environment v. City of Richmond* (*"CBE v. Richmond"*) (2010) 184 Cal.App.4th 70, 94; *Sundstrom v. County of Mendocino* (1988) 202 Cal.App.3d 296, 308-309.

   Deferral is also precluded because no performance specification is provided. The requirement that the Plan be "state-of-the-art" is not a meaningful performance specification because it fails to provide objective criteria for success. *CBE v. Richmond, supra,* 184 Cal.App.4th at 95.

   Regarding the purchase of cap and trade offsets, the DEIR concludes,

   > The fossil fuel power plants that would generate the electricity that would be used by the project are already subject to and participate in CARB's cap-and-trade program. For these reasons, it does not make practical sense to recommend mitigation to offset emissions associated with PG&E's power portfolio because those emissions have already been regulated pursuant to cap-and-trade legislation and are therefore considered to be consistent with CARB's current strategy for reducing GHG emissions consistent with the State's GHG reduction goals. As a result, this EIR/EIS focuses on mitigation strategies that are aimed at reducing the project's consumption of electricity from PG&E's electrical power grid. (DEIR P. 4.11-19)

   The DEIR's stated threshold of significance is 2,000 tons of CO2e. As long as emissions have not been mitigated below that significance threshold, the impact remains significant. Accordingly, the project must implement all feasible mitigation because CEQA bars project approval "if there are feasible alternatives . . . or mitigation measures available" that would substantially lessen the project's significant environmental effects. P.R.C., § 21002; Guidelines, § 15021(a).

   There is no basis for the DEIR's claim that mitigation via offsets is not "practical." A business may buy GHG emission allowances under the cap-and-trade system from other entities that have reduced emissions below the amount of allowances held.

   The EIR should be revised to propose additional mitigation, including purchase of GHG emission offsets under the cap and trade program or under some other arrangement for purchase of offsets.

LWMC-5

6. Since the proposed project and environmentally superior project would generate surplus water (DEIR Table 2-4), a smaller, less energy-demanding desalination plant should be feasible. The EIR should be revised to propose and evaluate a smaller scale alternative that reduces significant and unavoidable climate change impacts.

LWMC-6

7. Chapter 6's analysis of growth inducement resulting from the proposed project finds that the allocation of the hospitality industry bounce-back is 200 af/yr over-estimated (DEIR p. 6-16). It

LWMC-7

further finds that there are no sufficient data to support the estimate of 1,180 af/yr for lots of record (DEIR 6-17). The EIR should be revised to propose and evaluate a smaller scale alternative that reduces output by at least the amount of the over-estimated bounce-back as well as the amount of surplus water discussed in comment 6 above because a smaller scale alternative would reduce significant and unavoidable impacts such as climate change impacts.

LWMC-7 cont.

8. The DEIR also concludes that once the water is allocated to local jurisdictions by the MPWMD, it could be used for any land uses including the 325 af/yr for the Pebble Beach Entitlement and the 500 af/yr for the hospitality industry. (DEIR 6-17) The finding that the 2005 af/yr could be used for any purpose, just not those identified above, is inconsistent with the following project objectives of the MPWSP:

> Provide sufficient water supplies to serve existing vacant legal lots of record; and accommodate tourism demand under recovered economic conditions.

This finding identifies a major flaw in the project and undermines its credibility given the overwhelming support for water for legal lots of record. Without a limitation on the use of 1,810 af/y for legal lots of record, the same issue in future applications will emerge if water for legal lots is allocated to other land uses and the need for legal lots remains unmet.

LWMC-8

Instead of estimating the growth potential associated with 2005 af/yr beyond existing demand, the analysis is based on the assumption that the water for growth is addressed in adopted general plans and their environmental documents. The DEIR provides an extensive list of significant impacts identified in various general plans and concludes that the growth would be significant and unavoidable. The most recently adopted general plans by local jurisdictions within the boundary of the MPWMD is 2010. All others were adopted between 1994 and 2005. Any conclusions regarding the significance of impacts is underestimated because base-line conditions have changed dramatically during the past 20 plus years, e.g., traffic, green house gas emissions, visual degradation, scenic and biological resources, etc.

Based on an assumption of 0.25 af/yr per dwelling unit, a total of 8,020 dwelling units could be constructed within the MPWMD. The impacts of over 8,000 dwelling units would be staggering, e.g., at 9.5 trips per unit, a total of 76,190 trips would be added to an already over-burdened transportation system. While this represents a worst-case scenario, it identifies a potential outcome that was unintended by those who have supported the proposed project.

LWMC-9

The DEIR should be revised to include a mitigation measure limiting the use of water in excess of current demand to the actual future demand for lots of records, hospitality bounce-back and the Pebble Beach entitlement to those uses.

If the CPUC determines that such mitigation is not legally feasible, the EIR should be revised to identify a potentially significant impact if surplus water is used for purposes other than lots of records, hospitality bounce-back and the Pebble Beach entitlement. This determination should be coupled with a finding under CEQA Guidelines § 15091(a)(2) that the required mitigation in the form of water allocation priorities is "within the responsibility and jurisdiction of another public agency" and that "such changes have been adopted by such other agency or can and should be adopted by such other agency." In this case, those other agencies may include local land use control jurisdictions and the MPWMP.

LWMC-10

9. The DEIR states:

> 2.6.4 Effect of Annexation Agreement
> In 1996, the MCWRA, the MCWD, the City of Marina, the owners of Armstrong Ranch and then owners of the CEMEX property (RMC Lonestar) entered into an *Annexation Agreement and Groundwater Mitigation Framework for Marina Area Lands* ("Annexation Agreement").37 The agreement established a framework for management of groundwater from the Basin and included terms and conditions for the annexation of lands (including the Armstrong Ranch and CEMEX properties) to MCWRA's benefit assessment zones as a financing mechanism to fund groundwater resource protection and reduction of seawater intrusion (MCWD, et al. 1996).
>
> Under the Annexation Agreement, MCWD's authority to withdraw potable groundwater from the Basin would be limited to 3,020 afy year until such time as a plan for development of a long-term potable water supply capable of mitigating seawater intrusion was developed and implemented. <u>If and when the Armstrong Ranch property were annexed to MCWD's benefit assessment zones</u>, non-agricultural use of Basin groundwater withdrawn from that property would be capped at 920 afy. If and when the CEMEX property was annexed to MCWD's benefit assessment zones, withdrawal of groundwater from that property would be capped at 500 afy." (DEIR, p. 2-41, emphasis added.)

LWMC-11

The 1996 Annexation Agreement states:

> 7.2 Quantity Limitations. <u>Commencing on the effective date of this Agreement and Framework</u>, Lonestar shall limit withdrawal and use of groundwater from the Basin to Lonestar's historical use of 500 afy of groundwater. (Annexation Agreement attached, emphasis added).

The DEIR's statement that the 500 afy limitation is contingent on annexation is inconsistent with the statement in the Annexation Agreement that the limitation occurs on the effective date of the agreement.

10. In developing thresholds of significance for groundwater impacts, the DEIR purports to take cognizance of the forms of potential injury identified by the SWRCB 2913 opinion on water rights and groundwater harms. (DEIR, 4.4-52.) However, the DEIR's identified thresholds of significance do not include "a reduction in groundwater elevations that requires users to expend additional pumping energy to extract water from the Basin" as specified by the SWRCB opinion (DEIR, p. 4.4-52 (listing SWRCB's "foreseeable injuries").) Instead, in defining and applying significance thresholds, the DEIR only considers reductions in groundwater elevations to be a significant impact if that reduction leads to physical damage from exposed screens of wells or reduced well yields. (DEIR, p. 4.4-41 (thresholds of significance), p. 4.4-68 (project-specific impact conclusion), p. 4.4-90 (cumulative impact conclusion).) The EIR should be revised to assess whether the acknowledged permanent reduction in groundwater elevations would requires users to expend any additional pumping energy. If so, the EIR must specify and apply a threshold of significance for increased pumping energy use as well as a threshold for what constitutes a considerable contribution for increased pumping energy use in the cumulative context, as discussed below.

LWMC-12

Furthermore, the DEIR does not define what constitutes a significant reduction in well yields due to lower groundwater levels, even though the DEIR implies that some level of reduced yield would be a significant impact. The EIR should be revised to specify and apply a threshold of significance for reduction in well yields as well as a threshold for what constitutes a considerable contribution to reduced well yields in the cumulative context, as discussed below

LWMC-13

11. Cumulative analysis must consider all sources of "related impacts," including those past, present, and potential future projects. Guidelines, § 15130(a)(1), (b); *Laurel Heights Improvement Assn. v. Regents of the University of California* (1988) 47 Cal.3d 376, 394 (omission of foreseeable future sources is error); *Environmental Protection Information Center v. California Dept. of Forestry and Fire Protection* ("*EPIC*") (2008) 44 Cal.4th 459, 525 (omission of relevant past sources is error). Thus, CEQA requires an agency to identify cumulative sources either by listing the projects or by providing "a summary of projections contained in an adopted local, regional or statewide plan, or related planning document, that describes or evaluates conditions contributing to the cumulative effect." Guidelines, § 15130(b)(1)(A), (B).

    The DEIR provides a list of future projects that it uses for cumulative analysis of various resource area impacts. (DEIR, pp. 4.1-15 to 4.1-24.) This list includes numerous future water-using projects that would contribute to impacts groundwater resources, such as development of residential and commercial land uses in the Salinas Valley Groundwater Basin ("SVGB"). Many of the future water-using projects are located within the western half of the Pressure Area, which is the geographic scope identified as the area of cumulative effect for the cumulative water supply analysis. (DEIR, p. 4.4-87 to 4.4-88.) Many other projects are outside of the Western half of the Pressure Area, but would still contribute to that cumulative effect. For example, pumping in the Eastside Area is known to contribute to the depletion of the Pressure Area and to seawater intrusion.

    LWMC-14

    The DEIR's analysis of cumulative groundwater resource impacts purports to use the "list of projects" approach to identifying future projects that affect the groundwater resources rather than the "summary of projections" method. (DEIR, p. 4.4-88.) However, the DEIR includes in that list of projects only three projects, all of which are water supply or groundwater management projects: RUWAP, SVWP Phase II, and the Interlake Tunnel. Omission of future water-using projects within the geographic scope of the cumulative analysis is an error. The thresholds of significance and analysis are based on effects such as aquifer depletion and seawater intrusion, and these effects are clearly determined by total groundwater demand from all sources.

    The groundwater analysis in DEIR Appendix E-2 contains a future impact scenario for the year 2073, but the only variable that was apparently changed in that scenario is the sea level assumption. There is no indication in the EIR that the 2073 scenario incorporates a revised groundwater demand projection for the 2073 scenario. If the analysis did incorporate any revision to demand assumptions, it should be made clear how it was derived and what projects were included from the list of projects in the DEIR's Table 4.1-2.

    The EIR should be revised and recirculated to either 1) explain and provide any revision to future demand assumptions used in the cumulative analysis, or 2) provide a cumulative impact analysis that includes the effect of future water demand within the SVGB that contributes to the cumulative effects of aquifer depletion and seawater intrusion.

Furthermore, it is inappropriate to treat water management and water supply projects that are intended to mitigate existing impacts to the aquifer as projects that cause related impacts because the kind of impacts that matter in cumulative analysis are adverse impacts. Indeed, the DEIR's discussion of the significance of cumulative impacts appears to rely on the expected additional benefits of these projects. Since these proposed future projects are neither certain nor identified as enforceable conditions of this project's approval, their beneficial effects should not be assumed in evaluating cumulative significance. Mitigation must be enforceable. Guidelines, § 15126.4(a)(2). LWMC-15

12. An agency may not arbitrarily limit the geographic scope of cumulative analysis or omit relevant projects. *Kings County Farm Bureau v. City of Hanford* (1990) 221 Cal.App.3d 692, 721-724 (error to confine cumulative air quality analysis to County where evidence showed impacts were caused by basin-wide sources); *Bakersfield Citizens for Local Control v. City of Bakersfield* (2004) 124 Cal.App.4th 1184, 1213-1214 (ignoring other impact sources was "overarching legal flaw"). Thus, an agency must "define the geographic scope of the area affected by the cumulative effect and provide a reasonable explanation for the geographic limitation used." Guidelines, § 15130(b)(3), emphasis added; *Citizens to Preserve the Ojai v. County of Ventura* (1985) 126 Cal.App.3d 421, 126 Cal.App.3d at 430 (failure to explain limited scope of cumulative analysis is error). LWMC-16

    The DEIR limits the geographic scope of analysis to the western half of the Pressure Area. (DEIR, p. 4.4-87.) The EUIR must be revised to explain the basis of that geographic limitation.

    Again, note that CEQA distinguishes the geographic scope of the "area affected by the cumulative effect" and the identification of the "conditions contributing to the cumulative effect." Guidelines, § Guidelines, § 15130(b)(1)(A), (B). Thus, even if the geographic scope of the area affected by the project were limited to the western half of the Pressure Area, groundwater pumping in other areas that also contributes to the cumulative effect should be identified in the "list of projects" or "summary of projections."

13. The DEIR states that in evaluating cumulative impacts, where its analysis finds that the cumulative impacts of past, present, and future projects would be significant and adverse, the DEIR then determines whether the project's contribution would be considerable. (DEIR, p. 4.1-13.) This approach would be consistent with CEQA's requirement for a two-step process that requires an agency to make the following determinations: (1) whether the impacts of the project in combination with those from other projects are cumulatively significant, and (2) if so, whether the project's own effect is a considerable contribution. Guidelines, § 15130(a); see Kostka and Zischke, *Practice Under the California Environmental Quality Act* (2nd Ed., 2011 Update), §§ 13.39. 15.52. However, as explained below, both the step-one and step-two determinations should be made explicitly, because an agency must first determine the severity of the cumulative impact in order to determine whether the project contribution is "considerable." LWMC-17

    Cumulative analysis must recognize that "considerable contribution" threshold may be an "individually minor" impact where the resource is severely degraded. In particular, an EIR may not conclude a cumulative impact is insignificant merely because the project's individual contribution to an unacceptable existing condition is, by itself, relatively small. *Los Angeles Unified School Dist. v. City of Los Angeles* ("*LAUSD*") (1997) 58 Cal.App.4th 1019, 1025-1026 (rejecting EIR's reasoning that individually minor noise increments would necessarily be cumulatively insignificant); *Communities for a Better Environment v. California Resources Agency* ("*CBE v. CRA*") (2002) 103 Cal.App.4th 98, 117-118, 121 (invalidating CEQA

Guidelines provision that de minimis impacts are necessarily less than considerable). Thus, the proper threshold for the step two determination whether a project's contribution to an existing significant impact is considerable must reflect the severity of the cumulative problem: "the greater the existing environmental problems are, the lower the threshold should be for treating a project's contribution to cumulative impacts as significant." *CBE v. CRA, supra*, 103 Cal.App.4th at 120. *see also* Guidelines, §§ 15355(b), 15065(a)(3); LAUSD, supra, 58 Cal.App.4th at 1024-25.

LWMC-17 cont.

The DEIR identifies three potential cumulative impacts: substantial depletion or interference with groundwater supplies, violation of groundwater standards, and degradation of water quality standards. (DEIR, p. 4.4-88). However, the DEIR fails to clarify whether each of these three potential cumulative impacts to groundwater resources are significant. That is, for each of these potential cumulative impacts, there is no "step-one" determination as to whether there is a significant cumulative impact from all projects taken together, and, if so, how severe that impact is. Without that determination, there is no basis to conclude that this project's contribution is less than considerable. As explained, determining the threshold for "considerable contribution" requires assessment of the severity of the cumulative impact. *CBE v. CRA, supra*, 103 Cal.App.4th at 120.

LWMC-18

The EIR should be revised to provide an assessment as to whether all existing and future projects result in a significant cumulative impact by causing substantial depletion or interference with groundwater supplies, violation of groundwater standards, or degradation of water quality standards. If so, the EIR should identify the severity of that impact and the threshold for determining whether an additional project would make a "considerable contribution."
The EIR's discussions of "direct and indirect effects," e.g. the project-specific analyses in Impact 4.4-3 and 4.4-4, use a threshold of significance that represents the level of effect that would be considered significant if caused by the project by itself. However, even if these project-specific impacts are not by themselves significant, they may nonetheless constitute a considerable contribution to significant cumulative impacts.

The failure to consider cumulative depletion or interference with groundwater supplies is particularly problematic. As discussed below, without the return water provisions, the project would make a considerable contribution to an existing significant cumulative impact, i.e., the aquifer depletion and declining groundwater levels in the Pressure Subarea. The EIR should acknowledge that the return water provisions are essential mitigation for this contribution.

LWMC-19

In particular, the EIR concludes that the change in available water supply in the SVGB caused by the project itself is less than significant in part because the area of influence, measured by the zone suffering a one-foot drawdown, extend only about 4 miles without the mitigating effects of the return water provision. (DEIR, p. 4.4-47 to 4.4-59.) This conclusion is in the discussion of "direct and indirect effects," i.e., the project-specific impacts. However, the EIR fails to consider whether a drawdown of less than one foot may nonetheless be a considerable contribution to a significant cumulative impact, particularly in the context of declining groundwater levels due to all cumulative projects.

Clearly, there is a significant cumulative impact in the form of declining groundwater levels and aquifer depletion in the Pressure Subarea.[1] The Pressure Subarea is one of the eight subbasins

LWMC-20

[1] Brown And Caldwell, State of the Salinas River Groundwater Basin, January, 2015, available at http://www.mcwra.co.monterey.ca.us/hydrogeologic_reports/documents/State_of_the_SRGBasin_Jan16_2015.pdf.

making up the Salinas Valley Groundwater Basin (SVGB).[2] Overdraft in the Pressure Subarea has averaged about 2,000 acre-fee per year ("afy") from 1944 to 2014, and the Basin as a whole is "currently out of hydrologic balance by approximately 17,000 to 24,000 afy."[3] Pumping from the Basin has exceeded recharge since the 1930s, causing seawater intrusion as inland groundwater elevations dropped below sea level, permitting the hydraulically connected seawater to flow inland.[4]

The California Department of Water Resources (DWR) is required by the Sustainable Groundwater Management Act to designate as "critically overdrafted" basins those groundwater basins for which "continuation of present water management practices would probably result in significant adverse overdraft-related environmental, social, or economic impacts."[5] DWR identified the 180/400-Foot Aquifer of the Salinas Valley Groundwater Basin as critically overdrafted in January 2016.[6]

LWMC-20 cont.

The DEIR acknowledges that a "net deficit in aquifer volume" would be a significant impact. (DEIR 4.4-41.) Accordingly, the current groundwater pumping from all cumulative projects is clearly causing a significant cumulative impact in the form of aquifer depletion leading to a net deficit, i.e., the serious and continuing overdraft conditions identified by DWR and the MCWRA reports. The DEIR also acknowledges that declining groundwater levels are a significant impact, at least if they lead to well yield reductions or exposed screens and pumps. (DEIR, p. 4.4-41).

Again, the current groundwater pumping from all cumulative projects is clearly causing a significant cumulative impact in the form of declining groundwater levels in the Pressure Area.[7] The project will make some contribution to the net deficit in aquifer volume and declining groundwater levels because it will change the balance of flows and remove water from the aquifer so as to cause a permanent depression in groundwater elevations. The DEIR acknowledges that the project, without provision of return water, would cause a drawdown of 1 foot in areas that are 4 miles inland. It would also cause drawdowns of some lesser magnitude in areas farther than 4 miles. These impacts would be mitigated by provision of return water. The EIR should be revised

LWMC-21

[6] DWR, Critically Overdrafted Basins (1/2016), available at http://www.water.ca.gov/groundwater/sgm/pdfs/COD_BasinsTable.pdf.

[7] As discussed above, the DEIR only considers falling groundwater levels to be a significant impact if it results in physical damage due to exposed screens or pumps or reduced well yields. It fails to consider increased energy costs from higher lifts as a significant impact even though identified in the SWRCB 2013 opinion. Nor does it actually define what constitutes a significant reduction in well yields due to lower groundwater levels, even though the DEIR implies that some level of reduced yield would be a significant impact.

to identify this as a considerable contribution to a significant cumulative impact and to identify the return water provisions as essential mitigation.

LWMC-21 cont.

Furthermore, the DEIR dismisses the impact of aquifer depletion based on the argument that that the zone of the 1-foot drawdown does not extend beyond the 500 mg/L seawater intrusion boundary. Although the magnitude of drawdown attenuates with distance, the EIR fails to evaluate drawdown effects of less than one foot. Thus, the DEIR provides no evidence that a drawdown effect of at least some magnitude would not occur in inland areas south of the seawater intrusion boundary that do enjoy potable water quality. Even if the drawdown in areas of potable water were less than the DEIR's arbitrarily selected one-foot drawdown threshold for significant project-specific impacts, the drawdown may nonetheless be a considerable contribution to the significant cumulative impact of aquifer depletion and declining groundwater levels. The DEIR simply fails to consider this.

LWMC-22

14. The DEIR's rationale to dismiss the impact of aquifer depletion, that the zone of the 1-foot drawdown does not extend beyond the 500 mg/L seawater intrusion boundary and so does not affect potable water use, is not supportable for another reason. The DEIR admits that there are at least two sources of competing demand for the non-potable or brackish water in the project: existing wells are used for non-potable purposes ("minor irrigation and dust control") and foreseeable future source wells for the MCWD desalination facility would also draw brackish water. (DEIR, p. 4.4-90). Because there are existing and foreseeable uses for non-potable water drawn by the project, the depletion of this supply cannot be dismissed out of hand as less than significant.

LWMC-23

Sincerely,

Michael DeLapa

Re: Comments of Pebble Beach Company on Cal/Am Monterey Peninsula Water Supply Project Draft EIR/EIS
Our File: 2037.29635

Ladies and Gentlemen:

Our firm represents Pebble Beach Company ("PBC"). The Draft EIR/EIS ("DEIR") for the Cal/Am Monterey Peninsula Water Supply Project ("MPWSP") addresses the water entitlements granted to PBC by the Monterey Peninsula Water Management District ("MPWMD") in several sections of the DEIR. We wish to make clear in these comments the panoply of rights which attach to the Pebble Beach water entitlements.

In Section 2.3.3.1, describing the Pebble Beach Water Entitlements, the DEIR correctly recites that the water entitlements were granted by MPWMD in exchange for PBC's guarantee of financing for the CAWD-PBCSD Wastewater Reclamation Project. PBC has guaranteed a total of $33.9 million in debt instruments and funded an additional $33 million directly, for a total financial commitment to the Wastewater Reclamation Project of nearly $67 million. This project is presently supplying approximately 1,000 acre feet per year ("afy") of water to meet all of the needs of the eight Del Monte Forest golf courses and certain athletic fields.

I. HISTORY

We have enclosed a more complete history of the Wastewater Reclamation Project and the Pebble Beach water entitlements for the record. A summary of that history is as follows. PBC-1

{THJ-6413139;3}

Due to insufficient legal rights for Cal-Am's withdrawals from the Carmel River, the State Water Resources Control Board ("SWRCB") issued Orders limiting the amount of water Cal-Am can withdraw from the Carmel River. This limitation has had the effect, on a general basis, of precluding water for new development within the Cal-Am service, with some exceptions. One of these exceptions is the Pebble Beach water entitlement, which has its genesis in the Carmel Area Wastewater Services District ("CAWD") – Pebble Beach Community Services District ("PBCSD") Wastewater Reclamation Project ("Recycled Water Project").

In 1989, MPWMD and PBC entered into an agreement in which PBC guaranteed financing for a wastewater reclamation project designed to reclaim approximately 800 afy of wastewater for irrigation use on golf courses and other open space in the Del Monte Forest. The recycled water would conserve approximately 800 afy of Cal-Am potable water then being used to irrigate these areas. The project was to be constructed and operated by CAWD and PBCSD. In return for its fiscal guarantee, MPWMD granted PBC a water entitlement of 365 afy of potable water for specific "benefited" properties in the Del Monte Forest. MPWMD granted two other property owners who also participated in the agreement an additional 15 afy entitlement for Areas S and W in the Del Monte Forest, for a total of 380 afy.

In 1994, CAWD and PBCSD completed construction of the Recycled Water Project and began supplying treated water. Between 1994 and 2008, the Recycled Water Project supplied on average about 750 afy of recycled water for irrigation of the eight golf courses and other recreational areas in the Del Monte Forest. During this period, the recycled water supply was supplemented with potable water usage of approximately 250 afy.

PBC-1 cont.

To eliminate the use of potable water, in 2005 PBC agreed to fund upgrades to CAWD's recycled water facilities to address salinity issues, and to fund the retrofit of the Forest Lake Reservoir owned by PBCSD to provide additional recycled water storage capacity. By 2011, due to these upgrades, the Recycled Water Project was capable of providing about 1,000 afy of recycled water – an amount sufficient to meet the irrigation demands of the golf courses and other open space areas served by the Recycled Water Project, without any use of potable water.

By virtue of its funding of the Recycled Water Project, PBC has enabled the conservation of far more potable water (through replacement with recycled water) than the 365 afy potable water entitlement granted to it. Thus, it has been consistently determined that the use of the Pebble Beach water entitlement does not result in a net increase in withdrawals from the Carmel River. In fact, it has resulted in a net benefit.

The MPWMD-PBC agreement, including as modified in 2004, identifies the water entitlement as a vested property right and allows PBC the right to reallocate the water entitlement among its properties, as well as the ability to sell up to 175 afy of its remaining entitlement to other Del Monte Forest property owners for residential use, provided that the annual water usage among all of PBC's properties and buyers' properties does not exceed the

aggregate 365 afy water entitlement granted to PBC. As of the end of 2017 PBC has sold approximately 140 afy in this fashion to other Del Monte Forest property owners. PBC-1 cont.

II. Proper Classification of the Pebble Beach Water Entitlements.

The DEIR in Section 2.3.3 treats the Pebble Beach water entitlements as one of the "Other Service Area Demand Assumptions", as if the MPWSP is necessary to serve it as "future demand." However, the facts indicate that the Pebble Beach water entitlements total of 365 afy must be classified as "Existing Demand" of the Cal-Am system. As explained in the attached Memorandum, the Pebble Beach water entitlement is described as "an irrevocable, divisible binding entitlement to potable water, *as a vested property right and interest*, in and for the Benefitted Properties, for use on and by the Benefitted Properties." The Fiscal Sponsorship Agreement with MPWMD recites that the "Water Entitlement evidenced by each Water Use Permit … shall not be terminated or diminished by reason of any water emergency, *water moratorium or other curtailment on the setting of meters for the Cal-Am water system*, and … shall not be subject to diminishment or revocation except as provided [in circumstances not applicable here]." Further, Cal-Am in its Ancillary Project Costs Agreement with PBC to provide service to the properties owned by holders of the Pebble Beach water entitlements has covenanted that *Cal-Am shall at all times reserve, and have the capability of providing, an amount of Water sufficient to meet its service obligations to all of such properties, and shall not serve or commit service of Water to other persons or entities which would, at any time, have the effect of impairing such capability.* PBC-2

The point is that the Pebble Beach water entitlements must be treated and classified as "Existing Demand" because Cal-Am has an obligation to serve the full 365 afy of the water entitlements no matter what, i.e., even if the MPWSP (or any other water supply project) is not realized. We recognize that the full 365 afy is not being delivered currently by Cal-Am, and in that sense may affect project sizing to make sure it is accounted for. But it must be accounted for as "Existing Demand" because Cal-Am is obligated to serve the entire 365 afy from whatever sources are currently available to it.

III. The Pebble Beach Water Entitlements Are Not Growth-Inducing.

With these considerations in mind, the effect of the Pebble Beach water entitlements cannot be classified as "growth inducing" (see DEIR p. 6-14). The use of water represented by the Pebble Beach water entitlements must be satisfied no matter what, from Cal-Am's existing sources if necessary, whereas the other demand uses (e.g., lots of record, hospitality industry rebound) are dependent on realization of the MPWSP (or some other new source of supply). Stated differently, water is not a constraint to any growth utilizing the Pebble Beach water entitlements. PBC-3

IV. MPWMD and the County Do Not Have the Power to Allocate the Pebble Beach Water Entitlement.

Further, the DEIR on page 6-17 mistakenly assumes that MPWMD has the power to allocate (specifically to the County) the unused portion of the Pebble Beach water entitlement as part of its allocation program. This is emphatically not the case. Only PBC has the power to utilize and/or assign portions of the PBC water entitlement, and only (at least presently) for properties in Del Monte Forest. Water entitlements that are assigned to owners other than PBC must be used for residential use (as defined by MPWMD). The use and/or assignment of portions of the water entitlement is not considered an "allocation" by MPWMD under its allocation program or in any other sense. It is simply the exercise of the rights granted to PBC and other holders of the Pebble Beach water entitlements. Thus, the assumption that the County, based on an "allocation" from MPWMD, could elect to then "allocate" portions of the Pebble Beach water entitlement to "other development" (i.e., development other than that for which use of the Pebble Beach water entitlement is authorized) is not realistic – and could not occur without the concurrence of PBC. PBC-4

Thank you for the opportunity to comment on the DEIR.

Very truly yours,

FENTON & KELLER

Dear Sirs/Madams,

We appreciate the opportunity to comment on the revised Draft Environmental Impact Report/Statement (the document, hereafter) for the Monterey Peninsula Water Supply Project (MPWSP). Point Blue Conservation Science (founded as Point Reyes Bird Observatory in 1965) is a non-profit 501c3 organization dedicated to conserving birds, other wildlife, and their ecosystems through science, partnerships and outreach. Point Blue has been studying the population of western snowy plovers (*Charadrius nivosus nivosus*) at the slant well portions of the MPWSP project site and in the greater Monterey Bay area for more than 30 years. I personally have monitored plover activity at the project site for more than 15 years (1996-2013).

We are pleased to see that the revised document addresses the points that Point Blue raised in our June 2015 letter. However, we still have some minor concerns about the impacts analysis to the plover and offer the following information for consideration to better address impacts.

1. Changed Habitat Conditions

- As noted in the document, the beaches west of the slant well portions of the project site are important for wintering plovers and the slant well project site itself historically has been used by wintering plovers. In the past two years, this outer beach habitat has been reduced as a result of intense winter storms that have caused beaches to narrow significantly and become lower in elevation. This pattern of habitat loss is likely to continue with increasing frequency and intensity of coastal storms projected due to climate change (see below).

- The outer beach to the south of the slant well site receives frequent visitation from pedestrians with unleashed dogs under current management policies. Thus we suggest reclassifying the disturbance regime of the area from "relatively undisturbed" to "disturbed" (4.6 – p. 130 and 136). Point Blue-1
- Though the impact of a temporary reduction of wintering habitat at the inland slant well site during the construction phase seems like a minor impact, when combined with recent habitat losses and high levels of disturbance from unleashed dogs at the outer beach wintering sites, the temporary habitat loss is likely to have a greater impact than stated in the document. Point Blue-2

2. Climate Change

- The habitat at the proposed slant well site has the potential to become more important for both nesting and wintering plovers over time due to long-term habitat reductions on the outer beach caused by sea level rise (SLR) associated with global climate change. The predicted effects of SLR include reduced beach width, more frequent storm inundation of beaches, and gradual inland retreat of the beach margin towards the slant well project site.
- As overall habitat area for plovers is incrementally reduced by construction of the project and from current storm patterns and long-term climate effects, the impacts of human-caused disturbance on the remaining habitat and on snowy plovers also will intensify. Point Blue-3
- At Point Blue, we strongly believe that considering the effects of climate change is a critical component of effective conservation planning. In the document, considerable attention has been paid to the effects of SLR (via the long-term erosion rate, p. ES-16) in the planning and siting of the slant wells; however the cumulative impacts analysis of the project on snowy plovers and the subsequent mitigation plan for plovers may be inadequate without consideration of the impacts of climate change.

3. Mitigation Plan

- The current mitigation concept for plovers is combined with the mitigation concept for plants and mentions the option of stabilization of dune sands (Mitigation Measure 4.6 1d - p. 170). Whereas this strategy may be beneficial to some species of dune plants, stabilization is not consistent with the habitat needs of plovers. Plovers occupy open primary successional habitat with low-lying plants, and sites with relatively unobstructed view-sheds are preferred for nesting (Point Blue unpubl. data). This ecological requirement should be incorporated into revegetation plans that cover current or historic plover habitat, including at the more inland slant well site. Point Blue-4
- Also, under Mitigation Measure 4.6 1d, 8b (p. 4.6 – 170), we recommend that Point Blue-5

mitigation funds be directed toward existing restoration programs in areas where recreational impacts to plovers are adequately managed. Sites that do not meet these criteria should not be considered suitable mitigations for impacts to plover wintering or breeding habitat unless management is improved.

Point Blue-5 cont.

- The concept of a mitigation ratio is good; however the proposed minimum 2:1 ratio may not be an adequate minimum ratio given the previous points related to "Changed Conditions" and "Climate Change" (above) and the significant amount of plover nesting that has occurred at the proposed slant well site over the past two decades. We suggest increasing the minimum ratio.

Point Blue-6

Thank you very much for consideration of this information.

Sincerely,

Kriss Neuman

8.6.16 Public Trust Alliance (PTA)

CPUC/MBNMS

c/o Environmental Science Associates

550 Kearny Street, Suite 800, San Francisco, CA 94108

March 27, 2017

Dear Commission and Sanctuary,

On behalf of our members who are ratepayers in Monterey and our members who are the beneficiaries of the public trust resources in Monterey as Californians, Public Trust Alliance submits the following comments on the Draft Environmental Impact Report/ Environmental Impact Statement on the CalAm Monterey Peninsula Water Supply Project. The analysis in this EIR/EIS does not meet the standards of CEQA or NEPA and must be corrected. Specifically:

1) The assessment of water demand fails to account for the improvements in water use efficiency implemented by the people and businesses of Monterey and as a result uses an unrealistically high estimate of system demand. This in turn means the analysis of growth inducing impacts is inaccurate.
2) The range of alternatives is unrealistically limited to only desalination as a potential supply source in Monterrey. Several potential sources are presented and then ignored, while findings of infeasibility for others are not supported by substantial evidence.
3) The project is inconsistent with the Guidelines for a use permit from the Monterey Bay National Marine Sanctuary ("MBNMS") and findings of consistency are not supported by substantial evidence.
4) The analysis of sea level rise and flooding uses out of date estimates that the DEIR/EIS points to as flawed. This requires reanalysis of the exposure to erosion and flooding.
5) The potential growth inducing impacts are incorrectly analyzed and underestimated.
6) The errors in estimates of growth inducing impacts renders the analysis of the indirect impacts incorrect throughout, especially with respect to traffic, recreational resources and greenhouse gas emissions.
7) The analysis of greenhouse gas emissions fails to incorporate the emissions attributable to the project through growth inducement.

8) The proposed mitigations for greenhouse gas emissions are neither effective nor valid as a matter of law under CEQA.
9) The proposed project fails to comply with the requirements to reasonably allocate the state's water resources under the California Constitution.

Given the significant and fundamental problems with the analysis in the DEIR/EIS, we urge the Commission and MBNMS to correct these issues and recirculate the DEIR/EIS such that the public may review the impacts and that the Commission may engage in informed decision-making based on a more accurate and reasonable assessment of the far-reaching impacts of this project.

1. **The Assessment of Water Demand is greatly exaggerated, resulting in greater water for new development.**
    a. **The estimate of existing system demand ignores mandatory and voluntary conservation programs.**

The analysis of existing system demand inappropriately ignores the history of water conservation measures that have limited the possibility of increases in total system demand in the service area to 2010 levels. The failure to consider the enduring reductions in water use resulting from these conservation measures means that the estimated service demand is too high. This in turn means that should the people of Monterey continue to conserve as they have and the conservation measures installed continue to reduce demand, the project will result in substantially more water being available to induce new development.

The analysis of water demand in the DEIR/EIS assumes, unrealistically, that the interannual variation in water supply is due solely to random variation across years and not due to any systematic trend in water use. However, Monterey Peninsula has been subject to a series of mandatory and voluntary measures to improve water efficiency (e.g., see label measures listed in Figure 1.1.) Because many of these measures are permanent (e.g., installation of new fixtures and tighter standards for new development), these gains in water efficiency cannot be expected to reverse due to the normal variation in peak demand or the return of wetter water years. Thus, it is unrealistic to anticipate such high demand from existing users who have moved sharply to conserve water. These measures are not going to be reversed, as the hardware is already installed, and new construction and renovations would be subject to tighter standards than prevailed twenty or even seven years ago. As noted the peak demand is to be determined based on the prior ten years, but that record shows the last ten years continue a trend of greater efficiency and reduced demand that has continued across many business cycles over the last 20 years (see Figure 1 for the

PTA-1

Figure 1.1 Declining Demand over 20 years on the Monterrey Peninsula

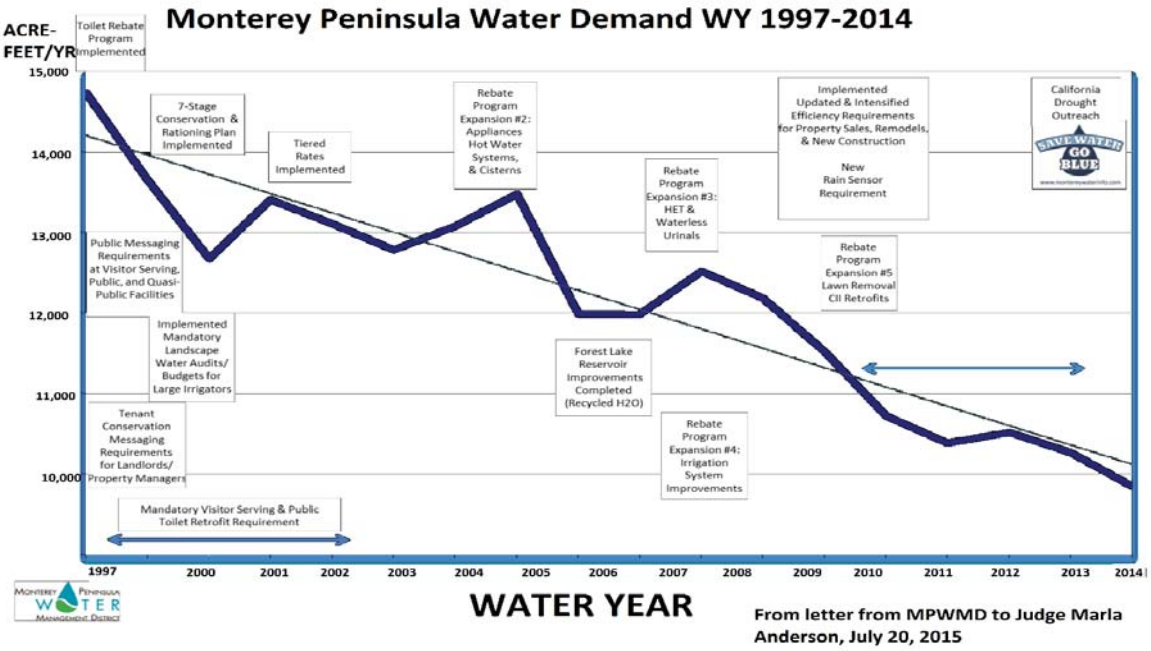

Figure 1.2 Declining Existing System Demand in CalAm service area (AFY by year)

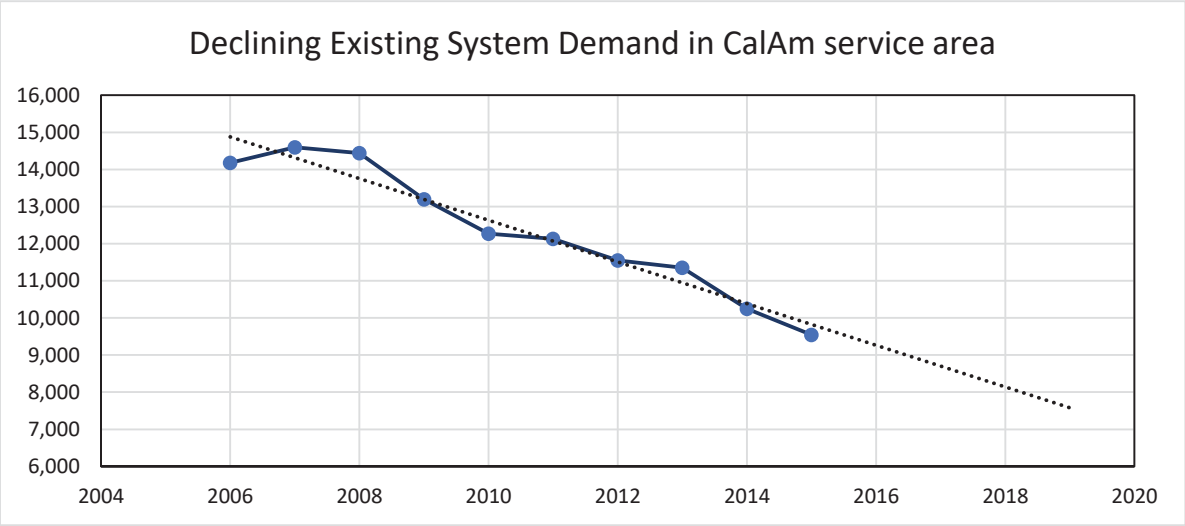

declining demand on the Monterey Peninsula and the list of water conservation measures implemented driving that decline.). As noted repeatedly throughout the DEIR/EIS, state and local authorities have taken heroic steps to require and incentivize increased conservation and have been dramatically successful

PTA-1 cont.

in doing so. Failing to take these trends into account serves to dramatically understate the environmental impacts of this project.

In fact, the data presented demonstrate that a much lower estimate of 2019 maximum system demand is supported by substantial evidence. Table 2-2 demonstrates a sharp decline in existing demand of roughly 600 AFY/ year. Furthermore, peak demand has not exceeded the trendline by more than 1,400 AFY in any year since 1997. Under those trends, the average system demand would be expected to be approximately 7,800AFY. Using the historical record of deviations from the trend, that would suggest a more reasonable estimate of maximum system demand in 2019 of 10,200 AFY, not 12,250 AFY as estimated in the current DEIR/EIS. Thus, accounting for the impacts of mandatory and voluntary permanent conservation efficiency gains that have resulted from conscious effort and mandatory programs, the system demand that would be expected to exist in 2019 would be considerably lower than the 12,250 AFY estimate used here.

PTA-1 cont.

Of course, the environmental impacts of such an error would be to free up additional water for new construction above and beyond the some 2,000 AFY described in the DEIR/EIS. Indeed, should current trends in conservation hold, the underestimate would likely double the water available to new development to over 4,050AFY. Naturally, this would exacerbate growth inducing impacts above what is estimated and potentially in excess of what has been analyzed in this DEIR/DEIS. As a result of the provision of water for ghost demand that no longer exists, the excess supply for new development would be on the order of 3,700 AFY, not the 1,755 used in this DEIR/DEIS. The implications of this error are further analyzed in Section 6 below.

b. The estimate of a 500 AFY allotment to increased hotel occupancy is not supported by substantial evidence.

Similar issues arise in the overestimate of increased water use for "rebound" of the hospitality industry. In fact, the 500 AFY number cited as the water demand by a recovered hotel occupancy rate has no basis in the evidence presented in the DEIR and is substantially higher than any increment over existing supply supported by evidence. Here, the key question is the elasticity of demand in response to increased occupancy rates. The DEIR/EIS relies entirely upon CalAm's estimates based on "discussion with industry representatives" (also known as guestimates), rather than any analysis of the actual trends and data available. We remind the Commission that CEQA's definition of "substantial evidence" does not include "[a]rgument, speculation, or unsubstantiated opinion or narrative...." (CEQA Guidelines 15384.)

PTA-2

By contrast, the DEIR/EIS markedly ignores the analysis of MPWMD, which derived a substantially lower estimate of the increase due to increased occupancy based on the relationship between occupancy and water Use. Based on that evidence based methodology, a 7 percent increase in occupancy would increase by 194 AFY. In addition, as noted above, even this estimate is likely too high, because it relies upon past relationships between occupancy and water use, and therefore does not incorporate changes in that relationship due to the numerous improvements in water efficiency have been made between 2011 and 2017. Therefore, at most the best estimate of the reasonable increment due to greater occupancy based in substantial evidence is 194AFY. The difference between the 500AFY assumed here and the 194 AFY based on substantial evidence would also become available to support additional growth, increasing that total by some 300AFY to approximately 4,050 AFY.

PTA-2 cont.

c. Table 13 water is inappropriately excluded from analysis

We also note that the DEIR/DEIS analysis of Table 13 water is inconsistent. The DEIR does not include Table 13 water as available supply, because such water is available only in wet years. Thus, while the DEIR does not incorporate increases in supply during wet years, the DEIR does incorporate increased demand during wet years. Naturally if the higher system demand estimates of 12,252 AFY used in the DEIR/EIS is chosen because of expected increases in demand during wetter years, then the supply rebound from Table 13 water must also be incorporated into the supply total to accommodate that peak annual demand as well. Furthermore, it is not necessarily true that this water is only available in wet year, since the DEIR/DEIS notes that this water is available to storage though the ASR project, and so could be used in dry years as well. Thus, estimates of total supplies should include some annualized accounting of Table 13 water that could either be used for wet year peak demand or stored for dry year demand.

PTA-3

2. The range of alternatives is unreasonably narrow and precludes *any* water supply solution other than desalination.

As noted in the DEIR/EIS, the analysis must consider feasible alternatives which would reduce significant impacts. (CEQA Guidelines 15126.6, *Citizens of Goleta Valley v. Board of Supervisors* (1990) 52 Cal.3d 553, *Laurel Heights Improvement Association v. Regents of the University of California* (1988) 47 Cal.3d 376). While the choice of alternatives is subject to the rule of reason, the choice of alternatives must not presuppose the ultimate decision by the agency.

PTA-4

Here, the entirety of the alternatives selected all involve desalination and all other alternatives are dismissed, even though several options have been considered and held for further analysis. Eliminating all non-desalination options as "infeasible" is particularly astonishing in a state that gets its water supply almost entirely from sources other than desalination. Such a narrow range of alternatives clearly presupposes that the solution to Monterey's water supply issues must be a desalination plant, which means that the impacts inherent to desalination cannot be avoided by any means whatsoever. Similarly, NEPA also requires the consideration of common sense alternatives. Here, that means looking at other potential water supply sources other than desalination, even if those alternatives are not within the jurisdiction of the lead agency. 40 CFR §1502.14 (c)).

The elimination of several alternatives is however not supported by substantial evidence. "Feasible" means "capable of being accomplished in a successful manner within a reasonable period of time, taking into account economic, environmental, social, and technological factors." (Pub Res. Code s 21061.1). Demonstrating that options are not feasible would require substantial evidence that is not present in the DEIR/EIS. In fact, several options have been discarded with little or no analysis as "not as promising." At minimum, each of the "hold" options under Plan B not shown to be infeasible should be brought forward. Although they may have drawbacks of various kinds, few involve the substantial environmental and energy impacts of desalination. Until these have been reviewed in greater detail, the Commission is in no position to make an informed decision regarding the relative merits of these less environmentally destructive approaches.

PTA-4 cont.

In particular, the Interlake Tunnel was rejected based on perceived difficulties on obtaining rights to any of the more than 50,000 AFY that project would develop. However, we note that the inability to obtain rights is predicated on the rights passing to the property owners and other stakeholders. However, since the project itself is contingent on funding from a Proposition 218 election that has not yet occurred, today the final disposition of those rights remains as yet undetermined. Given the failure of past attempts to fund the project in Sacramento (e.g., AB 1585) and other opposition to the structure of the project, it is far from certain that the rights could not be obtained. For example, it remains entirely potentially feasible for CalAm to offer funding for some component of the project, reducing the burden on local tax payers, in exchange for some portion of the rights to the developed water.

As noted in the EIR, the SWRCB points out that "[d]eveloped water is water that was not previously available to other legal users and that is added to the supply by the developer through artificial

means as a new water source." Since much of the water that would be diverted in the Interlake Tunnel would otherwise flow to the sea, this should constitute "developed water." Furthermore, when it comes to the rights to such water, "[t]he key principle of developed water is if no lawful water user is injured, the effort of an individual to capture water that would otherwise be unused should be legally recognized." Thus, to the extent that a project to develop water if no lawful user is harmed, Cal-Am could potentially obtain the rights to water developed through the Interlake Tunnel by contributing to the project in exchange for rights to a water supply that might otherwise not be developed. Thus, in absence of substantial evidence that such an arrangement is not possible, especially in light of the difficulties in obtaining financing for the project, elimination of this project from consideration as an alternative is inappropriate.

We also note that the Interlake Tunnel would be superior to the proposed project in that the proposed project fails to meet two of CalAm's and the Commission's objectives: namely to "[m]inimize energy requirements and greenhouse gas emissions per unit of water delivered" and to '[m]inimize project costs and associated water rate increases." As discussed below, desalination uses extraordinary quantities of energy with associated greenhouse gas emissions. Thus, the proposal could not be fairly characterized to minimize energy requirements. Furthermore, CalAm requires not more than 30% of the potential developed water from the Interlake Tunnel Project, suggesting that CalAm could potentially obtain water rights from funding a third of the project costs of $25 million. Spending some $322 million on a desalination cannot be said to "minimize project costs" in light of a possible project costing under 5% as much.

In addition, several other possible alternatives do not appears to have been considered including a combination of increased conservation funding, maximizing wastewater recycling, and other sources of water that may not be as favorable, but absent substantial evidence that they are concretely infeasible, they must be carried forward as reasonable lower cost and environmentally favorable alternatives.

PTA-4 cont.

3. The Proposed project is inconsistent with several elements of the MBNMS Guidelines.

The DEIR/EIS appears to erroneously conclude that the special use permit by MBNMS would be consistent with the guidelines for desalination within the sanctuary. For example, the guidelines state that "[d]esalination should only be considered when other preferable alternatives for meeting water needs, such as increased conservation and wastewater recycling are maximized or otherwise determined not feasible, and it is clear that desalination is a necessary component of the region's water supply portfolio."

PTA-5

However, as noted above there is no substantial evidence that waste water recycling has been maximized. For instance, the GWR program appears to be successful in recycling waste water on a limited basis and similar projects could be developed. Also, wastewater from the Salinas Valley may be potentially recyclable to acceptable standards, but is not analyzed here nor demonstrated to be infeasible. Thus, there is no substantial evidence that the project meets this guideline.

Furthermore, this DEIR singularly fails to "identify measures available to reduce electricity use and related emissions" and to mitigate for all remaining emissions." As discussed below, the DEIR/EIS fails to consider several potential mitigation measures that could fully mitigate greenhouse gas emissions, but instead relies on a standardless and unenforceable "good faith efforts" to offset some 20% of emissions as mitigation. This approach is facially not consistent with this Guideline. (DEIR at 6-50)

PTA-5 cont.

Finally, as described below, the DEIR/EIS relies on an entirely inadequate estimate of sea level rise and potential erosion. Consequently, the project also fails to meet the Guidelines that "[d]esalination plants in MBNMS should not contribute to coastal retreat and should not be designed to anticipate the possibility of installing coastal armoring at any time in the future to protect the plant or its infrastructure from effects of coastal erosion, wave action of sea level rise." As described below, greater sea level rise than estimated here is likely to contribute to greater erosion and an unspecified risk of coastal armoring being required in the future.

4. The DEIR/EIS underestimates the level of sea level rise and fails to consider changes in the best science regarding sea level rise.

The DEIR/EIS uses estimates of sea level rise that are out of date and too low. As the DEIR/EIS acknowledges, sea level rise estimates have steadily increased in the last few years as prior estimates have been shown to have failed to incorporate substantial effects, such as ice melt from Antarctica or Greenland which alone may double prior estimates.[1] Indeed, the three citations cited in the DEIR/DEIS show increasing sea level-rise estimates by 2100. Inexplicably, the DEIR uses the oldest estimate of the three of 55 inches in Figure 4.3-1, rather than the most recent estimate from the gold standard of climate change assessments, the Assessment Report of the IPCC from 2016. As cited in the Assessment Report, the mean sea level rise is now expected to be in excess of 20 feet, not under 5 feet as is used in this DEIR/EIS. In fact, recent scientific information has come to light since the 2014 *Analysis of Historic and Future*

PTA-6

[1] R.M. DeConto & D. Pollard (2016) Contributions of Antarctica to past and future sea-level rise. Nature 531:591-597. doi:10.1038/nature17145

Coastal Erosion with Sea Level Rise study by ESA. Thus, the estimates of both flooding and coastal erosion are certainly lower than the substantial evidence presented both here and in the DEIR/EIS itself.

Given that level of sea level rise, clearly, both erosion and flooding is likely to have substantially greater impacts on the project and greatly increase the potential need for coastal armoring to eventually protect the project. In light of new information in the Assessment Report and additional recent studies, the DEIR underestimates the degree to which the project will expose significant structures to erosion and flooding. To the extent that such impacts will necessitate sea walls, the project would also be inconsistent with the Coastal Act and MBNMS guidelines. Thus, the conclusions regarding the impacts of sea level rise and flooding cannot be seen as supported by substantial evidence, when the evidence in the DEIR/EIS itself contradicts the foundational assumptions of the analysis.

PTA-6 cont.

5. **Growth inducing impacts are not properly analyzed nor attributed to the project**

   a. **The DEIR/EIS inappropriately fails to analyze induced growth based on an inappropriate application of environmental review of local general plans.**

The DEIR/EIS improperly excludes the impacts of the project as indirect growth based on a theory that they do not occur or are not attributable to the project because the growth may have been included in the analysis of various general plans. Certainly, it is not controversial that "[w]ater supply capacity to serve new development would remove water supply limitations as an obstacle to such development and would be considered growth-inducing under CEQA and NEPA." (DEIR at 6-20.)

However, the analysis of that growth cannot be avoided or ignored simply because it may have been considered in environmental review of entirely different projects. While the impacts of growth may have been previously analyzed under general plans, CEQA requires a comparison to *existing physical conditions*, not the conditions that may have been permitted but have not yet. This point was recently reemphasized by the California Supreme Court: "A long line of Court of Appeal decisions holds, in similar terms, that the impacts of a proposed project are ordinarily to be compared to the actual environmental conditions existing at the time of CEQA analysis, rather than to allowable conditions defined by a plan or regulatory framework. This line of authority includes cases where a plan or regulation allowed for greater development or more intense activity than had so far actually occurred...." (*Communities for a Better Environment v South Coast Air Quality Management Dist.* (2010) 48 Cal. 4th 310, 320. See also, *Woodward Park Homeowners Assn., Inc. v. City of Fresno* (2007) 150 Cal.App.4th 683, *Christward Ministry v. Superior Court* (1986) 184 Cal.App.3d 180.)

PTA-7

As acknowledged in the DEIR/EIS, most if not all of the general plans characterized the future development planned for as being contingent upon the development of new water supplies to support that development. Indeed, the DEIR/EIS concedes that "[a]ll of the jurisdictions cite limited water supply as a key factor limiting planned development within their boundaries." In several instances, development permits have been limited by the available water supply at levels even below those considered in the general Plans. Thus, the provision of additional water will allow for additional development that otherwise would not have occurred. Consequently, there will be changes in the existing physical environment that would not otherwise occur with the provision of the additional water in this proposal. Under CEQA case law, the authorized levels of environmental impact are immaterial to the assessment of the physical changes in the environment that would occur and those changes must be considered throughout.

Furthermore, the DEIR/EIS should disclose throughout that the prior analyses of buildout found significant and unavoidable impacts, and not simply conclude that there are no significant impacts from development by ignoring those analyses. For example, the DEIR/EIS relies on the analysis of induced growth in the Monterrey General Plan, but fails to disclose in its discussion of greenhouse gas emissions attributable to the project that the environmental documents for the 2007 Monterrey County General Plan Update concluded that "buildout within the County beyond 2030 is determined to make a considerable and unavoidable contribution to cumulative GHG emissions and global climate change." (Draft EIR for the 2007 Monterey County General Plan Update, at 4.16-38.) Thus, the DEIR/EIS should not ignore that the induced growth has already been found to result in considerable and unavoidable contributions to cumulative GHG emissions and global climate change.

PTA-7 cont.

Furthermore, the DEIR/EIS is correct in determining that growth in excess of that previously analyzed requires additional analysis and disclosure and would be a potentially significant impact for failure to be consistent with general plans. "A project that would induce growth that was inconsistent with those plans and policies could result in adverse environmental impacts not previously addressed in the CEQA review of those plans" (DEIR at 6-26.)

b. The amount of water made available to new development is vastly too low and therefore fails to capture induced growth in excess of planned growth.

As noted above, the estimate of system demand of 12,270 AFY is likely over 2,000AFY too high, once conservation measures are taken into account. This has the effect of freeing that additional water to new development. However, we also note that even the allotment to "meet anticipated future demand"

PTA-8

includes water supplies for currently undeveloped lots of record. As the DEIR/EIS acknowledges, development of these lots that would not occur without water supplies by definition is new development and must also be included in the estimate of water available for new development. Furthermore, as the DEIR/EIS also acknowledges, some portion of the 500 AFY for rebounded hotel use also could be diverted to new development to the extent that 500AFY is an overestimate. Furthermore, the allocations for SVGB return would also be available for future development in 25 years' time and should be properly included in the estimates of increased water available for development.

The total amount that would be available for development, either in 2019 or in 2044 is included below.

Table 6.1 – FUTURE WATER DEMAND AND AVAILABLE SUPPLIES UNDER CONSERVATION ASSUMPTIONS.

Category	Water for new Development
TOTAL SUPPLIES	**16,294 AFY**
Service Area Demand after Conservation Measures	10,200AFY
Hospitality bounce-back	194 AFY
Supply available for other uses	**5,900 AFY**
6%/12% SVGB return	1,620 AFY/3,240 AFY
Surplus for future development (2019)	4,280/2,660 AFY
Total for Future Development	**5,900 AFY**
Future Supply Needs Revised/Reduced	**3,526 – 2820 AFY**
MPWSP supply for Future Development as % of future needs	**75% (12% SGVB return, no conservation) to 152% (6% return, with conservation)**
MPWSP supply in 2044	**209% of need.**

PTA-8 cont.

Thus, a full accounting of the conservation effects, the overestimate of hospitality demand and inclusion of all new development suggests that the MPWSP may supply up to twice as much water for new development as was analyzed under prior general plans. Given the track record of conservation over the last twenty years, known factors reducing future per capita consumption in new and existing development, and CalAm's track record of consistently overestimating demand, a fully informed analysis of growth

inducing impacts must include an analysis of the growth inducing impacts should the state and local conservation estimates be successful, as they have been in the past.

The DEIR/EIS must analyze potential growth in excess of planned growth that may result from a failure to adequately predict the degree of conservation. As demonstrated above, should the extensive conservation measures implemented by state and local authorities result in permanent and continuing decline, the present project may allow for induced growth that exceeds planned growth by over 50%. Given the substantial evidence underlying this possibility, the DEIR/EIS should disclose and assess that potential more fully so that the Commission may determine whether approval of the project and the attendant potential explosion of growth is in the public interest.

PTA-8 cont.

6. **Land Use and recreational and traffic impacts are underestimated for failure to account for induced growth.**

In fact, as acknowledged in Section 6.3, the project would have growth inducing impacts and these are likely substantially underestimated. As discussed below, since this growth represents a change in the existing physical environment that would not occur but for this project, these impacts are fairly attributable to the project. To the extent that the underestimate in existing demand causes growth to exceed that previously analyzed in any general plan CEQA documents, this induced growth has not heretofore been analyzed. Since the EIR/EIS document is to assess both direct and *indirect* impacts, as well as cumulative impacts, such that these indirect impacts must be evaluated throughout.

In particular, the conclusions in Section 4.8.5. that the project would not have the effect of increasing housing or residents in the area is directly contradicted by the acknowledgement of the growth-inducing impacts of increased water supply in Section 6.3. Furthermore, the conclusion that the project would not cause increased use of existing neighborhood and regional parks and other facilities is similarly not tenable. Indeed, the project specifically calls for water to supply an expanded tourist industry that very clearly would be directed at use of regional parks and other facilities. The analysis of traffic impacts utterly fails to incorporate any indirect or cumulative impacts of induced growth. Whether or not these impacts were previously analyzed for some different project, these changes from the existing physical environment that would not occur but for this project must be incorporated into the analysis.

PTA-9

7. **The DEIR/EIS fails to incorporate increased greenhouse gas emissions attributable to induced growth.**

As discussed above, the impacts of induced growth are fairly attributable to the project. While many impacts are difficult to discern and under the control of local governments, the greenhouse gas emissions from induced growth can be assessed regardless of where and how new development proceeds. Since those contributions from induced growth have been deemed cumulatively considerable to the contributions of greenhouse gasses to the atmosphere in prior general plan analyses, these analyses must be carried forward and disclosed in the DEIR/EIS to facilitate informed decision making. PTA-10

8. **The mitigation measures for indirect greenhouse gas emissions are both legally and technically inadequate.**

Greenhouse gas emissions are clearly a major concern and serious environmental impact of desalination plants generally. As noted in the DEIR/EIS, water production and distribution is already a major component of the state's water use and GHG emissions. Consequently, CARB requires water projects to reduce the magnitude and intensity of energy use by 20 percent through implementation of energy-efficient production, treatment, and conveyance infrastructure. Furthermore, Executive Order B-30-15 directs state agencies such as the Commission to factor climate change into planning decisions. Both considerations cut heavily against engaging in energy intensive water production such as desalination unless there is truly no other option. PTA-11

The DEIR/EIS appropriately uses the local agency standard for non-emitting land uses of 2,000 metric tons CO_2eq as a significance threshold and correctly determines that the project is greatly in excess of that threshold.

However, the DEIR/EIS singularly fails to identify obvious mitigation measures as required by CEQA. CEQA Guidelines in fact require consideration of energy conservation measures, such as measures to increase reliance on renewable energy. CEQA Guidelines 15126.4(a)(1)(C). Indeed, alternative fuels or renewable energy supplies are not specifically called out for consideration and discussion at all, despite the clear call for consideration of such measures under CEQA Guidelines, Appendix F, II.D.4. Indeed, these measures are required to be considered, and may include off-site measures, including offsets that are not otherwise required, to mitigate a project's emissions. CEQA Guidelines 15126.4(c)(3).

The notion that the CPUC of all agencies deems the reduction of carbon emission "unavoidable" simply beggars belief. In fact, establishing mitigations to reduce emissions below the significance threshold is not complicated and squarely within the Commission's expertise. Reducing the emissions of the project from the aggregate carbon emissions of 8,370 metric tons would involve the production of procurement of enough renewable energy to account for 6370 metric tons, or 12,043,302 pounds of CO_2e. At the quoted rate of PG&E's mix of 290 pounds per MWh, this works out to obtaining an additional 48,425MWh per year of renewable power, either through construction of onsite solar, contracting independently or through PG&E for supplemental renewable power, or some combination thereof. For example, a very modest size solar farm could produce this power. In fact, this quantity of power could be obtained with a solar array of slightly over 140 acres, according to NREL calculations requiring 2.9 acres per GWh of annual energy production.[2] We note that the 46-acre site itself would provide for potentially enough space for fixed tilt photovoltaics to produce some 16 GWH onsite, or over a quarter of the total. Furthermore, given that Power Purchase Agreements for solar and other renewables are close to grid parity, the economic costs associated with purchasing renewable power would be far from prohibitive. In fact, regardless of what those costs are, they are properly included as a cost of energy intensive water production. If such mitigation measures render the project too costly, then price signals will have appropriately forced a conclusion that the project is not feasible when mitigation for environmental impacts are properly accounted for. In such a case, presumably one of the other alternatives would become the properly preferred alternative.

PTA-11 cont.

We note also that the approach to measuring energy usage is inappropriate. The estimate of energy use by the project makes little sense, since subtracting existing water system electricity use from the project's demand assumes that none of the existing supplies and operations would be ongoing. This is not consistent with the discussion of existing supplies. The marginal increase should be for the full emissions associated with the plant, without subtraction of energy use for infrastructure that would be continuing.

PTA-12

In addition, the DEIR/EIS approach to mitigation is wholly inadequate under CEQA. First, disregarding a significance threshold simply because one cannot imagine mitigations is not a legitimate approach under CEQA. Under CEQA the DEIR/EIS is to evaluate the impacts to the physical environment, whatever they may be, and the failure to see an effective mitigation is not a valid reason to ignore the potential significance of an impact. As demonstrated above, mitigation measures for carbon

[2] S. Ong, C. Campbell, P. Denholm, R. Margolis, and G. Heath (2013) National Renewable Energy Lab Land-Use Requirements for Solar Power Plants in the United States, NREL Technical Report NREL/TP-6A20-56290

impacts from electricity use are both well understood and feasible. Here, the plant will use extensive electricity and those emissions have a significant contribution to statewide GHG emissions, regardless of whether the Commission can envision a method for reduction or not.

Second, the structure of the mitigation measure 4.11-1 is not valid under CEQA, because the energy reduction plan represents both deferred mitigation and non-binding mitigation. To be valid, mitigations measure must be fully enforceable through some legally binding instrument. CEQA Guidelines 15126.4(b)(2). "Good faith" efforts are standardless and do not constitute legal mitigation measures. Furthermore, imposing a mitigation measure to require a plan to develop mitigations constitutes inappropriate deferred mitigation. Since the results, if any, of such a plan cannot be in any way assessed, such measures cannot constitute a valid mitigation measure. Courts have been entirely clear that future efforts to identify mitigation measures are not adequate as mitigation measures under CEQA. (See, e.g., *Communities for a Better Environment v. City of Richmond* (2010) 184 Cal.App.4th 70))

PTA-12 cont.

Finally, we also note that the project also fails to comply with CARB's mandates to employ less energy intensive water infrastructure. Whether compared to alternatives, such as the Interlake Tunnel, recycling or water purchases or existing supplies, such as diversion from the Carmel River, the project would consume vastly greater quantities of energy. Therefore, the Commission can determine not only that the project would not reduce energy consumption, but that that the desalination plant would greatly increase the energy use per acre-foot of water by employing particularly energy intensive production methods. Thus, it is clear that this project is not consistent with CARB's mandates.

PTA-13

As a consequence of the above analysis, we recommend that the Commission protect the public trust atmospheric resources by imposing a requirement that CalAm obtain or produce onsite sufficient renewable power to reduce emissions below the 2,000 metric tons CO2eq per year (by our estimate, 48,425MWh per year of renewable power)

9. The project as proposed fails to safeguard and reasonably allocate the state's public trust resources.

Finally, CEQA requires consideration of whether the project would conflict with any applicable policy or regulation adopted for the purpose of avoiding or mitigating an environmental effect. (CEQA Guidelines, Appendix G, Section X(b).) In fact, Article X, section 2, requires that "the waste or unreasonable use or unreasonable method of use of water be prevented." (California Constitution, Article X.) The present project fails to prevent the unreasonable use of water and represents just such an

PTA-14

unreasonable method of use. In addition, the California Water Code has long favored domestic use over agricultural use. Here, the Commissions fails to uphold its public trust responsibilities and violates this provision of the Constitution by failing to even consider alternative water supplies that divert water from lower priority uses such as water intensive agriculture or recreation to use by urban domestic users. Insofar as this project uses an environmentally damaging, resource intensive, and expensive method to avoid such diversion, this proposal represents an unreasonable method of use, and facilitates, rather than prevents, the unreasonable use of water.

Under the California Constitution, the Commission has a continuing duty of supervision over the allocation of water resources. Although reallocations of the state's public trust water resources lie within the jurisdiction of the State Water Resources Control Board, the Commission can make a finding under CEQA Guidelines 15091(a)(2) to recommend that the State Water Resources Control Board can and should be adopt mitigation measures for the unreasonable use of the state's public trust waters by reallocation of water resources to higher priority domestic water users from lower priority agricultural or recreational uses.

PTA-14 cont.

CONCLUSION

For the foregoing reasons, Public Trust Alliance requests that the Commission reanalyze the issues above a recirculate the DEIR/EIS with adequate mitigation measures of the likely impacts of the project.

Respectfully submitted,

Douglas M. Karpa

Comment on MPWSP - Cal Am A1204019

Public Water Now (PWN) objects to two significant omissions in the January 13, 2017 DEIR/EIS.

1. The shutdown of MLPP once-through cooling ocean intakes in 2017.
2. Recent legislative mandates in the Sustainable Groundwater Management Act.

1. **Shutdown of MLPP once-through cooling ocean intakes in 2017 is a massive new positive impact on the marine ecology and environment.**

The CA Energy Commission is not mentioned in the list of agencies having a role in this project. Only one state agency is listed, the CSU Monterey Bay.

This omission of the CEC relates to the massive change taking place at the Moss Landing Power Plant (MLPP), and the associated environmental benefits.

There is no discussion of the planned shutdown of major water-cooled turbines at the Moss Landing Power Plant (MLPP). There is no mention of this in the list of projects that may contribute to cumulative impacts. The shut-down of Units 6 and 7 will occur in 2017. This will terminate a high volume of open ocean intake for once-through cooling. The capacity for Units 6 and 7 intake is 320mgd.

PWN1-1

How could the DEIR/EIR team miss the largest change on the local marine environment in decades? And directly adjacent to proposed projects? And not see the beneficial impacts? And not see a relationship to the alternatives analysis?

The only discussion of the shutdown issue was in Appendix I, Intake Option #7 – Disengaging Basin at Moss Landing Power Plant (Water from Spent Cooling System) (page I2-5 to 7). Throughout the entire discussion, no mention was made of the reduction of ocean intake, and no reference to the benefits on the marine environment. The shutdown was presented only as a complicating factor, leading to unpredictable planning for use in a proposed desal.

Had the beneficial impact of the shutdown received adequate attention, there would have been mitigating positive circumstances in order to continue to consider all the projects at Moss Landing. By not mentioning the shutdown, the DEIR could only muster negative references to 'complications'.

All alternative water supply projects located in the Moss Landing area use ocean water intakes. One is subsurface intake (Cal Am), and three are screened ocean intake (Cal Am, Peoples, and Deep Water). A full evaluation of those alternatives should include some information on the reduction of ocean intake by MLPP, which is a plus to Elkhorn Slough and the ocean marine ecology. This is important because this volume reduction is far greater, by several magnitudes, than any new ocean intake for nearby desal facilities.

PWN1-1 cont.

While the DIER/EIS comments negatively about ocean intake, this omission leaves the picture only half told. The DEIR is one-sided and narrow. It excludes a new and enormous positive environmental impact on the ocean, which could be a balancing comment about desal ocean intakes.

Please include this fact and a related analysis. Or please explain why it is not relevant as an offset to negative impacts. Surely when the DEIR looks out 40, 60, 100 years, this shutdown in 2017 is a major omission. This fact and a related analysis should be included.

Such omissions shows how a DEIR can be slanted to favor one project over others. This shortcoming reveals just how a key and fundamental omission can distort the analysis of alternatives, weaken the quality of analysis, and weaken the overall DEIR/EIS.

Please add this analysis and make the presentation of fact and opinion relevant and valid. Otherwise, this hole, this omission, makes the DEIR extremely vulnerable.

2. Sustainable Groundwater Management Act is ground-breaking legislation that has a nexus with MPWSP.

PWN1-2

There is no mention in the DEIR/EIS nor the Appendices of the Sustainable Groundwater Management Act (SGMA).

This far-reaching state legislative mandate applies to all local water jurisdictions in California. There are implications of this law for the MPWSP. The production of a water supply specifically from the over-drafted Salinas River Basin obviously intersects with SGMA. Responsibilities of Marina Coast Water District intersects with Cal Am's plans and MCWD's plans. The DEIR/EIS should at least mention the potential for a nexus.

PWN1-2 cont.

Mitigations may have a nexus with SGMA.

Will the CPUC continue to claim it has authority superior to local governments so long as Cal Am operates its wells? The nexus may lead to disputes over jurisdiction and response.

The DEIR is not a treatise on legal matters, yet it addresses the water rights issues in great detail and over many pages. It appears that the CEQA/NEPA team felt comfortable including documents like the SWRCB memo that supported the MPWSP and its need for water rights. Did the team find it convenient to omit other material that could have supported other options? And if not other options, at least the SGMA could have presented a connection to future scenarios.

Please add comments on the potential inter-connection. At least address the timing, and explain away the nexus if there are no implications. Or explain where there may be inter-connections, but at a later date. To leave it unmentioned puts a blind eye on the most significant new state legislation affecting future water management and supply issues. To ignore it completely, when the DEIR contains many comments on related matters, is to leave a major topic and issue unaddressed. This omission is another major deficiency. Please add it, or at least comment on it's relevancy or not.

DEIR/EIS on MPWSP Released January 13, 2017

Public Water Now Comments (georgetriley@gmail.com)

Page	DEIR Reference, Quotes	Comment	
	ES.2 Project Background		
Q1 ES-2	The water supply challenges facing CalAm and the Monterey Peninsula are substantial and have been well-documented in a number of venues including the SWRCB, the Monterey County Superior Court, the CPUC, and the California Legislature.	Also in the local media. Very well documented are the many failures by Cal Am management. Cal Am over-drafted the Carmel River. Cal Am contributed to over-drafting Seaside Groundwater Basin. Cal Am initiated 3 supply projects after the initial CDO in 1995, and all failed or were discontinued. Will ESA include more context on the Peninsula challenges?	PWN2-1
Q2 ES-2	In September 2015, after considering the Draft EIR comments and based on conversations with MBNMS and internal CPUC deliberations, the CPUC Energy Division announced that the Draft EIR would be modified and recirculated.	The conflict of interest with Cal Am's hydrogeologist was the trigger for review. That weakness continues within the heralded Hydrogeologic Working Group (HWG). Will this context be included in future documents?	PWN2-2
Q3 ES-5	...subsurface slant wells (eight active and two on standby) extending offshore into the submerged lands of MBNMS... ...extract 24.1 million gallons per day (mgd) of source water through the seafloor in MBNMS.	These statements declare Cal Am intention to mine seawater from under the ocean floor. Yet the project has 90% of all intake screens inland of the sea floor. The statements are misleading. Surely the DEIR/EIS team knows these facts. Will these statements be clarified in the Final DEIR?	PWN2-3
Q4	Footnote 2. In October 2014,	This is misleading. There were Mitigated Negative	PWN2-4

ES-6	MBNMS finished its NEPA review of the construction of the test slant well and the operation of the pilot program. In November 2014, the City of Marina and the California Coastal Commission completed their CEQA review.	Declarations. Not much of a review. Furthermore, City of Marina voted against the project. Will this be explained, in order to be factual? Otherwise the narrative is biased, or suggests a bias. That does not help this document.	PWN2-4 cont.
Q5 ES-13 to 17	ES.8 Areas of Controversy and Issues to be Resolved	Therer is absolutely no mention of Cal Am's invasion of a neighboring public water jurisdiction (Marina Coast Water District) to take its water for diminished supply in Cal Am's area (Monterey Peninsula). This is significant because the environmental impacts from the MPWSP are direct impacts on the MCWD jurisdiction. To ignore this aspect of Cal Am's project location is to abandon relevancy to the real world. Regional perspectives are expected in the DEIR. Yet this aspect is totally missing. Nothing seems more proof of an incomplete DEIR than to ignore this fact. Will the Final EIR address this huge omission?	PWN2-5
Q6	Comment/Question	While it is an embarrassment to the entire Peninsula that Cal Am mismanaged our local water supply sources (Carmel River and Seaside Groundwater Basin), it is not the responsibility of MCWD or the City of Marina to jeopardize or compromise its own water supply source and cause harm to its own customers and citizens in order to rescue Cal Am from the hardship it has inflicted on its own customers. The law protects MCWD from such injury. The CPUC must do the same.	PWN2-6
Q7 ES-13	"The proposed subsurface slant wells at CEMEX would extend offshore..." "...the subsurface slant wells would draw seawater... from beneath the ocean floor..."	Here and elsewhere, the specific description is 'under the ocean or sea floor'. Yet the fact is that the test well has been known to only be about 5-10% under the 'ocean or sea floor'. 90-95% of the intake screens are located inland of the mean high water (MHW) line. This fact is not even a footnote in the numerous references to 'under the ocean or sea floor'. This is consistently misleading. Will the intended and engineered locations of the slant well intakes, and the planned intake system, be accurately described? To ignore this fact is to compromise the accuracy of the DEIR, which then undermines the purpose of the DEIR. Will you please add corrections and clarifications as appropriate? Will this be addressed?	PWN2-7
Q8	Several state and federal regulatory	Nowhere in the DEIR is language from SWRCB or	PWN2-8

ES-16	and permitting agencies (SWRCB, California Coastal Commission (CCC)) will not consider permitting an open-water intake unless a subsurface intake has been deemed infeasible or would result in greater environmental impacts.	CCC documents that describe the 'feasibility' criteria. Also the CEQA law provision re 'feasibility' is omitted. This omission leaves it to the ESA writers to wing it on language. Since 'feasibility' is a common theme throughout intake discussions in this DEIR, will the Final EIR include specific language so the record is accurate and complete?	PWN2-8 cont.
Q9 ES 2-35	Footnote34. The EIR/EIS preparers have also had the benefit of working closely with, and receiving input from, the Hydrogeologic Working Group (HWG) that was formed as a result of the proposed settlement in the CPUC proceeding on the MPWSP. The HWG is composed of experts representing myriad parties in the CPUC proceeding with diverse interests related to the Basin, including but not limited to the Monterey County Farm Bureau, the Salinas Valley Growers Association and CalAm. The EIR/EIS preparers obtained feedback from the HWG as to the groundwater aquifer characterization and the groundwater modeling assumptions.	The DEIR fails to include a key fact that may have a bearing on the credibility of the HWG. One member representing Cal Am (Dennis Williams of Geoscience) holds the patent on the exact technology used in this project. The potential bias from the patent holder is apparent to any observer. In fact this conflict of interest was pointed out, and the CPUC admitted this conflict, and changed its evaluation team because of it. This seemingly obvious bias continues with Williams/Geoscience in the HWG, which in turn compromises the credibility of the HWG. Please explain how this bias is not a reason to question the credibility of the HWG. Or please explain why this fact is helpful to the credibility of the HWG.	PWN2-9
	Chapter 1, Intro and Background		
Q10 1-6	1.3.2 MBNMS Purpose and Need for Proposed Actions Four federal proposed actions are addressed in this document and consist of the following: 1) authorization of a Coastal Development Permit to be issued by the City of Marina for CalAm to drill into the submerged lands of the Sanctuary to install a subsurface seawater intake system;...	This is misleading. The CA Coastal Commission over-ruled the denial of the Coastal Development Permit by City of Marina. The language ignores the contentious nature of that process, ignores a jurisdictional denial, and the over-ruling by a state agency. The narrative sugarcoats the history, and seems to be a political message that the DEIR is telling all the facts, and in the context that approval is a normal conclusion. The DEIR is not presenting an objective view. Where does 'trust' fit, and where does it fail? This DEIR is showing a bias.	PWN2-10
Q11	Footnote 4 The Applicant proposes to use subsurface intakes (slant wells) to supply the desalination plant with	Here, as elsewhere throughout the proposed project discussion, the proposed project design consistently refers to source water being extracted from under the	PWN2-11

	source water. The well casings, or pipes, would extend seaward of MHW...	sea floor. Yet the recommended project allows intakes from under the overlying land (not the overlying ocean), inland of the Mean High Water line, which is a sharp and significant difference in water rights. The lack of noticing this difference within the document is a major shortcoming of this DEIR. Will this be corrected with appropriate notes and language?	PWN2-11 cont.
Q12 1-8	1.4.1 The Coastal Water Project Footnote 5. The North Marina Project alternative included most of the same facilities as the previously proposed Coastal Water Project and, like the previously proposed Coastal Water Project, would only provide replacement supplies to meet existing demand. The key differences between this alternative and the previously proposed Coastal Water Project were that the slant wells and desalination plant would be constructed at different locations (Marina State Beach and North Marina, respectively), and the desalination plant would have a slightly greater production capacity (11 mgd versus 10 mgd).	This comment that MPWSP parallels the Coastal Water Project is vastly inaccurate, and the intent is insincere. The Coastal Water Project included these huge differences: 1) Had public ownership 2) consistent with County Ordinance, 3) vertical wells, 4) with water rights, 5) was regional, 6) did not require NEPA review, and 7) was not an invasion of another water jurisdiction. To state unequivocally that these projects are very similar is to ignore the facts. When such bias is noted, and not corrected, the entire DEIR shows itself to be inadequate, to be fanciful not factual, and to seem to serve a political purpose rather than a factual and science-based purpose. Will corrective language be included?	PWN2-12
Q13 1-9	It (old Regional Desal Project) included vertical seawater intake wells...	The loose language about seawater, brackish water, contaminated water, intruded seawater, and fresh water does not add clarity for the reader. The Regional Desal Project intended to take brackish water, not seawater. Will this be corrected?	PWN2-13
Q14 1-9	The Coastal Water Project Draft EIR and Final EIR are available for review during normal business hours at the CPUC, 505 Van Ness Avenue, San Francisco, California.	This is a slap in the face to the Monterey Peninsula. Same with the notice of this DEIR release. Many documents backing up this DEIR are available in SF, at CPUC offices. Why not on the Peninsula, where the project is located? The DEIR is complicated enough, without making it even more difficult to access the information.	PWN2-14
Q15 1-9	1.4.2 The Monterey Peninsula Water Supply Project In April 2012, CalAm submitted Application A.12-04-019 (CalAm, 2012), asking the CPUC's permission to build, own, and operate a desalination facility for water supply.	But this DEIR omits reference to the differences, all of which are critical to many locals: Invasion of neighboring water jurisdiction without invitation, without water rights, without compliance with County ordinance, without regional benefits within the invaded jurisdiction.	PWN2-15

	This project is the MPWSP. The MPWSP incorporates many of the same elements previously analyzed in the Coastal Water Project EIR...		PWN2-15 cont.
Q16 1-11	Footnote: ...In November 2014, the City of Marina and the California Coastal Commission completed their CEQA review....	This implies City of Marina gave its approval. In fact, it specifically denied the permit. CCC over-ruled the City. The suggestion of shared approvals here is a bias. Will this bias be removed?	PWN2-16
	CHAPTER 2 Water Demand, Supplies, and Water Rights		
Q17 2-13	2.3.3.2 Hospitality Industry Rebound	Although the DEIR includes much data on population and housing projections, nowhere does the DEIR relate the data to actual per capita water consumption. For instance, Cal Am documents and this DEIR continues to suggest that one acre foot of water supports four average families for one year. But actual conservation data suggests that one AFY will support at least 5 average families, thus suggesting a growth inducing impact that is 25% higher than DEIR calculations. Please explain why current per capita water use is not applied to growth inducing impacts. Please explain the relationship between population projections and conservation data on per capita use, and growth inducing impacts. Or please explain why the DEIR does not contain such analysis.	PWN2-17
Q18 2-15	The Management Plan indicates that the population of CalAm's entire Monterey District was 99,396 in 2010 and that the combined population of the main system and the Bishop, Hidden Hills, and Ryan Ranch satellite distribution systems, which would also be served by the proposed project, was 95,972.	Please explain the discrepancy between these population numbers. A population of 99,396 in the entire Monterey District but when additional areas are added in, the population is lower at 95,972.	PWN2-18
Q19 2-16	2.3.4.2 Urban Water Management Plan Demand Estimates The Management Plan presents CalAm's calculation of baseline, interim (2015) target, and 2020 target per-capita water use rates for the Monterey District as required by	These data undermine the DEIR statements about growth inducement potential. When the DEIR "assumed the 115 gpcd rate", it ignored the fact that current usage is about one-half that amount. As a minimum, the DEIR should include calculations of growth inducing impact that include known facts on current consumption. What is the rational to omit	PWN2-19

	Senate Bill 7: the baseline, 2015, and 2020 per-capita use rates were be 144, 131, and 118 gallons per capita per day (gpcd), respectively. But the Monterey District's actual 2010 per-capita water use was 115 gpcd, which was less than its 2020 reduction target, and the Management Plan projections of future water demand between now and 2030 assumed the 115 gpcd rate. Appendix K-4 SWRCB staff calculated that annual average residential per capita usage in CalAm's Monterey District service area from June 2014 through May 2016 was 55 to 57 gallons per capita per day, based on reporting required under emergency conservation regulations. This level is in the lowest 12 percent of urban users in the state (SWRCB, 2016).	current facts? Please explain these differences in baseline information and how they relate to growth inducing impacts.	PWN2-19 cont.
Q20 2-22	2.5.1 Salinas Valley Groundwater Basin Return Water The amount of SVGB groundwater included in the source water is expected to decrease over time (CalAm et al., 2016b).	How does the theory that MPWSP wells will draw more groundwater toward the pumping locations support the statement that groundwater in the source water will decrease over time? Two problems. 1. These are contradictions. 2. The limited duration of continuous test slant pumping produces insufficient data to make that conclusion. What is the duration period that is sufficient for these conclusions? Please explain.	PWN2-20
Q21 2-22 to 23	Discussion of Return Water	Completely omitted is the option to return water to a customer in the Marina Coast Water District. Such an obvious option shows short-sightedness, if not a bias. This is serious since the DEIR is supposed to evaluate all apparently implementable alternatives. How can such an obvious option be overlooked? Please analyze this option, or please explain this omission.	PWN2-21
Q22 2-32 to 40	2.6.1 State Water Resources Control Board Report and 2.6 Water Rights	In the entire discussion on SWRCB report and water rights, not one mention is made that the project is located within the jurisdiction of MCWD. MCWD has rights and responsibilities. To ignore MCWD, to assume there is no effect on MCWD, to not even mention this elephant in the room, shows an	PWN2-22

		intentional effort to avoid the subject. This omission by SWRCB is astounding. Omission in this DEIR/EIS is even more astonishing. It must be corrected. Please explain this DEIR/EIS omission, and/or why it is not worthy of discussion. Furthermore, to incur millions of dollars of expenditures (and ratepayer liability) without having obtained the fundamental water right, is surely putting the cart before the horse. This would not be happening if the corporation were using its own money! Please explain why it is acceptable to proceed without an appropriate water right.	PWN2-22 cont.
Q23 2-34	Specifically on the topic of the return options for any fresh water drawn from the Basin by the MPWSP, the (SWRCB) Report provides: Cal-Am could use one of several possible options to replace any fresh water it extracts from the Basin. Cal-Am could return the water to the aquifer through injection wells, percolation basins, or through the CSIP. Cal-Am would need to determine which of these methods would be the most feasible, and would in fact, ensure no harm to existing legal users. The feasibility analysis would depend on site-specific geologic conditions at reinjection well locations and at the percolation areas. <u>These studies need to be described and supported in detail before Cal-Am can claim an appropriative right to export surplus developed water from the Basin.</u> Report at 39. (Underlining added.)	This suggestion by the SWRCB that "These studies need to be described and supported in detail..." seems to have been overlooked; mainly because MCWD was not included in the options. Until an assessment is made about a MCWD option, this DEIR/EIS is deficient. Please correct this substantive omission.	PWN2-23
Q24 2-35	Footnote 34: The EIR/EIS preparers have also had the benefit of working closely with, and receiving input from, the Hydrogeologic Working Group (HWG) that was formed as a result of the proposed settlement in the CPUC proceeding on the MPWSP. The HWG is composed of experts representing myriad parties in	This footnote affirms that the preparers did not consult with Marina Coast Water District, the site of Cal Am's MPWSP. Such omission shows a bias not to collect perspective on the full range of issues, nor to understand the potential impact in that locality and the region. This neglect is significant, and undermines the thoroughness of the DEIR. Please explain the rationale for excluding MCWD services from impact analyses.	PWN2-24

	the CPUC proceeding with diverse interests related to the Basin, including but not limited to the Monterey County Farm Bureau, the Salinas Valley Growers Association and CalAm. The EIR/EIS preparers obtained feedback from the HWG as to the groundwater aquifer characterization and the groundwater modeling assumptions.		PWN2-24 cont.
Q25 2-35	Once the test well results are complete, the modeling will be verified and will be re-run as warranted.	When will the test results be complete? When a final report be issued? Where are the thresholds defined so that 'meeting them' will be understandable? How and under what circumstances will 'success' be attained? There is no deadline, no threshold date, no identified objectives, except to keep on collecting. What does this DEIR statement mean? When will the HWG be terminated? When will termination even be discussed? Will it be a factor? Since the test slant well is a 'test', there needs to be a plan for a final report. What is it? Please explain how this will occur.	PWN2-25
Q26 2-35	Thus, the full panoply of evidence concerning the project's relationship to groundwater (and thus water rights) may continue to evolve and be refined throughout the CPUC proceeding.	This statement admits that the CPUC decision may be made without a full availability on data, and without a concluding analysis and understanding of evolving issues. This is especially true on two strategic and significant matters: 1) The test well analysis has no precise ending date because it does not have threshold targets for test well performance. 2) Water rights are not on any time line, and its lack is a threat to MPWSP feasibility. As costs accrue, these omissions and unresolved issues create a formidable liability for ratepayers. Any clarity in this DEIR would be helpful. Please address these matters.	PWN2-26
Q27 2-35	2.6.2 Project Water Rights As explained in Chapter 4.4, Groundwater Resources, the modeling is specifically targeted to isolating the change in groundwater levels that would be generated by the MPWSP. This modeling, however, cannot project the amount of Basin water that is expected to be drawn into the supply wells.	"...cannot project the amount of Basin water that is expected to be drawn into the supply wells." ??? Really? Cannot project the amount! What is the test well all about? Are its data not included, or are they too sketchy, or unreliable, or erratic, or incomplete? This statement undermines the value of the "test" nature of the test slant well. It also undermines credibility regarding project feasibility. What is the reason for the statement? Please explain what is meant. Furthermore, how can the DEIR conclude a 'no harm' if this is the observation? No evidence suggests no	PWN2-27

		reason to conclude 'no harm'.	PWN2-27 cont.
Q28 2-35	Footnote 34: The EIR/EIS preparers have also had the benefit of working closely with, and receiving input from, the Hydrogeologic Working Group (HWG) that was formed as a result of the proposed settlement in the CPUC proceeding on the MPWSP. The HWG is composed of experts representing myriad parties in the CPUC proceeding with diverse interests related to the Basin, including but not limited to the Monterey County Farm Bureau, the Salinas Valley Growers Association and CalAm. The EIR/EIS preparers obtained feedback from the HWG as to the groundwater aquifer characterization and the groundwater modeling assumptions.	The HWG does not represent 'diverse interests'. It does not the Monterey Peninsula, nor does it represent ratepayer or consumer or public interests. All three HWG members (Cal Am, FB, SVWC) represent private owner and profit-seeking interests. Cal Am is entirely self-serving, and needs no explanation. Farm Bureau and Salinas Valley Water Coalition represent agriculture owners, and are specifically desiring that absolutely no fresh groundwater leaves the Basin, which is the law under the Agency Act (described in 2.6.3 of this section). All three have proprietary interests in the fresh water component. To present the HWG as representing a broad interest is ludicrous. And to say (see Q27) that the modeling cannot predict the amount of Basin water drawn into the wells makes the cost of the HWG a waste. Based on this DEIR narrative, the cost of the HWG should not be passed onto ratepayers. Please explain the representation on the HWG. Please be more honest with the facts, and be less misleading in the process.	PWN2-28
Q29 2-38	Citing the SWRCB report: The feasibility analysis would depend on site-specific geologic conditions at reinjection well locations and at the percolation areas. These studies need to be described and supported in detail before Cal-Am can claim an appropriative right to export surplus developed water from the Basin.	Such a study(ies) was not cited in the list of references. Were these studies undertaken? Were there any efforts to conduct such a study? Who sponsored the studies? Were they evaluated by the DEIR/EIS consultants? Please explain what research material was reviewed in relation to this SWRCB instruction. Please explain this reference and what was done about it.	PWN2-29
Q30 2-38	CalAm proposes to deliver fully desalinated water to end users for use in lieu of existing groundwater production from the SVGB. The two points of delivery would be (i) to the Castroville Community Services District (CCSD) to supply water for municipal purposes (e.g., typical drinking, bathing, sewer, watering and other non-agricultural water uses) and (ii) to the Castroville Seawater Intrusion Project (CSIP) pond or directly into the reclaimed water CSIP pipe for use by the agricultural users that obtain water through CSIP.	This scenario is fully developed and analyzed. But CEQA requires an assessment of other possible scenarios. One obvious alternative, containing the identical approach, is to return water to Marina. It is closer with less construction, has the identical seawater intrusion dilemma, uses groundwater from the SVGB, will cause less environmental disturbance, be less expensive. How could this alternative have been overlooked? Please analyze this option, and change your conclusion. Or explain why it would be more damaging than the return water plan with delivery to Castroville and CSIP. In either case, a new narrative is needed. This omission is another crevice in the foundation intended by this DEIR/EIS.	PWN2-30

	Under these return water locales, the clean desalinated water would be provided for municipal or agricultural use (respectively) in lieu of pumping Basin water in an amount equal to the quantity of return water.		PWN2-30 cont.
Q31 2-40	Citing the SWRCB report: As currently proposed, the project would use slanted wells and have screened intervals located seaward of the beach.	The SWRCB report refers many times to the project plans for intake to be 'seaward of the beach'. The DEIR/EIS ignores the fact that intake screens are dominantly located landward of the beach, NOT seaward of the beach. This DEIR contains multiple figures showing the slant well layout on the land, terminating very near the Mean High Water line, yet it fails to make clear that the intake screens are located under land, not under the sea. This distinction is huge, but is omitted. Why? There needs to be an entirely new section explaining this, and showing just why the question of water rights is so critical. Seaward water rights are not at issue. But landward water rights have volumes of court documents and case law that govern it. To omit the fact of landward screened intakes is a fatal omission, rendering this part of the DEIR/EIS misleading, if not fallacious. The fact of intake screen locations being omitted suggests a bias. Please explain these omissions. Also the DEIR should be recirculated if these facts are clarified. Please explain why recirculation is not warranted if that is the conclusion.	PWN2-31
Q32 3-8	**CHAPTER 3 Description of the Proposed Project** **3.2.1 Seawater Intake System** **3.2.1.1 Subsurface Slant Wells** TABLE 3-1 FACILITIES SUMMARY FOR THE PROPOSED PROJECT	There is no description of the plan for location of intake screens. This omission calls attention to its absence. ESA and others know the intake screens are to be located dominantly 'landward of the sea'. This is critical to the question of water rights. The DEIR is expected to be full disclosure. It is not. Why not? Please explain why the intake screen locations, even in general terms, is omitted from the DEIR. Any new language of explanation would justify recirculation, since it is such a critical piece to the determination of water rights and ultimate feasibility considerations.	PWN2-32
Q33 3-13	Figure 3-3a MPWSP Seawater Intake System	Figure 3-3a clearly shows the plan for well locations. By simple observation, intake screens are landward. This surely did not escape the attention of the consultants. The DEIR has not explained intake screen locations. This is a major omission.	PWN2-33

		Another significant omission is the obvious questions from looking at Figure 3-31. The terminus of all slant wells appear to be are within Marina city boundaries. Or is the terminus in the Sanctuary? Those two lines showing the city boundary and the Mean High Water line are different. Or are they in fact different? This needs an explanation. And if this figure is wrong, what other diagrams and representations have omissions or errors. Credibility is at stake here. Please explain.	PWN2-34
Q34 3-15	The environmental effects associated with construction and operation of the test slant well were evaluated in accordance with CEQA and NEPA requirements by the City of Marina/California Coastal Commission (CCC) and MBNMS in November 2014, respectively.	This overly simplistic language ignores the opposition and rejection of the permit for the test slant well by the City of Marina. The objection was over the Mitigated Negative Declaration. Full transparency is compromised here. The appearance here is of a non-controversial project. This is not true, and transparency is the victim.	PWN2-35
Q35 3-16, 17	TABLE 3-2 LENGTH OF PERMANENT SLANT WELLS SEAWARD OF 2020 MEAN HIGH WATER (MHW) LINE (feet) "+ env" stands for envelope of change that accounts for the alongshore variability in shore profile. "storm" considers the potential erosion from a large (100-year) coastal storm.	Table 3-2 is an obvious attempt to emphasize the part of the well being under the ocean. Yet the Figure diagram shows the wells ending under the shore. The Table and the Figure clearly do not line up and do not represent the facts. The extra effort to calculate variables related to a 100 year coastal storm does show sensitivity to the issue of where intake screens are located. But this appears to be more of an intent to magnify the illusion that intake screens will be substantially under the ocean, given several 100 year storm events. This is a sham on facts and an exaggerated logic. It is a devious attempt to argue beyond facts in order to support the conclusions. Shame on the writers and final editors. Please explain why the Table and the Figure do align. Please correct them. Or please explain how these data and graphics apply to the facts for the life cycle of the project (which is clearly not 100 years).	PWN2-36
Q36 3-19	"The nine new permanent slant wells would be approximately 700 to 800 feet long at a minimum angle of approximately 14 degrees below horizontal..." and "...angles of 19 degrees for the test	Where is there evidence that another departure from the test well angle of 19 degrees is a good idea. What engineering report supports this plan? Remember, this is the first time this slant well test for ocean intake has ever gotten this far. There needs to be some effort to prove, or show evidence, that new plans, never applied to date, have a likelihood of success. But where is that evidence? It is not in this DEIR. If design problems emerge during construction, would	PWN2-37

	slant well and 14 degrees for all other slant wells off the horizontal toward the Monterey Bay." (Pg 4.2-59)	this untested design and experiment be continued as an experiment of the backs of ratepayers? Or would responsibility fall on Cal Am stockholders? A minimum of curiosity is expected by the consultants, or by CPUC, especially for something that has never been operational before. How many experiments is Cal Am allowed to have? When will CPUC require proof, or at least supporting evidence? Please provide evidence that 9 wells at 14 degrees from horizontal have some likelihood of success. Without some evidence, this is hope triumphing over proof. Please address this.	PWN2-37 cont.
Q37 4.1-8	**4.1.3 Baseline Conditions** The baseline for this EIR/EIS is the existing condition on or about October 5, 2012, which is when the CPUC issued a Notice of Preparation (NOP) for the proposed project... and Since the CPUC issued its NOP in 2012, the Lead Agencies have developed or received new data on some of the resource areas, so they have updated the baseline data as appropriate.	Was there a specific report on 'the baseline'? Was there a report that got updated with 'baseline data as appropriate'? Where is that report? Please cite this report. Please provide a link to or cite the source(s) of that report. If there was not such a report, what data base or data files were referred to that were updated as appropriate? One major failing in the work of the Hydrogeologic Working Group is the lack of a baseline that is presented and explained for comparison purposes. Without such a baseline, projections cannot be made with confidence. The evidence of a baseline is missing. Please explain how the project (or maybe the HWG) baselines were developed, who has them, how they have been resented to the professionals and the public. Please explain if they have been released to the public, and where and how they are accessed.	PWN2-38
Q38 4.2-69	The subsurface slant wells would originate at an above-ground well head vault behind the beach and radiate out a distance of between 900 and 1,000 feet at an angle of 19 degrees off the horizontal for the existing test slant well and about 14 degrees for all other slant wells off the horizontal toward the Monterey Bay.	The 14 degree angle has never been drilled for seawater intakes. Are there potential complications or impacts from such a sharp angle, like maintenance and cleaning? The ability to maintain such shallow angled screened intake pipes that have never been tried before. This requires some investigation. This DEIR fails to pursue this question. Please provide support that this question is irrelevant, or provide analysis.	PWN2-39
Q39 4.4-6 to 8	The upper portions of the proposed slant wells at the CEMEX site would have well screens installed across them, and would draw water from	By describing the use of the Dunes Aquifer by Cal Am, and by omitting the plan of Marina Coast WD to use the same source, this DEIR/EIS ignores a major impact of the MPWSP. This omission is substantial.	PWN2-40

	these deposits. (Dunes Aquifer and 180' aquifer) Page 4.4-8	By this omission, the DEIR avoids any evaluation of cumulative impacts on this aquifer, thus creating a fatal flaw. Please explain this omission, and the reason for not including analysis of this impact.	PWN2-40 cont.
Q40 4.4-42	Special Condition 11 of the Coastal Development Permit, "Protection of Nearby Wells," requires the MPWSP HWG to establish baseline water and TDS levels prior to commencing the long term pumping tests (Geoscience 2015b). The long-term pumping test began in mid-April 2015, and results are available at http://www.watersupplyproject.org/#!test-well/c1f1l.	The "long term pumping test" has never been defined. It was intended to test impacts from 'continuous pumping'. Cal Am suggested it was to be 18 to 24 months. However there were major interruptions in the pumping period that started in April 2015. Pumping stopped completely from 6/5/15 to 10/27/15 (more than 4 months) for CCC permit violations. Pumping stopped again from 3/4/16 to 5/2/16 (2 months) for an outfall repair. (Documented in HWG reports) There has been continuous pumping for about 7 months (May 2016 thru December 2016) before the DEIR went to print and released in January 2017. This is less than one-half the 18 months proposed. The DEIR does not include any relevant continuous pumping data (12 months or longer). This is not acknowledged in the DEIR. To ignore the plan for continuous pumping tests, and to suggest there has been continuous pumping from April 2015 is wrong. It is dishonest to the analysis, and to decision makers and the public. Please explain why these facts were omitted. Or please explain why continuous pumping is not a factor in a feasibility analysis, or in environmental considerations. Or add it, and adjust the Final EIR to include it.	PWN2-41
Q41 4.13-7	4.13 Public Services and Utilities 4.13.2.2 State Regulations California Coastal Act The MPWSP has been designed to accommodate existing and projected future demand consistent with the General Plans (and Local Coastal Programs) of the jurisdictions in CalAm's service area. As future development in the service area would need to be consistent with General Plan and Local Coastal Program requirements, the project would not conflict with Coastal Act policies related to public works facilities.	The MPWSP is not consistent with Marina's Local Coastal Plan. The EIR/EIS needs to verify if its statement is true. Litigation has been initiated over this very point. Please be transparent here. Please verify this point, and explain it and its relevancy as appropriate.	PWN2-42

Q42 4.13-11	TABLE 4.13-2 APPLICABLE REGIONAL AND LOCAL PLANS AND POLICIES RELEVANT TO PUBLIC SERVICES AND UTILITIES	Marina's Local Coastal Plan is omitted from this table. Did the consultants review Marina's LCP and its requirements? This plan is so important to local planning goals, and the impact of the MPWSP on that region. Ignoring it does not make it go away. Please add it and an analysis to the DEIR. Or please explain why it is not necessary to include it in Cumulative Impacts discussions.	PWN2-43
Q43 5.3-1	**5.3 Alternatives Development, Screening and Evaluation Process** Footnote 6: NEPA requires alternatives to be reasonable, or feasible, which could include consideration of whether the alternative is capable of complying with regulations governing desalination plants in order to receive the required regulatory approval.	The DEIR/EIS needs criteria and clear definitions on what constitutes 'reasonable or feasible'. With so much emphasis on the unproven test well, and the lack of history with subsurface ocean intake, the DEIR/EIS should include a few remarks on these definitions. If undefined, who defines it? Is it in the mind of the reader? The purpose of the CEQA and NEPA requirement is to be transparent on the benchmarks of protection and feasibility. The DEIR/EIS needs criteria and definitions on what is reasonable and feasible. Please explain these terms. Will you add such clarifications? If not, please explain why not.	PWN2-44
Q44 5.3-3,4	5.3.1.2 MBNMS Guidelines for Desalination Plants Key relevant guidelines include: Desalination plant proponents should pursue collaborations with other water suppliers and agencies currently considering water supply options in the area to evaluate the potential for an integrated regional water supply project.	The DEIR does not explain why such collaboration was not initiated with MCWD. Even though the short history of the Regional Desal Project was included, there was no update on a potential two-party option (Cal Am and MCWD). Especially so when Cal Am's project is in the jurisdiction of MCWD, Regardless, the DEIR/EIS and the MBNMS must meet its obligations. This potential collaboration between MPWSP and MCWD should be discussed If denied as workable, then explain it. But to ignore it is to ignore the nose on your face. Please explain why this MBNMS guideline for collaboration was not addressed in the DEIR/EIS.	PWN2-45
Q45 6-6 and 6-13	**6.3.2 Relationship between Land Use Planning and Water Supply** and **6.3.5 Growth-Inducement**	(Also see Q17) Although the DEIR includes much data on population and housing projections, nowhere does the DEIR relate the data to actual per capita water consumption. For instance, Cal Am documents and this DEIR continues to suggest that one acre foot of water supports four average families for one year. But actual conservation data suggests that one AFY will support about 5 families, thus suggesting a growth	PWN2-46

	Potential	inducing impact that is 25% higher than DEIR calculations. Please explain why current per capita water use is not applied to growth inducing impacts. Please explain the relationship between population projections and conservation data on per capita use, and growth inducing impacts. Or please explain why the DEIR does not contain such analysis.	PWN2-46 cont.
	APPENDICES		
Q46	**Appendix E2** Results of Test Slant Well Predictive Scenarios Using the Focused CEMEX Area Model DRAFT by Geoscience 8-Jul-14 5.0 FINDINGS ▼ Based on preliminary ground water modeling, the salinity in the test slant well increases with time approaching 96% ocean water after 16 months of pumping. Data collected during the long-term pumping test will be used to establish salinity trends. (pg 15)	"Long-term" is not defined. How long is this? Cal Am schedule calls for an 18 to 24 month period. CA Coastal Commission agreed when it issued the test well permit. The prediction was to reach 96% ocean water salinity after 16 months of continuous pumping. It has not happened. No specific document in the DEIR/EIS supports this prediction to reach 96% salinity. In fact, there is no supporting document that a continuous pumping test protocol has been identified or pursued. 'Continuous' has never been defined. This DEIR claims to include pumping data, but it leaves out the fact that there have been serious interruptions in pumping durations. Interruptions are a fact, and have been reported in HWG documents, but this DEIR completely omits all discussion of it. The most recent period of continuous pumping is about 6-7 months. This is far short of the "16 months", and embarrassingly so, for the DEIR. This is a failure of the 'test protocol'. And it is a serious flaw in this DEIR. Please explain the failure to include a discussion of the actual continuous pumping periods, the interruptions, and those effects on continuous pumping data and analysis. This shortcoming in the DEIR is so large that a truck can drive through it. No operational sub-ocean intake slant well exists anywhere in the world. How can the DEIR be legitimate when there is no specific continuous pumping data that can justify moving ahead? This flaw has to be corrected. Please explain why the data is inadequate, or irrelevant. But please address it.	PWN2-47
Q47	**APPENDIX C3** Exploratory Borehole Results. Monterey Peninsula Water Supply Project	Comment/Question This was the first report by the Hydrogeologic Working Group put in place to steer and oversee the	PWN2-48

	Hydrogeologic Investigation Technical Memorandum (TM1) Summary of Results - Exploratory Boreholes dated July 8, 2014	scientific component of Cal Am's MPWSP. In 70 pages of narrative, there is not one mention of establishing a baseline. The bore holes were to provide data for comparisons. But the baseline data points were never established. The baseline became a moving target. And it became essentially useless for making projections. Or it became useful for not being precise. What is true? What do professional statistical experts say about a baseline? All say baselines are critical. And especially so for an experimental project like this one. Yes, projections can be made by tracking and plotting data points, but the point of a baseline is to help form judgments about 'progress' (or impacts or cautions). The failure to establish a baseline meant there was no way to judge progress. Four significantly qualified scientifically-trained professionals failed to address this fundamental requirement for an experiment – start with a base line. This 'test' well was described as new and needing to pass a generally-described (by SWRCB) objective to be 'feasible'. The California Coastal Commission coastal development permit (A-3-MRA-14-0050) (and amended permit A-3-MRA-14-0050-A1) required measurements. This omission of a baseline shows the lack of focus on 'evaluation' of the test. Please explain why a baseline was not established. Or please explain what is considered the baseline that is not in the HWG report.	PWN2-48 cont.
Q48 Pg 1 of Report	EXECUTIVE SUMMARY 1.1 Introduction The investigation and findings described in this Technical Memorandum are the result of collaborative planning and discussions among the hydrogeologic experts that represent key stakeholders for groundwater use and management in the Salinas Valley and Monterey Peninsula area of central California. The Hydrogeologic Working Group (HWG) consisted of the following experts: Mr. Tim Durbin and Mr. Martin Feeney (both representing the Salinas Valley Water Coalition and the Monterey County Farm Bureau), Mr. Peter Leffler	This Appendix C3 proudly promotes the composition of the HWG, and the representatives. After this report in 2014, a conflict of interest was discovered involving Dennis Williams, Cal Am and CPUC. Leaving this scandal unexplained, while the report here is prominently displayed, leaves the impression that the membership and representation are the same and that there is no reason to be skeptical. There is so much more to this picture. If the DEIR/EIS is to be credible, it must air the dirty laundry that emerged. Ignoring it only suggests that any negative information is to be avoided, all in the service to approve Cal Am's MPWSP. This is a serious shortcoming, and specifically leaves the impression that things are OK. Many know the conflict of interest history. Omission leaves doubt, and undermines credibility. Please explain the	PWN2-49

	(representing CalAm), and Dr. Dennis Williams (representing the CPUC CEQA Team). The HWG was formed as a result of a 2013 Settleme nt Agreement among parties to an ongoing CPUC-proceeding resulting from CalAm's proposed Monterey Pe ninsula Water Supply Project, to revie w and approve the scope of field inve stigation and development of a hydro geologic conceptual model from whic h to construct the groundwater modeli ng tools. The names of the HWG me mbers are presented here to indicate the general agreement among the members on the core findings of the investigative work described herein.	circumstances and the differences after this HWG report was issued. If credibility is the soul of a DEIR, then you lose some with glaring omissions.	PWN2-49 cont.
Q49 Pg 1 of report	Hydrogeologic Working Group (HWG) "The HWG was formed as a result of a Settlement Agreement among parti es to an ongoing CPUC-proceeding r esulting from CalAm's proposed Mon terey Peninsula Water Supply Project, to review and approve the scope of fi eld investigation and development of a hydrogeologic conceptual model fro m which to construct the groundwater modeling tools."	1.a) Dennis Williams and his company Geoscience owns international patents for slant well design and installation. Williams subcontracted to Cal Am AND the CPUC for evaluating the substance of test well modeling, data collection, and evaluation. Cal Am did not disclose to CPUC, nor the other members of the Hydrogeologic Working Group, that Williams had these patents. This conflict of interest, and not reporting it, continues to haunt the project.	PWN2-50
Q50	Re Technical Memo 1, July 8, 2014, page 1, in DEIR (Appendix C3)	The HWG is currently composed of four members retained by these entities. Cal Am, Farm Bureau, Salinas Valley Water Coalition. FB and SVWC narratives are from their websites: 1. Cal Am, the sponsor of the slant well and desal project, has 2 representatives: a) Dr. Dennis Williams (Geoscience) and b) Peter Leffler. Re 1a. The CPUC determined there was a conflict of interest and terminated its involvement with Williams/Geoscience.	PWN2-51

		This conflict is extremely serious because first, Williams/Geoscience can profit the most by a successful slant well test, and second, is helping to determine if the test is successful. A more astonishing conflict of interest is hard to find. Both Cal Am representatives are serving in support of a positive outcome for Cal Am. The possibility of bias in favor of the project is obviously high. And this undermines its credibility. 2. Monterey County Farm Bureau: (from its website): "Our organization serves as a collective voice for farmers and ranchers and provides information, benefits and services to our members. We...offer individual farmers and ranchers the opportunity to unite with others who share their concerns and interests, so they can speak with one powerful voice at the local, state and national levels." The Farm Bureau representative serves the interests of agriculture. There is no presumption that the Farm Bureau rep serves interests of Peninsula ratepayers nor regional urban interests. 3. Salinas Valley Water Coalition (from its website): "SVWC supports an appropriate and just solution to the water problems of the Salinas Valley.... The Coalition Board of Directors and its' members are committed to maintaining an active role in the Salinas Valley in an effort to ensure these goals." The SVWC rep also serves agricultural interests. It does not represent Peninsula ratepayers or regional urban interests. Both FB and SVWC are dominantly interested in protecting the Agency Act forbidding the export of Salinas Basin groundwater. Their roles are self-serving, and are not relative to the context of 'feasibility' or viability of slant wells. Missing from representation are public agency interests by Monterey Peninsula Water Management District (MPWMD), Marina Coast Water District (MCWD), and Monterey County Water Resources Agency. Specifically MPWMD and MCWD could have represented ratepayer and regional urbanized	PWN2-51 cont.

		interests. This omission of ratepayer and urban interests is a marked shortcoming for input and analysis. These omissions are notable. The existing HWG is a highly self-interested group in a key role. If this can be explained, it should be. Otherwise the self-serving nature will continue.	PWN2-51 cont.
Q51 Pg 50 of report	5.4 Determining Average Central California Coast Seawater Quality Average salinity estimates for the central California coastal region were established based on historical salinity measurements taken at …....	The baseline for salinity must be reported and used in the narrative. Cal Am Engineer Rich Svindland recently reported the salinity to be about 92%. The question is what is the denominator for calculations. Is the seawater composition from the central coast seawater TDS an average of 33,694 PPM, or is it the Monterey Bay TDS average that is closer to 35,000 PPM. When the denominator is a lower number the calculation will generate a larger percentage. If the denominator was 35,000 the result would be about 89% TDS. Numbers don't lie. Therefore it is important that accurate baseline data be clear and be presented. Where are the citations for the TDS values used in this analysis? What studies confirm the relevancy of using the lower TDS base? Please explain why one is more accurate than the other, and cite the sources. Can you please bring together the vernacular and the science.	PWN2-52

Q52 ** Not included in the DEIR /EIS	*NOT INCLUDED IN THE DEIR/EIS* *Coastal Development Permit amendment A-3-MRA-14-0050-A1 -Page 3* **SPECIAL CONDITIONS** This **Special Condition** modifies **Special Condition 11** as initially imposed by the Commission in Coastal Development Permit A-3-MRA-14-0050. Standard Conditions 1-5 and Special Conditions 1-10 and 12-17 of that permit shall remain in full force and effect**. Special Condition 11** now requires: "**Protection of Nearby Wells**, PRIOR TO STARTING PROJECT-RELATED PUMPING TESTS, the Permittee shall install monitoring devices at a minimum of four wells on the CEMX site, within 2000 feet of the test well, and one or more offsite wells to record groundwater and salinity levels with the wells and shall provide to the Executive Director the baseline groundwater and Total Dissolved Solids ("TDS") levels in those wells prior to commencement of pumping from the test well. (Underlining added.)	The DEIR narrative does not mention this requirement from the Coastal Commission. It is not in the Appendices. It is clearly a required protocol for evaluating the test slant well impacts. It is fundamental to the adequacy of the test. It is fundamental to the determination of 'feasibility'. It is fundamental to computer modeling. Where is this required report? What are the inputs from the HWG? Where is it published for public access? What are the baseline data? Where in the DEIR/EIS is this baseline information referred to? Please add it to the DEIR/EIS. Or please explain why it is not appropriate to be included or even referenced.	PWN2-53
Q53	**APPENDIX E2**	Comment/Question: Nowhere in this Appendix, and the extensive discussion of return water modeling, is there a single mention of returning water to the Marina Coast Water District, the very site where the extraction occurs. This was clearly an option, but it was ignored. This is a major oversight, and diminishes the integrity of the DEIR. Please explain this omission. Or please give adequate attention to this option.	PWN2-54

Q54 Pg 1172	HydroFocus GW Model North Marina Groundwater Model Review, Revision, and Implementation for Slant Well Pumping Scenarios November 23, 2016 6.0 Uncertainty "...we quantify the uncertainty in model-calculated drawdown to hydraulic conductivity and the assumed allocation of extracted groundwater..." (pg 41 of report)	See comment below re pg 1174 (Q55).	
Q55 Pg 1174	7.0 Summary The most likely sources of error in the superposition NMGWM2016 arise from uncertainty associated with modeled boundary conditions including sea level rise, specified hydraulic conductivity values, and assumed project operations including pumping rates and relative contributions of groundwater in aquifers represented by Model Layer 2 and Model Layer 4 to total slant well pumping. (pg 43 of report)	Applying data from a new ERT survey would be helpful here, to help quantify the baseline data, and to add specificity to the model, and thereby produce more accurate projections. It would surely reduce uncertainty. If new ERT data were available for a wide swath of relevant territory, it would be enormously useful to the modelers. But would the data be useful to DEIR consultants? Probably. If available, please include it in an updated analysis?	PWN2-55
Q56 Pg 1182	NMGWM(2016) section lines. Figure 3.2a from HydroFocus GW Model North Marina Groundwater Model Review, Revision, and Implementation for Slant Well Pumping Scenarios November 23, 2016	The computer model is cited here. Its section lines show a distance of 5 miles between A-A1 and C-C1; 3 miles between C-C1 and B-B1; and 2 miles between D-D1 and E-E1. Huge assumptions need to be made for these distances. New ERT data would eliminate these gaps, and would replace assumptions with facts. Would the DEIR consultants (ESA) include new ERT data in an updated analysis?	PWN2-56
Q57 Pg 1230	Example Problem, Figure A1.1	The superposition of interpolated data creates a decent picture. But analysis from an ERT data base would create a far more accurate picture. An ERT project will be conducted for much of the MPWSP area. If ERT data is produced, will the consultants be interested in reviewing it? If so, would the two Lead Agency teams produce a supplemental DEIR/EIS?	PWN2-57
Q58 I2-11	**Appendix I2** A potential constraint to the implementation of slant wells at this	Nowhere in the discussions on Cal Am's location of its slant wells is there mention that it is located squarely in another water jurisdiction – Marina Coast Water District. Even here, it references location in general, but not the fact that Cal Am is located in the MCWD	PWN2-58

	location is Marina Coast Water District's existing 300 acre-foot/year desalination (currently non-operational) and associated intake well, as well as MCWD's plans for developing a future 1.5-mgd (or larger) desalination facility that would include development of a subsurface seawater intake system on nearby/adjacent property. Implementation of subsurface slant wells for the MPWSP at this same location could result in well interference.	jurisdiction, only nearby. There are references to potential "interference", but no analysis of this potential. MCWD has its responsibilities and rights to resources within its jurisdiction, including water rights and engineering options. Nowhere are these issues mentioned. The DEIR seems biased in favor of the MPWSP project because of these omissions. Such a bias can be removed if a more thorough analysis of impacts on MCWD plans were included, and various aspects of 'potential interference' were described. Moreover the issue of mitigation is ignored in regard to "interference' with MCWD. Will a new mitigation analysis be conducted? Will this omission be corrected? Can the DEIR be considered a fair assessment of 'potential harm" if these matters are omitted? Please explain these omissions.	PWN2-58 cont.
Q59 Pg 1579	**Appendix J1.** Cited from the CalAm Coastal Water Project Final Environmental Impact Report as certified on December 17, 2009 The submittal expressly excludes development on lands located within the former Fort Ord army base, which has another water supply source (MCWD). (Page 8-18)	There are 29 pages of description of Peninsula plans. Yet MCWD plans are reduced to the quoted one line, made in 2009. This shortcoming misleads the decision makers that MCWD does not count. Yet it has been acknowledged that the MPWSP may interfere with MCWD plans. Please explain how this DEIR can refer to an interference, but not address it. Please explain how MCWD plans are irrelevant to the DEIR analysis of cumulative impacts.	PWN2-59
Q60 pg 1385	**APPENDIX G2** Trussel Technologies Inc. Technical Memorandum, Response to CalAm MPWSP DEIR In contrast, the test slant well water is considered the "worst-case" water because the seawater it is drawing is not fresh. Figure 3 shows that it could take up to four years for the slant well to be drawing 96% seawater, and the well has only been operating intermittently since April 2015. (pg 4 of report)	There is little discussion of Cal Am's target to reach 96% salinity for its project ocean intake supply. This target has larger implications, since it relates to return water required by the Agency Act, the mitigation for extraction, question of 'no harm', and the cost to Peninsula ratepayers. Furthermore it is tied to project feasibility. There needs to be some assurance that targets have detailed support. Especially significant targets like this. There is no engineering or other report mentioned in the DEIR on how this target is expected to be met. The only mention in Trussel's report "it could take up to four years" is only an educated guess. This educated guess is based on data from 2014, and completely precedes all test slant well data. The HWG data over the past 6 months shows the	PWN2-60

		percent of seawater pretty much stuck on 92%. It would be beneficial for the FEIR to disclose how Cal Am made a determination that the seawater component would go to 96%. This crucial omission leaves one to assume the details are there. But without citing them, the DEIR is deficient. Please explain how the proposed project, and the test well, gives proof that the 96% target will be met. Or please explain the reason this issue does not need to be analyzed.	PWN2-60 cont.
Q61 Pg 1386	Figure 3 Time for Slant Well to Pull 96% Seawater (GeoScience 2014b).	Figure 3 is based on 2014 data. This is far too dated to be useful. Recent HWG data tracks salinity up to 92%. But the curve has flattened out, no longer projecting a consistent increasing pattern toward 98%. There is current information. It must be reviewed. Otherwise this part of the DEIR is based on false hope. Please review this data. Please add it and the associated analysis. Furthermore, a new ERT survey would shed important light on this.	PWN2-61

Public Water Now (PWN)
Letter 3 (PWN3)

To: MPWSP DEIR/DEIS Team
From: Public Water Now, George T. Riley
Subject: Feasibility of Slant Wells
Date: March 27, 2017

Why are we hung up on slant wells? The State Water Resources Control Board has demanded that entities seeking to pump ocean water for desal must consider subsurface intakes first, if feasible. Four site specific criteria are proposed, again if feasible: site, design, technology and mitigation.

But since the world has never used slant wells for ocean intake, the question of 'feasibility' must include factors and conditions beyond the site. The science of evaluation must go beyond engineering. It must include cost, and objective science, and issues of harm, and advisability in the face of all factors.

So far, Cal Am engineering has been perhaps OK. Outside of inefficient permit processing with Marina, exceeding the Coastal Commission permit limits, and a funky outfall design that failed in a winter storm, it could be called 'passable'. But many other factors have been ignored, or are being sidelined. Look at events so far. PWN3-1

Cal Am and other supporters agreed to form the Hydrogeologic Working Group (HWG) to design and evaluate test slant well data collection and analysis. It started poorly. The HWG did not establish a baseline for later comparisons. Then it got caught with a conflict of interest whereby Cal Am's consultant (Dennis Williams of Geoscience) was retained by the CPUC without knowing about two matters of importance: Williams held patents on the technology being used, and Williams also worked for Cal Am. Cal Am admitted to knowing about both, and not informing the CPUC until the conflict of interest was revealed by Public Water Now. PWN3-2

The HWG continues in a less than informative way. Cal Am claims the HWG has 20 months of data. This is misleading. Two major interruptions occurred: 4 months for exceeding permit thresholds, and another 2 months for its funky outfall design that failed in a recent storm. It has not been 20 months of continuous pumping. PWN3-3

The HWG was expected to produce a report to be useful for required environmental reviews, which had a deadline of March 27, 2017. The report was expected to help determine if harm has occurred to the Salinas Basin. There is still no HWG report. Besides, the science for determining 'harm' has been very shallow. This weakness will haunt the project. PWN3-4

Cal Am project description states it "shall focus its production from a shallow portion of the aquifer system, sometimes referred to the Sand Dunes Aquifer..." This is the fresh water aquifer that Marina Coast Water District (MCWD) hopes to develop for its customer base. Harm to overlying water rights holders includes seawater intrusion, and lose of source water. This is a head-on collision largely because Cal Am has invaded another water jurisdiction, and has not acquired any water rights to any water in the Salinas Basin. PWN3-5

Furthermore Cal Am sold the public, and many public agencies, on its plan to draw water from under the Bay. All that has changed. Now most water will be pumped from aquifers inland of the coastline, not from under the Bay, and from the fresh water Dunes Aquifer within the jurisdiction of MCWD. PWN3-6

If that is not enough, the HWG has a biased composition, on top of its conflict of interest. It has 4 members - 2 for Cal Am, and 2 for agricultural interests. There are no representatives for local water agency or city interests, nor ratepayer interests. Therefore expect a biased report, if there is one. PWN3-7

Feasibility questions, so far, have served Cal Am interests. Its focus has been only on site specific criteria: site, design, technology and mitigation.

Other factors must be considered, particularly because the initial review process has been compromised and is too narrow. These include:

1. History. No ocean intake slant wells exist. Therefore this is an experiment. Our community should not be expected to embrace a new unproven technology for the bulk of our water supply without a robust evaluation.

2. Cost of the experiment. All costs are based on one test well in Orange County. No operational experience exists. Costs estimates for long term maintenance and replacement are speculative guesses. For such an experiment, grant funds must be allocated. After all, state agencies are pushing this experiment. Ratepayer pocketbooks must not be exposed to such unknowns.

3. Cost of long range operations. This needs more input than Cal Am engineers and consultants. There must be a more robust evaluation of long range projections of demand and the cost of meeting that demand. It should include comparisons to other supply options. And it could include potential changes required by the new Sustainable Groundwater Management Act.

4. Timeliness. The State's Cease and Desist Order (CDO) had deadlines. The community has expectations. Cal Am is forcing its experiment and the CDO deadlines onto the community without adequate time for evaluation.

5. Quality and history of the sponsor. Cal Am has no water supply success on the Peninsula. It has failed in three previous attempts on traditional engineering approaches – a dam, power plant water intake and discharge, and vertical wells for desal. And we are expected to rely on this company for an experimental solution? Stranded costs falling on ratepayers is the norm. And it looks like another failure is quite possibly in the works. PWN3-8

6. Other options. Cal Am has other options. It could seek another engineering solution, such as Ranney wells. There are competitors to Cal Am for a desal supply. Two private entrepreneurial ventures may have traction locally, and could be encouraged to join the race for cost, schedule, design and management comparison. vOther source waters could be evaluated, consistent with the current low level of actual water use.

7. Leadership. Cal Am has not been a dependable partner for water projects. It has avoided partnering with the major Peninsula water agency, MPWMD. It has reneged on three partners for the regional desal project, Monterey County, MCWRA and MCWD. Cal Am has pressured the MCWD to stretch its interpretation of permitting regulations to advance slant well tests. The atmosphere for cooperation on slant wells has been soured by Cal Am's careless approach to permitting.

The most frightening fact is this language in the Large Settlement Agreement being supported by all the major players in Cal Am's project: "...whether a source water project or program is feasible shall be determined by California American Water." (Sect 5.3) This is the fox guarding the hen house.

This appeal is to the DEIR/EIS review team, the Peninsula Mayors Water Authority, local water agencies, and others claiming a role in leadership. It goes without saying that ratepayers are interested.

PWN contends that the current track for determining 'feasibility' is inadequate and inappropriate. Unless other relevant feasibility factors are clearly identified and rigorously evaluated, the money pit of slant wells should be abandoned.

8.6.18 Salinas Valley Water Coalition (SVWC) and Monterey County Farm Bureau (MCFB)

Re: Joint Comments of Salinas Valley Water Coalition and Monterey County Farm Bureau on January 2017 CalAm Monterey Peninsula Water Supply Project Environmental Impact Report/Environmental Impact Statement

Dear Ms. Borak and Ms. Grimmer:

The Salinas Valley Water Coalition (SVWC) is a not-for-profit organization comprised of agricultural landowners, farmers and businesses within the Salinas Valley. The SVWC's primary purpose is to participate in various governmental proceedings in order to preserve the water rights of its members, to protect their water resources and to affect water policy decisions in a manner that provides this protection while sustaining agricultural production and quality of life.

The Monterey County Farm Bureau (MCFB) is a California not-for-profit organization founded in 1917 that represents family farmers and ranchers in the interest of protecting and promoting agriculture throughout Monterey County. MCFB strives to improve the ability of those engaged in production agriculture to provide a reliable supply of food and fiber through responsible stewardship of our local resources.

Community participation is essential to any project and is critical to obtaining support for that project. Toward that end, we appreciate the efforts made by Applicant California American Water Company (Cal-Am) and various agencies to reach out to the Salinas Valley agricultural community to discuss how the use of wells to produce source water for the Monterey Peninsula Water Supply Project (MPWSP) will affect the Salinas River Groundwater Basin (SRGB or Basin[1]) — the source of water supply on which the Salinas Valley's agricultural economy depends.

SVWC/MCFB-1

[1] Note: The terms Salinas River Groundwater Basin and Salinas Valley Groundwater Basin are both used in the DEIR. The Salinas River Groundwater Basin, or SRGB, is the term referenced in the Monterey County Water Resources Agency Act. The SRGB is the area of the Salinas River and the Valley that is recharged by the alluvium of the Salinas River.

After analyzing the MPWSP's first Draft EIR, the SVWC and MCFB submitted comments describing serious flaws in the Draft EIR's conclusion that use of wells to produce source water for the MPWSP would not substantially deplete the overdrafted Salinas River Groundwater Basin (Basin) and cause significant direct, indirect and cumulative impacts. Those comments showed that the MPWSP's use of wells to produce source water from the overdrafted SRGB would cause significant adverse impacts and explained why the MPWSP would be infeasible as a result of Cal-Am's lacking the groundwater rights needed to operate production wells in the overdrafted groundwater Basin.

After the comment process closed on the MPWSP's first Draft EIR, the SVWC, MCFB, Cal-Am and other parties negotiated and executed an agreement that would avoid significant impacts to the Basin and make the MPWSP feasible with respect to groundwater rights. The Settlement Agreement on MPWSP Desalination Plant Return Water, commonly referred to as the "Return Water Settlement Agreement" (RWSA), would return to the Basin the portion of source water that the MPWSP's wells produce from Basin groundwater (as opposed to seawater). Under the RWSA, the "Return Water" would be delivered for use in lieu of existing groundwater pumping in the area threatened by seawater intrusion — so that there would be no net increase in Basin groundwater use as a result of ongoing MPWSP well production. In other words, approval and performance of the RWSA would mean that the MPWSP's ongoing well production would have a net-zero impact on Basin groundwater on which the Salinas Valley's farms, families and workplaces depend. In turn, that net-zero impact on Basin groundwater would make the MPWSP legally feasible by avoiding conflict with prior groundwater rights of the Basin's overlying landowners and prior appropriators, like the Castroville Community Services District (CCSD). And finally, the net-zero impact on Basin groundwater would avoid significant adverse physical impacts to the Basin and to the remarkable agricultural economy it sustains.

SVWC/MCFB-1 cont.

The Salinas Valley suffers from seawater intrusion that has degraded groundwater quality. Members of the SVWC, MCFB and other landowners have paid decades of costly assessments to fund development and operation of groundwater recharge projects—including two reservoirs (Nacimiento and San Antonio), the Castroville Seawater Intrusion Project (CSIP), and the Salinas Valley Water Project (SVWP). The purposes of those projects are to recharge the SRGB to assure water availability during the irrigation season, to stop seawater intrusion, to bring the SRGB into hydrologic balance, and to manage the SRGB for long term sustainability. The two reservoirs capture high winter streamflows from Salinas River tributaries for gradual release into the porous Salinas River bed during the dry season to recharge Salinas River underflow and the SRGB (direct recharge). The CSIP delivers highly treated municipal wastewater for agricultural irrigation use in lieu of groundwater pumping (in lieu recharge). And the SVWP modified and reoperates Nacimiento Reservoir to increase its yield for increased recharge releases into the Salinas River (more direct recharge) and to supply a new surface water diversion for increased CSIP water deliveries in lieu of groundwater pumping (more in lieu recharge).

SVWC/MCFB-2

The hundreds of millions of dollars in groundwater recharge investment by the SVWC and MCFB members and other Salinas Valley landowners sustains an $8 billion agricultural economy that generates more than 76,000 jobs. The Salinas Valley's agricultural economy depends on irrigation with Basin groundwater.

The MPWSP's Proposed Use of Wells to Produce Source Water From the Overdrafted Salinas River Groundwater Basin Risks Making the Monterey Peninsula's Water Supply Solution Legally Infeasible

SVWC/MCFB-3

To help solve the Monterey Peninsula's water supply problems, the MPWSP proposes to construct eight slant wells in the Salinas River Groundwater Basin to pump 26,995 acre-feet per year (AFY) of source

water to deliver approximately 10,753 AFY (9.6 million gallons per day [MGD]) of desalinated water for Cal-Am's urban service area within the Monterey Peninsula — outside the Basin. The 6.4 MGD alternative would produce 7,168 AFY of source water to deliver approximately 3,010 AFY of desalinated water for the Peninsula.

The Draft EIR/S explains that the Basin experiences approximately 51,000 AFY of overdraft (Draft EIR/S at p. 4.4-19.) Accordingly, the Draft EIR/S correctly concludes that use of Basin wells to produce source water for the MPWSP's desalination process will make the project legally infeasible, because there is no surplus groundwater available for new appropriative uses — unless the well production would be undertaken without causing injury to overlying and prior appropriative groundwater rights. (DEIR/S at 2-30 to 2-32 ["what rights factors in as a key project feasibility issue"].)

The Draft EIR/S asserts that "[t]he area influenced by the MPWSP groundwater pumping is within a zone that is degraded by seawater intrusion and therefore unusable for potable water supply due to its high salinty." (DEIR/S at p. 4.4-60.) From there, the Draft EIR/S erroneously asserts that the MPWSP's production of brackish groundwater exceeding state water quality objectives for chlorides and total dissolved solids (TDS), by definition, cannot injure prior groundwater rights (i.e., overlying rights of farmers and prior appropriative rights of the CCSD) — unless the MPWSP well production directly causes acute impacts, like dewatering nearby wells currently being used for agricultural irrigation or potable water supply. (DEIR/S at pp. 2-35 to 2-37.)

SVWC/MCFB-3 cont.

The preceding assertion of the DEIR/S is wrong and risks misleading the Commission into concluding that the MPWSP's use of Basin wells to produce source water might be legally feasible, even if the MPWSP does not return to the Basin the portion of produced source water originating as Basin groundwater (instead of seawater).

First, the Draft EIR/S admits that as a result of the MPWSP's well production, "changes in water quality could be realized within the first 5 years of project operation," that "throughout the life of the project, local groundwater quality around the slant wells and within the cone of depression could change from the brackish quality it is now to higher salinity groundwater . . . because the slant wells would draw in the brackish water that is currently in the aquifer formation and seawater would flow in to replace it." (DEIR/S at p. 4.4-76.) New water quality degradation caused by MPWSP pumping would injure the Basin and Basin groundwater rights, unless it is offset. Without an offsetting water quality improvement effect, the MPWSP's pumping would injure prior groundwater rights in the Basin, making the use of Basin wells to feed the MPWSP infeasible from a water rights perspective.

Second, as the tension between water demand and water supplies continues to intensify, competition is building for degraded water supplies – like municipal wastewater or groundwater that cannot be beneficially used without treatment (e.g., tertiary treatment of wastewater or desalting of brackish groundwater). The notion that degraded water supplies that fail to meet state water quality objectives are per se "surplus" is an anachronism that defies modern water management reality.

SVWC/MCFB-4

For example, there is competition for recycled wastewater produced by the Monterey Peninsula Water Pollution Control Authority and many other municipal wastewater treatment agencies across the state. Municipal wastewater that used to be considered a costly disposal problem is now a coveted water resource. With respect to the SRGB's brackish groundwater, the Draft EIR/S describes competing demands for non-potable, brackish groundwater in the project area, including "minor irrigation and dust

control" and potential future source wells for at least one other, unrelated desalination project. (DEIR/S at 4.4-90.)

Further, in Southern California's adjudicated West Coast Basin, the Superior Court in 2007 ruled that a desalting plant's use of wells to produce brackish groundwater exceeding state water quality objectives must stop operating unless its owner leases adjudicated pumping rights to cover well production. That was so, absent consideration of whether the desalter's pumping harmed nearby wells. (*See* Joint Stipulation and Order re Operation of Goldsworthy Desalter, *California Water Service Company v. City of Compton,* Los Angeles County Superior Court Case No. C506-806 [filed July 24, 2007], attached hereto as **Exhibit A.**) Further, the West Coast Basin adjudication Judgment regulates production of highly contaminated groundwater for industrial cleanup sites under a "nonconsumptive water use right" requiring that "essentially all such produced water is returned without quality impairment, to the aquifer of the Basin from which the same was produced." (Exh. B Judgment at 59:1-6, attached hereto as **Exhibit B**.) The fundamental groundwater rights principles underlying the desalter order and nonconsumptive use right point to the need for the Return Water Settlement Agreement in the SRGB.

If the Commission were tempted to embrace the anachronistic position that brackish groundwater exceeding water quality objectives is per se surplus unless its production dewaters third party wells, it would be committing the MPWSP to a significant legal feasibility – and defensibility — problem when there is no need to do so.

SVWC/MCFB-4 cont.

Approval of the Return Water Settlement Agreement Would Ensure that MPWSP Well Production Is Legally Feasible

The solution to the MPWSP's water rights feasibility problem is for the Commission to approve the Return Water Settlement Agreement that already has been approved by the Applicant, the Monterey County Water Resources Agency (MCWRA), the Monterey Peninsula Water Management District, the Monterey Peninsula Regional Water Authority, LandWatch Monterey County, the Salinas Valley Water Coalition, the Monterey County Farm Bureau and other parties.

The Return Water Settlement is legally necessary if the Commission is going to approve a project allowing the Monterey Peninsula to take water pumped from the Salinas River Groundwater Basin wells. Absent Return Water, the MPWSP will be legally infeasible from a water rights perspective and also will violate the MCWRA enabling act prohibition against exporting groundwater from the overdrafted Basin. Absent Return Water, litigation is certain.

The MPWSP's Well Pumping Will Cause Significant Adverse Environmental Effects, Unless the Return Water Settlement Agreement is Approved and Implemented

The Draft EIR/S states that the MPWSP would have a significant adverse effect on groundwater resources of the overdrafted Basin if, among other things, "[e]xtraction from the subsurface slant wells substantially depleted groundwater in the SVGB such that there would be a net deficit in aquifer volume." (DEIR/S at 4.4-41.)

SVWC/MCFB-5

The Draft EIR/S states that the MPWSP would have significant cumulative impacts on groundwater resources if they would substantially deplete or interfere with groundwater supplies, violate water quality standards, or degrade water quality. (DEIR/S at 4.4-88.)

The Draft EIR/S admits that, based on groundwater effects modeling: "If the proposed project did not return any water, localized depressed groundwater levels would persist in the three affected aquifers throughout the life of the project." (DEIR/S at p. 4.4-60.) That impact would be a significant direct impact to groundwater resources. It also would be a significant cumulative impact to groundwater resources, because the MPWSP's reduction in groundwater levels would be a considerable contribution to an existing condition of overdraft (i.e., existing substantial depletion).

The attached Technical Memorandum from consulting groundwater engineer Timothy Durbin explains that "the DEIR's groundwater impacts analysis supports the need to approve and implement the proposed Return Water Settlement Agreement ("RWSA")." The Technical Memo is attached as **Exhibit C** hereto. Mr. Durbin has reviewed the RWSA and is a member of the Hydrological Working Group that has reviewed the groundwater effects modeling used in the current Draft EIR/S. Mr. Durbin explains that the RWSA "will help to ensure that operation of slant wells to produce source water for the MPWSP desalination process will not substantially deplete groundwater resources within the Salinas River Groundwater Basin and would help prevent the source water production from making a contribution to ongoing depletion of the groundwater resources . . . ."

SVWC/MCFB-5 cont.

Based on the preceding significance criterion, and the Draft EIR/S's groundwater effects modeling, the Commission's approval and the Applicant's implementation of the Return Water Settlement Agreement as an enforceable component of the MPWSP is necessary to avoid significant adverse impacts with respect to groundwater resources. And based on the criterion for cumulative impacts, implementation of the Return Water Settlement Agreement is necessary to avoid a significant cumulative impact to groundwater resources.

The approval of the Return Water Settlement Agreement by the Applicant and other necessary parties (e.g., MCWRA, CCSD) shows this component of the MPWSP is feasible. Failure to approve the Return Water Settlement Agreement would result in a significant impact despite the availability of feasible mitigation, which would violate the California Environmental Quality Act (CEQA).

"From the time the slant wells begin pumping, and throughout the life of the project, local groundwater quality around the slant wells and within the cone of depression could change from the brackish quality it is now to higher salinity groundwater." (DEIR/S at 4.4-78.) However, the DEIR/S incorrectly concludes that impact is less than significant, because "the localized change in groundwater quality that could occur as a result of slant well pumping is not expected to violate water quality standards or interrupt or eliminate the potable or irrigation groundwater supply available to other basin users." (DEIR/S at 4.4-76.)

SVWC/MCFB-6

The Draft EIR/S states that the MPWSP would have a significant adverse effect on groundwater resources of the seawater-intruded Basin if, among other things, the project's well production would "[v]iolate any ground water quality standards or otherwise degrade groundwater quality," including "exacerbating seawater intrusion . . . ." (DEIR/S at 4.4-41.)

As noted above, the Draft EIR/S admits that as a result of the MPWSP's well production, "changes in water quality could be realized within the first 5 years of project operation," that "throughout the life of the project, local groundwater quality around the slant wells and within the cone of depression could change from the brackish quality it is now to higher salinity groundwater . . . because the slant wells would draw in the brackish water that is currently in the aquifer formation and seawater would flow in

to replace it." (DEIR/S at p. 4.4-76.) That is an admission that the MPWSP's well production will cause water quality degradation — unless the degradation is offset.

Here, the Return Water Settlement Agreement would offset water quality degradation by delivering Return Water for use by CCSD and CSIP in lieu of existing groundwater pumping along the coast, which in turn will help to stop seawater intrusion from degrading Basin water quality. If the Commission approves, and the Applicant implements, the Return Water Settlement Agreement, the significant adverse water quality impact of the MPWSP's well production will be mitigated to a less-than-significant level.

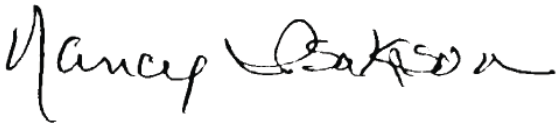
SVWC/MCFB-6 cont.

The SVWC and the MCFB believe that there is substantial agreement amongst the settling parties of the RWSA that provides a pathway in providing a solution that offers multiple benefits to the groundwater users of SRGB, CCSD and CSIP.

SVWC/MCFB-7

On behalf of the SVWC and the MCFB, we thank you for the opportunity to provide comments on the DEIR/S.

Sincerely,



Nancy Isakson, President
Salinas Valley Water Coalition

Sincerely

Norm Groot, Executive Director
Monterey County Farm Bureau

Re: Surfrider Foundation's Comments on Draft Environmental Impact Report/Statement – Monterey Peninsula Water Supply Project

Dear Ms. Borak and Ms. Grimmer:

This firm represents Surfrider Foundation regarding the California Public Utilities Commission's consideration of an application for a certificate of public convenience and necessity for California-American Water's proposed Monterey Peninsula Water Supply Project (the "Project"). Surfrider is a non-profit organization dedicated to the protection and enjoyment of the world's ocean, waves and beaches. In particular, Surfrider's work focuses on five key areas: beach access, clean water, coastal preservation, ocean protection, and preventing marine plastic pollution. While Surfrider is generally supportive of the Project, it continues to have reservations regarding the Project's size, specific design features, and potential impacts to the Monterey Bay National Marine Sanctuary (the "Marine Sanctuary").[1] Surfrider-1

The Project will provide replacement water that the applicant, California American Water ("Cal-Am"), must acquire to reduce its present over-pumping of the

[1] Surfrider commented on the Commission's original draft EIR for the Project, which was circulated for public review in 2015. Surfrider also submitted scoping comments on the National Oceanic and Atmospheric Administration's Notice of Intent to prepare the DEIS in 2015. To the extent that they remain relevant to the current DEIR, Surfrider incorporates its prior comments by this reference, and restates them below.

Carmel River and comply with a State Water Resources Control Board Cease and Desist Order. *See* SWRCB Order WR 2009-0060. The importance of the Project for protecting the Carmel River means that its environmental review must be of the highest quality and must fully support the PUC's decision. The current Draft Environmental Impact Report/Statement ("DEIR") does not, and without revision will not, meet these standards.

As identified below, the DEIR falls short of requirements of the California Environmental Quality Act ("CEQA"), Public Resources Code section 21000 *et seq*., the CEQA Guidelines, California Code of Regulations, title 14, section 15000 *et seq*. ("CEQA Guidelines") and the National Environmental Policy Act ("NEPA"), 42 U.S.C. section 4321 *et seq*. The DEIR should likewise confirm that the Project has complied with all elements of the Marine Sanctuary's regulations that apply to the proposed Project activities.[2]

Surfrider-1 cont.

The Commission and the Marine Sanctuary (collectively, the "Agencies") must resolve the DEIR's multiple deficiencies before they may legally grant the requested Project approvals. Surfrider therefore urges the Agencies to remedy the identified defects in the DEIR's analysis and mitigation, and to adopt all feasible mitigation to reduce the Project's environmental impacts.

I. The DEIR Fails to Adequately Mitigate the Project's Contribution to Climate Change.

Analysis and mitigation of the Project's climate change impacts are particularly important because the global economy has already exceeded the atmosphere's capacity to absorb additional greenhouse gas emissions without risking catastrophic and irreversible consequences. Therefore, even seemingly small additions of greenhouse gas emissions into the atmosphere will create cumulatively significant impacts. *See Communities for a*

Surfrider-2

[2] For instance, we note that the DEIR includes only an incomplete discussion of the requirements necessary for the Marine Sanctuary to "authorize" otherwise prohibited Project activities like the proposed brine discharge. *See* DEIR 1-7 (citing 15 CFR § 922.49(a)). The final environmental document must contain evidence that the applicant has complied with all sections of the applicable regulations, including 15 CFR section 922.49(a)(1), which mandates that the applicant notify NOAA within 15 days of submitting its application to the Commission for authorization of an otherwise prohibited activity.

Better Environment v. Cal. Resources Agency (2002) 103 Cal.App.4th 98, 120 ("[T]he greater the existing environmental problems are, the lower the threshold for treating a project's contribution to cumulative impacts as significant."); *Center for Biological Diversity v. National Highway Traffic Safety Administration* (9th Cir. 2007) 508 F.3d 508, 550 ("[W]e cannot afford to ignore even modest contributions to global warming."). Here, the DEIR correctly recognizes that the Project will lead to significant greenhouse gas emissions, yet fails its statutory duty to identify legally adequate and feasible mitigation measures to minimize the Project's contribution to climate change.

The DEIR measures the Project's contribution to the cumulative impact of global climate change. It anticipates that multiple sources will contribute to the Project's total greenhouse gas emissions. Because desalination plants require large quantities of electricity to operate, much of the Project-related greenhouse gas emissions occur indirectly through the carbon emissions from energy production. In addition to indirect greenhouse gas emissions from electricity consumption, other sources include emissions from construction, operation of diesel emergency generators, vehicle trips necessary for Project operation, loss of carbon sequestration, and degassing from brine storage. DEIR at 4.11-17.

The DEIR evaluates the Project's climate-change contribution against different thresholds of significance. 4.11-10. For each one, it determines that the Project will have a significant impact from greenhouse emissions. DEIR at 4.11-15. When an agency's analysis indicates that a proposed project will have a significant project-specific or cumulative impact, the agency must identify and adopt feasible mitigation measures to address that impact. CEQA Guidelines § 15126.4(c).

Here, the DEIR proposes two mitigation measures to reduce greenhouse gas emissions from Project operations and construction. The first measure requires Cal-Am to submit a plan for PUC approval before Project construction that (1) describes potential greenhouse gas emissions in detail, and (2) requires Cal-Am to identify and incorporate "feasible" energy recovery and conservation technologies. That measure likewise obligates Cal-Am to make "good faith efforts" to use up to 20 percent power energy for the Project.[3] DEIR at 4.11-19.

Surfrider-2 cont.

[3] The identified sources of renewable power are installation of onsite solar photovoltaic panels and methane gas from the Monterey Regional Waste Management District's adjacent landfill-gas-to-energy facility.

The second measure requires a Cal-Am consultant to prepare a "Construction Equipment Efficiency Plan" that "identifies specific measures that Cal-Am (and its construction contractors) will implement" to reduce construction-related energy use. Cal-Am must also submit that plan for approval before beginning Project construction. DEIR at 4.11-20, 4.18-16. Thus, in both instances, the DEIR defers formulation of the specific mitigation requirements to an uncertain future date.

An EIR generally may not defer evaluation of mitigation until a later date. CEQA Guidelines §§ 15126.4(a)(1)(B). CEQA allows a lead agency to defer mitigation only when three narrow, specific prerequisites are met: (1) an EIR contains criteria or performance standards to govern future actions implementing the mitigation; (2) practical considerations preclude development of the measures at the time of initial project approval; and (3) the agency has assurances that the future mitigation will be both "feasible and efficacious." *Communities for a Better Environment v. City of Richmond* (2010) 184 Cal.App.4th 70, 94-95; *San Joaquin Raptor Rescue Center v. County of Merced* (2007) 149 Cal.App.4th 645, 669-71; CEQA Guidelines § 15126.4(a)(1)(B).

The DEIR fails these standards. First, it does not show why the Agencies cannot develop definite and enforceable mitigation measures now. The DEIR lacks any evidence demonstrating that more precise greenhouse gas mitigation requirements cannot be formulated. Cal-Am and the Agencies appear to have all of the information required to formulate a conservation plan and to determine whether and how much renewable electricity will be available. At the very least, DEIR can produce a clear menu of options and calculate potential emissions reductions from each. Similarly, the Agencies can evaluate all currently-known construction efficiency standards now, instead of shielding those measures from public review by deferring this mitigation.

Courts have recognized that the DEIR's approach of deferred mitigation violates CEQA precisely because it undermines informed decisionmaking and public participation:

> "[t]he success or failure of mitigation efforts . . . may largely depend upon management plans that have not yet been formulated, and have not been subject to analysis and review within the EIR . . . . A study conducted after approval of a project will inevitably have a diminished influence on decisionmaking. Even if the study is subject to administrative approval, it is analogous to the sort of post hoc rationalization

Surfrider-2 cont.

> of agency actions that has been repeatedly condemned in decisions construing CEQA."

Communities for a Better Environment, 184 Cal.App.4th at 92.

Nor is this mitigation feasible or efficacious. *See id.* at 94-95. The DEIR itself reveals the deficiency of its vague, deferred mitigation measures. It states that it "cannot substantiate that the mitigated greenhouse gas emissions would be reduced to a less-than-significant level." DEIR at 4.11-23. The DEIR cannot do so because the proposed mitigation is so uncertain that it is impossible to know whether it will come close to reducing greenhouse gas impacts below identified significance thresholds.

The DEIR thus necessarily concludes that the Project's greenhouse gas emissions will cause a significant impact even after adopting the proposed mitigation measure. The DEIR cannot, however, simply determine that an impact is significant and unavoidable and ignore its mitigation obligations. *Lotus v. Department of Transportation* (2014) 223 Cal.App.4th 645, 653. The Agencies must adopt any and all feasible mitigation to reduce those impacts. CEQA § 21002 ("[A]gencies should not approve projects as proposed if there are . . . feasible mitigation measures available which would substantially lessen the significant environmental effects of such projects." Surfrider-2 cont.

In light of the admitted failure of its improperly deferred mitigation, the DEIR must consider whether formulating and adopting additional mitigation measures could further reduce the Project's greenhouse gas emissions and the extent of such reductions.

The Agencies should consider whether the following measures would reduce the Project's greenhouse gas emissions below the DEIR's thresholds, and adopt those that would:

- Incorporate the U.S. Green Building Council's LEED or comparable standards for energy- and resource efficient building during pre-design, design, construction, operations and management;
- Design buildings for passive heating and cooling, and natural light, including building orientation, proper orientation and placement of windows, overhangs, skylights, etc.;
- Design buildings for maximum energy efficiency including the maximum possible insulation;

- Reduce the use of pavement and impermeable surfaces;
- Require water reuse systems;
- Maximize water conservation measures in buildings and landscaping, using drought tolerant plants in lieu of turf, planting shade trees;
- Install the maximum amount of solar photovoltaic panels available onsite, including solar canopies over parking areas
- Install solar water heating systems to generate all of the Project's hot water requirements;
- Install electric vehicle and plug-in hybrid vehicle charging stations to reduce emissions from vehicle trips;
- Install energy storage systems to ensure that the energy generated can be used on-site;
- Require recycled, low-carbon, and otherwise climate-friendly building materials such as salvaged and recycled-content materials for building, hard surfaces, and non-plant landscaping materials;
- Minimize, reuse, and recycle construction-related waste;
- Landscape to preserve natural vegetation and maintain watershed integrity;
- Use low or zero-emission construction vehicles.

Surfrider-2 cont.

The Agencies should also follow the lead of other agencies that have approved energy-intensive projects and require Cal-Am to purchase carbon offsets for the Project's greenhouse gas emissions. The DEIR argues against offsets by claiming that indirect emissions from electricity use would be governed by the state's cap and trade program and therefore do not need be offset. DEIR at 4.11-20. This position is faulty for multiple reasons. First, the cap and trade program is currently scheduled to end in 2020. In contrast, the Project has a 40-year planned life. DEIR at 4.11.11. Consequently, there is no guarantee that California's cap and trade program will regulate power-generating emitters for the bulk of the Project's life.

Surfrider-3

Second, even if cap and trade remains in place past 2020, it does not control emissions from out-of-state electrical-generation sources. In 2015, over a third of California's electricity was imported from out of state, a large percentage of which came from coal and natural gas combustion.[4] The DEIR cannot assume, as it does, that the indirect greenhouse gas emissions associated with the Project's electricity use will be entirely regulated by *California*'s cap and trade program.

Finally, roughly 20 percent of the Project's greenhouse gas emissions directly result from Project construction or operations that would not be subject to cap and trade regulation. DEIR at 4.11-16 through 4.11-17. If these greenhouse gas emissions cannot be mitigated through other means, then the Agencies must require that they are mitigated through emission offsets.

Surfrider-3 cont.

II. The DEIR Must Adequately Evaluate and Mitigate Coastal Erosion Impacts.

A. CEQA Requires Evaluation of Coastal Hazard Impacts.

The DEIR claims that information on potential Project impacts stemming from sea level rise and coastal erosion are only for "information purposes" and are not required as part of the CEQA analysis. DEIR at 4.2-45 (citing *California Building Industry Association v. Bay Area Air Quality Management District* (2015) 62 Cal.4th 369 ("*CBIA*")). Regardless of CEQA's requirements, under NEPA, federal agencies also consider environmental hazards' potential impacts on a project. *See, e.g., Fuel Safe Wash. v. FERC* (10th Cir. 2004) 389 F.3d 1313, 1331-32 (evaluating an EIS's consideration of seismic hazards).

Surfrider-4

Additionally, the DEIR misstates the applicable CEQA standard. In *CBIA*, the court held that "CEQA *generally* does not require an analysis of how existing environmental conditions will impact a project's future users or residents." *Id.* at 386 (emphasis added). But this general rule is subject to a significant exception. When the project exacerbates existing environmental hazards, an agency must consider "how such worsened conditions could affect a project's future users or residents." *Id.* at 389.

Here, the DEIR admits that the Project will contribute to global climate change, which will exacerbate various climate-related impacts including sea level rise. DEIR at 4.11-18. CEQA therefore mandates that the Agencies adequately evaluate and mitigate

[4] *See* http://www.energy.ca.gov/almanac/electricity_data/total_system_power.html.

potential impacts related to sea-level rise and attendant coastal erosion. This analysis is not simply for "information purposes" and is subject to CEQA's legal standards and requirements.

Surfrider-4 cont.

B. The DEIR Should Ensure that Mitigation Measures Related to Coastal Erosion Impacts Are Adequate.

The DEIR notes that Cal-Am has revised its Project proposal to locate wellheads for the two southernmost slant well clusters 400 feet inland, behind the existing sand dunes at the proposed intake site. DEIR at 4.2-60. Surfrider had previously raised concerns regarding the original slant well locations proposed in Cal-Am's application because future coastal erosion and storms could compromise the wellheads.[5] Surfrider believes that relocating the slant wells inland helps avoid these foreseeable impacts and is consistent with Surfrider's previous recommendations in this proceeding. Consequently, while Surfrider does not advocate for any particular slant well site, Surfrider supports the decision to revise the Project to move the wellheads inland to more protected locations.

Surfrider-5

Even with this revised wellhead location, however, the DEIR's analysis reveals that the northernmost wellhead cluster (located at the CEMEX sand mining property) will become exposed by erosion and potentially compromised under extreme storm conditions by 2060.[6] *See* Figure 4.2-7. The DEIR thus proposes Mitigation Measure 4.2-9, which requires annual monitoring of coastal retreat at the CEMEX site and relocation of the northernmost well cluster if and when data indicates that slant wells are expected to become exposed within five years.

CEQA requires that an EIR contain sufficient evidence to indicate that a mitigation measure is adequate to reduce a potentially significant impact to a less-than-significant level. *See National Parks & Conservation Assn. v. County of Riverside* (1999) 71 Cal.App.4th 1341, 1366. Yet the DEIR does not demonstrate that Mitigation Measure 4.2-9 can adequately reduce the identified erosion impact. First, Measure 4.2-9 does not

[5] *See* A.12-04-019, Testimony of Bradley Damitz on Behalf of Surfrider Foundation (February 22, 2013) at 6-7.

[6] The DEIR's "erosion profiles" are predicted beach cross-sections perpendicular to the waterline. These profiles attempt to depict how the beach and dune profile will retreat landward in response to sea-level rise, erosion, and storm events over different time horizons.

specify how Cal-Am should calculate when threatened exposure is five years away, thus triggering planning and permitting for slant well relocation.

Using simple average erosion rates is not sufficient. As the DEIR shows elsewhere, a single 100-year storm event could erode the dune profile near the site by roughly 130 feet inland. DEIR at Figure 4.2-7 (compare 2060 erosion profile with the profile showing the combined impact of 2060 erosion and a 100-year storm event). This single-event erosion is roughly equivalent to the average erosion that would be expected to occur over twenty years. *See id.* (compare 2040 erosion profile with 2060 erosion profile).

Every year brings a possibility of such an extreme storm event. And as has been noted at Commission workshops on climate adaptation, "the frequency and magnitude of [storm] extremes" is expected to "increase markedly" with climate change.[7] The 2015-2016 El Nino was one of three strongest on record and brought unprecedented levels of erosion to the California coast, especially in sediment-deprived areas like the CEMEX site.[8]

Surfrider-5 cont.

In fact, the CEMEX site might be even more threatened than the DEIR reveals. The beach and dune profile used for the test well erosion analysis is actually located to the south of the CEMEX sand mining operation. The DEIR does not evaluate how sand mining activities will further exacerbate coastal erosion, claiming that "No data is available to quantify the uncertainty in adjacent beach and dune erosion related to sand mining activities." DEIR Figure 4.2-7, n. 3. Thus, the potential magnitude of erosion at this location is very likely greater than the DEIR reveals.

The mitigation measure's proposed monitoring and DEIR's erosion projections overlook the possibility that extreme climate and storm events, like those associated with last year's El Nino, could erode the beach to within the range of a single storm's erosion at the especially vulnerable CEMEX site. While that risk exists, the measure could fail to

[7] *See* Dan Canyan, "Planning for climate change on top of already high climate variability" at pdf p. 16, available at www.cpuc.ca.gov/NR/rdonlyres/52D8EFC3-B79C-4854-8714-DB8151C8664F/0/Dan_Cayan_CEC_PUC_27JULY2015_Web.pdf.

[8] *See* Nature Communications, Extreme oceanographic forcing and coastal response due to the 2015-2016 El Nino, available at http://www.nature.com/articles/ncomms14365#s1.

trigger relocation in time. This possibility undermines the DEIR's conclusion that this mitigation measure is sufficient to avoid significant erosion impacts.

At a minimum, to address this flaw in the DEIR's erosion analysis and to fully protect against large storm events, Mitigation Measure 4.2-9(1) should be revised to read:

> CalAm shall conduct annual monitoring of the rate of coastal retreat relative to the slant wells at the CEMEX site. The data shall be used to estimate the year at which the wells and associated pipelines have 5 years before exposure, assuming that at least one 100-year storm event will occur within that exposure timeframe.

Surfrider-5 cont.

Finally, even if the DEIR is properly revised to protect from 100-year storm events at CEMEX, the DEIR lacks any information indicating whether the 5-year period will allow sufficient time to plan and permit the necessary decommissioning and relocation of the threatened slant wells. The DEIR must substantiate the time threshold for removal and replacement of the northernmost slant well cluster, especially in light of the extended permitting process that has been required for the test well for this very Project.

III. The DEIR Should Consider Alternatives that Reduce the Size of the Desalination Plant.

A proper analysis of alternatives is essential to comply with CEQA's mandate that significant environmental damage be avoided or substantially lessened where feasible. Pub. Res. Code § 21002; CEQA Guidelines §§ 15002(a)(3), 15021(a)(2), 15126(d); *Citizens for Quality Growth v. City of Mount Shasta* (1988) 198 Cal.App.3d 433, 443-45. The primary purpose of CEQA's alternatives requirement is to explore alternatives to proposed actions that will reduce or avoid their adverse impacts on the environment. *Watsonville Pilots Ass'n v. City of Watsonville* (2010) 183 Cal.App.4th 1059, 1089. Therefore, the discussion of alternatives must focus on project alternatives that are capable of avoiding or substantially lessening any significant effects of the project, even if such alternatives would impede to some degree the attainment of the project objectives or would be more costly. CEQA Guidelines § 15126.6(b); *see also Watsonville Pilots,* 183 Cal. App. 4th at 1089 ("[T]he key to the selection of the range of alternatives is to identify alternatives that meet most of the project's objectives but have a reduced level of environmental impacts"); 40 C.F.R. § 1502.14 (CEQ regulations describing the alternatives analysis as "the heart of the environmental impact statement").

Surfrider-6

Here, the DEIR improperly circumscribes its analysis of potential Project alternatives. Specifically, it fails to consider an alternative that reduces the desalination plant's size within either the large desalination plant project scenario or the smaller desalination plant plus groundwater replenishment variant ("GWR Alternative"). By reducing the desalination plant's size, such an alternative could reduce the Project's net greenhouse gas, brine discharge, and groundwater impacts. *See, e.g.,* DEIR at 5.6-7.

Surfrider-6 cont.

In fact, a reduced-Project alternative is very likely feasible. As Surfrider has raised previously in this proceeding, Cal-Am justifies the size of the proposed Project on the basis of artificially inflated demand projections. The DEIR carries forward these inflated demand assumptions in multiple ways, including (1) unsupported assumptions about future water use for tourism and undeveloped "lots of record," and (2) the arbitrary assumption that future water use will be similar to water use in 2010 when, in fact, water use in Cal-Am's service area has fallen dramatically every year for the past decade.[9] If the DEIR revises the Project's demand assumptions to accurately portray future water use, it will show that a reduced Project alternative not only is environmentally superior, but is also feasible.

Surfrider-7

Significantly, the DEIR's alternatives analysis already recognizes the environmental benefits of reducing the size of the Project's desalination component. The DEIR labels one version of the GWR Alternative as an environmentally superior alternative to the larger desalination scenario. DEIR at 5.6-7. The DEIR recognizes that because the GWR Alternative includes a smaller desalination plant, it would reduce the Project's long-term and "more severe" operational impacts related to groundwater and greenhouse gas emissions. *Id.* Other potentially significant operational impacts, like potential water quality impacts from brine discharge, would also diminish as the proposed desalination plant becomes smaller. Thus, the DEIR correctly shows that reducing the desalination plant's size will reduce the Project's most significant environmental impacts.

Surfrider-8

Despite the environmental gains realized by further reducing the size of the desalination plant, the DEIR does not consider an alternative that can shrink the plant's size independent of the GWR Alternative. As part of the No Project alternative, the DEIR analyzed foreseeable water conservation and water recycling measures within Cal-Am's service district that could partially offset a water supply shortfall if the Project is not

[9] http://www.watersupplyproject.org/system-delivery.

built. DEIR at 7-184 through 7-196. The DEIR rejects a No Project alternative because it does not provide sufficient water to fully satisfy the impending water deficit in Cal-Am's service district and achieve other Project objectives. *Id.* at 7-197. But the DEIR inexplicably fails to consider whether these conservation measures, demand offsetting measures (including conservation pricing), or new local water projects (such as the Pacific Grove Local Water Project or Pebble Beach Recycled Water Project Phase II) could be combined with the Project to reduce the size of the desalination plant and its long-term environmental impacts. CEQA requires the DEIR to consider such a Project alternative, especially considering that it could reduce the Project's "most severe" environmental impacts under either large-desalination or GWR Alternative scenarios. *See Watsonville Pilots Ass'n*, 183 Cal.App.4th at 1087.

Surfrider-8 cont.

IV. Cal-Am Should Monitor for and Mitigate Any Brine-Related Impacts.

Surfrider notes that the DEIR has substantially revised its brine dispersal modeling to provide greater information regarding the location and salinity of brine plumes associated with the Project's discharge. While the DEIR's modeling indicates that the plumes will not increase background salinity above 1.56 ppt at the zone of initial dilution boundary, it is important that Cal-Am monitor actual discharge conditions to confirm that the Project will not degrade marine water quality or significantly impact marine organisms more than the models suggest.

Surfrider-9

Surfrider generally supports the DEIR's proposed monitoring program, which substantially complies with the core elements of the monitoring program from the Brine Settlement Agreement (which Surfrider, Cal-Am, and other parties filed with the Commission on June 14, 2016). *See* Mitigation Measure 4.3-4. Surfrider also supports additional monitoring for potential impacts to marine life that might occur even if the Project's discharge otherwise falls below established salinity and effluent standards.

Surfrider is concerned, however, that the proposed biological monitoring lacks meaningful thresholds to determine when impacts to the benthic community or other organisms would trigger corrective measures. The DEIR states that a monitoring plan shall require that no "statistically significant" change to the benthic community occur from the Project's operations. DEIR 4.3-89. But the DEIR does not disclose the level of statistical significance that will actually trigger relocation. Without such a standard, it would be impossible for the Agencies or Cal-Am to determine when impacts to the benthic community or other marine life become statistically significant. The DEIR should therefore formulate and explain these standards for the monitoring plan.

Surfrider-10

V. The DEIR Must Consider Cumulative Impacts from Other Proposed Desalination Projects in the Project's Vicinity.

The DEIR asserts two other proposed desalination projects—the People's Project and DeepWater Desal Project—would develop supplemental water supplies to serve the same Cal-Am customers as the proposed Project. *See* DEIR 4.3-123. However, the DEIR asserts that the People's Project and this Project could not both be implemented since their purposes and customers would largely be the same. Therefore, the DEIR does not consider the People's Project to be a reasonably foreseeable project in the cumulative scenario, and does not consider its cumulative impacts.

As to DeepWater Desal, the DEIR notes that water could be provided to other customers in Santa Cruz County or the City of Salinas, and that project could be approved in addition to this Project. Therefore, the DEIR does consider cumulative impacts of the DeepWater Project. In seeming contradiction, however, the DEIR later notes that either DeepWater Desal or the People's Project could be built, but not both. Yet the DEIR still only considers DeepWater Desal for cumulative impact purposes. *See* DEIR 4.5-67. Surfrider-11

Surfrider agrees that the existing water need cannot possibly justify the development of these other projects, if this Project moves forward. However, there is no binding prohibition on building either or both of the People's or DeepWater desalination projects if this Project is built. Without assurance that these other proposals cannot move forward if Cal-Am's Project is approved, the DEIR cannot assume that some combination of these three projects will not create cumulative impacts in the region. Unless such a binding restriction exists, the DEIR must consider all cumulative impacts from both the DeepWater and People's projects.

VI. Conclusion.

For all of the reasons described above, the Agencies should revise the DEIR to provide the public all of the information required to understand the Project's potentially significant environmental effects and prescribe mitigation measures to address those impacts. Surfrider-12

Very truly yours,

SHUTE, MIHALY & WEINBERGER LLP

The MPWSP "Return Water" Proposal is Counterfactual and Illegal

Because Cal Am has no water rights in the Salinas Valley, it has proposed in the MPWSP to draw its source water primarily from the sea via slant wells near the shore. WRAMP1-1

Its test well shows that not all the water to be drawn will come from the sea, however. WRAMP1-2

Much of it will come from aquifers in the Salinas River groundwater basin. Even if Cal Am had water rights in the valley, its project would still face a legal hurdle. The state Agency Act prohibits the exportation of *any* valley groundwater outside the valley: "[N]o groundwater from that basin may be exported for any use outside the basin." Quoting that from the Agency Act on p. 2-39, the 2017 MPWSP draft EIR/EIS observed earlier, on p. 2-31, that "if Cal Am does not have the right to the supply water for the proposed project, the proposed project could not proceed and would thus prove infeasible." So, the feasibility of the MPWSP depends on its making the groundwater that its wells extract somehow disappear. WRAMP1-3

That is where the "return water" doctrine comes in. The draft 2017 EIR/EIS explained that doctrine thoroughly and succinctly on p. 4.4-49 (italics added): "The MPWSP proposes to return a certain fraction of water (referred to here as return water) extracted by the slant wells to water users in SVGB [Salinas Valley Groundwater Basin] as desalinated product water. As a brief review, the Agency Act does not allow groundwater pumped from the SVGB to be expelled for any use outside the SVGB . . . Since the groundwater in this area has been intruded by seawater for decades, the proposed slant wells at CEMEX would extract brackish water, which is a mixture of ocean water and water originating from the inland aquifers of the basin. *The freshwater portion of the brackish source water that originated from the inland aquifers would constitute the proposed return water. To achieve consistency with the Agency Act, the MPWSP proposes to return the*

freshwater component of the brackish water that is extracted through the slant wells. The exact quantity of water to be returned annually would vary and would be determined each year using a mathematical formula. However, for groundwater modeling and impact analysis purposes in this EIR/EIS, it is estimated that somewhere between O and 12 percent of the source water withdrawn for the project would comprise water originating from the inland aquifers, and thus would be returned to the basin . . . through deliveries of up to 800 afy of desalinated product water to the Castroville Community Services District (CCSD). This water would be piped to the CCSD and the CSIP [Castroville Seawater Intrusion Project] and provided to water customers instead of their pumping an equal amount from the ground. This method of returning water is referred to as in-lieu recharge because the delivered water would reduce the need to pump ground water in corresponding quantities. The NMGWM [North Monterey Ground Water Model] accounts for the O to 12 percent range by simulating the aquifer response in the various scenarios with a 0, 3. 6, and 12 percent returned product water.''

Translating the return-water doctrine into action, Cal Am in a 2 August 2016 settlement agreement with a number of other parties to the CPUC proceeding on the MPWSP, an agreement not yet approved by the CPUC, proposed to circumvent its lack of rights to Salinas Valley groundwater and to satisfy the state Agency Act's prohibition of the exportation of groundwater from the Salinas River groundwater basin by returning to the valley a small fraction of the water extracted and exported from the valley, about half exported as purified water to the Monterey Peninsula and the remainder to the bay. On the face of it, this proposal appears to make no sense, and in fact it does not make sense, but Cal Am and its settlement partners justify it by claiming that almost all of the water to be drawn by its slant wells from aquifers beneath the

WRAMP1-4

shoreline consists of seawater percolated directly from the bay. This claim seems reasonable enough to win many supporters. What could possibly be wrong with it? WRAMP1-4 cont.

The answer is "plenty." First of all, Cal Am has not investigated or, if it has, not reported, the chemical composition of the dissolved solids in the water extracted from its test well to determine if those dissolved solids consist of sodium chloride in an amount characteristic of seawater.[1] In a 26 May memorandum to the Marina Coast Water District, hydrogeologist Curtis Hopkins reported that the chemical composition of the total dissolved solids in well water along the shoreline does not in fact include sodium chloride in an amount characteristic of seawater but consists instead of a blend of other dissolved solids, mostly calcium chloride and calcium carbonate. Hopkins explained this finding as follows: "[T]he groundwater perched above the Salinas Valley Aquitard equivalent flows toward the coast and results in a downward recharge where the aquitard layer thins (or ends) and provides freshwater recharge into the coastal unconfined Dune Sand Aquifer and the underlying 180-Foot Aquifer," providing "in the Marina Subarea . . . an effective layer preventing seawater intrusion … all along the coast … that effectively forms a linear recharge barrier within a mile of the shoreline." **This memorandum by Hopkins is conspicuously absent in the 2017 MPWSP draft EIR/EIS**. Evidently, the return-water doctrine is based not on chemistry, but on sophistry, to circumvent the illegality of extracting and exporting subsurface water from the Salinas Valley. WRAMP1-5 WRAMP1-6

Return water is the fraction of fresh water in well water estimated to come from inland groundwater, the remainder assumed to come directly from seawater. The fraction computed is not a fraction of *water*, however. It is a fraction of *total dissolved* WRAMP1-7

[1] Table 4.4-4 on p. 4-4-22 of the 2017 MPWSP draft EIR/EIS compares the chemical composition of the total dissolved solids in seawater with the chemical composition of the total dissolved solids in water drawn from the test well on 19 May 2016, but the comparison involves chemical elements (ions) rather than compounds.

solids (TDS) in a liter of water. Reported as a percent, that fraction is the proportion of the TDS in test-well water that comes from the 180-foot aquifer computed from the expression of the test-well TDS as a weighted average of the known inland aquifer TDS and the known seawater TDS, the first weight being the proportion of aquifer TDS and the second the proportion of seawater TDS in the well water.[2] The computation relies on the correctness of the assumption that all the non-inland-aquifer TDS in the well water comes from directly-intruded seawater. The return-water doctrine is that compliance with the Agency Act requires only the return to the Salinas Valley groundwater basin of the percentage of fresh water in the well water that comes from the inland aquifer, that percentage considered to be equal to the percentage of inland-aquifer TDS in the well water. As noted earlier, the 2017 MPWSP draft EIR/EIS indicates that this percentage is no larger than 12.

WRAMP1-7 cont.

Just as the facts concerning water composition indicate otherwise, however, so the facts concerning the percentage of return water also indicate otherwise. Field data, reported by HydroFocus on p. 28 in Appendix E2 of the 2017 MPWSP draft EIR/EIS, show that one-third of the groundwater drawn by the test well comes from the 180-foot aquifer, not 12 percent or less, and that two-thirds comes from the Dune Sand aquifer, none of the water coming directly from the sea, according to the Hopkins memorandum cited earlier.[3] Likewise, most of the TDS in the well water comes from the Dune Sand aquifer which, computed from the return-water formula with weights equal to one-third and two-thirds, contains 38 percent more TDS than seawater. That makes sense

WRAMP1-8

[2] Appendix D of the 2 August 2016 joint-parties settlement agreement filed with the CPUC presents this formula.

[3] The return-water doctrine also underestimates the freshwater contribution of basin groundwater by using the amount of TDS in the inland 180-foot aquifer prior to seawater intrusion. The seawater-intruded 180-foot aquifer directly supplying water to the well site contains a much greater amount of TDS. That is the amount of TDS that should be used to determine the basin contribution of fresh water at the well site. Even seawater-intruded aquifers can contain over 96.5 percent fresh water.

considering the industrial activity that has been going on for years at the CEMEX well site. Conclusion: Existing and reported data, a critical portion of which is absent from the 2017 MPWSP draft EIR/EIS, indicate that 100 percent of the fresh water extracted by MPWSP wells must be returned to the Salinas River groundwater basin to comply with the Agency Act. The return-water doctrine indicating the percent should be no larger than 12 is contrary to the facts. To apply it would be illegal.

WRAMP1-8 cont.

In numerous filings with the CPUC, Water Plus has tried to expose this fatal flaw in the MPWSP, but Cal Am has so far successfully dodged the issue procedurally by persuading the CPUC to exclude most of those filings from the official record on the MPWSP proceeding. Frustrated by that impasse, the Water Plus board decided to take the issue to court. The attached petition for a writ of mandate filed with the Monterey Superior Court last November is the current amendment of the version filed originally earlier in the year.

WRAMP1-9

Summary. In the MPWSP, Cal Am has proposed to replace the illegality of over-pumping water from the Carmel River groundwater basin with the illegality of pumping and exporting water from the Salinas River groundwater basin. The return-water doctrine is the company's attempt to circumvent the second of those illegalities. As proposed, this doctrine is counterfactual and its application would fail to meet the requirements of state law.

WRAMP1-10

Recommendation. A fatally-flawed return-water doctrine being at the core of the MPWSP, Water Plus (aka Water Ratepayers Association of the Monterey Peninsula) recommends that the CPUC either order Cal Am to go back to the drawing board or to purchase water from one of two competing desalination projects as soon as the project has a certified EIR/EIS, just as the CPUC has done for Pure Water Monterey.

WRAMP1-11

Water Ratepayers Association of the Monterey Peninsula (WRAMP) Letter 2 (WRAMP2)

Mary Jo Borak
California Public Utilities Commission

Dear Ms. Borak,

Thank you for your prompt response.

You are suggesting the problem may exist in the input files. That does not make sense. MODEFLOW output would not exhibit the anomalies I observed without manipulation of the program's output in a postprocessor, regardless of the input data. That is because MODEFLOW output would never yield a statistically significant non-zero correlation between calibrated and error values prior to post-processing. To do so would produce calibrated and error value variations that together either fell short of or exceeded the variation of observed measurements. Falling short would mean some of the observed-measurement variation was neither predicted nor unpredicted by the model, and exceeding would mean some of the observed-measurement variation was both predicted and unpredicted by the model. Such MODEFLOW results would be illogical and impossible prior to post-processing.

The data manipulation must have occurred in post-processing. Otherwise, how do you explain the zero correlation between calibrated and error values for the 900-foot aquifer, an aquifer untapped by the proposed intake wells?

The EIR/EIS indicates that LBNL and HydroFocus did not use the proprietary Groundwater Vistas program used by Geoscience as a package including MODEFLOW. If that is true, as you confirm, did LBNL and HydroFocus use a postprocessor that, together with MODEFLOW, confirmed the results obtained by Geoscience? If so, please email me the computer code for that postprocessor, *the very same* postprocessor they used. If they used different postprocessors, I would like particularly the computer code for whatever program or programs HydroFocus used to process and output the results obtained from MODEFLOW. I would also like to know who may have provided that postprocessor to HydroFocus. Thank you.

WRAMP2-1

Most respectfully,

Ron Weitzman

Water Ratepayers Association of the Monterey Peninsula (WRAMP)
Letter 3 (WRAMP3)

Ms. Borak:
Thank you for your reply. I understand from it that you are **not** going to provide me the postprocessor computer program that HydroFocus used to put the MODEFLOW output data in the form of the file you sent me in response to my request during the comment period for the previous EIR. The reason I requested that postprocessor is that I believe it must contain the computer code that is the source of the corruption of the model output data for the 180-foot aquifer. That corruption is so massive as to render the model output data for the 180-foot aquifer useless for any purpose other than to provide evidence of data tampering. Please also consider this letter a comment on the DEIR/DEIS. Thank you.
Respectfully,
Ron Weitzman

16 March 2017

Fallacy of the Return Water Doctrine (for People who have had 1st-year Algebra)

According to Appendix D of the Joint Motion for Approval of the Settlement Agreement on Desalination Plant Return Water filed with the CPUC on 2 August 2016, the return-water doctrine depends upon the equation expressing the total dissolved solids (TDS) in well water (W_{TDS}) as a weighted average of the TDS in groundwater (G_{TDS}) and the TDS in seawater (S_{TDS}): WRAMP4-1

$$W_{TDS} = XG_{TDS} + (1 - X)S_{TDS} ,$$

the weights being the proportion of groundwater (X) and the proportion of seawater (1 – X) in the well water. The solution of this equation for X yields the proportion of TDS in the well water that comes from groundwater:

$$X = \frac{S_{TDS} - W_{TDS}}{S_{TDS} - G_{TDS}} .$$

Proponents of the return-water doctrine consider this to be the proportion of return water, which is the proportion of fresh water extracted and exported from groundwater in the Salinas Valley that needs to be returned to the valley groundwater basin to satisfy the state Agency Act's prohibition of the exportation of groundwater from that basin.

WRAMP4-1 cont.

Solution of this equation for X requires knowledge of the three different TDS values on the right side of it. Little dispute exists about two of the values:

S_{TDS} = 33500 and W_{TDS} = 31076,

33,500 being an acceptable approximation and 31,076

being determined from the test well. The third value, G_{TDS}, however, is subject to dispute.

Proponents of the return-water doctrine assume this value to be equal to the TDS in the 180-foot aquifer at the inland edge of seawater intrusion into that aquifer, generally agreed upon to be equal to about 500. On this assumption, the amount of extracted and exported fresh water that needs to be returned to the Salinas Valley to satisfy the Agency Act is equal to about 7 percent:

WRAMP4-1 cont.

$$X_{500} = \frac{33500-31076}{33500-500} = \frac{2424}{33000} = .073 .$$

Why the dispute? Three major reasons:

Reason 1. Despite a TDS as high as 33,500, seawater still contains 96.5 percent fresh water (pure H_2O). The return-water doctrine assumes that all that

WRAMP4-2

fresh water accompanying the 3.5 percent TDS in the seawater intruded into the 180-foot aquifer comes from the sea and therefore cannot be considered to be groundwater which, without seawater intrusion, consists of even a greater percentage of fresh water. The fact is, however, that, once intruded into the aquifer, the 96.5 percent fresh water in the intruded seawater becomes part of the groundwater because it is now water under the ground. All the water in the 180-foot aquifer, regardless of its source, is groundwater.

WRAMP4-2 cont.

One of Water Plus's attorneys provided the following helpful analogy. The rain falling into your neighbor's water-containment barrels belongs to your neighbor. Even though the water comes from the sky, you cannot use it later on to water your garden. It is not your water. It belongs to your neighbor. Likewise,

even though much of the water in the 180-foot aquifer comes from the sea, it is not water you can use because it belongs to the 180-foot aquifer, which captured it and which the Agency Act prohibits you from using.

So, if 500 is not the correct value to use for G_{TDS}, then what is? According to Table 2 of the Hydrological Working Group Monthly Report #15 (p.44), the TDS in Monitoring Well 4 (MW4) for the 180-foot aquifer was equal to about 22,600 on 11 January 2017. The HWG claims this represents a steady-state value. Taking this to be the appropriate value for G_{TDS}, obtained from the 180-foot aquifer just outside the pumping well's cone of depression, we must conclude that the return-water percentage is equal to, not 7 percent, but 22 percent:

WRAMP4-2 cont.

$$X_{22,600} = \frac{33500-31076}{33500-22600} = \frac{2424}{10900} = .222 \ .$$

Reason 2. Twenty-two percent might be the correct return-water percentage if all the groundwater in the well water came from the 180-foot aquifer, but it does not. According to HydroFocus on p. 28 in Appendix E2 of the MPWSP EIR/EIS, as much as 66 percent of the groundwater in the well water comes from the Dune Sand aquifer, only the remaining 34 percent coming from the 180-foot aquifer. So, a tacit, though critical, assumption of the return-water doctrine is plainly incorrect. The Dune Sand aquifer is largely free of seawater intrusion, and therefore, prima facie, much of the fresh water in the well water must come from Salinas Valley groundwater, most likely a percentage much larger than 22.

WRAMP4-3

Reason 3. The MPWSP EIR/EIS failed to cite the 26 May 2016 memorandum to the Marina Coast Water

WRAMP4-4

District by hydrogeologist Curtis Hopkins in which he showed that none of the water in the test well comes directly from the sea. That being the case, all the fresh water in the well must come from the Salinas Valley groundwater basin. The meaning is clear: All the fresh water extracted and exported from that basin must be returned to it to avoid violation of the Agency Act. Equally clearly, without its return-water foundation, the MPWSP cannot work.

WRAMP4-4 cont.

Recommendation. The CPUC must dismiss the MPWSP proceeding before Cal Am can claim repayment from ratepayers of any additional ratepayer money spent on the project. In fact, ratepayers should be responsible for no money spent on that project at least from the time Water Plus filed its first motion to dismiss the proceeding.

WRAMP4-5

8.6.1 Responses to Comments from Ag Land Trust

8.6.1.1 Responses to Comments from Ag Land Trust – Letter 1

ALT1-1 The EIR/EIS does not evaluate or recommend mitigation for the test slant well pumping for several reasons. First, the construction and existing operation of the test slant well under its current permits and authorizations is not part of the proposed project; rather, the conversion of the test slant well to a permanent well was described as part of the proposed project in EIR/EIS Section 3.2.1.1. Therefore, the impacts of the test slant well as currently installed and operated are not attributable to the proposed project. Second, the California Coastal Commission (CCC), not the CPUC, issued a Coastal Development Permit (CDP) for the test slant well; the CPUC had no jurisdiction to evaluate or authorize the test slant well. As described in Master Response 11, CalAm Test Slant Well, the CCC and MBNMS, in their independent CEQA and NEPA analyses of the test slant well, adopted necessary mitigation measures relevant to that project, and the results of test slant well pumping have not indicated a degradation of groundwater quality attributable to the test slant well operation. To the extent that the comment expresses concerns over the effects of the proposed project, see EIR/EIS Section 4.4, Groundwater Resources, which indicates that the project will not adversely impact the quality or quantity of water available to Ag Land Trust. With respect to water rights, see EIR/EIS Section 2.6, Water Rights, and Master Response 3, Water Rights.

ALT1-2 Impacts 4.4-3 and 4.4-4 in Section 4.4, Groundwater Resources, evaluate groundwater quality and quantity, which indirectly relate to agricultural production in the Salinas Valley Groundwater Basin. That analysis identifies less-than-significant impacts on existing users of wells that may be affected by the proposed project, including agricultural users (such as Ag Land Trust, whose wells in the vicinity of the proposed slant wells at CEMEX are identified in EIR/EIS Table 4.4-10). Because the proposed project would not affect groundwater quality or levels in a way that would adversely affect existing agricultural users, it would not result in a change in the existing environment that would indirectly result in the permanent conversion of Prime Farmland, Unique Farmland, or Farmland of Statewide Importance to non-agricultural use. No purchase and conversion of such lands is projected to occur as a result of the proposed project; thus, there would be no loss of employment or displacement of farmworkers associated with such conversion. See also response to comment MCRMA-5 in Section 8.5.4.

Regarding the topic of groundwater pumping from the basin, water rights issues are addressed in the Master Response 3, Water Rights.

ALT1-3 CEQA and NEPA require that the respective lead agencies provide specific opportunities for public involvement. These opportunities include the scoping process (described EIR/EIS Section 1.5.1 and in Appendix A) and the public review and comment period following the release of the draft environmental document (described

in EIR/EIS Section 1.5.2). Ag Land Trust has regularly contributed to these processes with timely submittals, for example, with a November 9, 2012, scoping letter included in Appendix A. However, no scoping comment was received from Ag Land Trust in response to the NEPA Notice of Intent issued by NOAA in August 2016.

The visit to the Ag Land Trust farm described in the comment, occurred following the release of the April 2015 Draft EIR. The Draft EIR had stated that "Ag Land Trust has indicated that it has one well that is active and located about one-mile northeast of the proposed slant wells in the agricultural fields" but that field reconnaissance could not locate the well and the SWRCB did not have any record of a well at the location indicated by Ag Land Trust. Representatives of the Lead Agencies contacted the Ag Land Trust after the release of the April 2015 Draft EIR to inquire about a site visit to its wells, and received the following email response: "The Ag Land Trust, in compliance with CEQA, is already preparing comments on your draft EIR and we will submit those comments and all documents previously delivered to the CPUC before your deadline of June 30, 2015. The Trust [would be] willing to arrange to show our farm to you after the comment period is completed so that you may fully evaluate our comments, and others that you may receive, with the facts and physical conditions that exist near the "project area" prior to your determinations regarding both the adequacy of the Draft and/or the significant adverse impacts to adjacent potable groundwater resources and productive coastal farmland (and loss of farm workers' jobs) that would be required to be identified/mitigated in the Final EIR." (Ag Land Trust, 2015)."

The comment period on the April 2015 Draft EIR was extended to September 2015, and the Ag Land Trust submitted timely comments on the April 2015 Draft EIR. In October 2015, the representatives of the Lead Agencies again inquired with Ag Land Trust about a site visit; a field visit was conducted on December 15, 2015, and field notes were prepared (ESA, 2016). Much of what was communicated verbally at the site visit confirmed information that was provided by the Ag Land Trust in its comments on the April 2015 Draft EIR. The representatives of the Lead Agencies viewed two Ag Land Trust wells during the December 15, 2015 site visit. Subsequently, both of these wells (the "Big Well" and the "Small Well") were identified as active wells in the current EIR/EIS; see EIR/EIS Table 4.4-10).

ALT1-4 See Master Response 1, EIR/EIS Authorship. The analyses and conclusions in the EIR/EIS reflect the independent judgment of the Lead Agencies; therefore, the CPUC and MBNMS, not the consultants, are responsible for the scope, content, adequacy, and objectivity of the EIR/EIS.

Impacts on groundwater resources are evaluated in EIR/EIS Section 4.4, Groundwater Resources. Known active supply wells within the vicinity of the proposed MPWSP slant wells are shown in EIR/EIS Table 4.4-10 and in Figures 4.4-14 (Dune Sands Aquifer), 4.4-15 (180-FTE Aquifer), and 4.4-16 (400-Foot Aquifer) and are considered in the impact analysis under Impacts 4.4-3 and 4.4-4. The Ag Land Trust "Small Well"

(14S/2E-18C1) is screened within the 400-Foot Aquifer, and its location relative to the 1-foot response resulting from proposed project pumping is shown in Figure 4.4-16. The project's impact on water availability and water quality related to this well would be less than significant as explained in EIR/EIS Section 4.4.5.2. The "Big Well" is screened within the 900-Foot Aquifer and modeling indicates that no impacts would occur in the 900-Foot Aquifer as a result of proposed project pumping; see Master Response 7, The Deeper Aquifers of the Salinas Valley Groundwater Basin.

The Lead Agencies acknowledge receipt of the first letter of objection (2006), as well as copies of correspondence since 2006 including to and from the CCC, Monterey County Water Resources Authority (MCWRA), and The Law Offices of Michael Stamp, provided as attachments to the comment. The Lead Agencies have considered this correspondence and attachments. Many of these attachments are in regard to the test slant well, the relevance of which to the proposed project is described in response to comment ALT1-1. See also response to comment ALT1-3.

ALT1-5 The CPUC exceeded the public noticing requirements of CEQA Guidelines Section 15087 by providing an approximately 75-day public review and comment period of the Draft EIR/EIS beginning in January 2017. The Lead Agencies mailed a Notice of Availability (NOA) and a 2-CD set of the Draft EIR/EIS to every organization and individual who previously requested such notice (including Mr. Del Piero and Ag Land Trust; see EIR/EIS Appendix A1, p. A1-2), at the same time that a Notice of Completion was mailed to the Office of Planning and Research. That NOA/CD mailing included 390 recipients. Owners and occupants of all properties contiguous with or within 300 feet of a proposed project feature (and alternative proposed project feature) were also mailed a copy of the NOA. That mailing included approximately 2,410 addresses from the latest equalized assessment roll and with the NOA/CD mailing, satisfied CEQA Guidelines Section 15087(a). The Lead Agencies also published the NOA as a quarter-page advertisement in the Monterey Herald on January 13 and 27 and February 6, 2017; and in the Carmel Pinecone on January 13 and February 3, 2017. The NOA was also published in the Federal Register on January 13, 2017, and it was posted on the project website at http://www.cpuc.ca.gov/Environment/info/esa/mpwsp/ann_and_sched.html.

ALT1-6 For responses to the comment letters referenced in this comment, see: Section 8.6.20, Responses to Comments from Water Ratepayers Association of the Monterey Peninsula; Section 8.7.18, Responses to Comments from Larry Parrish; Section 8.7.2, Responses to Comments from David Beech; Section 8.7.1, Responses to Comments from Michael Baer; Section 8.7.22, Responses to Comments from Nancy Selfridge; Section 8.7.3, Responses to Comments from Kathy Biala; Section 8.6.7, Responses to Comments from Citizens for Just Water; Section 8.6.17, Responses to Comments from Public Water Now (signed by George Riley); and Section 8.7.11, Responses to Comments from Myrleen Fisher. No comments received on the Draft EIR/EIS were signed "Water Plus."

The Lead Agencies acknowledge receipt of the attachments to ALT Comment Letter 1, and note that the additional information and objections raised in those attachments and correspondence consist primarily of comments on the test slant well and the April 2015 Draft EIR. Note also that the comment letter and attachments do not raise issues that would require revisions to or recirculation of the Draft EIR/EIS. See also response to comment ALT1-4 and MR-3, Water Rights.

8.6.1.2 Responses to Comments from Ag Land Trust – Letter 2

ALT2-1 See response to comment ALT1-3.

ALT2-2 See Master Response 3, Water Rights. There is no evidence to indicate that the project would effect a taking of land or water rights.

ALT2-3 Master Response 12, The North Marina Groundwater Model (v. 2016), explains that the North Marina Groundwater Model (NMGWM) that was used for the 2015 version of the North Marina Groundwater Model ($NMGWM^{2015}$) was peer reviewed by Lawrence Berkeley National Laboratory (LBNL, see EIR/EIS Appendix E1), and how the Lead Agencies' hydrogeology consultant (HydroFocus) revised the $NMGWM^{2015}$ consistent with LBNL's recommendations, and incorporated additional improvements (see EIR/EIS Appendix E2). These efforts were undertaken under contract to and direction of the Lead Agencies and not the Hydrogeologic Working Group (HWG). All of this information was also provided in the EIR/EIS Appendices E1 and E2. See Master Response 1, EIR/EIS Authorship; the consultants that form part of the CEQA/NEPA team are contractually obligated to the CPUC and MBNMS, as co-Lead Agencies. See Master Response 5, The Role of the Hydrogeologic Working Group and its Relationship to the EIR/EIS, regarding the HWG. See also Master Response 11, CalAm Test Slant Well, Section 8.2.11.4, regarding the baseline water levels and total dissolved solids (TDS) levels established prior to the long-term pump test in the report titled *Baseline Water and Total Dissolved Solids Levels* referenced in EIR/EIS Section 4.4, Groundwater Resources, as Geoscience, 2015b. Finally, see Master Response 12, The North Marina Groundwater Model (v. 2016), Section 8.2.12.3, regarding the use of superposition in the analysis based on the 2016 version of the NMGWM ($NMGWM^{2016}$).

ALT2-4 The comment does not specify what available data was omitted, and does not specify or clarify what impacts it is referring to. Impacts on groundwater resources are presented in Section 4.4, Groundwater Resources, of the Draft EIR/EIS. See also response to comments ALT1-2 and ALT1-3.

ALT2-5 See response to comment ALT1-3. Both the "Small Well" and "Big Well" are acknowledged as active wells in EIR/EIS Section 4.4, Groundwater Resources. The comment does not convey the manner in which the proposed project may have an impact on the dune restoration projects, or that the EIR/EIS omitted important information regarding unmitigated significant and adverse environmental impacts.

Potential project impacts on dune habitat are described in EIR/EIS Section 4.6, Terrestrial Biological Resources. See also response to comment ALT1-2 and ALT1-3.

The Lead Agencies acknowledge receipt of the attachments to ALT Comment Letter 2. The comment letter and attachments do not raise issues that would require revisions to or recirculation of the Draft EIR/EIS. See also response to comment ALT1-4 and Master Response 1, EIR/EIS Authorship; the CPUC and MBNMS, not the consultants, are responsible for the scope, content, adequacy, and objectivity of the EIR/EIS.

8.6.1.3 Responses to Comments from Ag Land Trust – Letter 3

ALT3-1 Receipt of the attachments is acknowledged. As acknowledged in EIR/EIS Section 2.6, Water Rights, one of the three relevant types of water rights in the Salinas Valley Groundwater Basin is "overlying rights whereby those who own land atop the Basin may make reasonable use of groundwater on such overlying land." Further, EIR/EIS Section 4.4, Groundwater Resources, acknowledges Ag Land Trust's two existing, active wells. The documents provided in the comment letter do not present new information that would affect the analysis of project water rights or impacts on groundwater resources.

ALT3-2 Receipt of the July 2009 water analysis report is acknowledged. This report does not identify the date that the sample was drawn, or from which well; thus, it is unclear which aquifer was the source of the sampled water. Regardless, both of the Ag Land Trust wells (the "Big Well" and "Small Well" as described in response to comment ALT1-3) are identified as active water supply wells in EIR/EIS Table 4.4-10, and thus have been considered in the EIR/EIS analysis of potential project impacts on water quality in Impact 4.4-4. Neither the comment nor the water analysis report provides evidence of an intentional omission of significant adverse impacts necessitating revision to or recirculation of the Draft EIR/EIS.

8.6.2 Responses to Comments from California Unions for Reliable Energy

8.6.2.1 Responses to Comments from California Unions for Reliable Energy – Main Letter

CURE-1 See responses to comments MCWD-78 and MCWD-79 in Section 8.5.2.

CURE-2 The Draft EIR/EIS at page 4.2-71 acknowledges that "the anticipated future presence of the test slant well on the beach due to coastal retreat would result in a significant impact." As noted by the commenter, Mitigation Measure 4.2-10 would reduce the impact to less than significant and only applies to the wells that become vulnerable to the effects of coastal retreat. Impact 4.2-10 has been revised to include a discussion of the secondary impacts of this mitigation measure (i.e., of abandonment of the converted test slant well). Unlike the test slant well as currently permitted, which unless converted to a production well pursuant to further permits would be decommissioned per the terms of its CDP, there is no decommissioning phase of the proposed MPWSP. See also response to comment MCWD-80 in Section 8.5.2.

CURE-3 See responses to comments MCWD-78 and MCWD-79 in Section 8.5.2.

CURE-4 See responses to comments MCWD-78, MCWD-79, and MCWD-82 in Section 8.5.2. For the reasons explained therein, the 20- to 25-year "useful life" used in project cost amortization calculations is not equivalent to a time period after which the slant wells would necessarily be decommissioned. Therefore, the suggestion that the slant wells would need to be replaced after 20 to 25 years is not applicable.

CURE-5 The slant wells are described in EIR/EIS Section 3.2.1.1 (see Draft EIR/EIS pages 3-7 and 3-15 through 3-18) which includes details of the slant wells, a plan view map of the well layout (Figure 3-3a), Table 3-2 that lists the lengths of the permanent wells seaward of MHW, and an illustrative cross-sectional view of the subsurface slant wells. This description of the slant wells is adequate to allow for the necessary evaluation of impacts under CEQA and NEPA. As noted correctly by the comment, the test well's purpose was to inform the design of the proposed slant wells. See response to comment Beech2-8 in Section 8.7.2 and Master Response 11, CalAm Test Slant Well, Section 8.2.11.7 for an explanation of the proposed 14-degree angle of the slant wells.

CURE-6 As noted by the commenter and EIR/EIS Section 3.3.2.1, the pump would be lowered several hundred feet into each well. See response to comment CURE-Sobczynski-1. As noted in EIR/EIS Section 3.2.2.2, the 24.1 mgd of source water would run through a first pass and partial second pass through the RO membranes (see Table 3-1), which is why a simple calculation of a 42 percent recovery rate multiplied by the feedwater supply rate does not yield the 9.6 mgd of product water. The EIR/EIS explains how

the project would catch-up on production following a 2-day shutdown in Table 3-7. As noted in the text in Section 3.4.1, any fluctuations in daily production would not affect total monthly production.

CURE-7 Unlike the test slant well, the production wells would not include an inflatable/deflatable packer. See also response to comment CURE-Sobczynski-1.

CURE-8 Degradation of the slant wells due to biofouling and/or corrosion is not discussed because as noted on Draft EIR/EIS page 3-48, the wells would be completed with super-duplex stainless steel well screens, to avoid corrosion and biofouling. The EIR/EIS disclosed the technical characteristics of all proposed project components, facilities, and activities, and evaluated the environmental impacts thereof in accordance with CEQA and NEPA requirements. See also responses to comments MCWD-78 and MCWD-79 in Section 8.5.2 regarding decommissioning.

CURE-9 See Master Response 10 regarding CEQA and NEPA baseline, as well as responses to comments CURE-10 through CURE-17, below.

CURE-10 A detailed and comprehensive assessment of impacts to receiving ocean water quality from operational discharges and associated impacts to marine biological organisms is presented in EIR/EIS Sections 4.3 and 4.5. Section 4.3.1 and Appendices D1 through D3 present detailed baseline water quality information specific to Monterey Bay, including site-specific water quality data for the area immediately surrounding the MRWPCA outfall diffuser, sufficient for assessing the potential impacts from implementation of the MPWSP. Under Impact 4.3-5, baseline water quality data is utilized to conservatively assess impacts from a wide range of water quality constituents present in operational discharges (see Table 4.3-15 for a comprehensive list of constituents assessed).

Regarding the ionic composition of seawater and the common ion effect within the context of the desalination process, the reverse osmosis process, when applied to desalination of seawater, typically rejects major ions and salts at approximately the same ratio. The ratio of major ions and salts in the brine concentrate would be approximately the same as those ratios in the ambient seawater. However, as discussed in the comment, the interactions of various constituents and parameters related to water chemistry are complex and water quality data is not available for all constituents, parameters, and potential interactions. While the water quality assessment conducted for the EIR/EIS is comprehensive in scope and range of potential contaminants assessed under varying ocean season conditions under a variety of operational discharge scenarios, it is acknowledged under Impact 4.3-5 that a compliance determination could not be made for a number of constituents due to insufficient available data. In the absence of such data, it was conservatively concluded that the MPWSP could result in a significant impact on receiving ocean water quality.

Significant impacts related to the discharge of unknown contaminants, and associated impacts on marine biological resources that may result from disturbance or adverse water quality conditions, would be reduced to a less-than-significant level by implementing Mitigation Measures 4.3-4 and 4.3-5. Mitigation Measure 4.3-4, which includes consideration of impacts to marine organisms related to toxicity from operational discharges (such as may occur due to ionic imbalance or resulting precipitates), would ensure that monitoring be conducted in the immediate vicinity of the outfall diffuser within the area of influence. Monitoring would include benthic community health and aquatic life toxicity. Mitigation Measure 4.3-4 ensures that all collected data is assessed against defined performance standards and that corrective actions are implemented in the case that performance standards are not met. Mitigation Measure 4.3-5 requires CalAm to perform an extensive water quality assessment as part of a waste disposal study. Specifically, CalAm would be required to analyze MPWSP operational discharges for the full range of regulated water quality constituents specified in the Ocean Plan *as well as NPDES water quality requirements* (italics added for emphasis), in accordance with protocols approved by the RWQCB. Should performance standards for marine organisms or water quality criteria not be met, a suite of corrective actions is detailed for implementation as part of Mitigation Measure 4.3-5.

As described in Section 4.3.2 and further discussed under Impact 4.3-5, in order for MRWPCA to commingle MPWSP brine with wastewater, the associated NPDES permit will need to be updated and amended to reflect the physical and chemical changes in the commingled effluent plume. As part of the NPDES amendment or update, Whole Effluent Toxicity (WET) testing will be required, representing an integrated approach for assessing the potential for toxicity of discharges occurring under the various proposed operational discharge scenarios (e.g., brine only, brine with waste water, etc.). The primary objective of WET testing is to ensure that effluent released from industrial and municipal facilities into the nation's waters does not cause unacceptable levels of toxicity to aquatic life. To determine whether an effluent has the potential to be toxic, WET tests are performed on various aquatic test species. Specifically, WET testing is a standardized measure of the aggregate toxic effect of an effluent (such as brine or a brine/municipal wastewater mix) measured directly by a toxicity test and is used to evaluate biological impacts of discharges for NPDES permitting. Ion imbalances can cause a toxic response in a WET test.

Toxicity cannot be measured analytically. Chemical analyses are practical only when all potential constituents present in an effluent are known. WET testing assesses the combined toxic effects of all constituents of an effluent, known or unknown. The use of biological testing provides a means to evaluate the impact of chemical and physical mixtures at the site of discharge and, consistent with Mitigation Measure 4.3-4, will consider benthic species and/or species most relevant to the site. As discussed in detail in EIR/EIS Sections 4.3 and 4.5, benthic habitat is of primary concern for effluents that are denser than seawater and sink to the bottom. For these reasons, full ionic

composition testing is not practical, but WET testing is sufficient to assess the potential impact or toxic effect of water constituents, including ionic constituents.

CURE-11 See responses to comments CURE-8, regarding biofouling, and CURE-Sobczynski-3, regarding clay in the area of the slant wells. It would not be possible to have an algal bloom inside of the slant wells. Algal blooms are the result of a combination of environmental factors including available nutrients, temperature, sunlight, ecosystem disturbance (stable/mixing conditions, turbidity), hydrology (river flow and water storage levels) and the water chemistry (pH, conductivity, salinity, carbon availability). The insides of the slant wells would have no sunlight; therefore, an algal bloom would not be possible.

See EIR/EIS Section 4.5.1 for a discussion of the marine resources environmental baseline.

CURE-12 See response to comment CURE-Owens-1.

CURE-13 See reponse to comment CURE-Owens-3.

CURE-14 See response to comment CURE-Owens-4 and CURE-Owens-5.

CURE-15 See response to comment CURE-Owens-8.

CURE-16 EIR/EIS Section 4.6.1.8, Special-Status Species, includes a thorough discussion of the status of western snowy plover within the project area and the potential for this species to occur within the project area based on known occurrence records and habitat conditions. See Draft EIR/EIS page 4.6-50. This information provides an adequate baseline to evaluate potential project impacts on this species. See responses to comments CURE-Owens-4, CURE-Owens-9, and CURE-Owens-10.

CURE-17 NEPA (40 CFR 1502.15) requires that an EIS "succinctly describe the environment of the area(s) to be affected or created by the alternatives under consideration. The descriptions shall be no longer than is necessary to understand the effects of the alternatives." The setting presented in EIR/EIS Section 4.20, as well as in other Chapter 4 sections referenced by Section 4.20, provides an adequate description of the affected environment relevant to potential project impacts. As described in Draft EIR/EIS Sections 4.3 and 5.5.3 and Sections 4.20 and 5.5.20, respectively, the proposed project and alternatives would not have adverse project-level or cumulative impacts related to drinking water contamination or unemployment. Therefore, incorporation of information sourced from CalEnviroScreen on existing drinking water contamination or unemployment (in addition to information from other sources already described and cited on such topics in Sections 4.3 and 4.20) is not necessary to understand the effects of the proposed project and alternatives.

CURE-18 Responses to general comments on the adequacy or accuracy of the Draft EIR/EIS analysis of various resources are provided where the commenter provides further

specificity. Regarding impacts on ocean water quality, see response to comment CURE-19. Regarding impacts on marine resources, see responses to comments CURE-20 through CURE-28. Regarding impacts on biological resources, see responses to comments CURE-29 through CURE-32. Regarding impacts on air quality, see responses to comments CURE-33 through CURE-37 and CURE-40. Regarding impacts on public health, see responses to comments CURE-38 and CURE-39. Regarding impacts related to vibration, see responses to comments CURE-41 and CURE-42. Regarding impacts related to decommissioning, see response to comments CURE-1 through CURE-3 and CURE-43.

CURE-19 The EIR/EIS does not omit assessment of impacts on ocean water quality or marine biological resources within the Zone of Initial Dilution (ZID), nor does it state that excessive constituents within the ZID would not result in a potentially significant impact. The analyses presented in EIR/EIS Sections 4.3.5 and 4.5.5 assess site-specific impacts of the project, including cumulative impacts (see EIR/EIS Sections 4.3.6 and 4.5.6), related to water resources and marine biological resources from the point of discharge out to various regulatory compliance points and beyond. The analyses presented in EIR/EIS Sections 5.5.3 and 5.5.5 assess similar site-specific impacts of the proposed alternatives, including cumulative impacts, related to water resources and marine biological resources. The impact analyses include assessment of compliance with various relevant regulations, including the California Ocean Plan narrative requirements and numeric WQOs. Additionally, an assessment of impacts on water quality and marine organisms in the area immediately surrounding the point of discharge was conducted for impacts that may occur even if regulatory compliance is achieved, as discussed in EIR/EIS Sections 4.3.5 and 4.5.5.

Impact 4.3-4 relating to water quality standards presents an assessment of incremental salinity increases above ambient, from the point of discharge to the edge of the ZID (18 to 55 meters from point of discharge), and to the edge of the Brine Mixing Zone (BMZ; 100 meters from point of discharge), as well as an assessment of potential changes to dissolved oxygen concentrations and the risk of an occurrence of hypoxia. This analysis focuses not solely on Ocean Plan compliance, but also with waste discharge requirements issued by the Regional Water Board. These water quality results are then utilized under Impact 4.5-4 (see EIR/EIS Section 4.5.5.2) to assess impacts on marine habitat and organisms from the point of discharge to the edge of the ZID (i.e., within the ZID) and to the edge of the BMZ (i.e., within the BMZ). The analyses presented under Impact 4.5-4 describe, for example, that due to the predicted incremental salinity increases considered within the context of various representative species' salinity tolerances, the area outside the ZID and within the BMZ would continue to be suitable for squid spawning. The area within the ZID, however, could become unsuitable for squid spawning if the area exceeding 2 ppt above ambient were to contact the seafloor, which modeling demonstrates it would not; see EIR/EIS Figure 4.3-10. And the impact analysis presents a quantified assessment of the potential loss of habitat area within the ZID and within the context

of total available squid spawning habitat within the Monterey Bay area if it were to contact the seafloor, which is estimated to be approximately 0.0042 to 0.0163 percent of the suitable spawning habitat available in the area. The impact analysis presented in Section 4.5.5.2 similarly assesses and quantifies unanticipated effects on benthic and pelagic communities in the vicinity of the discharge.

Under Impact 4.3-5, the potential for operational discharges to increase the concentrations of a wide range of constituents is assessed and it is concluded that, due to gaps in available data, it is possible that Ocean Plan water quality objectives would be exceeded as a result of operational discharges. It was therefore conservatively concluded that the MPWSP could result in a significant, yet mitigable, impact related to water quality. Similar to the analyses presented for salinity and dissolved oxygen, the water quality results presented under Impact 4.3-5 are then utilized under Impact 4.5-4 (see EIR/EIS Section 4.5.5.2) to assess and quantify impacts to marine habitat and organisms from the point of discharge to the edge of the ZID (i.e., within the ZID). Additionally, the transfer of bioaccumulated contaminants from benthic infauna to higher trophic levels as well as to predators from prey is assessed for the area around the point of discharge independent of regulatory compliance at the edge of the ZID.

Regarding impacts relating to ionic imbalance, the potential for complex chemical interactions, and associated toxicity effects on marine wildlife and human health, see response to comment CURE-10. Regarding comments related to mitigating potentially significant effects related to operational discharges and ocean receiving water quality see responses to comments CURE-10, Surfrider-11 and Surfrider-12 in Section 8.6.19, Marina-39 and Marina-41 in Section 8.5.1, and ERF-10 in Section 8.6.10.

The use of environmentally inert biodegradable additives proposed for use as part of construction (e.g., well drilling) and maintenance (e.g., well screen cleaning) is comprehensively assessed in EIR/EIS Section 4.3.5.1 (water quality) as well as under other resource topics (see Section 4.5.5.1 for an assessment of impacts to marine organisms from the use of environmentally-inert biodegradable additives for construction and maintenance activities). As described, the use of such materials, if discharged directly, could adversely affect water quality in Monterey Bay or other down gradient receiving waters. Consistent with the described regulatory requirements relevant to such actions (e.g., General Permit for Stormwater Discharges Associated with Construction and Land Disturbance Activities [Order No. 2009-0009, NPDES No. CAS000002]), any effluent containing environmentally inert biodegradable materials would be pumped to a storage container or portable holding tank where any chemical residuals and sediment would settle out for offsite hauling and disposal. Additional detailed analyses relating to the use of environmentally inert biodegradable additives are presented in EIR/EIS Section 4.7.5 (hazards and hazardous materials).

CURE-20 The EIR/EIS impact conclusion would remain the same, even if the infiltration rate calculated by Dr. Sobczynski was used in the analysis. See response to comment CURE-Sobczynski-1.

CURE-21 As the Draft EIR/EIS stated on page 3-48, a submersible pump would be lowered several hundred feet into each well. That would put the pump in the upper third of the well, and approximately 300 to 400 feet inland from mean high water in 2020. See response to comment CURE-Sobczynski-1.

CURE-22 See response to comment CURE-Sobczynski-1.

CURE-23 See responses to comments CURE-7 and CURE-Sobczynski-1.

CURE-24 See response to comment CURE-Sobczynski-2.

CURE-25 See response to comment CURE-Sobczynski-1.

CURE-26 See response to comment CURE-Sobczynski-1.

CURE-27 See response to comment CURE-Sobczynski-2.

CURE-28 EIR/EIS Section 4.1.7 presents the methods used to evaluate cumulative impacts, and lists projects in Table 4.1-2 that may have cumulative effects when combined with the impacts from the proposed project or alternatives discussed in the Draft EIR/EIS. There are two other desalination proposals for the Moss Landing area of Monterey Bay, and they are listed Table 4.1-2 as Project No. 34, Monterey Bay Regional Water Desalination Project (DeepWater Desal, described in Section 5.4.5) and Project No. 57, the People's Moss Landing Water Desalination Project (People's Project, described in Section 5.4.6). Both of these projects propose to utilize screened open water intakes for source water, and not subsurface intakes. The EIR/EIS evaluates these projects in the cumulative analyses as proposed by their applicants, and does not speculate on their use of subsurface intakes. It is not clear why the organic matter that originated in the ocean would contaminate the ocean upon its release. See also response to comments CURE-Sobczynski-1, CURE-Sobczynski-2, and CURE-Sobczynski-4 and Master Response 15, Alternative Desalination Projects – Status, Information Sources, and Cumulative Scenario.

CURE-40 See responses to comments CURE-Fox-106 through CURE-Fox-122.

CURE-41 This comment is a summary of comments CURE-Fox-137 through CURE-Fox-150, which are responded to in depth at responses to comments CURE-Fox-137 through CURE-Fox-150.

CURE-42 The proposed project would not be constructed in the vicinity of any of historic buildings or structures in the City of Monterey. As shown in Figure 3-2 (Draft EIR/EIS p. 3-5), the only project component within the City of Monterey would be a portion of the Ryan Ranch-Bishop Interconnection Improvements. This component is not located near any of the properties listed in the City of Monterey's Vibration Control Plan. No additional analysis is warranted for potential vibration impacts to historic buildings or structures in the City of Monterey because no project construction would occur near these structures.

CURE-43 See responses to comments MCWD-78, MCWD-79, and MCWD-82 in Section 8.5.2.

CURE-44 See responses to comments CURE-Owens-7, CURE-Owens-14, CURE-Owens-17, CURE-Owens-20, CURE-Owens-21, CURE-Owens-22, CURE-Owens-23, CURE-Owens-24, and CURE-Owens-25.

CURE-45 This comment provides legal background for arguments in comments CURE-46, CURE-47, and CURE-48; see responses to these substantive comments below.

CURE-46 Compliance with the law is not a discretionary action and is required as a condition of certification of the project and approval of permits. This includes the regulations discussed in the Regulatory Framework of every impact analysis section and also the regulations cited by the commenter relating to the Ocean Plan and NPDES permit

process. Regulations are enforceable because (1) the project applicant cannot acquire certification of the EIR without committing to comply with all relevant and applicable regulations and (2) the various permitting agencies will not approve of permits that do not include compliance with all relevant and applicable regulations.

CURE-47 See response to comment CURE-Owens-2.

CURE-48 Compliance with the law is not a discretionary action and is required as a condition of certification of the project and approval of permits. This includes the regulations discussed in the Regulatory Framework of every impact analysis section and also the regulations cited by the commenter. Regulations are enforceable because (1) the project applicant cannot acquire certification of the EIR without committing to comply with all relevant and applicable regulations and (2) the various permitting agencies will not approve of permits that do not include compliance with all relevant and applicable regulations.

CURE-49 See response to comments MCWD-168 and -170. The reverse osmosis system proposed by CalAm, described in EIR/EIS Section 3.2.2.2, would be modular and would comprise six active and one standby module, each capable of producing 1.6 mgd of desalinated water. The EIR/EIS did not identify any impacts that would need to be lessened or avoided by using packaged desalination systems.

CURE-50 EIR/EIS Section 6.3.3 presents the requirements of CEQA Guidelines Section 15126.2(d); the growth inducement analysis in the EIR/EIS Section 6.3 adheres to those guidelines and the NEPA requirements. As discussed in Section 6.3.5, some water provided by the proposed project would replace supplies that are no longer available to CalAm to meet existing demands. Water supply used to meet existing demands would not be available to serve additional growth and would not be growth inducing. As also discussed in Section 6.3.5, the project would provide some water supply to serve new development that cannot currently be served because existing supplies are limited. Supply provided for this purpose would be growth-inducing. For example, the EIR/EIS states that "water supply that would serve currently vacant lots of record would remove water supply limitations as an obstacle to the development of these lots and would induce growth under CEQA and NEPA" (see Draft EIR/EIS page 6-17). The analysis of the proposed project's growth inducement was evaluated in this EIR/EIS, and not in a negative declaration.

With respect to water quality, the EIR/EIS Section 4.3 addresses non-point source as well as point source discharge impacts (see Table 4.3-8). Urban runoff is a nonpoint source discharge regulated under the NPDES General Permit WDRs for Stormwater Discharges from Small Municipal Separate Storm Sewer Systems (MS4s). As described on Draft EIR/EIS pages 4.3-40 and 4.3-41, Monterey County and its cities are permittees regulated by the Phase II Municipal General Permit, which requires regulated small MS4s to develop and implement best management practices, measurable goals, and timetables for implementation, designed to reduce the discharge

of pollutants to the maximum extent practicable and to protect water quality. As described in the cumulative impact analysis in Section 4.3.6, in July 2013, the Central Coast RWQCB adopted Resolution No. R3-2013-0032, which prescribes new Post-Construction Requirements for projects that create or replace 2,500 square feet or more of impervious area and receive their first discretionary approval for design elements after March 6, 2014. The requirements of the Resolution are implemented through the Monterey Regional Stormwater Management Program and NPDES Municipal Stormwater Permit. The stormwater requirements are part of a regional program designed to address the potential cumulative effects of past, present, and foreseeable projects within the region; adherence to these requirements would ensure hydrology and water quality effects related to the alteration of drainage patterns would not cause a significant cumulative impact. Accordingly, the NPDES General Permit requirements are themselves measures based, in part, on the consideration of cumulative effects on receiving waters; therefore, discharges would be within parameters considered not to result in a cumulatively significant effect on water quality.

Discharges from the MRWPCA outfall would be point source discharges that are currently regulated by RWQCB Waste Discharge Requirements (WDRs) for the Monterey Regional Water Pollution Control Agency Treatment Plant (Order No. R3-2014-0013, NPDES Permit No. CA0048551). As described on Draft EIR/EIS pages 4.3-42 and 4.3-43, the NDPES permit incorporates the Ocean Plan water quality objectives to ensure the protection of the beneficial uses of Monterey Bay, and would need to be amended to include brine discharges prior to the implementation of the MPWSP and operation of the MPWSP Desalination Plant. The EIR/EIS evaluates water quality constituent concentrations in effluent discharged to Monterey Bay via the MRWPCA outfall for multiple discharge scenarios including brine-only, and brine combined with varying flows of secondary treated wastewater.

Table 4.3-16, referenced in Footnote 640 in this comment, presents the results of the MPWSP Operational Discharge Scenarios and does not, as the comment states, indicate the levels of contaminants are already at the brink of exceeding Ocean Plan thresholds. The table presents results of the brine discharge modeling and demonstrates which constituent, under which operating scenario, would come closest to its Ocean Plan water quality threshold. In response to comments on the Draft EIR/EIS received from MRWPCA, however, 60 additional modeling runs were conducted for this Final EIR/EIS and as a result, Tables 4.3-15 and 4.3-16 have been revised accordingly. See response to comment MRWPCA-9 and the revised Appendices D1and D3 in this Final EIR/EIS for more information on this additional modeling. The additional modeling confirmed, and the Final EIR/EIS maintains the conclusion of a potentially significant impact due to possible exceedences of Ocean Plan water quality thresholds for 2 constituents (that are contained in the wastewater, and not the brine) and data gaps regarding Ocean Plan compliance for 10 other constituents. The implementation of Mitigation Measures 4.3-4 and 4.3-5 would result in an impact determination of less than significant with mitigation.

Because this is a water supply project, the water demands anticipated as a result of development of the general plans was compared with the portion of MPWSP supply that would be available for new development. The analysis in EIR/EIS Section 6.3 does show that growth supported by the proposed project would be consistent with growth anticipated in adopted general plans. The general plan future water supply needs were prepared by the MPWMD in 2006 in consultation with cities in the CalAm service area, Monterey County, and Monterey Peninsula Airport District, as described in EIR/EIS Section 2.5.3.4. The future supply needs identified in 2006 have since been updated as warranted, as recently as 2015, as shown in Table 2-5. In most cases the updated estimates reduce the jurisdiction's original demand estimate; in one case, for the City of Seaside, the estimate increased to account for new development not previously considered, consistent with a concern raised in this comment. The amount of water provided by the project would not fully meet demands associated with general plan buildout, nor does the project propose to serve general plan buildout.

The growth inducement analysis in EIR/EIS Section 6.3.6 makes clear that growth that is consistent with adopted plans can result in significant environmental impacts, and impacts that are cumulatively significant. In fact, the analysis determined that the indirect growth inducing impacts of the proposed project would be significant and unavoidable.

EIR/EIS Section 4.1.7 explains that the cumulative impact analysis in the respective EIR/EIS sections considers the impact on the environment which may result from the incremental impact of the proposed project when added to other past, present, and reasonably foreseeable future actions. The growth inducement potential of cumulative water supply projects is addressed in Section 6.3.7.

The reference to "The Port" in this comment is unclear; no Port entity is participating as a lead or responsible agency or project sponsor of the MPWSP; this part of the comment may concern a different project.

Table 6.3-9 in Section 6.3.6 and Table J2-1 in Appendix J2 have been revised to refine and clarify impacts identified in the adopted general plans of service area jurisdictions. These revisions do not change the conclusion that the indirect growth inducing impact of the proposed MPWSP would be significant and unavoidable.

CURE-51 The above responses to this comment letter demonstrate that the EIR/EIS satisfies both CEQA and NEPA procedural and evidentiary standards. The EIR/EIS and revisions included in the Final EIR/EIS adequately describe the project and environmental setting, sufficiently address potential impacts to the environment, proposes adequate mitigation measures, and provides sufficient alternatives. For these reasons, the Lead Agencies are not required to recirculate a revised Draft EIR/EIS.

8.6.2.2 Responses to Comments from California Unions for Reliable Energy – Fox Letter

CURE-Fox-1 The third paragraph of the comment includes incorrect information about the project size. As stated in Section ES 5.1 and throughout the EIR/EIS, the project would produce approximately 10,750 acre-feet per year (afy) of desalinated water, and nine new slant wells would be constructed. In addition, approximately 22 miles of pipeline would be constructed under the proposed project, not 30 miles.

CURE-Fox-2 The comment includes a bullet list introducing the themes of the subsequent comments. For detailed responses to each of the specific comments, refer to responses to comments CURE-Fox-3 through CURE-Fox-152. With respect to comments on the April 2015 Draft EIR, as described on Draft EIR/EIS pages 1-10 and 1-11, per CEQA Guidelines Section 15088.5(f)(1), regarding the treatment of comments when recirculating a substantially revised, complete EIR, the CPUC need not provide individual responses to comments received on the April 2015 Draft EIR, and such responses are therefore not provided in this EIR/EIS. Instead, the comments received on the April 2015 Draft EIR by September 2015 are part of the administrative record of this proceeding, and key substantive comments and themes of comments received on the April 2015 Draft EIR have been addressed in the appropriate sections of this EIR/EIS. Accordingly, no individual responses to the referenced July 2015 letter are provided.

CURE-Fox-3 The commenter's experience and credentials are noted.

CURE-Fox-4 The comment is a summary statement of the types of air pollutants that would be generated during construction and operation of the project, which are consistent with the analysis in EIR/EIS Section 4.10, Air Quality.

CURE-Fox-5 For responses to comments related to the adequacy of the construction air quality mitigation measures, refer to responses to comments CURE-Fox-19 through CURE-Fox-40.

CURE-Fox-6 Documentation related to the operational emissions estimates was provided in Draft EIR/EIS Appendix G1.1 on pages labeled G1.1.8 (On-Road Operational Criteria Pollutant Emissions), G1.1.10a (Proposed Action Emergency Generator Testing Criteria Pollutant Emissions), G1.10b (Alternative 3 Emergency Generator Testing Criteria Pollutant Emissions), and G1.1.12 (GHG Operational Emissions – includes five pages). For each category of operational emissions estimates, emission factors and usage assumptions used to derive emissions estimates were provided.

Documentation related to emissions estimates for construction-related worker and hauling trips was provided in Draft EIR/EIS Appendix G1.1 on pages

labeled G1.1.3 (Construction Worker Auto and Truck Trips), G1.1.6 (Construction Criteria Pollutant Exhaust Emissions – includes seven pages), and G1.1.13 (EMFAC 2014 On-Road Emission Factors). For each category of construction-related emissions estimates, emission factors and usage assumptions used to derive emissions estimates were provided. The construction-related fugitive dust emissions were inadvertently omitted from Draft EIR/EIS Appendix G1.1. Appendix G1 Section G1.1.7, Construction Fugitive Dust, has been inserted into Final EIR/EIS Appendix G1.1 between sections G1.1.6 and G1.1.8. And while this additional data does not amount to significant new information, it also does not change the impact determination.

Although this page was inadvertently omitted from the Draft EIR/EIS Appendix G1, Draft EIR/EIS Air Quality Section 4.10.4, Approach to Analysis, did include a comprehensive discussion of the methods and formulas used to estimate construction-related fugitive dust emissions, including identification of the specific emission factors and the associated regulatory reference documents (refer to Draft EIR/EIS page 4.10-19). Thus, the Draft EIR/EIS provided adequate opportunity for the public to independently review the Lead Agencies' conclusions regarding the significance of the Project's construction and operational emissions.

In addition, pursuant to its February 8, 2017 Public Records Act request, the unlocked Appendix G1 spreadsheet, including Section G1.1.7 (Fugitive Dust), was provided to Adams Broadwell Joseph & Cardozo on February 13, 2017.

CURE-Fox-7 For the EMFAC 2014 model inputs (assumptions) and outputs, refer to Draft EIR/EIS Appendix G1, Section G1.1.13, EMFAC 2014 On-road Emission Factors. All emissions factors used to estimate on-road operational and construction emissions are for running exhaust, with the exception of factors for particulate matter, which include running exhaust as well as brake and tire wear factors. The units for running exhaust and the wear factors are grams per mile, so are summed for the PM10 and PM2.5 emission factors. Emissions of running loss and diurnal/resting loss, idling, and hot soak and start would be negligible for this project and were not estimated.

CURE-Fox-8 See response to comment CURE-Fox-7, above.

CURE-Fox-9 See responses to comments CURE-Fox-6 and CURE-Fox-7, which demonstrate that the EIR/EIS did include the underlying technical data necessary to verify estimates of the project's impacts. As the unlocked Appendix G1 spreadsheet was provided to Adams Broadwell Joseph & Cardozo on February 13, 2017, it is clearly part of the administrative record for this project.

CURE-Fox-10 See responses to comments CURE-Fox-6 and CURE-Fox-7, which demonstrate that the Draft EIR/EIS provided adequate opportunity for the

public to independently review the Lead Agencies' conclusions regarding the significance of the project's construction and operational emissions.

CURE-Fox-11 For responses to individual comments on mitigation to reduce NO_x emissions, refer to responses to comments CURE-Fox-12 through CURE-Fox-40.

CURE-Fox-12 Mitigation Measure 4.10-1a has been revised to include Tier 4 equipment use requirements. Refer to response to comment MBARD-1 in Section 8.5.3.

CURE-Fox-13 Regarding the use of Tier 4 equipment, Mitigation Measure 4.10-1a has been revised to include Tier 4 equipment use requirements and/or alternatively powered equipment, where feasible. See Response MBARD-1 in Section 8.5.3.

As indicated by the commenter, it is likely that Tier 4 equipment would be available locally; however, because the availability of Tier 4 equipment at the time of construction cannot be substantiated at this time, the exclusive use of such equipment during construction cannot be assumed. Nonetheless, Mitigation Measurement 4.10-1a requires CalAm and/or its contractors to make efforts to obtain high-tiered equipment or, as revised in response to comment MBARD-1 in Section 8.5.3, construction equipment powered by electricity, natural gas, propane, ethanol blends, or gasoline, where feasible. A requirement to obtain Tier 4 equipment from vendors within 1,000 miles of the project site would be overly burdensome to CalAm and its construction contractor(s) and could result in overall higher amounts of diesel exhaust emissions due to tractor truck hauling that could be required to transport the equipment over such distances.

The commenter also suggests that if Tier 4 equipment for construction of the project cannot be obtained, the lower-tier, higher emitting engines used should be retrofitted to meet Tier 4 standards. Given that the majority of equipment that would be used to construct the project would be owned by a third party, such a mitigation requirement would pose practical and economic constraints that do not meet the CEQA Guidelines feasibility criteria. As revised, Mitigation Measure 4.10-1a includes requirements for all available feasible equipment emission controls, and includes the requirement that CalAm or its construction contractor provide documentation to the CPUC from two local heavy construction equipment rental companies that indicates that the companies do not have access to Tier 4 equipment or alternatively powered equipment. Additional revisions to Mitigation Measure 4.10-1a are not warranted.

CURE-Fox-14 Mitigation Measure 4.10-1a has been revised to include Tier 4 equipment use requirements. Refer to Response MBARD-1. No Initial Study/Mitigated Negative Declaration (IS/MND) has been prepared for the MPWSP.

CURE-Fox-15 It is true that the measure references idling limits required by State law; however, the intent of the measure in the EIR/EIS was primarily to increase

awareness of the law by requiring signs to be posted that would be viewed by construction workers at all access points to construction areas, which is not a State requirement. However, in response to this comment and in recognition that idling-related NOx emissions would contribute to overall NOx emissions that result in a significant unavoidable impact during construction, Mitigation Measure 4.10-1b has been revised to clarify the requirement to post signage, to require that CalAm and/or its contractors prepare and maintain a written idling policy and distribute it to all equipment operators, and to lower the idling time limit for off-road diesel engines to 2 minutes (all other engines remain subject to existing law).

Pursuant to the Mitigation Monitoring, Reporting, and Compliance Program (MMRCP) that would be prepared for the project or an alternative if approved, the CPUC would be required to ensure that CalAm and its contractors effectively implement all mitigation measures, including Mitigation Measure 4.10-1b.

CURE-Fox-16 For specific discussion of each of the identified measures, see responses to comments CURE-Fox-17 through CURE-Fox-38.

CURE-Fox-17 Per the requirements of Mitigation Measure 4.18-1, Construction Equipment Efficiency Plan, CalAm would be required to implement procedures to ensure that all construction equipment is properly tuned and maintained at all times (see EIR/EIS Section 4.18, Energy Conservation, Impact 4.18-1 discussion). Therefore, this suggested measure already was incorporated in the Draft EIR/EIS.

CURE-Fox-18 As described in response to comment MBARD-1 in Section 8.5.3, Mitigation Measure 4.10-1a has been revised to include requirements for construction equipment powered by electricity, natural gas, propane, ethanol blends, or gasoline, as an alternative to Tier 4 diesel engines, where feasible.

CURE-Fox-19 See response to comment CURE-Fox-18.

CURE-Fox-20 Per the requirements of Mitigation Measure 4.18-1, CalAm would prepare a Construction Equipment and Vehicle Efficiency Plan that identifies the specific measures that CalAm (and its construction contractors) would implement to increase the efficient use of construction equipment to the maximum extent feasible and to ensure that construction activities are conducted in a fuel-efficient manner (see Draft EIR/EIS Section 4.18, Energy Conservation, Impact 4.18-1 discussion). Implementation of Mitigation Measure 4.18-1 would achieve the apparent intent of the commenter's suggested measure. Mitigation that would reduce emissions by limiting simultaneous construction activities would pose practical and economic constraints that do not meet the CEQA Guidelines feasibility criteria, as explained in detail in response to comment MBARD-5 in Section 8.5.3.

CURE-Fox-21 Implementation of Mitigation Measure 4.18-1, described above, would achieve the apparent intent of the commenter's suggested measure.

CURE-Fox-22 Beginning in 1975, most gasoline-powered vehicles have been required to be equipped with catalytic converters per U.S. Environmental Protection Agency (USEPA) exhaust emission regulations. In addition, State aftermarket catalytic converter requirements include the prohibition of installing used catalytic converters, as well as standards for new aftermarket catalytic converters. Thus, the existing gasoline-powered equipment fleet is equipped with catalytic converters, and there is no need for the suggested measure.

CURE-Fox-23 See response to comment CURE-Fox-15.

CURE-Fox-24 As described in Impacts 4.10-3 and 4.10-5, air quality impacts on sensitive receptors would be less than significant. Therefore, no mitigation is required to reduce such impacts; though mitigation measures recommended to reduce other air quality impacts would further reduce emissions affecting sensitive receptors.

CURE-Fox-25 This measure is the same as that listed in comment CURE-Fox-21, and is addressed in response to comment CURE-Fox-21.

CURE-Fox-26 This measure is the same as that listed in comment CURE-Fox-20, and is addressed in response to comment CURE-Fox-20.

CURE-Fox-27 Final EIR/EIS Mitigation Measure 4.18-1, *Construction Equipment and Vehicle Efficiency Plan*, has been revised as follows to include a requirement to provide worker carpooling options.

> **Mitigation Measure 4.18-1: Construction Equipment <u>and Vehicle</u> Efficiency Plan.**
>
> CalAm shall contract a qualified professional (i.e., construction planner/energy efficiency expert) to prepare a Construction Equipment Efficiency Plan that identifies the specific measures that CalAm (and its construction contractors) will implement as part of project construction and decommissioning to increase the efficient use of construction equipment <u>and vehicles</u> to the maximum extent feasible. Such measures shall include, but not necessarily be limited to: procedures to ensure that all construction equipment is properly tuned and maintained at all times; <u>requirement to provide options for worker carpooling;</u> a commitment to utilize existing electricity sources where feasible rather than portable diesel-powered generators; and identification of procedures (including the routing of haul trips) that will be followed to ensure that all materials and debris hauling is conducted in a fuel-efficient manner. The plan shall be submitted to CPUC and the Sanctuary for review and approval at least 30 days prior to the beginning of construction activities and at least 30 days prior to the beginning of decommissioning activities.

CURE-Fox-28 Mitigation Measure 4.10-1a has been revised to include requirements for construction equipment to be alternatively powered, including powered by methanol, propane, and natural gas, where feasible. See response to comment MBARD-1 in Section 8.5.3.

CURE-Fox-29 Mitigation Measure 4.10-1a has been revised to include requirements for construction equipment to be alternatively powered, where feasible. See response to comment MBARD-1 in Section 8.5.3.

CURE-Fox-30 Given that the majority of construction equipment would be owned and operated by a third party, a mitigation requirement to modify construction equipment engines with retrofits would pose practical and economic constraints that do not meet the CEQA Guidelines feasibility criteria. As revised, Mitigation Measure 4.10-1a includes requirements for all available equipment that meets the highest USEPA-certified tiered emission standards, and includes the requirement that CalAm or its construction contractor provide CPUC documentation from two local heavy construction equipment rental companies that indicates that the companies do not have access to Tier 4 equipment or alternatively powered equipment for any given equipment need. Additional revisions to Mitigation Measure 4.10-1a are not warranted.

CURE-Fox-31 Mitigation Measure 4.10-1a has been revised to include Tier 4 equipment use requirements or alternatively powered equipment, where feasible. See response to comment CURE-Fox-13.

CURE-Fox-32 Given that the majority of construction trucks would be owned by a third party, a mitigation requirement to convert part of the construction truck fleet to natural gas would pose practical and economic constraints that do not meet the CEQA Guidelines feasibility criteria. However, as described above, Mitigation Measure 4.10-1a has been revised to include requirements for alternatively powered equipment, such as natural gas, where feasible.

CURE-Fox-33 As described in response to comment MBARD-1 in Section 8.5.3, Mitigation Measure 4.10-1a has been revised to include Tier 4 equipment use requirements or alternatively powered equipment where feasible. These revisions would have the same effect as requiring the use of new or rebuilt equipment where feasible.

CURE-Fox-34 A recent study has indicated mixed results related to the ability of heavy-duty hybrid construction equipment to reduce emissions compared to conventional construction equipment (Johnson, et al., 2013). As part of the study, the University of California, Riverside College of Engineering – Center for Environmental Research and Technology facilitated the deployment of ten hybrid bulldozers and six hybrid excavators within eight California-based fleets. Hundreds of hours of in-use dozer and excavator activity were observed

and logged at six locations to develop typical in-use hybrid dozer and excavator duty cycles.

The findings of the study suggest that although the use of the hybrid construction equipment resulted in consistent reductions of carbon dioxide (CO_2) emissions of between 14 and 16 percent compared to emissions from the conventional equipment, hybrid construction equipment emissions of nitrogen oxides (NO_x) were up to 13 percent higher than emissions from the conventional construction equipment, and hybrid construction equipment emissions of particulate matter were up to 27 percent higher than emissions from the conventional construction equipment. Given the mixed results of this study, and the potential for the use of hybrid off-road construction equipment to increase emissions of NO_x (already a significant and unavoidable impact as described in Section 4.10) and particulate matter relative to the use of conventional off-road construction equipment, the Lead Agencies have not incorporated the suggested measure into project mitigation measures.

CURE-Fox-35 The California Air Resources Board (CARB) approved the Tractor-Trailer Greenhouse Gas regulation to reduce greenhouse gas emissions produced by certain heavy-duty tractor-trailers. The regulation requires the use of USEPA SmartWay verified aerodynamic technologies and low rolling resistance tires on vehicles operating on California highways. The compliance deadline for the regulation was January 1, 2013, for tractors and January 1, 2017, for trailers (CARB 2012). Therefore, the suggested measure has not been incorporated since it is already required in California and therefore would not further reduce emissions.

CURE-Fox-36 See responses to comments CURE-Fox-15 and CURE-Fox-24, which explain that equipment and vehicle idling during construction would be addressed by requiring signs to be posted at all access points to construction areas that identify the idling limit requirements per Mitigation Measure 4.10-1b. No evidence has been provided that indicates use of idling reduction technology would result in meaningful exhaust emission reductions compared to the recommendations identified in Mitigation Measure 4.10-1b. The suggested measure has not been incorporated.

CURE-Fox-37 This measure is the same as that listed in comment CURE-Fox-32, and is addressed in response to comment CURE-Fox-32.

CURE-Fox-38 The cited sources recommend the use of equipment idle reduction and control, engine preventive maintenance, equipment operator training, ultra-low sulfur diesel and biodiesel, equipment retrofit technologies, engine upgrades, and equipment electrification. As discussed in previous responses to comments, Mitigation Measure 4.10-1a has been revised to include Tier 4 equipment use requirements or alternatively powered equipment, where feasible. See response

to comment MBARD-1 in Section 8.5.3. Use of newer equipment that meets Tier 4 emission standards and/or use of alternative fuels, including electricity, is consistent with these USEPA recommendations to reduce diesel equipment emissions. Mitigation Measures 4.10-1b addresses equipment idle reduction and control. Mitigation Measure 4.18-1 addresses engine preventive maintenance and operator training.

CURE-Fox-39 The construction mitigation program for the project would be carried out by CPUC through implementation of its MMRCP. Mitigation Measure 4.18-1 already requires implementation of procedures to ensure that all construction equipment is properly tuned and maintained at all times.

CURE-Fox-40 For discussion of each of the identified measures, including whether or not they are considered to be feasible and have been incorporated into the Final EIR/EIS, refer to responses to comment CURE-Fox-17 through CURE-Fox-38. All feasible mitigation measures have been incorporated as described therein, and no new significant impacts or substantially more severe significant impacts have been identified. Therefore, these comments do not provide a compelling reason to recirculate the Draft EIR/EIS.

CURE-Fox-41 As stated in the first paragraph of Impact 4.10-4 on Draft EIR/EIS page 4.10-31, it is acknowledged that indirect emissions of criteria pollutants associated with electricity use from the regional power grid are not addressed in the Draft EIR/EIS air quality analysis, because it would be impractical and impossible to do so with any certainty.

CURE-Fox-42 The statement quoted from the Monterey County General Plan EIR about the indirect impacts of water supply projects is acknowledged. To the extent feasible, all relevant indirect impacts on water resources, biological resources and energy conservation have been analyzed in the EIR/EIS. The Monterey County General Plan EIR air quality analysis (Monterey County, 2008) did not address or quantify indirect emissions of criteria pollutants associated with electricity usage.

CURE-Fox-43 Basic understandings of the energy sources, their emission rates, and their locations are critical to conducting a meaningful analysis relative to the potential for the project to contribute to a violation of an ambient air quality standard since attainment of standards is based on the amount of pollutants generated within specific geographical air basins. This is different than analysis for greenhouse gas (GHG) emissions, where it is appropriate to estimate indirect emissions associated with electricity use because GHG emissions have global climate change implications that are not limited to specific locations.

The comment includes reference to an EIR prepared over 10 years ago, apparently as evidence that EIR air quality analyses “routinely” include

indirect emissions from electricity generation. This evidence is not persuasive for that argument. In addition, the sentence referenced in the comment from the Monterey Bay Air Resources District's (MBARD)[1] 2008 CEQA Guidelines is out of context. The comment omits the footnote at the end of the referenced sentence, which identifies the air district's definition of "indirect sources" relative to its significance thresholds for criteria pollutants. As shown below, indirect sources are defined as mobile sources in the footnote explaining the referenced sentence:

> Indirect emissions come from mobile sources that access the project site but generally emit off-site; direct emissions are emitted on-site (e.g., stationary sources, onsite mobile equipment). (MBARD, 2008, p. 5-4)

When discussed in proper context, the commenter's suggestion that the Draft EIR/EIS should include quantification of criteria pollutants relative to the project's electricity use is not supported.

CURE-Fox-44 Although the Lead Agencies agree that indirect emissions of criteria pollutants would not be limited to the air basin of the project location, there must be some evidence to identify what other air basins should be considered. With regard to electricity use for the project, there is no way to ascertain with specificity where the electricity would be generated, so it would be speculative to attempt to identify other air basins that should be considered. Furthermore, significance thresholds for criteria pollutants are specific to the air district, and govern emissions that occur on a project basis within the air basin. Thus, including indirect emissions from facilities outside the air basin would be inconsistent with the MBUAPCD's guidance on the use of significance thresholds.

CURE-Fox-45 The sources of electricity for Pacific Gas and Electric Company (PG&E)'s power grid are known, but it is not known which of those sources would generate the electricity that would be used by the project. In this situation, a worse-case analysis is not required. CEQA does not require the lead agency to engage in speculation about impacts that are not reasonably foreseeable (CEQA Guidelines §15145) and NEPA does not require a worst-case analysis when confronted with incomplete or unavailable information (40 CFR §1502.22). The reason the EIR/EIS does not include any of the information that would be required to estimate indirect criteria pollutant emissions associated with electrical use is that the information is unknown, and for the Lead Agencies to suggest otherwise would have been overly speculative.

Also refer to responses to comments CURE-Fox-43 and CURE-Fox-44.

[1] The Monterey Bay Air Resources District was formerly known as the Monterey Bay Unified Air Pollution Control District (MBUAPCD)

CURE-Fox-46 As explained in response to comment CURE-45, neither CEQA nor NEPA require an analysis of the "maximum plausible" (i.e., worst case) scenario for indirect emissions from stationary sources already subject to air district permitting. For the specific responses related to the commenter's emission estimates for project electricity use, see to responses to comments CURE-Fox-47 through CURE-Fox-50.

CURE-Fox-47 The assumption that electricity for the project would be generated by an uncontrolled gas turbine plant is not supported by evidence. To the contrary, as shown in Table 4.18-1 on Draft EIR/EIS page 4.18-3, only 25 percent of PG&E's electric power mix as of 2015 was generated by natural gas plants, and it is unrealistic to assume that all electricity generated by such plants would occur under startup/shutdown or uncontrolled conditions, nor is such an assumption supported by evidence.

CURE-Fox-48 As explained in response to comment CURE-Fox-47, the calculation in the comment is based on overly speculative assumptions about the emissions from PG&E-provided electricity, and likely overestimates NOx emissions by using unrealistic and unnecessary worst-case assumptions. Further, as clarified in response to comment CURE-FOX-43, the MBARD's significance threshold for NOx is only applicable to direct (on-site) and indirect (off-site *mobile source*) emissions, and all MBARD thresholds are only applicable to sources within the North Central Coast Air Basin because they have been set based on the need to attain and maintain ambient air quality standards (AAQS) within the Basin. The comment includes no evidence to suggest that the emissions would be generated within the North Central Coast Air Basin.

CURE-Fox-49 See responses to comments CURE-Fox-47 and CURE-Fox-48 regarding the speculative nature of the commenter's emission estimates. Based on evidence and analysis provided in the Draft EIR/EIS, the Project would generate NOx emissions in excess of the MBUAPCD's NOx significance threshold with or without mitigation. See, e.g., Table 4.10-5, Estimated Maximum Daily Construction Emissions (pounds/day).

CURE-Fox-50 Even if it could be assumed that all electricity for proposed project operation would be generated at the Gateway Generation Station (a 600-megawatt (MW) power station in Antioch), an assumption not supported by evidence, the use of the maximum daily emissions of NOx from the entire power plant is grossly over-conservative compared to the energy needs of the project, which would amount to a net increase in electrical demand of approximately 6 MW, or 1 percent of the capacity of the Gateway Generating Station.[2] At most, this would add approximately 12 pounds per day (1,152*0.01) to the total

[2] 51,698 MWh/year (Draft EIR/EIS page 4.18-16) is equivalent to approximately 6 MW. (51,698MWh/year)* (year/365day)*(day/24hour) = 5.90 MW.

operational NOx emissions, which would not cause an exceedance of the MBARD significance threshold. However, for the reasons stated in this response and in responses to comments CURE-Fox-41 through CURE-Fox-49, this is not an appropriate approach to estimating operational criteria air pollutant emissions.

CURE-Fox-51 The Lead Agencies do not agree that the maximum daily emissions associated with the Gateway Generation Station should be disclosed as a significant impact associated with the MPWSP for the reasons described above in response to comment CURE-Fox-50. Therefore, mitigation to offset emissions generated at the Gateway Generation Station is not warranted or appropriate.

CURE-Fox-52 For the reasons described in responses to comments CURE-Fox-43 through CURE-Fox-51, the lead agencies do not agree with the commenter that the EIR/EIS should include quantification of indirect criteria pollutant emissions associated with electricity use from PG&E's power grid.

CURE-Fox-53 See responses to comments CURE-Fox-54 through CURE-Fox-70 for specific responses to this summary comment.

CURE-Fox-54 The summary of general NO_2 emissions and its sources is acknowledged. See responses to comments CURE-Fox-55 through CURE-Fox-69 for specific responses to NO_2 and NOx-related comments.

CURE-Fox-55 As stated in the first sentence of Section 4.10.4.2 on Draft EIR/EIS page 4.10-18, for the purposes of the air quality evaluation, the NO_x significance threshold represents emissions of all NO_x, including NO_2. The Draft EIR/EIS disclosed a significant and unavoidable impact due to the project's potential to contribute to an exceedance of the ozone and NO_2 standards (see Impact 4.10-1, *Impact Conclusion*, discussion in EIR/EIS Section 4.10.5.1).

The NO_x emission threshold of 137 pounds per day that was used to make that impact determination is based on California Clean Air Act (CCAA) offset requirements identified in Monterey Bay Air Resources District Rule 207, *Review of New or Modified Sources*. Rule 207 does not identify a CCAA offset requirement for NO_2; however, it does identify 150 pounds per day NO_x (as NO_2) as the emissions where Best Available Control Technology (BACT) requirements apply (MBUAPCD, 2011).

As stated in Section 3.3 of Rule 207:

> In no case shall the emissions from the new or modified stationary source, or in conjunction with other increases in emissions, cause or contribute to the violation of an ambient air quality standard or exceed any air quality increment…" and "In making this determination the

> District shall take into account the mitigation of emissions through offsets obtained pursuant to this Rule.

All pollutants with ambient air quality standards are applicable to Rule 207; however, the NO_x and NO_2 limits discussed above are likely focused on ozone standards as opposed to NO_2 standards because, as illustrated in EIR/EIS Table 4.10-1, ozone concentrations in the air basin are higher than NO_2 concentrations and the ambient air quality standards for ozone are more stringent compared to NO_2. The fact that Rule 207 does not include an offset requirement for NO_2 indicates that the MBARD did not identify a need to address the potential for an NO_2 ambient air quality standard to be exceeded when it adopted this rule. Nonetheless, in the absence of an NO_2-specific significance threshold, the Lead Agencies determined it was prudent to use the NO_x significance threshold as such.

CURE-Fox-56 The adverse health effects of NO_2 are acknowledged. The project-related NO_2 emissions have been evaluated relative to the NO_2 ambient air quality standards. See response to comment CURE-Fox-55.

CURE-Fox-57 As indicated in EIR/EIS Section 4.10.1.2, it is acknowledged that NO_x and SO_2 can convert in the atmosphere to sulfates and nitrates, thereby contributing to fine particulate matter emissions; this section also acknowledges contributions of SO_2 to acid rain formation. However, similar to the formation of ozone, such conversions are highly variable and occur due to complex chemical reactions in the atmosphere generally downwind and at some distance from the original emission sources. Current air pollution emission estimating models, such as CalEEMod that was used to estimate project construction emissions, are not capable of estimating secondary pollutant emissions such as these, and the Lead Agencies are not aware of any established methods or guidance available to estimate those emissions that would be associated with the project. The analysis in EIR/EIS Section 4.10 follows established guidance from MBARD for estimating and mitigating, as needed, construction emissions of criteria pollutants.

CURE-Fox-58 The project-related NO_2 emissions have been evaluated relative to the NO_2 ambient air quality standards. The federal annual average secondary ambient air quality standard for NO_2, which is designed to protect public welfare, including damage to crops, is the same as the primary standard at 0.053 parts per million (ppm). The Draft EIR/EIS disclosed a significant and unavoidable impact due to the project's potential to contribute to an exceedance of the NO_2 standards (see Impact 4.10-1, *Impact Conclusion* discussion in EIR/EIS Section 4.10.5.1). Also see response to comment CURE-Fox-55.

CURE-Fox-59 Impacts associated with construction-related NO_2 emissions were evaluated in the Draft EIR/EIS relative to the MBARD mass emissions significance threshold for NO_x. See response to comment CURE-Fox-55.

CURE-Fox-60 There is no annual average ambient air quality standard for NO_x and the EIR/EIS presents no ambient concentrations for NO_x. EIR/EIS Table 4.10-includes recorded maximum hourly concentrations of NO_2. Annual average NO_2 concentrations were not included in Table 4.10-1 because those concentrations are very low relative to the standards. For example, CARB data suggest that the maximum annual average NO_2 concentrations for years 2011 through 2015 was 0.006 parts per million (ppm) (CARB, 2017). This represents one fifth of the State NO_2 ambient air quality standard of 0.030 ppm.

The EIR/EIS evaluated NO_2 emissions and disclosed a significant and unavoidable project-related impact for the potential to contribute to an exceedance of the NO_2 standards (see Draft EIR/EIS page 4.10-24). See response to comment CURE-Fox-55.

CURE-Fox-61 Impacts associated with construction-related NO_2 emissions were evaluated in the Draft EIR/EIS relative to the MBARD's mass emissions significance threshold for NO_x. See response to comment CURE-Fox-55.

CURE-Fox-62 It is not apparent that the significance thresholds used by the counties listed in the comment were developed to assess impacts other than those related to the ozone ambient air quality standards, nor why these thresholds would be applicable to emissions generated in the North Central Coast Air Basin. Shasta County is not in attainment of state ozone standards, and Colusa County has been in attainment only since 2013, following the preparation of the BAAQMD source cited in the comment for these thresholds (CARB, 2016a; BAAQMD, 2009). Mendocino and Modoc Counties, both of which *are* in attainment of ozone standards, have notably higher significance thresholds for NOx than Shasta and Colusa Counties, in many cases higher than the MBUAPCD thresholds used in the Draft EIR/EIS. All of the air basins in California, including the North Central Coast Basin and all basins in which the counties cited in the comment are located, have been in attainment of NO_2-specific state ambient air quality standards for at least the last 20 years (CARB, 2016b), so the cited thresholds do not provide evidence that the districts mentioned have developed these thresholds to address anything other than ozone concentrations. Regardless, impacts associated with NO_x and NO_2 emissions were evaluated in the Draft EIR/EIS relative to the MBUAPCD's mass emissions significance threshold for NO_x. See response to comment CURE-Fox-55.

CURE-Fox-63 For a detailed response about why the health risk assessment (HRA) conducted for the project did not evaluate the health effects of speciated emissions of ROG, see response to comment CURE-Fox-78.

CURE-Fox-64 The commenter appears to suggest that the significance of NO_x as a respiratory irritant was not evaluated in the Draft EIR/EIS because air dispersion modeling was not performed. The Lead Agencies note that this comment seems to contradict comment CURE-Fox-62, which recommends use of one out of a group of other mass (weight-based) emissions thresholds similar to that used in this EIR/EIS, as opposed to a concentration-based threshold that would require a dispersion modeling analysis, as is recommended by this comment. See also response to comment CURE-Fox-55.

CURE-Fox-65 See response to comment CURE-Fox-55.

CURE-Fox-66 With respect to the health-related properties of NO_2 that are unrelated to its property as an ozone precursor, the MBUAPCD CEQA Guidelines do not provide a significance threshold for NO_2 alone. The Basin does not come close to exceeding ambient air quality standards for NO_2 as shown in Table 4.10-1.

CURE-Fox-67 See response to comment CURE-Fox-57.

CURE-Fox-68 See responses to comments CURE-Fox-55 through CURE-Fox-67. As explained therein, the EIR/EIS adequately addresses concerns related to the effects of NO_2 as an air pollutant.

CURE-Fox-69 The comment states that other air districts that are in attainment of state and federal ozone standards have established significance thresholds for NOx of 25 lb/day to 180 lb/day, but goes on to suggest that Shasta County provides an appropriate threshold of 25 lb/day that should be applied to the project's NOx emissions. However, as described in response to comment CURE-Fox-62, Shasta County is in non-attainment of ozone standards, and indeed identifies ozone pollution as "the major air contamination concern" in the county (Shasta County, 2004, p. 6.5.02).

The Lead Agencies disagree that the project operational emissions of NO_x should be considered significant because they would exceed Shasta County's "Level A" threshold of 25 pounds per day of NO_x. Shasta County's Level A thresholds are designed to identify the level at which appropriate best available mitigation measures should be applied. Shasta County's "Level B" thresholds serve as significance criteria by screening for a level of significance that would require the preparation of an EIR. Shasta County's guidance suggests that if project emissions can be reduced to below Level B thresholds, a mitigated negative declaration can be prepared, and if emissions exceed the Level B threshold even after application of Shasta County's uniform mitigation approaches and offsets, then an environmental impact report must be prepared (Shasta County, 2004). Notably, Shasta County's Level B thresholds for NO_x and ROG are 137 pounds per day, which are equivalent to MBARD's NO_x and ROG thresholds of significance used to evaluate operational emissions that

would be associated with the MPWSP. Therefore, these thresholds provide no new information for assessing the significance of the proposed project's NOx emissions.

CURE-Fox-70 The commenter's estimated electricity-related emissions for the project not only use speculative assumptions that are not supported by evidence, but also includes use of an overly conservative emissions estimate not scaled properly for the project. See response to comment CURE-Fox-50, which explains why the Lead Agencies properly identified no significant operational NOx impact.

CURE-Fox-71 For responses to the commenter's more specific individual comments that are summarized in this comment, see responses to comments CURE-Fox-72 through CURE-Fox-78.

CURE-Fox-72 Construction activities associated with Wells ASR-5 and ASR-6 were evaluated in the HRA conducted for the EIR/EIS. Those wells make up the construction site identified as the ASR Injection/Extraction Wells Site in EIR/EIS Table 4.10-6, Maximum DPM Concentrations, Cancer Risks, and Chronic Health Indices. As the comment acknowledges, the ASR Injection/Extraction Wells was evaluated in the HRA and in the EIR/EIS.

CURE-Fox-73 As indicated in Section 4.10.4, Approach to Analysis, pipeline construction activities were not evaluated in the HRA conducted for the project because they would proceed linearly at a rate of 150 feet to 250 feet per day, which would limit the duration of exposure for any given receptor. The Office of Environmental Health Hazard Assessment (OEHHA) does not recommend assessing cancer risk for projects lasting less than 2 months at the maximum exposed individual resident (OEHHA, 2015). Factoring the daily progress rate of proposed pipeline construction, individual receptors along the pipeline routes would be exposed to construction emissions for periods that would be substantially less than 2 months. Therefore, the EIR/EIS's approach to evaluating health risk associated with pipeline construction is consistent with OEHHA guidance.

CURE-Fox-74 The excerpts of the OEHHA 2015 guidance cited by the commenter are acknowledged.

CURE-Fox-75 The comment is incorrect. For health risk related to construction of the Carmel Valley Pump Station, in addition to evaluating exposures of 3 months after birth, exposures were also evaluated for 3 months prior to birth, for a total exposure period of 6 months. This approach to analysis is consistent with OEHHA guidance.

CURE-Fox-76 The MBARD recommends the use of 10 in one million as a cancer risk threshold, and has not identified a more stringent threshold for short-term

exposure periods. In addition, OEHHA's 2015 guidance includes calculations that account for higher risks for infants. That 2015 guidance was used to calculate the health risks described in the EIR/EIS. The 2015 guidance includes a factor that accounts for the higher breathing rates of infants. That same 2015 guidance also includes age sensitivity factors (ASFs) for infants. The ASFs increase risks by a factor of 10 for exposure during the third trimester to age 2 years, and by a factor of 3 for exposure during ages 2 through 15 years. These ASFs and the higher breathing rates for infants were used to estimate the risks shown in the EIR/EIS. Consequently, both the risk approach and the risk thresholds used in the EIR/EIS correctly evaluate potential health risks to infants.

CURE-Fox-77 The EIR/EIS uses the 10 in a million threshold recommended by the MBARD's CEQA guidance document (MBUAPCD, 2016). The comment does not provide evidence to support the suggestion that a 1 in a million threshold would be more appropriate. The cited source for this suggestion is a presentation on surface water quality and refers to human-health-based criteria to protect people from consumption of fish, shellfish, and drinking water. This is not relevant to the air quality analysis prepared consistent with MBARD's CEQA Guidelines.

CURE-Fox-78 Appendix D of OEHHA's 2015 Guidance describes risk assessment procedures to evaluate emissions from diesel-fueled engines. According to Section 2.3 of Appendix D, there may be certain situations where an evaluation of the speciated chronic or acute health effects of diesel exhaust may be warranted if requested by the local air district.

OEHHA has established a chronic reference exposure level (REL) for inhalation of diesel exhaust, which is the REL used in the Draft EIR/EIS chronic health risk analysis. However, Appendix D of the OEHHA 2015 Guidance states that the local air district may elect to require a multi-pathway analysis if: 1) reliable data are available to speciate diesel exhaust; and 2) the district feels that such an analysis is warranted. Speciation of diesel exhaust would need to include both metal and ROG components. The MBARD recommends using its current CEQA guidance to conduct health risk assessments, which does not require speciation of diesel exhaust (MBARD, 2017). Since the air district's guidance does not require a multi-pathway, speciated analysis to evaluate diesel exhaust chronic hazards, the approach used in the Draft EIR/EIS was the correct approach for evaluating the project's chronic health risks.

OEHHA has not developed an acute REL for diesel exhaust. To analyze acute health risks from diesel exhaust, the exhaust would need to be speciated into its metal and ROG constituents. Appendix D of OEHHA's 2015 guidance states that acute health risks from diesel exhaust could be estimated if: 1) reliable data are available to speciate diesel exhaust; and 2) the district feels that such an analysis is warranted. The MBARD was also asked about the need for an acute

hazard analysis from diesel exhaust. The air district recommends using its current CEQA guidance to conduct HRAs, which does not require speciation of diesel exhaust to evaluate acute risks. The air district indicated that their preferred option would be not to estimate the chronic and acute health hazards of speciated diesel exhaust, but instead require the use of Tier 3 and Tier 4 equipment to minimize diesel emissions (MBARD, 2017). Mitigation Measure 4.10-1a in the EIR/EIS does just that by minimizing diesel emissions, including the ROG component of diesel exhaust, by requiring all construction equipment meets the highest USEPA-certified tiered emission standards.

CURE-Fox-79 The information on Valley Fever provided by the commenter is acknowledged.

CURE-Fox-80 The information on Valley Fever provided by the commenter is acknowledged. For discussion about the commenter's specific concerns related to the Draft EIR/EIS analysis on sensitive receptor exposure to *coccidioides immitis* spores, refer to Responses CURE-Fox-81 through CURE-Fox-105, below.

CURE-Fox-81 The Draft EIR/EIS statement regarding the substantial decline in cases of Valley Fever in 2014 and the inference that Valley Fever appears to be decreasing locally in Monterey County was based on facts available at the time of its writing. However, based on new information, the Final EIR/EIS Section 4.10.1.4, *Valley Fever*, has been revised as follows:

> ~~Incidences of Valley Fever appear to be decreasing locally in Monterey County.~~ Cases of Valley Fever in Monterey County between 2011 through 2013 ranged between 68 and 75~~3~~ cases per year, which equaled rates of 16.2~~0~~ to 17.8~~3~~ cases per populations of 100,000. In 2014 and 2015, cases of Valley Fever dropped substantially to ~~19~~ 20 and 34 cases, respectively, which were equal to ~~a~~ rates of 4.7~~5~~ and 7.9 per population of 100,000, respectively (CDPH, 2016~~5~~);~~.~~ however, the unofficial number of Valley Fever cases in 2016 rose back to pre-2014 levels with 78 cases (MCHD, 2017).

The following revision and new reference have been added to the Final EIR/EIS Air Quality Section 4.10 references.

> California Department of Public Health (CDPH), 2016~~5~~. Yearly Summaries of Selected General Communicable Diseases in California, 2011 – 201~~5~~4, last updated June 2016~~5~~.
>
> Monterey County Health Department (MCHD, 2017). Personal communication between Kristine Michie, Epidemiologist/Project Manager I at Monterey County Health Department, and Matt Fagundes, Environmental Science Associated, May 22, 2017.

CURE-Fox-82 The EIR/EIS points out that construction activities associated with the project would result in localized ground disturbing activities similar to those that occur continually within the County as a result of other construction projects, and that therefore the project would not result in a substantial increase in spore release compared to existing and ongoing ground disturbance. This is the basis for the conclusion that construction of the project would not represent an increased risk to public health (see Impact 4.10-3). In this context and consistent with the EIR/EIS analysis, the Lead Agencies agree that County residents that have been exposed to *coccidioides immitis* spores are part of environmental baseline.

CURE-Fox-83 It is acknowledged that the higher the concentration of PM_{10} and $PM_{2.5}$ fugitive dust emissions in the air from disturbed soils that contain *coccidioides immitis* spores, the greater the potential would be to cause the spores to become airborne and inhaled. That is why implementation of Mitigation Measure 4.10-1c is referenced due to its potential to control spore-containing dust from becoming airborne (see Impact 4.10-3, Draft EIR/EIS page 4.10-28). The measure requires application of fugitive dust control measures to ensure that fugitive dust that could contain *coccidioides immitis* spores would be controlled to the maximum extent feasible.

The EIR/EIS does not suggest that previous exposure to the spores guarantees immunity to Valley Fever.

CURE-Fox-84 The comment provides no supporting evidence for the claim that earth-disturbing activities that would occur under the project would increase the amount of *coccidioides immitis* spores in the atmosphere, other than identifying the total area of disturbance that would be associated with the project. Although there is a potential that some of the soil disturbed during construction of the project would contain spores, and could thus release them into the atmosphere as a result of project construction, the Lead Agencies are not aware of any evidence that suggests that these soils definitively contain the spores. Thus, there is no basis to conclude that impacts would be significant. Nonetheless, as described in response to comment CURE-Fox-83, implementation of Mitigation Measure 4.10-1c would have the potential to control spore-containing dust from becoming airborne.

CURE-Fox-85 Valley Fever-related less-than-significant impacts identified in the EIR/EIS are discussed in terms of increased risk to public health in general (see Impact 4.10-3). It is acknowledged that people who have jobs where dirt and soil are disturbed, including construction workers that would be associated with the project, may have a higher risk of getting infected than others. It is important that workers understand the potential hazards related to their work and how to protect themselves. Employers also have responsibilities to control

workers' exposure to hazardous materials, including spores that cause Valley Fever. For worker safety laws designed to protect workers from exposure to spores that cause Valley Fever that must be implemented by the project, refer to the response to Marina-99.

CURE-Fox-86 It is acknowledged that the potentially exposed population would be larger than the number of project construction workers and that *coccidioides immitis* spores can stay entrained within the atmosphere longer than some fractions of particulate matter; however, no evidence has been provided by the comment to support the claim that dust raised during construction of the project would expose a large amount of people to spores hundreds of miles away. Instead, the comment includes reference to a discussion that appears to be related to the most severe dust storm on record that occurred in Bakersfield in 1977 (NOAA, 2008). Such a storm does not represent reasonably foreseeable conditions.

CURE-Fox-87 The Draft EIR/EIS does not argue that prior exposure to *coccidioides immitis* spores confers immunity to Valley Fever. Instead, it discloses that much of the population of Monterey County has already been exposed to *coccidioides immitis* spores and would continue to be exposed because of the various earthmoving activities that occur as a result of agricultural and construction activities throughout the region; thus, the project would not represent a substantial increase in exposure compared to existing conditions. Construction activities associated with the project would result in similar localized ground disturbing activities to those that occur continually within the County and the project would not result in a substantial overall increase in spores emitted to the atmosphere that would represent an increased risk to public health (see EIR/EIS Impact 4.10-3).

CURE-Fox-88 See response to comment CURE-Fox-85.

CURE-Fox-89 See response to comment CURE-Fox-85.

CURE-Fox-90 As pointed out in comment CURE-Fox-91, and as evidenced by the Monterey County Health Department's recommended prevention measures (2017), dust control is an important defense against Valley Fever infection.

The commenter indicates that the Draft EIR/EIS does not contain any mitigation that specifically addresses fine particulate matter ($PM_{2.5}$) as a subset of PM_{10}. Although it is acknowledged that Mitigation Measure 4.10-1c is required to reduce construction related PM_{10} impacts to a less-than-significant level, its implementation would also reduce emissions of $PM_{2.5}$.

CURE-Fox-91 See response to comment CURE-Fox-90.

CURE-Fox-92 The connection between the small size and potential low settling rate of *Coccidiodes* spores and the effectiveness of Mitigation Measure 4.10-1c is

unclear; in fact, the intent of Mitigation Measure 4.10-1c is to reduce the potential for spore-containing dust to become airborne in the first place.

CURE-Fox-93 It is acknowledged that on an annual basis, Valley Fever infections in California tend to peak during the late summer and early fall when conditions are driest.

CURE-Fox-94 The potential effect of drought periods on Valley Fever infection rates is acknowledged.

CURE-Fox-95 Valley Fever-related impacts associated with the project are considered to be less-than-significant as described in Impact 4.10-3; therefore, additional mitigation measures to further reduce the potential impact are not warranted. Further regarding valley fever, see Response to comment CURE-Fox-85.

Regarding construction-related PM10 emissions and fugitive dust control more generally, see EIS/EIS Mitigation Measure 4.10-1c (Construction Fugitive Dust Control Plan). The actions recommended in this mitigation measure, including watering active construction areas multiple times daily; covering all trucks hauling soil, sand, and other loose materials; applying water or non-toxic soil stabilizers on unpaved access roads, parking areas, and staging areas at construction sites; hydroseeding or applying non-toxic soil stabilizers to inactive construction areas; and replanting vegetation in disturbed areas as quickly as possible; among other actions, are consistent with the County of Monterey Health Department's *coccidioidomycosis* prevention guidance (Monterey County Health Department, 2017).

See also EIR/EIS Mitigation Measure 4.6-1p (Control Measures for Spread of Invasive Plants), which requires that tools, equipment, and vehicles be cleaned before entering and leaving worksites (e.g., wheel washing stations at project site access points). While not specifically developed to address a risk of transporting cocci outside endemic areas, the implementation of Mitigation Measure 4.6-1p would reduce the risk of spores being transported on- or off site on project equipment, vehicles, or other items.

CURE-Fox-96 See responses to comments CURE-Fox-85 and CURE-Fox-95. The commenter's preference for use of trenchless methods to construct pipelines (as described in the EIR/EIS) is acknowledged; however, because no significant impact has been identified, there is no basis to require that CalAm use trenchless construction methods to reduce the potential to release spores.

CURE-Fox-97 See responses to comments CURE-Fox-85 and CURE-Fox-95.

CURE-Fox-98 Mitigation Measure 4.10-1c has been revised at the request of MBARD to require all active construction areas to be watered at least three times daily. See responses to comments CURE-Fox-95 and MBARD-8 in Section 8.5.3.

CURE-Fox-99 The daily sweeping required by Mitigation Measure 4.10-1c would be conducted with water sweepers that are designed to control fugitive dust.

CURE-Fox-100 See response to comment CURE-Fox-95.

CURE-Fox-101 See response to comment CURE-Fox-95.

CURE-Fox-102 See response to comment CURE-Fox-95.

CURE-Fox-103 See responses to comments CURE-Fox-85 and CURE-Fox-95. As noted in the Greentech Media article cited in the comment, the remedy to the Antelope Valley air district notices of violation included the implementation of dust control measures that had been shown to work in other parts of the valley, and to comply with the provisions of the company's conditional use permit ("They have been told it is time to use things to control dust that have worked elsewhere in the valley," Hickling told the town council. "Fines are not issued unless [the company] fails to correct the problem. They have to demonstrate they have dealt with the dust, re-vegetation and landscaping issues as outlined in the CUP.") (Trabish, 2013). A different company's noncompliance with a different air district's rules and regulations to control construction dust is not evidence that the applicant for this project will fail to comply with applicable permit obligations and other requirements.

CURE-Fox-104 The comment regarding construction workers that contracted Valley Fever in San Luis Obispo is noted. See response to comment CURE-Fox-85 for more information about construction worker exposure to valley fever.

CURE-Fox-105 See responses to comments CURE-Fox-85 and CURE-Fox-95.

CURE-Fox-106 The comment is an introductory statement summarizing comments on the greenhouse gas (GHG) emissions analysis conducted for the project. For responses to the commenter's individual comments, see responses to comments CURE-Fox-107 through CURE-Fox-136.

CURE-Fox-107 See responses to comments CURE-Fox-108 through CURE-Fox-136 for responses that address the commenter's specific concerns regarding the Draft EIR/EIS GHG mitigation measures.

CURE-Fox-108 In *Keep Berkley Jets Over the Bay Committee v. Board of Port Commissioners of the City of Oakland*, the court found that an EIR for a project with a significant and unavoidable environmental impact must sufficiently explore the significant environmental effects created by the project, and that the EIR's approach of simply labeling the effect "significant" without accompanying analysis of the project's impact is inadequate to meet the environmental assessment requirements of CEQA (CNRA, 2001).

The EIR/EIS GHG emissions analysis did not simply label the effect of project-related GHG emissions significant without an accompanying analysis of the project's impact. EIR/EIS Section 4.11.5 includes a robust analysis and quantification of the GHG emissions that would be associated with the project and included discussion of whether or not these emissions would be consistent with the State's GHG emissions reduction goals. Impact 4.11-1 provides a quantitative estimate of total amortized GHG emissions of the project and acknowledges that unmitigated emissions would exceed the 2,000 metric tons per year significance threshold. Mitigation measures are then described that would require that construction activities be conducted in a fuel-efficient manner (Mitigation Measure 4.18-1), and that a GHG emissions reductions plan be implemented (Mitigation Measure 4.11-1). See response to comment USEPA-4 for the text of the revised Mitigation Measure 4.11-1, which would require that CalAm achieve net zero GHG emissions from operational electricity use. As a result of these revisions, GHG-related impacts are reduced to a less-than-significant level as described in Section 4.11 of the Final EIR/EIS.

CURE-Fox-109 The comment is a general statement that suggests the GHG mitigation measures identified in the EIR/EIS are unenforceable, ambiguous, and do not include all feasible mitigation. See responses to comments CURE-Fox-110 through CURE-Fox-136 for responses that address the commenter's specific concerns regarding the Draft EIR/EIS GHG mitigation measures.

CURE-Fox-110 See response to comment USEPA-4 for the text of the revised Mitigation Measure 4.11-1, which would require that CalAm achieve net zero GHG emissions from operational electricity use. As a result of these revisions, GHG-related impacts are reduced to a less-than-significant level as described in Section 4.11 of the Final EIR/EIS.

On-site solar power is one of the options provided in revised Mitigation Measure 4.11-1. However, regarding the comment that renewable generation sources should be built to provide 100 percent of the project's energy demand, this would not be feasible given the continuous and constant nature of the project's electricity demand and the scope of the renewable facilities that would be required. It is not reasonable to assume that 100 percent of the project's energy demand could be met by constructing dedicated renewable energy generation sources, such as solar and wind power. In addition, the size and nature of the renewable facilities would result in their own potentially significant environmental impacts.

Solar power for the project's electricity demand is only possible during hours of sunlight. For example, a solar power proposal considered by County of Monterey was predicted to generate electricity for approximately 7 hours per

day on an annual average (County of Monterey, 2014). Because the energy demand for the project is constant and continuous, this would equate to only 30 percent of the energy demand for the project. Assuming 30 percent of the project's electricity demand could be met by solar power generation, and 1 acre of solar plant in Monterey County can generate approximately 242 megawatt-hours (MWh) per year of electricity,[3] the solar plant would have to be over 63 acres in size, which would be equivalent to more than 2.5 times the size of the proposed MPWSP Desalination Plant. Such a conversion of land use to supply only 30 percent of the project's energy demand would have its own environmental and legal challenges that would be akin to a separate energy generation project, which the Lead Agencies do not consider to be fitting mitigation for this water supply project.

With regard to wind power, wind turbines generate electricity for fewer hours per day on average then solar power. For example, a wind turbine proposal considered by the City of Soledad was estimated to generate electricity for approximately 5 hours per day on an annual average (City of Soledad, 2013). This would represent an opportunity to satisfy approximately 21 percent of the project's electricity needs. Assuming that 1.5-MW wind turbines can each generate up to 2,700 MWh per year (City of Soledad, 2013), four wind turbines could satisfy approximately 21 percent of the project's energy needs. Based on research conducted by the National Renewable Energy Laboratory, the average land requirements for 1 MW of wind power ranges from 30 to 141 acres (NREL, 2013). Therefore, development of four 1.5 MW wind turbine towers would require up to 843 acres. It should also be noted that each turbine would be approximately 340 feet tall (City of Soledad, 2013). The conversion of land use that would be required to supply only 21 percent of the project's energy demand would have its own environmental and legal challenges that would be akin to a separate energy generation project, which the Lead Agencies do not consider to be reasonable mitigation for this water supply project.

CURE-Fox-111 See responses to comments USEPA-4, CURE-Fox-108, and CURE-Fox 110. The Lead Agencies do not agree that no regard is needed relative to the intra-year timing of when renewable energy facilities constructed for the project would generate electricity. As discussed in response to comment CURE-Fox-110, the electricity demand for the project would be continuous and constant, while power output from any renewable generation facility that would be built to provide power for the project would only be available to offset up to 30 percent of the daily load on annual-average basis.

[3] Based on the specifications of a 3,000-acre solar power plant recently evaluated by Monterey County that would have a capacity of 726.9 gigawatt-hours (GWh) per year (County of Monterey, 2014).

Procuring renewable energy through the Green Tariff Shared Renewables program does not appear to be an appropriate mitigation measure under CEQA. Per CEQA Guidelines Section 15126.4(c)(3), off-site measures can be used to mitigate GHG emissions impacts; however, they should include "offsets that are not otherwise required." This is interpreted to mean that offsets must be additional to baseline conditions of the project.

PG&E's Solar Choice program is part of its Green Tariff Shared Renewables Program and was created to expand access to renewable energy resources. The program offers a way for customers to meet their electrical needs with generation from renewable energy resources. For new enrollees in the Solar Choice program, the purchased solar energy is sourced from existing solar resources in PG&E's renewables portfolio, while new projects are built specifically for the program. Although these projects currently exist, PG&E refers to them as "incremental" because they will not be counted toward California's Renewable Portfolio Standards (PG&E, 2017). Therefore, the Lead Agencies do not consider this type of mitigation to be viable. However, other feasible offset options are provided in revised Mitigation Measure 4.11-1.

CURE-Fox-112 See response to comment USEPA-4 for the revised Mitigation Measure 4.11-1, which includes revised performance standards for the preparation and implementation of the Emissions Reduction Plan, consistent with CEQA Guidelines Section 15126.4(a)(1)(B).

CURE-Fox-113 Implementation of Mitigation Measure 4.11-1 would be strictly enforced by the CPUC pursuant to the MMRCP that would be legally binding pursuant to a Commission decision that would approve the project.

The comment cites *San Franciscans for Reasonable Growth v. City & County of San Francisco* (1984) as evidence that Mitigation Measure 4.11-1 is inadequate because it is vague and undefined; however, in that case, the court found that the cumulative impact analyses in the subject EIRs were legally defective because they were too narrowly defined, which understated the true impacts of the project, and thereby undermined any effort to provide adequate mitigation measures (CNRA, 2017a). This case does not support the commenter's position.

Kings County Farm Bureau v. County of Hanford (1990) is also not directly relevant. In the context of the comment, the concern for that case was focused on whether a groundwater mitigation agreement was relied upon for a finding of no significant impact (CNRA, 2017b). In the case of the Draft EIR/EIS, Mitigation Measure 4.11-1 was found to reduce the carbon footprint of the proposed project, but the impact associated with GHG emissions was found to remain significant and unavoidable because it is not possible to substantiate numerically that the GHG emissions would be reduced to a less-than-

significant level based on the information available. However, see response to comment USEPA-4 for text of the revised Mitigation Measure 4.11-1. Also see responses to comments CURE-Fox-110 through CURE-Fox-112.

CURE-Fox-114 As stated in the first sentence of Mitigation Measure 4.11-1, CalAm would be required to have a qualified professional prepare the GHG Emissions Reduction Plan. However, the first sentence of the measure has been revised as follows to identify what would constitute a qualified professional:

Mitigation Measure 4.11-1: GHG Emissions Reductions Plan.

(a) ***Energy Conservation Technologies*****.** CalAm shall have a qualified professional (a licensed mechanical engineer or other appropriately certified professional approved by the CPUC) prepare and submit a GHG Emissions Reduction Plan (Plan) to the CPUC ~~and the Sanctuary~~ for approval prior to the start of project construction activities.

CURE-Fox-115 The CPUC would confirm that Mitigation Measure 4.11-1 (and all approved mitigation measures) is properly implemented and would ensure that reporting would be conducted pursuant to the MMRCP.

CURE-Fox-116 See response to comment USEPA-4 for text of the revised Mitigation Measure 4.11-1, which includes additional measures to reduce or offset project operational GHG emissions. With implementation of this measure, total project GHG emissions would be less than significant (including amortized annual construction emissions), and further mitigation related to construction emissions would not be required.

CURE-Fox-117 See response to comment CURE-Fox-116.

CURE-Fox-118 See response to comment CURE-Fox-116.

CURE-Fox-119 Community energy conservation and demand management programs such as those recommended in the comment require third party voluntary participation and agreements. As separate programs that would not be under CPUC or MBNMS jurisdiction or CalAm's control, the Lead Agencies could not guarantee a level of participation that would be required to achieve meaningful energy savings. For these reasons, this mitigation approach was eliminated from further consideration. See response to comment USEPA-4 for text of the revised Mitigation Measure 4.11-1, which includes additional measures to reduce or offset project operational GHG emissions. With implementation of this measure, the impacts related to GHG emissions would be less than significant, and the measure suggested in the comment would not be required.

CURE-Fox-120 See response to comment USEPA-4 for text of the revised Mitigation Measure 4.11-1, which includes additional measures to reduce or offset project operational GHG emissions, including the purchase and retirement of carbon offsets.

CURE-Fox-121 See response to comment CURE-Fox-119, which also applies to water conservation programs such as those recommended in the comment.

CURE-Fox-122 As explained in Section 4.11.2.2, State Regulations, this executive order does not contain any requirements that would have to be complied with directly by the proposed project; however, future actions taken by the State to implement the goals of Executive Order S-3-05 may affect the project, depending on the specific implementation measures that are developed.

For discussion of the ability of solar power to supply 100 percent of the project's electricity demand, refer to response to comment CURE-Fox-110. In addition to a solar plant, the comment recommends installation of a battery storage facility, which could increase the daily amount of available power from a solar plant by several hours. Assuming that a battery storage facility could double the amount of available electricity output associated with a solar power plant to 60 percent of the project electricity demand, the size of the solar plant would have to be over 126 acres in size, which would be equivalent to more than five times the size of the proposed MPWSP Desalination Plant. A solar plant of this size would have its own environmental and legal challenges that would be akin to a separate energy generation project, which the Lead Agencies do not consider to be fitting mitigation for this water supply project.

CURE-Fox-123 See response to comment CURE-Fox-27 for changes to Mitigation Measure 4.18-1 subsequent to the Draft EIR/EIS. Mitigation Measure 4.18-1 is sufficient as drafted; it identifies specific measures that CalAm (and its construction contractors) would be required to implement as part of the Construction Equipment Efficiency Plan. The measures include, but are not limited to, procedures to ensure that all construction equipment is properly tuned and maintained at all times; a requirement to provide options for worker carpooling; a commitment to utilize existing electricity sources where feasible rather than portable diesel-powered generators; and identification of procedures (including the routing of haul trips) that would be followed to ensure that all materials and debris hauling is conducted in a fuel-efficient manner.

The amount of electricity and indirect energy consumption that would be associated with construction of the project is currently unknown and cannot be estimated as it would be too speculative given existing data. (see Draft EIR/EIS, p. 4.18-15.) More important, the precise plan of construction as to timing of elements, sequencing, and the precise exact types of construction equipment to be employed, etc., cannot be known until the project is approved,

a contractor in is hired, and construction level plans are available. Therefore, it is premature to prepare a fully-developed construction equipment efficiency plan at this time. Deferral of the specifics of mitigation ("the details of exactly how mitigation will be achieved") is permissible so long as the mitigation measures commit the project applicant to mitigation and list alternatives to be considered, analyzed, and possibly incorporated into a mitigation plan. (*California Native Plant Soc. v. City of Rancho Cordova* (2009), 172 Cal.App.4th 603, 621; see also *City of Hayward v. Board of Trustees of the California State University* (2015) 242 Cal.App.4th 833, 855-856.)

CURE-Fox-124 In this context, a "qualified professional" is defined as a construction planner/energy efficiency expert (see Impact 4.18-1in EIR/EIS Section 4.18, Energy Conservation). The Lead Agencies disagree that a registered civil engineer would possess a more appropriate qualification than a construction planner/energy efficiency expert to prepare the mitigation plan.

CURE-Fox-125 For responses relative to the specific mitigation recommendations, see responses to comments CURE-Fox-126 through CURE-Fox-133, below.

CURE-Fox-126 See response to comment CURE-Fox-17.

CURE-Fox-127 See responses to comments CURE-Fox-15 and CURE-Fox-23.

CURE-Fox-128 See response to comment CURE-Fox-12.

CURE-Fox-129 As stated in Section 4.13.1.3, *Solid Waste Services*, all solid waste generated by project construction or operation would be disposed of at the Monterey Peninsula Landfill or diverted for recycling or reuse at the Monterey Materials Recycling Facility. The materials that would be targeted by operators at the materials recovery facility include paper, cardboard, bottles and cans, commercial waste, wood waste and yard waste, and construction and demolition debris. An additional mitigation measure to require reuse and recycling of construction and demolition waste is not warranted.

CURE-Fox-130 Mitigation Measure 4.10-1a, Equipment with High-Tiered Engine Standards, has been revised to include requirements for construction equipment to be alternatively powered, where feasible. Refer to response to Comment MBARD-1.

As described in the Air Quality Impact 4.10-1 conclusion, construction of the proposed project could contribute to an exceedance of a state and/or federal standard for ozone and NO_2 based on the estimated maximum daily mass emissions levels of NO_x. Therefore, use of biodiesel fuel is not considered to be viable mitigation to reduce project GHG emissions during construction because its exhaust can include NO_x emissions 20 percent higher than exhaust from

standard diesel fuel (Rincon, 2014), which would substantially increase the severity of the significant and unavoidable air quality impact. Furthermore, because amortized construction emissions associated with the project would only account for less than five percent of the total project GHG emissions, even if all construction-related GHG emissions could be avoided, the overall project emissions would continue to exceed the significance threshold (see EIR/EIS Table 4.5-5). Such a mitigation requirement would do little to reduce the significant GHG emissions impact, but could substantially increase the severity of the significant air quality impact. The mitigation recommendation has not been incorporated. See also response to comment USEPA-4 which contains the revised text of Mitigation Measure 4.11-1.

CURE-Fox-131 Identification of procedures (including the routing of haul trips) that would be followed to ensure that all materials and debris hauling is conducted in a fuel-efficient manner would already be required pursuant to Mitigation Measure 4.18-1, Construction Equipment and Vehicle Efficiency Plan (see Impact 4.18-1 in EIR/EIS Section 4.18, Energy Conservation).

CURE-Fox-132 Pursuant to the MMRCP that would be implemented for the project, the CPUC would be required to ensure that CalAm and its contractors effectively implement all mitigation measures. The CPUC would have an on-site third-party mitigation monitor that would note any problems with monitoring, notify appropriate agencies or individuals about any problems, and report the problems to the CPUC. In addition, pursuant the program, the CPUC would conduct tracking/reporting on the implementation of mitigation measures.

CURE-Fox-133 See response to comment CURE-Fox-27.

CURE-Fox-134 CalAm would not solicit construction contractors for the MPWSP until after the project has been approved. At this point in the planning and review process, information about the actual construction equipment (e.g., the years equipment engines were produced) is not available. However, equipment inventory assumptions for each project component, including equipment horsepower ratings, hours of equipment use, equipment fuel types, and construction phasing, have been estimated for the Draft EIR/EIS analysis and are included in EIR/EIS Appendix G.1, Air Quality and Greenhouse Gas Emissions Estimates.

CURE-Fox-135 See response to comment CURE-Fox-132. The requested changes to Mitigation Measure 4.18-1 are not warranted.

CURE-Fox-136 See responses to comments CURE-Fox-118 through CURE-Fox-135.

CURE-Fox-137 Predicted vibration levels presented in Table 4.12-10 of the Draft EIR/EIS were calculated using FTA equations for vibration propagation on pages 11 and

12 of their document *Transit Noise and Vibration Impact Assessment*, cited in EIR/EIS Section 4.12.

$$PPV_{equip} = PPV_{ref} \times (25/D)^{1.5}$$

where: PPV (equip) is the peak particle velocity in in/sec of the equipment adjusted for distance

PPV (ref) is the reference vibration level in in/sec at 25 feet

D is the distance from the equipment to the receiver.

Reference vibration levels at 25 feet were taken directly from FTA's Table 12-2 in the same document. As an example, for a Bore/Drill Rig the reference vibration level at 25 feet is 0.089 inches per second, as indicated in Table 4.12-10 of the Draft EIR/EIS. Applying this vibration level in the above equation yields a resultant vibration level at 50 feet (for the ASR-5 and ASR-6 wells) of 0.031 inches per second. All other values in Table 4.12-10 were calculated in a similar fashion.

CURE-Fox-138 While the analysis in Impact 4.12-3 of the Draft EIR EIS is accurate, the impact conclusion paragraph on Draft EIR/EIS page 4.12-48 summarized the analysis incorrectly and is amended as indicated below:

Impact Conclusion

Construction of the subsurface slant wells, MPWSP Desalination Plant, ~~Pipeline to the CSIP Pond, Brine Discharge Pipeline~~ and Source Water Pipeline would result in less-than-significant vibration impacts with regard to structural damage, and no impact with regard to human annoyance. Construction of the Castroville Pipeline, ASR-5 and ASR-6 Wells, ~~Terminal Reservoir,~~ ASR ~~Conveyance Pipeline, ASR Recirculation Pipeline, ASR Pump-to-Waste~~ Pipelines, Ryan Ranch-Bishop Interconnection Improvements, Carmel Valley Pump Station, and Main System-Hidden Hills Interconnection Improvements would result in less-than-significant vibration impacts with regard to both structural damage and human annoyance. There could be significant vibration impacts related to structural damage and human annoyance from construction of the ~~Castroville Pipeline and Source Water Pipeline, as well as~~ the new Desalinated Water Pipeline and new Transmission Main where trenchless construction methods are required for these pipelines. However, with implementation of the mitigation measures identified above, all significant construction vibration impacts would be reduced to a less-than-significant level.

Additionally, Table 4.12-10 has been revised to reflect that no historic structures are located within distances of concern along these pipelines and the threshold of 0.3 inches per second applies. Consequently, the references to Mitigation Measure 4.15-1a have been deleted from Section 4.12.

Mitigation Measure 4.12-3 establishes a performance standard for addressing potential vibration impacts related to human annoyance and building damage and provides numerous measures of achieving this standard. As a practical matter, reducing vibration from rollers to below the building damage threshold would involve a minor reduction from 3.1 PPV to 2.9 PPV, which could be achieved with alternative compaction methods in areas close to structures.

With respect to addressing human annoyance impacts, Mitigation Measure 4.12-3 identifies restriction of construction activities to daytime hours. Given that installation of sheet piles for a given trench pit would take only a few hours and compaction using rollers could also be completed in proximity to receptors in a few hours, human annoyance effects of vibration would not occur during times when most people sleep and would only be perceptible for a brief period of time, if at all.

CURE-Fox-139 See response to comment CURE-Fox-138.

CURE-Fox-140 The City of Monterey's Vibration Control Plan addresses vibration impacts on historic structures in the Spanish Royal Presidio, in the Monterey Old Town National Historic Landmark District, near historically significant buildings, and in the Presidio of Monterey Historic District. The proposed project would not be constructed in the vicinity of any of historic buildings or structures in the City of Monterey.

CURE-Fox-141 The suggested measure is already incorporated into Mitigation Measure 4.12-3 on page 4.12-48 of the Draft EIR/EIS.

CURE-Fox-142 The suggested alternative shoring method, as well as the suggested alternative compaction method described in comment CURE-Fox-145, has been added to Mitigation Measure 4.12-3, as indicated below:

a. Vibration monitoring shall be conducted for the first 500 feet of pipeline construction for each segment to confirm vibration levels do not exceed the above vibration threshold. If vibration levels exceed the limits of this mitigation measure, construction practices shall be modified to use smaller types of construction equipment or excavator-mounted compaction wheels, operate the equipment in a manner to reduce vibration, or use alternate construction methods (such as use of manual shoring jacks), and monitoring shall continue for an additional 200 feet or until construction practices meet the required vibration levels. The monitoring in this

mitigation measure shall be repeated if the construction methods change in a manner that would increase vibration levels, or when structures are closer to the limits of construction than previous vibration monitoring have confirmed is below the vibration thresholds.

CURE-Fox-143 The suggested mitigation measure is incorporated into Mitigation Measure 4.12-3 on page 4.12-48 of the Draft EIR/EIS but with an implementing distance standard that addresses non-historic structures.

CURE-Fox-144 The suggested mitigation measure does not apply to proposed use of rollers or sheetpile drivers that have been identified as potential sources of vibration impacts.

CURE-Fox-145 See response to comment CURE-Fox-142.

CURE-Fox-146 The suggested mitigation measure does not apply to the proposed project, which would not impact historic structures as indicated in Impact 4.15-1 of the Draft EIR/EIS.

CURE-Fox-147 Mitigation Measure 4.12-3 on page 4.12-48 of the Draft EIR/EIS already identifies a requirement for vibration monitoring. The proposed project would not impact historic structures, as indicated in Impact 4.15-1 of the Draft EIR/EIS.

CURE-Fox-148 The suggested mitigation measure is already incorporated into Mitigation Measure 4.12-3 on page 4.12-48 of the Draft EIR/EIS.

CURE-Fox-149 The suggested mitigation measure appears to be taken from a proposed scope of work, as identification of a specific manufacturer of seismograph is not a necessary component of the mitigation measure. The monitoring task could be adequately performed by a number of different available seismograph types.

CURE-Fox-150 See response to comment CURE-Fox-140.

CURE-Fox-151 See response to comment CURE-42. The New Monterey Pipeline was previously included as part of the proposed project. However, it is no longer part of the proposed project and no components of the proposed project would be constructed in the vicinity of any historic buildings or structures in the City of Monterey.

8.6.2.3 Responses to Comments from California Unions for Reliable Energy – Owens Letter

CURE-Owens-1 The Draft EIR/EIS includes a thorough description of the regional environmental setting in Section 4.6.1.3, Regional Terrestrial Biological Resources, and describes the regional significance. On page 4.6-7 of this section, the Draft EIR/EIS states, "Monterey County is situated at the confluence of the San Francisco Bay, Central Coast, and South Coast Range floristic provinces. As a result, the flora of Monterey County is some of the most diverse in California. Monterey County represents the southern and northern population range limits of many rare species endemic to the northern and southern portions of the state, respectively." The Draft EIR/EIS describes the existing biological resources present, or potentially present, in the project area and evaluates potential project and cumulative impacts on these resources as required by CEQA and NEPA.

CURE-Owens-2 As noted in the comment "*Where the effect of the potential conflict would be significant*, feasible mitigation is identified to resolve or minimize that conflict" (emphasis added). The impact analysis in Section 4.6.5 finds that not all "potential conflicts" identified at the screening level in Section 4.6.2.3 would result in significant impacts; therefore, not all require mitigation under CEQA and NEPA. As disclosed in Impact 4.6-4, the project would have impacts on resources that could meet Marina LCLUP's definition of primary and secondary habitat, including species identified in the LCLUP's list of sensitive species and others not on that list. The commenter correctly notes that CalAm would be required to comply with independently enforceable requirements of agencies with jurisdiction. Such requirements are indeed effective independent of any reference in an EIR/EIS. Nevertheless, Mitigation Measure 4.6-2a requires CalAm to consult with the CCC and local jurisdiction (e.g., City of Marina) to verify the extent of ESHA within or adjacent to portions of the proposed project within the Coastal Zone (see Final EIR/EIS Section 4.6,1.5 for a description of the identification process to date) as part of the process of obtaining a Coastal Development Permit(s), and Mitigation Measure 4.6-2b requires CalAm to implement avoidance, minimization, and compensation measures for impacts on ESHA and primary habitat. Restoration and mitigation activities required for compensation lands under Mitigation Measure 4.6-2b would be included in the Habitat Mitigation and Monitoring Plan (HMMP) (Mitigation Measure 4.6-1n) which CalAm must implement after developing and submitting to the appropriate resource agencies, including the CCC and local jurisdictions, for approval prior to project construction. The EIR/EIS's mitigation measures appropriately place the responsibility for interpreting the local coastal plan policies in the hands of the applicable jurisdiction(s) considering and approving a Coastal Development Permit, and stipulate that the project shall not move forward until CalAm has heeded that interpretation. See response to comment CURE-Owens-4 regarding protocol surveys.

CURE-Owens-3 See response to comment CURE-Owens-2. The Draft EIR/EIS does consider seaside painted cup (*Castilleja latifolia* ssp. *latifolia*) and Eastwood's ericameria (*Ericameria fasciculata*). See the discussion of Monterey coast paintbrush (*Castilleja latifolia*) and Eastwood's goldenbush (Ericameria fasciculata), respectively in Section 4.6.1.8, Special-Status Species, for a discussion of the potential for these species to occur in the project area. The Final EIR/EIS includes an analysis of potential impacts on globose dune beetle (*Coelus globosus*) and Salinas kangaroo rat (*Dipodomys heermanni goldmani*) in Section 4.6.5; these analyses do not identify any new or substantially more severe significant impacts compared to the Draft EIR/EIS.

CURE-Owens-4 EIR/EIS Section 4.6.1.2, Information Sources and Survey Methodology, describes the numerous biological field surveys that have been conducted within the project area between 2012 and 2016. These surveys include a combination of reconnaissance-level field surveys and focused and protocol-level surveys for some species. Over 60 days of field surveys were conducted by experienced professional biologists well-versed in the local flora and fauna and also experienced in the standards and data requirements for CEQA and NEPA compliance. The EIR/EIS evaluates the potential for special-status species and sensitive natural communities to occur within the project area based on the results of these numerous surveys as well as multiple other sources, including, but not limited to CNDDB records, USFWS records, CNPS records, and several biological reports prepared in the region. The EIR/EIS evaluates potential impacts on these sensitive biological resources based on their potential to occur. See Section 4.6.4, Approach to Analysis for a discussion of this impact analysis. Protocol-level surveys are not required for all CEQA/NEPA documents. For example, under CEQA, where there is sufficient, current information regarding biological resources to determine potential impacts on sensitive biological resources and develop mitigation measures, new protocol surveys would not be necessary. The fact that additional studies might be helpful does not mean that they are legally required. (See e.g., *Association of Irritated Residents v. County of Madera* (2003) 107 Cal.App.4th 1383.) Generally, NEPA requires high quality, accurate data with scientific integrity.

In response to a Public Records Act request, the GIS data and all field survey notes used to support the determinations regarding potential to occur and impact analysis were provided to Adams Broadwell Joseph & Cardozo on March 15, 2017.

Comments regarding the adequacy of mitigation measures for impacts on sensitive species are addressed below where the commenter provides further specificity.

CURE-Owens-5 See the response to CURE-Owens-4 in regard to the need for focused and protocol level surveys and to the approach to analysis. Section 4.6.1.8,

Special-Status Species, includes a general description of the location of the nearest occurrence record for each special-status species with a moderate to high potential to occur at the site. The Draft EIR/EIS does not rely solely on CNDDB occurrence records or results from the California Native Plant Society's (CNPS) Inventory of Rare and Endangered Species. Results from the CNDDB and CNPS information have been used, along with an evaluation of habitat conditions and life history of each special-status species, to determine whether a special-status species has potential to occur within the project area. Additionally, many observations of these species were documented as part of the multiple biological surveys conducted within the project area between 2012 and 2016, in part for the specific purpose of obtaining primary source data for analysis of the proposed project.

The entire Section 4.6, Terrestrial Biological Resources, includes a thorough description of existing conditions. Section 4.6.1, Setting/Affected Environment, provides a thorough description of the existing site conditions including vegetation communities and habitat types, sensitive natural communties, wetlands and other waters, wildlife movement corridors, special-status species, and critical habitat based on the surveys listed in Section 4.6.1.2, Information Sources and Survey Methodology. Section 4.6.1.8, Special-Status Species, includes a description of each special-status species with a moderate or high potential to occur in the project area and includes a description of where each species has been observed in or around the project area during the surveys listed in Section 4.6.1.2. All of these observations are included on maps and spreadsheets that are in the administrative record for this EIR/EIS. This information and the GIS shapefiles were sent to CURE on March 15, 2017. This information was used to evaluate the potential for species to occur in the project area, determine whether impacts would be significant, and recommend mitigation measures where necessary to reduce impacts to less than significant. The cited sentence in the comment, "The impact analysis described in this section is based on special-status species observations available to Environmental Science Associates (ESA) as of June 20, 2016," is not intended to be read as a citation to a specific study or reference. The meaning of this statement is that the analysis in the Draft EIR/EIS was based upon all materials *available to* ESA as of that date – those materials have been referenced and included in the administrative record as described above.

With regard to the wetland delineation, wetland delineation mapping has been conducted by AECOM as part of its biological surveys conducted in support of the project. As described on Draft EIR/EIS page 4.6-35 in Section 4.6.1.6, wetlands or waters potentially regulated by the USACE, RWQCB, and/or CCC were mapped in the project's study area during wetland mapping conducted by AECOM and other field studies conducted by ESA between 2012 and 2016. A wetland delineation report, based on some of these field surveys, has been

prepared and is referenced in the Final EIR/EIS. Additionallly, the USFWS National Wetland Inventory (NWI) was queried to identify wetlands and other waters within or adjacent to the study area. In the absence of a wetland verification by the USACE, RWQCB, and CCC, and based on the best available information from numerous surveys, the EIR/EIS conservatively assumes that all areas mapped as potential wetlands or waters during surveys conducted by ESA and AECOM between 2012 and 2016, by the NWI, and in the wetland delineation would be considered potentially jurisdictional by the USACE, RWQCB, and/or CCC. A wetland delineation will be submited to the USACE, RWQCB, and CCC as part of project permitting, which is separate from the CEQA/NEPA analysis. In response to this comment, the text in Section 4.6.1.6, Wetlands and Other Waters has been revised to clarify these assumptions. See the response to comment MCWD-134 for the revised text. Additionally, in response to this comment, the following text from Draft EIR/EIS pages 4.6-69 and 4.6-70 has been revised as shown:

> The occurrence potential for special-status species considers the habitat requirements and life history of the individual species, site-specific reconnaissance-level biological surveys (habitat assessments) of the project area, and focused and protocol-level surveys of special-status species at select facility locations as described in Section 4.6.1.2.

CURE-Owens-6 See responses to comments CURE-Owens-4 and CURE-Owens-5. If CDFW or USFWS require additional focused and protocol surveys for federal and/or state-listed species in support of permit approvals, CalAm will be required to conduct these surveys. These permitting approvals are separate from this CEQA/NEPA analysis.

CURE-Owens-7 See response to comment CURE-Owens-5. Results from the plant surveys described in Section 4.6.1.2, Information Sources and Survey Methodology, are included in the description for each special-status species with a moderate or high potential to occur in the project area in Section 4.6.1.8, Special-Status Species.

Mitigation Measure 4.6-1e provides appropriate and adequate measures to ensure that impacts on special-status plants are reduced to less than significant. This measure has been revised in response to comment CDFW-4. The revised measure would ensure that impacts on special-status plant species are reduced to less than significant regardless of the size the population. It stipulates that impacts on special-status plants shall be avoided where possible, and if impacts cannot be avoided, then measures to minimize impacts shall be implemented. Regardless of the number of plants, CalAm would be required to implement these avoidance and minimization measures. The revised measure includes compensatory mitigation requirements that would ensure 1:1 ratios for temporary impacts and 2:1 ratios for permanent impacts and performance

standards to ensure that the restoration areas have either similar cover or a similar number of species as the impacted area. Regardless of the size of the impact, compensatory mitigation would be provided at least twice the size of the impact area, and restoration areas would be required to have similar conditions to those in the area affected.

This measure does not rely on "last-minute" pre-construction surveys to document special-status plant occurrences nor does it rely upon an assumed presence of a special-status species. Rather, the measure requires that focused botanical surveys be conducted during the appropriate blooming period prior to ground disturbance to determine the presence and abundance of special-status species specific to that season or year. Implementing these surveys will ensure that special-status plants are accurately documented within the project area prior to construction, and mitigation applied in accordance with the performance standards outlined in adopted measures.

CURE-Owens-8 See response to comment CURE-Owens-4. Figures 4.6-2a through 4.6-2c include a list of species with CNDDB occurrence records in the project area. The exact locations of special-status species records are not included in this public document in accordance with the CNDDB Data Use Guidelines (2011). Per the CNDDB Data Use Guidelines, "the concern is that, while it is important that the CNDDB information is available to those whose job it is to conserve species, there is the very real possibility that some people will use the detailed location information to do harm to a species or its habitat. Because of the sensitivity of the data, we try to limit the level of location detail that is made readily available to the public." In response to this comment, Figures 4.6-2a through 4.6-2c have been revised to include the CNDDB disclaimer.

Section 4.6.1.8, Special-Status Species, includes a general description of the location of the nearest occurrence record for each special-status species with a moderate to high potential to occur at the site.

CURE-Owens-9 The conservation status of western snowy plover is acknowledged in EIR/EIS Section 4.6.1.8, Special-Status Species. As described on page 4.6-2 of the Draft EIR/EIS, ESA requested western snowy plover occurrence data within the project area from Point Blue Conservation Science (i.e., data not published in their annual report), but Point Blue Conservation Science has not provided this data because they have not received authorization from CEMEX to share data specific to the CEMEX property with the Lead Agencies. This remains accurate as of publication of the Final EIR/EIS. In the absence of this information, ESA has relied on multiple western snowy plover resources to describe the status of western snowy plover in the project area. These resources are cited on Draft EIR/EIS page 4.6-50 in Section 4.6.1.8 and

include a Point Blue Conservation Science Publication, *Nesting of the Snowy Plover in the Monterey Bay Area, California in 2015* (a more recent version of the 2012 report cited in the comment's footnote 41), unpublished western snowy plover monitoring data provided in the *Technical Memorandum Biological Resources Assessment MPWSP Exploratory Borings Program Package 1 – CEMEX Active Mining Area*, as well as a letter from Kriss Neuman, Waterbird Ecologist, Point Blue Conservation Science, describing historic western snowy plover nest observations in the backdunes of the CEMEX active mining facility. All materials referenced in the Draft EIR/EIS were made available to the public during the public review period for the Draft EIR/EIS. The Final EIR/EIS relies on all of this information to acknowledge the high potential for this species to nest and winter in and around the project area. See the response to comment CURE-Owens-4, which explains that CEQA and NEPA do not require protocol-level surveys. The EIR/EIS provides sufficient information, based on the best available information, regarding the status of western snowy plover in the project area to adequately determine potential impacts on this species. Impacts are acknowledged to be potentially significant, and effective, multi-faceted mitigation measures are recommended to reduce these impacts.

Note that permitting under laws such as the federal Endangered Species Act (FESA) is a separate process from the CEQA and NEPA process and is being undertaken by CalAm and permitting agencies (e.g., USFWS) concurrent with and following CEQA and NEPA review. The Lead Agencies anticipate that the permitting process will result in additional specific mitigation requirements, and Mitigation Measure 4.6-1d, item 1, requires compliance with all avoidance and minimization measures required by USFWS as part of the FESA Section 7 consultation between the ONMS and USFWS, in addition to the actions specified in this mitigation measure.

CURE-Owens-10 See the response to comment CURE-Owens-4, which explains that CEQA and NEPA do not require protocol-level surveys. The Draft EIR/EIS references construction of the test slant well as an example of a similar, albeit smaller, project that has been implemented in the same project area and that used some of the same construction methods as would the proposed project. This example demonstrated that for the smaller-scale test slant well project, take of western snowy plover was avoided. The Draft EIR/EIS acknowledges that the scope of work for the test slant well is smaller than the scope of work for the proposed project. The revised Mitigation Measure 4.6-1d provides measures to reduce impacts from the proposed project and takes into account the scale of the proposed project.

The Draft EIR/EIS provides a description of the number of western snowy plovers in the breeding population in the Monterey Bay for context. In response to this comment, the Final EIR/EIS has been revised to include the

number of nests observed in the Marina subregion in 2015 and 2016. This information is based on breeding season surveys conducted along the beach, west of the project area. While protocol-level breeding season surveys have not been conducted within the project area, Mitigation Measure 4.6-1d requires CalAm to engage a qualified biologist to perform one year of surveys during the nesting season preceding construction. Additionally, the number and location of nests fluctuates year to year, so future predictions on the number of plovers that may occur within the project disturbance area during future construction are based on estimates. The EIR/EIS uses the best available information to analyze impacts and provide mitigation to reduce impacts to less than significant. This is based on the approach to analysis as described in Section 4.6.4.

CURE-Owens-11 The locations and primary constituent elements of western snowy plover critical habitat are described on Draft EIR/EIS pages 4.6-68 and 4.6-69. The EIR/EIS evaluates potential impacts on western snowy plover critical habitat and requires implementation of mitigation measures to reduce potential impacts to less than significant. See Impacts 4.6-2 and 4.6-7, which evaluate impacts, including direct and potential indirect impacts from foot traffic outside the construction area, trash and debris from construction, and/or the spread of invasive species, on snowy plover critical habitat that may result from construction of the subsurface slant wells (Draft EIR/EIS page 4.6-187) and Source Water Pipeline (Draft EIR/EIS page 4.6-190). These are the only project components that would have the potential for indirect impacts on snowy plover critical habitat. As stated on Draft EIR/EIS page 4.6-68, portions of the new Transmission Main and new Desalinated Water Pipeline alignments are located a minimum of 0.2 to 0.6 mile (1,000 to 3,000 feet) from snowy plover critical habitat. As shown on Figure 4.6-3, the closest portion of these pipelines to snowy plover critical habitat is an approximately 2-mile portion of the new Transmission main that would be located west of Highway 1 along the Transportation Agency for Monterey County (TAMC) right-of-way. Dunes separate the TAMC right-of-way from the snowy plover critical habitat (located on the beach) in this location, providing visual and topographical separation between the critical habitat and proposed construction activities, in addition to the 1,000-foot distance. Along other portions of these pipeline alignments, the distance to critical habitat is greater and intervening roadways (e.g., Highway 1) provide additional separation. No indirect effects on snowy plover critical habitat are anticipated from the new Transmission Main or new Desalinated Water Pipeline.

CURE-Owens-12 The Draft EIR/EIS acknowledges that loss of western snowy plover habitat (both breeding and wintering) and impacts on individual breeding and wintering birds would be a potentially significant impact. Construction impacts on western snowy plover are described in Impact 4.6-1, construction

impacts on western snowy plover critical habitat are described in Impact 4.6-2, operational impacts on western snowy plover are described in Impact 4.6-6, and operational impacts on western snowy plover critical habitat are described in Impact 4.6-7. Within those impact discussions, the proposed mitigation measures to reduce impacts on western snowy plover, including impacts on individuals and on habitat, to less than significant include Mitigation Measures 4.6-1a through 4.6-1d, 4.6-1n, 4.6-1p, 4.6-2b, 4.12-1b, and 4.14-2. Several of these measures have been revised to provide clarification or for consistency with permitting applications. The revised measures are provided in Final EIR/EIS Section 4.6.

Implementation of the measures described above would ensure that impacts on western snowy plover, including breeding and wintering birds, are reduced to less than significant. The revised Mitigation Measure 4.6-1d specifically requires that work be conducted during the non-breeding season if feasible and if it is not feasible, then measures would be implemented to avoid and minimize impacts on nesting birds. For work in the non-nesting season, measures will be implemented to avoid direct impacts on western snowy plover. Additionally, the measure specifies clear compensatory mitigation and performance standards for loss of habitat. As described in Impact 4.6-6, periodic maintenance of the subsurface wellsevery 5 years is assumed to result in a permanent loss of approximately 6 acres of habitat, because this area of habitat would be subject to repeated disturbance. Per revised Mitigation Measure 4.6-1d, this would be compensated at a minimum 3:1 ratio and would reduce the impact from the loss of western snowy plover habitat to less than significant.

In response to this comment, the following text revisions have been made in the “Subsurface Slant Wells” subsection of Impact 4.6-1 in Section 4.6.5.1:

> The 9-acre construction footprint for the subsurface slant wells is located within potential nesting habitat and construction of the nine subsurface slant wells and conversion of the test well to a permanent production well ~~during the breeding season~~ would result in the temporary loss of 8.0 acres (for temporary construction disturbance to areas that would be restored) and permanent loss of 1.0 acre (for new permanent above-ground facilities) of potential ~~wintering~~ habitat.

In response to this comment, the following text revisions have been made in the “Source Water Pipeline” subsection of Impact 4.6-1 in Section 4.6.5.1:

> Construction work within the western end of the proposed Source Water Pipeline would result in the temporary (since the construction area would be returned to pre-construction conditions and birds may breed in the area following construction) loss of approximately 0.2 acre of potential ~~nesting~~ habitat (some of this area may overlap with the impact area for the

subsurface slant wells as described above), a significant impact. The remainder of the Source Water Pipeline would be constructed away from the beach and foredunes where plovers typically nest and would not result in the temporary loss of plover ~~breeding~~ habitat.

CURE-Owens-13 In response to this comment, Mitigation Measure 4.6-1d has been revised to clarify the performance standards that CalAm must meet to obtain approval for work that cannot be completed during the non-nesting season. These performance standards would ensure that even if work extends into the breeding season (in instances where drilling is partially complete at the end of the non-breeding season and cannot be suspended until the next non-breeding season), avoidance and minimization measures will be implemented to ensure that nesting snowy plovers would not be significantly impacted. For wintering plovers, Mitigation Measure 4.6-1d has been revised to include a performance standard to ensure that plovers are not directly impacted by construction by implementing avoidance and minimization measures. Once the project has advanced beyond the preliminary design phase and the development of construction-level plans make it practicable to do so, then appropriate site-specific avoidance and minimization measures shall be determined and submitted to the Lead Agencies and USFWS for review and approval in final design submittals as required by Mitigation Measure 4.6-1d Subpart 3a, and implemented when determined to be necessary under Subparts 3d and 3e of this measure. Additionally, the selection and placement of these measures would vary depending on the exact location or the number of western snowy plovers present in the work area, their relation to existing vegetation and topography, individual sensitivity, weather conditions, etc., none of which can be known at this time. The process by which CalAm would identify feasible measures during final design, and obtain concurrence from lead and permitting agencies, has been clarified in revised Subpart 3a of Mitigation Measure 4.6-1d. The Lead Agencies have no authority over USFWS permitting or enforcement actions. However, regardless of any measures that are required as part of the permitting process, CalAm will still be held to the measures and performance standards described in Mitigation Measure 4.6-1d; the most stringent measures and performance standards will prevail whether they are EIR/EIS mitigation measures or permit conditions. Regarding the comment's claim that the permitting agencies may be pressured to authorize work during the breeding season, this portion of the comment does not address this specific project or the adequacy or accuracy of the Draft EIR/EIS; regardless, the underlying premise has been addressed by the revisions to Mitigation Measure 4.6-1d, which identify specific criteria and performance standards to apply both during breeding and non-breeding seasons.

Contrary to the commenter's claim, the Draft EIR/EIS does not conclude that impacts on western snowy plover by development of their habitat would be

avoided due to the fact there is abundant habitat nearby for them to relocate, forage, and breed. Rather, although the Draft EIR/EIS describes on page 4.6-129 and 4.6-130 that the abundance of suitable wintering habitat north and south of the site may provide alternative wintering habitat for the short-term, temporary displacement of wintering birds during construction, temporary and permanent impacts on wintering birds and western snowy plover habitat are nonetheless found to be potentially significant. Implementation of Mitigation Measure 4.6-1d would reduce impacts to western snowy plover habitat (both wintering and breeding) to less than significant. The text of the impact analysis has been revised to clarify this impact. See CURE-Owens-12 for this revised text.

CURE-Owens-14 The Draft EIR/EIS analyzes the potential direct and indirect impacts described in this comment in Impact 4.6-1 and Impact 4.6-6, and cumulative impacts are addressed in Impact 4.6-C. As described in these impact analyses, implementation of Mitigation Measures 4.6-1a, 4.6-1b, 4.6-1c, and 4.6-1d (as revised in the Final EIR/EIS, where applicable) would ensure that direct and indirect impacts on western snowy plover from human disturbance would be reduced to less than significant. These measures have been designed to ensure that a biological monitor will oversee construction, construction will be limited to the project boundary, a trash abatement program will be implemented to reduce the attraction of predators, nesting surveys will be conducted if work will occur during the nesting season, pre-construction surveys will be conducted, and other measures will be implemented to ensure that work would not cause an adult to abandon an active nest or young, change an adult's behavior so it could not care for an active nest or young, or directly impact individual plovers. The comment does not address the adequacy of these mitigation measures. The significance threshold used in this EIR/EIS to determine if impacts on special-status species would be significant is described in Section 4.6.4, Approach to Analysis. As stated therein, CEQA Guidelines Section 15065 directs lead agencies to find that a project may have a significant effect on the environment if it has the potential to substantially reduce the number or restrict the range of an endangered, rare, or threatened species. "Substantial" is further defined in Section 4.6.4 as a function of the magnitude or intensity and duration of the impact, rarity and context of the affected resource, and susceptibility of the affected resource to disturbance. These factors have been used to determine that project impacts on western snowy plover would be significant, as well as to determine that with implementation of avoidance and minimization measures required in the mitigation measures listed above, impacts would be reduced to a less-than-significant level.

CURE-Owens-15 The information provided in this comment (summarizing case studies of how human activities affect western snowy plover) has been reviewed and considered by the EIR/EIS preparers. It does not present new information that would affect the impact analysis and significance conclusions in Section 4.6,

Terrestrial Biological Resources, because the analysis in that section already acknowledges the potential for human activities to adversely affect plovers and their habitat. Specifically, Impact 4.6-6 concludes that project construction and ongoing maintenance would result in the permanent loss of up to 6 acres of western snowy plover habitat. The proposed project would not have an effect related to recreational use of the project site or adjacent areas.

CURE-Owens-16 This comment is a summary of comments CURE-Owens-11, CURE-Owens-12, CURE-Owens-13, and CURE-Owens-14. See the responses to those comments above.

Additionally, the commenter asserts that future development of the HMMP as part of mitigation is improper. Mitigation Measure 4.6-1d has been revised to include specific performance standards and compensation requirements that will be fully incorporated and described in the HMMP. The HMMP is described in Mitigation Measure 4.6-1n. Once the design has progressed beyond the preliminary design phase and the development of construction-level plans make it practicable to do so, the exact avoidance and minimization measures (among those listed in Mitigation Measure 4.6-1d, Subpart 3a) would be determined in consultation with the Lead Agencies and USFWS based on the exact impact area (see revised Mitigation Measure 4.6-1d for clarification of this process). CEQA and NEPA do not require a plan to be prepared prior to project approval if the mitigation measure includes performance standards and monitoring requirements and it is in impractical to prepare the plan prior to approval.

CURE-Owens-17 Comments regarding the lack of conservation strategies for western snowy plover in plans and policies adopted by the City of Sand City are beyond the scope of the proposed project, which would not be subject to Sand City plans and policies in any event. Similarly, comments regarding the lack of compliance with USFWS recommendations by cities and developers of other projects are also beyond the scope of the proposed project. As described in EIR/EIS Section 4.1.7, CEQA and NEPA require that an EIR/EIS cumulative impacts analysis consider the combination of the individual effects of two or more projects. Thus, the cumulative analysis for impacts on western snowy plover focuses on the physical environmental impacts of projects in the cumulative scenario, in combination with the physical environmental impacts of the proposed project.

CURE-Owens-18 The revised Mitigation Measure 4.6-1d requires that permanent loss of western snowy plover habitat be compensated at a minimum ratio of 3:1 and states that compensation may be in the form of on-site or off-site creation, restoration, enhancement, or preservation of habitat for western snowy plover. As described in Impact 4.6-1 and 4.6-6, implementation of this mitigation measure, as well as other mitigation measures, would reduce potential impacts on western snowy

plover to less than significant and no additional mitigation is required. As described in Impact 4.6-C, the incremental effects of the MPWSP would not result in a significant cumulative effect on western snowy plover.

CURE-Owens-19 The technical basis for the claims made in this comment are not clearly explained so this response provides clarification regarding the MPWSP slant well source water and the potential for slant wells to impact the groundwater available to the dune plants. The source of the fresh water available to the dune plants is precipitation and moisture from fog, which infiltrates into the dune surface and remains perched within the upper dune sand sediments. As indicated by the measurements of the groundwater level underlying the CEMEX area (see Appendix E-3), the brackish groundwater in the Dune Sands Aquifer that would contribute to the MPWSP slant well feedwater is 20 to 35 feet below the surface of the dunes. The perched freshwater available to the dune plants is not thought to be in hydraulic connection with the brackish Dune Sand Aquifer and water surface fluctuation in the aquifer would not translate to the upper perched freshwater. Furthermore, the slant wells have solid casing under the dunes with the screened sections beginning deeper and towards Monterey Bay so the slant wells screens would not pull on and capture the fresh water perched in the upper regions of the dunes. While the temporary localized disturbance of the dunes during construction and maintenance of slant wells is anticipated, as discussed in Section 4.6.5.1, Construction Impacts, and Section 4.6.5.2, Operational and Facility Siting Impacts, long-term operations of the slant wells would not directly affect the dune hydrology or intercept the naturally perched fresh water available to the dune plants.

CURE-Owens-20 CalAm would be required to implement all mitigation measures that become requirements in any permits or authorizations. This would include respecting the authority of the Lead Biologist, or other biological monitors, to stop work in accordance with provisions of adopted mitigation measures. Regarding the comment's claim that the biological monitors may be pressured by construction contractors, this portion of the comment does not address this specific project or the adequacy or accuracy of the Draft EIR/EIS. The comment correctly states that a project applicant (i.e., CalAm) has the authority to oversee its contractors; simultaneously, CalAm would have the legal responsibility to successfully carry out mitigation requirements, and the CPUC has the authority to enforce these measures. As the CEQA Lead Agency, CPUC proposes mitigation measures in this EIR/EIS, not CalAm. The assurance of the Lead Biologist's and biological monitors' authority to stop work or otherwise carry out their responsibilities in the mitigation measures, including reporting of violations, also is under the enforcement authority of the CPUC.

In response to this comment, Mitigation Measure 4.6-1a has been revised to clarify that

> "Work shall proceed only after the construction-related hazards to special-status species and habitats are removed and, if a special-status wildlife species is present, work shall proceed only if the species is no longer at risk of injury or death."

Further, in response to this comment and others, Subpart 10 of Mitigation Measure 4.6-1c has been revised to clarify that

> "If special-status wildlife species are found on the site immediately prior to construction or during project construction, construction activities shall cease in the vicinity of the animal until the animal moves on its own (if possible, as determined by the Lead Biologist or biological monitor) outside of the project area ~~(if possible)~~."

It is not practical to stipulate at what point it would be possible for an animal to move of its own volition. This would depend on the health and status of the animal and site conditions, which cannot be predicted. Further, Subpart 10 of Mitigation Measure 4.6-1c has been revised to clarify that avoidance, minimization, and relocation requirements for specific resources are provided in resource-specific mitigation measures and shall be followed (e.g., Mitigation Measure 4.6-1f describes the relocation requirements for Smith's blue butterfly, while Mitigation Measure 4.6-1h describes the relocation (exclusion) requirements for western burrowing owl).

CURE-Owens-21 See responses to comments CURE-Owens-4 and CURE-Owens-5 regarding the need for protocol surveys and where in the EIR/EIS the results from completed surveys and other sources of information are presented. See response to comment CURE-Owens-7 regarding the adequacy of Mitigation Measure 4.6-1e, as revised.

CURE-Owens-22 See response to CURE-Owens-4 regarding protocol surveys. Multiple biological surveys have been conducted within the project area (see Section 4.6.1.2, Information Sources and Survey Methodology). All occurrences of the host plants for Smith's blue butterfly observed in the project area during the surveys conducted in Section 4.6.1.2, as well as from other relevant biological resources documents, are described in Section 4.6.1.8.

Subpart 1 of Mitigation Measure 4.6-1f does not inappropriately defer mitigation. It does state that CalAm would be required to implement all avoidance and minimization measures imposed by USFWS, through its Biological Opinion, to comply with the Federal Endangered Species Act (FESA). CalAm would be bound to comply with FESA whether this item is listed in the measure or not. Mitigation Measure 4.6-1f does not rely solely on compliance with USFWS avoidance and minimization measures, but includes avoidance, minimization, and compensation measures in Subparts 2 through 5 to reduce impacts on Smith's blue butterfly to less than significant.

Subpart 2 of Mitigation Measure 4.6-1f does not innappropriately defer mitigation and does not prevent a thorough analysis of mitigation efficacy. This measure requires that plants be mapped and avoided where possible, and where they cannott be avoided, the measure includes minimization and compensation requirements subject to specific, enforceable performance standards to reduce the impact to less than significant.

Mitigation Measure 4.6-1f requires a minimum 2:1 compensation ratio for permanent impacts on habitat. Subpart 5 of this measure has been revised to specify performance measures for compensatory mitigation.

Although the commenter suggests that the measure limit work to outside of the Smith's blue butterfly flight season based on a recommendation in the USFWS 1984 Smith's Blue Buttefly Recovery Plan (USFWS, 1984), a recent Programmatic Biological Opinion prepared by USFWS for Highway 1 Management Activities that Affect the Smith's Blue Butterfly (USFWS, 2008) does not contain a similar measure, and so it has not been incorporated into EIR/EIS mitigation. USFWS did not provide any comments on the inadequacy of the Draft EIR/EIS or any of the mitigation measures; however, Subpart 1 of Mitigation Measure 4.6-1f specifies that CalAm and its construction contractor(s) shall implement all measures required by USFWS in its Biological Opinion; therefore, if USFWS determines that the 1984-era recommendation is applicable to this project and includes it in the Biological Opinion, CalAm will be required to implement it.

Although Impact 4.6-1 does not include the exact number of plants that would be impacted, it describes the approximate acreage of Smith's blue butterfly that would be impacted by construction, which is sufficient to describe the impacts and determine appropriate mitigation. The revised Mitigation Measure 4.6-1d includes performances standards that would ensure that mitigation areas have either similar cover or number of host plants to the impact area.

CURE-Owens-23 See response to comment CURE-Owens-4 regarding focused surveys. Mitigation Measure 4.6-1g requires that a qualified biologist conduct focused pre-construction surveys for black legless lizard, silvery legless lizard, and coast horned lizard to identify these species and, if present, relocate them outside of the project area. These surveys include walking transects for visual coverage specifically to identify coast horned lizard and hand raking soil and leaf litter specifically to identify legless lizards. The commenter does not describe or include a citation with information describing other habitats that these species may forage and move within beyond those recognized in the Draft EIR/EIS (the cited resources pertain to desert habitats not present at the project site). The Lead Agencies and the qualified biologists among their EIR/EIS consultants have described the habitats in the project area known to be used by these species based on the accounts and information cited in the EIR/EIS and consider the

EIR/EIS descriptions and analyses of these species to be adequate and supported by substantial evidence. The commenter insinuates that visual surveys may not adequately detect coast horned lizard. Coast horned lizard is designated a species of special concern by CDFW. CDFW does not provide a survey protocol for this species. In the absence of a standard survey protocol for this species, the Draft EIR/EIS has incorporated a survey protocol based on this species life history, EIR/EIS consultant's experience surveying for this species, and mitigation measures that have been approved for other similar projects. Based on the above, visual surveys have been proposed to identify coast horned lizard during pre-construction surveys for this species.

Regarding the relocation plan, see response to comment MCWD-120.

Mitigation Measure 4.6-1c has been revised to prohibit the use of insecticide.

CURE-Owens-24 Mitigation Measure 4.6-1i has been revised to include a measure for continuous monitoring, and if continuous monitoring is not feasible, then a no-disturbance buffer shall be maintained. This measure has been revised per the recommendation from CDFW, the entity that oversees the California Fish and Game Code, which protects nests or eggs of any bird, hawks, and owls. USFWS typically does not require pre-construction nesting survey reports. Mitigation Measure 4.6-1i includes avoidance and minimization measures to avoid take of birds protected under the Migratory Bird Treaty Act. A take permit would not be required if take is avoided. To allow for the remote possibility that the applicant may require a take permit, Mitigation Measure 4.6-1i has been revised.

If a bird initiates a nest within the vicinity of a construction activity that was started in the non-breeding season, it is common, accepted practice to assume that the bird is acclimated to that same type of construction activity. Subpart 3 of Mitigation Measure 4.6-1i has been revised to clarify that no surveys are required as long as a similar type of construction continues.

CURE-Owens-25 As described in Mitigation Measure 4.6-1n, the HMMP itself would not address the need for compensatory mitigation. Rather, compensatory mitigation requirements and ratios for permanent impacts on special-status species and sensitive natural communities are described in the revised species- and sensitive natural community-specific mitigation measures listed in Impacts 4.6-1 and 4.6-2. These measures, as revised, also include clarification of performance standards and monitoring durations. The HMMP required under Mitigation Measure 4.6-1n would include all of these requirements in a comprehensive plan.

CURE-Owens-26 The Draft EIR/EIS requires several measures to ensure that impacts on black legless lizard, silvery legless lizard, and coast horned lizard are reduced to less than significant. Mitigation Measure 4.6-1a requires a qualified biologist or

qualified biological monitor to be onsite during all fencing and ground disturbance activities to monitor for special-status species; in the event that several monitors are needed to cover the active construction sites, CalAm would be required to provide for this need. Subpart 9 of Mitigation Measure 4.6-1c requires installation of exclusion fence around all areas where special-status reptiles have potential to occur to ensure that these species do not enter the project construction area, including roadways within construction areas where shown in Chapter 3 figures. Subpart 10 of Mitigation Measure 4.6-1c requires that if any special-status wildlife species is observed in the project area, work shall be halted, and the animal either be allowed to move on its own or be relocated. Mitigation Measure 4.6-1g requires extensive pre-construction surveys to identify any special-status lizards within the work area and requires development and implementation of a relocation plan to identify suitable locations to relocate any special-status lizards observed in the work area. Per Mitigation Measure 4.6-1g, the relocation sites would be assessed to determine that they are not overpopulated and have suitable habitat conditions, which would facilitate success of relocation efforts. Traffic would be restricted by limiting vehicle speeds to 15 miles per hour on roads within the project sites, as described in subpart 3 of Mitigation Measure 4.6-1c. These measures are consistent with the commenter's recommendations, do not constitute deferred mitigation, and would avoid and minimize impacts on special-status lizards.

CURE-Owens-27 As defined in EIR/EIS Section 4.6.1.7, wildlife movement corridors "link together areas of suitable wildlife habitat that are otherwise separated by rugged terrain, changes in vegetation, or by areas of human disturbance or urban development." As the commenter states, some wildlife species utilize agricultural and developed areas. However, these types of habitats do not serve as unobstructed or undisturbed wildlife movement corridors for the majority of wildlife species. The presence of human disturbance, including tilling, cultivation of crops, harvesting, paving, grading, traffic, recreation, etc., will separate less disturbed areas and limit wildlife movement between these areas. As described in 4.6.3, Evaluation Criteria, the majority of the site is within or adjacent to developed or disturbed areas that do not serve as wildlife movement corridors, or are already in an impaired state. Since the majority of the work would occur within these developed or disturbed areas, the majority of work would only create short-term temporary impacts, and this work would be implemented in segments, the project would have no impact on migratory wildlife corridors and no mitigation is required.

CURE-Owens-28 The EIR/EIS acknowledges that the proposed project would conflict with the City of Marina's LCLUP policies governing protection of Primary and Secondary Habitats. See Impact 4.6-4.

8.6.2.4 Responses to Comments from California Unions for Reliable Energy – Sobczynski Letter

CURE-Sobczynski-1 The potential for impingement of organisms or fine particulate matter on the seafloor is evaluated in Impact 4.5-4 in the EIR/EIS. While various experts may have different methodologies and conclusions on infiltration rates at particular locations along a well's screen, the purpose of the analysis of Impact 4.5-4 is to determine the potential for the impingement of marine organisms or fine organic matter on the seafloor, or changes to soft substrate habitat, as a result of proposed project pumping.

While the California Ocean Plan notes that subsurface intakes collect water through sand sediment, which acts as a natural barrier to organisms and thus eliminates impingement and entrainment, EIR/EIS Section 4.5.5.2 explains that a key and fundamental concern about desalination facilities is the potential for impingement and entrainment of marine organisms during the intake of seawater. The Lead Agencies independently calculated the infiltration rate of the slant wells at the seafloor in Impact 4.5-4, assuming only the seafloor seaward of Mean High Water (MHW) would be affected. The commenter introduces a series of variables that could affect the calculation of the infiltration rate – including the location of the submersible pump in the well column, the sediment profile, the use of inflatable packer(s), and clogging in the seabed – to support a conclusion that the Draft EIR/EIS underestimates the infiltration rate.

It is correct that the pump would be located in the upper third of the well (approximately 300 to 400 feet inland from MHW in 2020), and water would flow through the Dune Sands and 180-Foot Equivalent (FTE) Aquifers (aka Terrace Deposits) at different rates (see EIR/EIS Appendix E1). The EIR/EIS does not address the use of inflatable/deflatable packers in the production wells since unlike the test slant well, inflatable packers are not included in the proposed project.

The commenter notes that the shallower section of the slant wells would pump from older dune sands (Dune Sand Aquifer) and the deeper section of the slant wells would pump from the deeper Terrace Deposits (180-FTE Aquifer) and states this sediment profile was not accounted for in the model. However, the sediment profile from which the slant wells would pump from is shown in Figure 4.4-3. The existing Test Slant Well is shown as pumping from both geologic units and the proposed slant wells would also be constructed across and pump from both units. Although the materials of both units are expected to be highly permeable, the shallower dune sand unit is expected to be more permeable than the deeper terrace deposits. As discussed in Appendix E2, the modeling takes this into account by assigning a higher hydraulic conductivity to the Dune Sand relative to the Terrace Deposits. The North Marina Groundwater Model (NMGWM) assigns a hydraulic conductivity of 150 feet per day to the Dune

Sand Aquifer and 50 feet per day to the 180-FTE Aquifer, as listed on Table 5.1 of Appendix E2. As a result, the modeling indicates that the ratio of water sources from the dune sand to terrace deposits is anticipated to be 66/34 percent, also listed in Table 5.1.

Several of the comments on clogging in the seabed challenge conclusions drawn by Williams 2015, which is a presentation Dr. Williams gave at the International Desalination Association World Congress on Desalination and Water Reuse. The commenter also makes repeated references to Williams 2010 and Jenkins 2010, both of which were prepared in support of the 2016 California Ocean Plan amendment, and address the Doheny Ocean Desalination Project and the Dana Point Test Well, and not the MPWSP. However, the EIR/EIS referred to but did not rely directly on Williams 2010, Jenkins 2010, or Williams 2015 for the impact analysis.

The commenter concludes that the EIR/EIS-calculated infiltration rate of 0.011 to 0.016 millimeters per second (mm/sec) underestimates the infiltration rate at the seafloor and thus underestimates the potential for clogging on the seafloor. When each factor introduced by the commenter is considered, the commenter asserts that the infiltration rate of a 19-degree slant well would be 0.16 mm/sec at its peak above the submersible pump, and 0.01 mm/sec at the well bore end. The commenter also opines that the infiltration rate for a proposed 14-degree angle slant wells would be 0.48 mm/sec but does not state if this rate would be over the pump or at the well bore end; it is assumed he meant inside or adjacent to the well casing. The commenter apparently concludes that his estimate of 0.48 mm/sec directly over the well pump would also occur at the seabed/ocean interface. Regardless of what the infiltration rate is at the pump, the infiltration rate at the seabed/ocean interface would be less since the pressure exerted by the pump at any given point in three-dimensional space would decrease with increasing distance from the pump. As an example, a vacuum cleaner will exert noticeable suction on your hand if held close to the nozzle but much less noticeable suction if held a few feet away. Similarly, the variable pressure distribution inside and next to the slant well will make little noticeable difference farther away from the slant well. Instead, the pressure created by the pump would generally radiate out in all directions, preferentially pulling in water along the paths of least resistance. Since the distance to open water without the restriction of sediment is to the ocean, the majority of flow will come from the ocean.

The EIR/EIS presents the swimming speeds of plankton, invertebrates, and larval fish in Table 4.5-8, which range from 0.2 mm/sec to 600 mm/sec, with all but phytoplankton and protozoa having swimming speeds above 0.5 mm/sec. The EIR/EIS concludes that "studies of invertebrate plankton have found swimming speeds substantially exceed the estimated vertical infiltration rate for the MPWSP slant wells (see Table 4.5-8) by several orders of magnitude. Therefore, no impingement from slant well operations is expected to occur." If the infiltration

rate reached levels calculated by the commenter at the well bore end, the conclusion drawn in the EIR/EIS would still be the same since an infiltration rate of 0.01 mm/sec would be exceeded by swimming speeds. The infiltration rate of 0.48 mm/sec calculated by the commenter for a well at 14 degrees would also be (marginally) exceeded by swimming speeds; if that infiltration rate were to occur above the well pump, it would be several hundred feet inland of MHW, as previously established, and impingement would not occur at all due to the inland location. Thus, clogging of the seafloor due to the impingement of plankton, invertebrates, and larval fish would not occur.

The same holds true for the potential impingement of organic matter on the seafloor. As the Draft EIR/EIS states on page 4.5-53, "normal wave generated water velocities at the seafloor locations of the slant wells is predicted to be 8 to 20 times greater than that required for fine-grained material to accumulate on the sea floor over the subsurface slant wells. As a result, there would be no potential for the impingement of fine organic matter on the sea floor or changes to soft substrate habitat." Thus, clogging of the seafloor due to the impingement of organic matter would not occur.

Based on the above-described considerations, while the methodologies, assumptions, and estimates by various experts on infiltration rates may vary, the ultimate conclusion of a less-than-significant impact on marine organisms from impingement remains unchanged. Therefore, no edits were made to the Draft EIR/EIS in response to this comment.

CURE-Sobczynski-2 The potential for impingement of organisms or fine particulate matter on the seafloor is evaluated in Impact 4.5-4 in the Draft EIR/EIS. As further explained in the response to comment CURE-Sobczynski-1 above, the clogging of the seafloor due to the impingement of plankton, invertebrates, larval fish, and organic matter would not occur. There would be no buildup of biomass due to the pumping of the slant wells. Without the buildup of biomass, the commenters speculation regarding changes to the dissolved oxygen and the resultant buildup of hydrogen sulfide buildup would also not occur.

Draft EIR/EIS Section 4.5.5.2 presents the operational and facility siting impacts of the MPWSP and presents a quote on page 4.5-52, from the California Ocean Plan that subsurface intakes eliminate impingement and entrainment. Footnote 81 in the comment letter suggests that since the Ocean Plan was cited, and since the quoted passage from the Ocean Plan included a reference to MWDOC, 2010, which included Jenkins, 2010 and Williams, 2010, that the conclusions reached in the Draft EIR/EIS are based on Jenkins' work. In fact, the analysis on impingement of marine organisms and organic matter on the seafloor was prepared independently by the Lead Agencies as previously noted in response to

comment CURE-Sobczynki-1, and relies on the data and assumptions presented in the section, and does not rely directly on Williams, 2010 and Jenkins, 2010.

In addition, even if the infiltration rate of slant wells on the seafloor would be as described in the comment (see response to comment CURE- Sobczynski-1 above), the analysis in the Draft EIR/EIS of impingement of marine organisms or organic matter on the seafloor still would not warrant revisions since the recalculated rates are exceeded by the orbital velocities of ocean waves presented in the Draft EIR/EIS on page 4.5-53 (i.e., 250 cm/sec to 600 cm/sec).

It is correct that the filter medium can be scrubbed from inside the well as the EIR/EIS describes in Section 3.4.1, and from the surrounding sediment through airlifting and blasting. However, the relevance to the proposed project of comments about suspended organic matter (SOM) that may become concentrated in the sand above an infiltration gallery is not clear, since the MPWSP does not propose to utilize an infiltration gallery. Nor is it clear why the SOM that originated in the ocean, and which is not a regulated contaminant, would contaminate the ocean upon its release.

CURE-Sobczynski-3

The complete sentence on Draft EIR/EIS page 4.3-39 in Section 4.3.2.2 that is referenced in the comment, regarding discussion of state regulations as they relate to surface water quality, reads as follows: "The muds and clay slurry generated during the drilling and development of the subsurface slant wells *and the proposed ASR-5 and ASR-6 Wells in the Fitch Park military housing area would fall under the category of 'Water Supply Well Drilling Muds*"' [emphasis added]. The sentence is not providing evidence of clay at the slant wells; it is discussing the waste discharge requirements in the RWQCB General Discharge Waiver.

A local geologic cross-section is shown in EIR/EIS Figures 4.2-3 and 4.4-3, and a cross-section of the test slant well is provided in the Baseline Water and Total Dissolved Solids Levels Technical Memorandum referenced in EIR/EIS Section 4.4 as Geoscience, 2015b. As described in EIR/EIS Section 4.4.1.2, the Terrace Deposits of the 180-FTE Aquifer are composed of former alluvial fan and river floodplain deposits, possibly with some marine terrace deposits that contain sand, silt, and gravel now buried under the coastal dunes. Clays are minimally present and would not be present in the sedimentary layers around the slant wells. In addition, well yield is determined by the coarse-grained sediment – little to no water is provided by the clays. If substantial clay deposits were present, then the well yield would be poor and the project infeasible. The results of the test slant well indicate that the well yield is good and the proposed project is feasible. The postulated build-up of organic matter around clays, if any, would therefore, have a negligible effect on well yield.

The Salinas Valley Aquitard (SVA), on the other hand, is a blue or yellow sandy clay formation up to 100 to 150 feet thick that lies mostly north of and generally parallel to the northwest-flowing Salinas River. The SVA thins and becomes discontinuous away from the centerline of the unit and at the Pacific Ocean, and was not observed in the exploratory borings at the CEMEX site. Thousands of vertical wells throughout the Salinas Valley penetrate the Salinas Valley aquifers, and most of them penetrate the clay that is the SVA. The concern about organic matter build-up on the clay is not necessarily unique to slant wells, and the extensive utilization of wells in the Salinas Valley that do not experience this issue suggests that it would not be of concern during project operation.

CURE-Sobczynski-4 EIR/EIS Appendix E2 Section 5.3 describes the slant well capture zone as the three-dimensional volume of aquifer that contributes the water extracted by the wells; see Master Response 8, Project Source Water and Seawater Intrusion. In map view, the capture zone is a two-dimensional surface that delineates the underlying aquifer volume and becomes the primary source for the wells. The model-calculated, steady-state ocean water capture zone for the proposed slant wells is shown in Appendix E2 Figure 5.6. Turning off one well among the 10 wells would not create an impermeable barrier within the capture zone. Rather, the distances between two adjacent wells would simply increase. The operating wells would continue to produce 24.1 mgd of oxygenated water that would move through the large well capture zone. Therefore, if biomatter were to build up on colloidal deposits above an inactive well, the water would not stagnate and respiration of bacteria would not become anaerobic.

EIR/EIS Section 4.11.5 includes a discussion of the project's CO_2 off gassing, and the total metric tons is quantified in Table 4.11-4. See also EIR/EIS Appendix G2, and responses to comments from William Bourcier in Section 8.7.4 for a further discussion of GHG off-gassing from the slant wells.

CURE-Sobczynski-5 As discussed above in the responses to comments CURE-Sobcyznski-1 through CURE-Sobcyznski-4, the Draft EIR/EIS presents all of the necessary relevant and supporting information in support of the impact conclusions.

8.6.3 Responses to Comments from California American Water Company

CalAm-1 The Lead Agencies' responses to CalAm's suggested technical corrections, clarifications, and/or revisions in Exhibit 1 of this letter are addressed in individual comment responses below.

CalAm-2 This comment regarding water rights is noted. Additional discussion of water rights is provided in Master Response 3, Water Rights.

CalAm-3 The requested clarification has been made.

CalAm-4 The requested technical corrections and clarifications have been made.

CalAm-5 Footnote 2 in the Executive Summary has been revised as follows:

> In October 2014, MBNMS finished its NEPA review of the construction of the test slant well and the operation of the pilot program. In November 2014, ~~the City of Marina and~~ the California Coastal Commission completed its ~~their~~ CEQA review.

CalAm-6 The requested technical correction has been made.

CalAm-7 Reference to Mitigation Measure 4.15-1a has been removed from Table ES-2 in the Executive Summary. Further, the Lead Agencies have revised the Impact Conclusion subsection under Impact 4.12-3 in Section 4.12, Noise and Vibration, to clarify that no significant vibration impact would occur from construction of the Source Water Pipeline. This clarification is consistent with the analysis provided for the Source Water Pipeline (see Draft EIR/EIS page 4.12-44), which explains that potential impacts from both open-trench and trenchless construction of the Source Water Pipeline would be less than significant (or that no impact would occur). Also consistent with this analysis and the clarification made in the Impact Conclusion subsection, reference to Mitigation Measure 4.15-1a. This reference was made inadvertently; no Mitigation Measure 4.15-1a is recommended in Section 4.15, Cultural and Paleontological Resources, and no mitigation is required for impacts on historic resources during construction because as described in Impact 4.15-1 in Section 4.15, no such impact would occur.

CalAm-8 The requested clarification has been made.

CalAm-9 The footnote in question in Chapter 1 has been revised to reflect that in September 2014, the City of Marina declined to adopt its Initial Study and Mitigated Negative Declaration and denied CalAm's CDP application for development of the test slant well, and in November 2014, the CCC approved the CDP application on appeal and documented its compliance with CEQA requirements.

CalAm-10 An in-text citation (NOAA, 2016) and reference for NOAA Administrative Order 216-6A have been added to Chapter 1.

CalAm-11 A citation and reference to CPUC Decision 16-09-021 was provided in Draft EIR/EIS Section 2.4.5. See Draft EIR/EIS page 2-20, "(CPUC, 2016)," and page 2-44, where the reference for this in-text citation for Decision 16-09-021 is provided. The paragraph referenced in the comment has been clarified to provide the decision number in addition to the in-text citation.

CalAm-12 The requested clarification has been made.

CalAm-13 The requested technical correction has been made.

CalAm-14 Section 2.6, Water Rights, has been updated to cite authority in the noted location.

CalAm-15 Section 2.6, Water Rights, has been revised to remove the repeated text.

CalAm-16 The requested clarification has been made.

CalAm-17 Footnote 2 in Chapter 3 has been revised as described in response to comment CalAm-9.

CalAm-18 The requested clarification has been made.

CalAm-19 The clarification that the pretreatment building would be 4,000 square feet in size and not 6,000 square feet has been made in Table 3-1, under the Desalination Facilities heading in the Pretreatment System row, and in the second paragraph of Section 3.2.2.1, Pretreatment System.

CalAm-20 The description of subsurface slant wells in Table 3-1 has been clarified as follows:

- Each well site would have one wellhead ~~vault~~ (Sites 1, 3, 4, and 5) or three wellheads ~~vaults~~ (Sites 2 and 6), ~~aboveground~~ mechanical piping <u>vault</u> (meter, valves, gauges), one electrical control cabinet, and one pump-to-waste ~~vault~~ basin.

- ~~Except for Site 1 (test slant well site), the aboveground facilities (at Sites through 6) would be built on a concrete pad ranging between 5,250 and 6,025 square feet in area.~~

CalAm-21 The requested clarification has been made.

CalAm-22 EIR/EIS Figure 3-3a identifies the wells from north to south; the test slant well is identified as SW-1, and the southern-most well is identified as SW-10. The text in the second bullet for the Subsurface Slant Wells in Table 3-1 has been clarified to indicate that the wells extend

"seaward of the Mean High Water (MHW) line (i.e., within MBNMS, except SW-#~~8~~10 which would not extend past the MHW line; see Table 3-2 and Figure 3-3a)."

In addition, the text from Draft EIR/EIS page 3-15 has been clarified in the same manner.

CalAm-23 The clarification that the Brine Discharge Pipeline would be 36 inches in diameter and not 30 inches has been made in Table 3-1, under the Brine Storage and Disposal Facilities heading in the Brine Storage and Disposal row, and in the first paragraph of Section 3.2.2.5, Brine Storage and Disposal.

CalAm-24 The clarification that there would be two large treated water pumps and not four has been made in Table 3-1, under the Desalinated Water Conveyance and Storage Facilities heading in the Desalinated Water Pumps row, and in the first paragraph of Section 3.2.3.2, Desalinated Water Pumps.

CalAm-25 Figure 3-3a has been revised to make the clarifications described in the comment.

CalAm-26 The requested clarification has been made.

CalAm-27 Figure 3-3b has been revised to make the clarifications described in the comment.

CalAm-28 The requested clarifications have been made, with the exception that details regarding the size of aboveground wellheads have not been removed, as no replacement details were provided by CalAm.

CalAm-29 The requested clarification has been made.

CalAm-30 The clarification that the pipeline alignment would be located within the TAMC ROW has been made in Section 3.2.1.2.

CalAm-31 Two clarifications have been made regarding pretreatment in Section 3.2.2.1: (1) that multimedia gravity filtration is more likely than not a required process, and (2) that coagulation, flocculation, and membrane filtration are processes that will be included in pretreatment only if necessary.

CalAm-32 See response to comment CalAm-23.

CalAm-33 See response to comment CalAm-24.

CalAm-34 The clarification that the pipeline alignment would be located within the TAMC ROW has been made in the first paragraph of Section 3.2.3.3.

CalAm-35 The requested clarification has been made.

CalAm-36 The requested clarification has been made.

CalAm-37 Reference to the Upper Tierra Grande Booster Station and related upgrades has been removed.

CalAm-38 A brief description of the purpose and function of the ASR system has been added as a clarification in the second paragraph of Section 3.2.4.

CalAm-39 The combined injection capacity of ASR 5 and 6 wells has been revised to 4.3 mgd (3,000 gpm) in the third paragraph of Section 3.2.4.1.

CalAm-40 The requested clarifications regarding Subsurface Slant Wells have been made in the sixth paragraph of Section 3.3.2.1.

CalAm-41 Section 3.3.3 has been revised to clarify that no import or export of fill material would be necessary during construction of the desalination plant.

CalAm-42 The referenced Table 5-7 does not exist in Chapter 3. The Lead Agency interprets comment 42 to reference 3-7. Daily production has been revised from 9.5 mgd to 9.6 mgd in Table 3-5 in Section 3.4.1.

CalAm-43 The requested clarifications have been made.

CalAm-44 The requested clarification regarding the fact that CDPH no longer regulates public water systems has been addressed. CDPH has been replaced in Row 4 of Table 3-8 with the correct agency: California Environmental Protection Agency, State Water Resources Control Board, Division of Drinking Water.

CalAm-45 The clarification regarding the location of Project No. 60 (Monterey Pipeline and Pump Station) has been added to Table 4.1-2, Cumulative Projects. The Project has also been added to Figure 4-1, Cumulative Projects.

CalAm-46 The introductory text for Table 4.2-6, Applicable Regional and Local Plans and Policies Relevant to Geology, Soils, and Seismicity, explains that this table is provided to screen policies for further discussion. That more detailed discussion is provided in the referenced impact discussion. This is true for all other Applicable Regional and Local Plans and Policies tables in all of the Chapter 4 resource sections.

CalAm-47 All of the references listed in the Final EIR/EIS are available at https://drive.google.com/drive/u/2/folders/0B63ty1hxcSNhV2JvMU15UW9VcHc

CalAm-48 Although the profiles shown in Figure 4.2-8 and discussed in the 2014 study have not changed, the proposed slant well locations have changed since the 2014 study. The text describing the Coastal Profile (Vertical Erosion Estimates) in Section 4.2.4.5, Coastal Retreat Study has been revised to clarify that the initially proposed locations

for the nine new slant wells are shown on the coastal profiles in Appendix C2 (whereas relocated slant wells are shown on Figure 4.2-8).

CalAm-49 The requested clarification has been made.

CalAm-50 The requested reference to Figure 4.3-3, Areas Subject to Sea Level Rise in the Project Area, has been added to Section 4.2, Geology, Soils, and Seismicity in Section 4.2.1.3, Sea Level Rise and Coastal Erosion, and in Section 4.2.4.5, Coastal Retreat Study.

CalAm-51 The requested clarification has been made regarding the definition of EFH. A definition of EFH, which stands for "Essential Fish Habitat" has been added to Section 4.3.2.1.

CalAm-52 The requested clarification has been made.

CalAm-53 In response to the comment, and to make units consistent within the section, the last sentence of the first paragraph on page 4.3-71 of the Draft EIR/EIS has been revised as follows:

> Seasonal average temperatures ranged between ~~11.5 and 14.5~~ 52.7°F and 58.1°F and seasonal salinity levels ranged from 33.3 to 33.9 ppt at the depth of the diffuser.

CalAm-54 The requested clarification has been made.

CalAm-55 A clarification/update has been added to Section 4.6.2.2 State Regulations, regarding the FORA *Draft Installation-Wide Multispecies Habitat Conservation Plan* publication schedule.

CalAm-56 In Mitigation Measure 4.6-1d, subpart 5, "several days" has been revised to "no more than 3 days" prior to construction.

CalAm-57 Mitigation Measure 4.6-1l, Subpart 2 has been revised to clarify that a qualified biologist will conduct pre-construction surveys within 14 days prior to disturbance of trees or structures identified as potential bat roosting habitat or active roosts.

CalAm-58 Mitigation Measure 4.6-4 has been revised to clarify that the tree survey shall be performed at least 30 days prior to start of planned ground disturbance or tree removal.

CalAm-59 Figure 4.8-1 has been revised to show that the Coastal Zone extends over the ocean.

CalAm-60 There are no parks, conservation areas, golf courses, or trails in the vicinity of the Main System-Hidden Hills Interconnection. Therefore, revising Figure 4.8-3 to include this component (e.g., by changing the scale of the figure) would not provide

additional information relevant to the analyses, and would reduce the scale of relevant resources shown in the figure.

CalAm-61 The cited sections describe the land use and recreational setting for the pipeline alignments. The placement of pipelines below ground is appropriately described in the impact analysis portion of Section 4.8, Land Use, Land Use Planning, and Recreation.

CalAm-62 Consistency with the Fort Ord Reuse Plan (including allowable/compatible uses such as subterranean pipelines) is addressed in Table 4.8-2.

CalAm-63 The requested clarification has been made in Section 4.8.2.2

CalAm-64 The settlement agreement is cited as CalAm, 2012, and included in the references list. All materials referenced in the Draft EIR/EIS were made available to the public during the review period for the Draft EIR/EIS, and will remain available (with updates and additions, as applicable) after publication of the Final EIR/EIS.

CalAm-65 The Lead Agencies acknowledge the discussion of desalination facilities in California policy documents such as Safeguarding California: Reducing Climate Risk – An update to the 2009 California Climate Adaptation Strategy (California Natural Resources Agency, 2014) as cited in the comment. However, inclusion of the recommended text would not affect the conclusions reached in Section 4.11, Greenhouse Gas Emissions. Because it would not change the conclusions in the analysis of impacts or comparison of alternatives, the recommended discussion has not been incorporated.

CalAm-66 Clarification has been added to Section 4.11.2.2 under the heading “Mandatory Reporting Requirements” regarding the fact that many of the project’s sources of GHG emissions are not directly subject to CARB’s mandatory reporting program.

CalAm-67 Clarification has been added to Section 4.11.2.2 under the heading “Market-Based “Cap-and-Trade” Compliance Mechanism” regarding the fact that the fossil fuel power plants that would generate the electricity that could be used by the project are already subject to and participate in CARB’s cap-and-trade program.

CalAm-68 The requested clarification has been made.

CalAm-69 Section 4.11.5 has been clarified to indicate that SB 350 has been signed into law.

CalAm-70 The cited Mitigation Measure 4.12-1d establishes a performance standard of 60 dBA, Leq at a distance of 50 feet for construction noise related to the ASR-5 and ASR-6 wells. The additional discussion regarding the attenuation capabilities of barrier blankets was included to demonstrate that the performance standard is achievable. However, the degree of attenuation for these blankets cited in the mitigation measure

may be more than necessary to achieve the identified performance standard. Consequently, the mitigation measure has been rewritten, as indicated below, to clarify that such blankets represent one of many options available to the applicant or its contractors.

> Additionally, acoustic barriers and/or enclosures shall be used with a goal of reducing noise from well drilling activities to 60 dBA, L_{eq} or less at a distance of 50 feet from the construction work area. There are a number of options available to achieve this performance standard. Barrier blankets are available with a sound transmission class rating of 32, ~~providing~~ which can provide 16 to 40 dBA of sound transmission loss, depending on the frequency of the noise source (ENC, 2014). The realized sound transmission reduction of barrier blankets need be sufficient to achieve the performance standard of 60 dBA, L_{eq} or less at a distance of 50 feet from the construction work area.

CalAm-71 The California Coastal Act subsection of Section 4.13.2.2, State Regulations, discusses MPWSP consistency with Coastal Act policies concerning public facilities, and the requested text clarification has been made.

CalAm-72 The requested clarification has been made.

CalAm-73 The requested clarification has been made.

CalAm-74 The requested clarification has been made.

CalAm-75 The requested clarification has been made in Section 4.14.3.2.

CalAm-76 The requested clarification has been made in Section 4.14.6.1

CalAm-77 Section 4.18.2.2 has been revised to reflect the most recent Integrated Energy Policy Report.

CalAm-78 The requested clarification that "the county" refers to "Monterey County" has been made in Section 4.19.1.2.

CalAm-79 Section 4.19.3 states that "The impacts *of growth* that could be indirectly induced by the MPWSP are addressed in Section 6.3, Growth Inducement" (emphasis added). Other indirect impacts related to the evaluation criteria in Section 4.19.3 are addressed in Section 4.19.5; no change has been made.

CalAm-80 The requested revisions have been made.

CalAm-81 EIR/EIS Section 5.3.5 explains that since the desalination facilities described for the proposed project would be required at any of the desalination plant site options, and since the proposed project would include a minimum of 15 acres of impervious surfaces (see EIR/EIS Section 3.2.2), a minimum of 10 acres was assumed for the alternative sites. However, as noted in Table 5.3-3, each plant site option has

adequate acres and the 10-acre minimum was not a constraint. The minimum acres could have been assumed to be more or less, and the conclusions would not be any different.

CalAm-82 The requested clarification has been made.

CalAm-83 The requested revisions have been made. However, CalAm provided a subsequent revision to the slant well layout (Ian Crooks, 2018) and the EIR/EIS text has been revised accordingly.

CalAm-84 The requested revisions have been made.

CalAm-85 The requested clarification has been made.

CalAm-86 The requested clarifications have been made.

CalAm-87 The clarification that Mitigation Measure ALT 2-Marine-1 would not apply to the proposed project or to any project that does not include an open water intake has been added to Section 5.5.5.5.

CalAm-88 The clarification that Mitigation Measure ALT 2-Marine-2 would not apply to the proposed project, or to any project that does not include an open water intake has been added to Section 5.5.5.5.

CalAm-89 The requested clarification has been made.

CalAm-90 The clarification that Mitigation Measure ALT3-NO would not apply to the proposed project has been added to Section 5.5.12.6.

CalAm-91 The clarification that Mitigation Measure ALT4-NO would not apply to the proposed project has been added to Section 5.5.12.7.

CalAm-92 The clarification that Mitigation Measure ALT1-CULT would not apply to the proposed project has been added to Section 5.5.15.4.

CalAm-93 The spelling of “Trussell” in Appendix G2 has been corrected.

CalAm-94 CalAm provided a subsequent comment on the Draft EIR/EIS. As a result, Applicant Proposed Measure 4.4-3, Groundwater Monitoring and Avoidance of Well Damage, has been revised accordingly.

Crooks, Ian. 2018. E-Mail to Eric Zigas. March 12.

8.6.4 Responses to Comments from Carmel River Steelhead Association

CRSA-1 CalAm's legal entitlement to 3,376 afy from the Carmel River system established in State Water Resources Control Board (SWRCB) Order 95-10 is a composite right made up of CalAm's pre-1914 appropriative right of 1,137 afy, its riparian right of 60 afy, and its post-1914 appropriative right at Los Padres Dam of 2,179 afy (License 11866). In Order 95-10, CalAm's pre-1914 direct diversion right is treated as a year-round right, with a season of diversion from January 1 through December 31. In contrast, CalAm's right to divert water to storage behind Los Padres Dam is limited to the season of October 1 through May 31. Thus, of the 3,376 afy entitlement, only 1,197 afy (pre-1914 and riparian rights) are currently not subject to seasonal restrictions. Similarly, Monterey Peninsula Water Management District's (MPWMD) and CalAm's SWRCB permits to divert water for the ASR Phase 1 and 2 projects include requirements to maintain minimum mean daily instream flows for the protection of fisheries and wildlife and other instream uses (as noted in Section 2.4.3), as does CalAm's permit to divert Table 13 water (discussed in Section 2.4.6.1). CalAm's existing Carmel River water rights are not part of the proposed project and thus are not analyzed in this EIR/EIS. However, implementation of the MPWSP and ASR programs is expected to provide CalAm with the operational flexibility to minimize its summer diversions to the greatest extent feasible.

8.6.5 Responses to Comments from Carmel River Watershed Conservancy

CRWC-1 The Lead Agencies acknowledge the Carmel River Watershed Conservancy's support for the proposed project and for Alternatives 5a and 5b, which would provide a desalinated water supply supplemented by the Pure Water Monterey Groundwater Replenishment Project.

8.6.6 Responses to Comments from CEMEX

CEMEX-1 The comment letter from CEMEX on the April 2015 Draft EIR has been received and comments are considered in the following responses since CEMEX incorporated the 2015 comments into the current comment letter.

With respect to the Annexation Agreement, please see Master Response 3, Water Rights, Section 8.2.3.8, Effect of Annexation Agreement. In accordance with revisions to EIR/EIS Section 2.6, Water Rights, it is not expected that an injection well would be constructed on the CEMEX property; therefore, it is not part of the proposed project and is not required to be analyzed in this EIR/EIS.

CEMEX-2 The comment is acknowledged, but addresses processes outside of the scope of the CEQA and NEPA review of the proposed project. CalAm's responsibility to prepare or bear the cost of preparing a reclamation plan amendment is a matter to be addressed between CalAm and CEMEX.

CEMEX-3 The slant wells would be constructed on a previously disturbed, retired portion of the CEMEX sand mining facility, south of the access road. This location would not interfere or interact with the ongoing sand mining operations located north of the access road and further inland. Other than the well heads, the wells and piping would be located underground. CalAm and its contractors would be required to implement all applicable worker and construction site safety laws and regulations. Environmental review under CEQA and NEPA should assume that the applicant complies with such applicable laws and regulations such that no further mitigation measures are warranted to ensure that duty is met. Further, Mitigation Measure 4.7-2a requires the implementation of a site-specific Health and Safety Plan as required by and in accordance with 29 CFR 1910.120. CalAm's responsibility to indemnify CEMEX for CalAm's actions at the CEMEX site is a matter to be addressed in agreements between CalAm and CEMEX and is outside of the scope of the EIR/EIS.

CEMEX-4 As stated on page 4.9-24 of the Draft EIR/EIS, the traffic control and safety assurance plan (Mitigation Measure 4.9-1) shall be developed on the basis of detailed design plans for the approved project, and shall include, but not necessarily be limited to, the elements listed on pages 4.9-24 to 4.9-26. The following additional element is added to the list of measures that could be included in the traffic control and safety assurance plan:

- Consult with non-jurisdictional parties (e.g., CEMEX), as appropriate, regarding strategies for reducing increased traffic on roads that would provide access to construction work areas.

CEMEX-5 CEMEX and CalAm mutually entered into an "Agreement for Temporary Investigatory Easement, Option for Permanent Easements, and Joint Escrow Instructions" on November 4, 2014. Subsequent to the release of the Draft EIR/EIS

in January 2017, CEMEX and the California Coastal Commission entered into a Consent Settlement Agreement dated July 13, 2017, that acknowledges the CalAm-CEMEX Option. See Master Response 14, CEMEX Settlement Agreement. CalAm will need to coordinate activities on the property with CEMEX or the new owners in accordance with the agreements between CalAm and CEMEX. In addition, EIR/EIS Section 4.17, Mineral Resources, found that the proposed project would have a less-than-significant impact on the mining operations at CEMEX.

CEMEX-6 Subsidence impacts were fully addressed in the EIR/EIS, including potential effects on the CEMEX property. The EIR/EIS conclusion that subsidence would not constitute a significant impact on the CEMEX lands was not based on the assumption that the slant wells would draw water from offshore coastal aquifers, as the comment suggests. Rather, the analysis considered the possibility of some inland groundwater being drawn into the supply wells. As explained in Section 4.2 Geology, Soils, and Seismicity, in Impact 4.2-8, sand- and gravel-rich soils are less prone to subsidence because the larger grains comprise a skeleton less dependent on water pressure for support. As shown on Figure 4.2-3, about the upper 200 feet of materials beneath the CEMEX facility, where the deeper extent of drawdown would occur, is primarily composed of sands and gravels. The maximum estimated amount of drawdown centered on the proposed slant wells area is estimated to be on the order of tens of feet at most. The maximum drawdown estimated at any of the onsite monitoring wells is less than 18 feet in Well MW-1M (see Appendix E2, Figure 5.2). In addition, because the subsurface slant wells would draw water from the offshore coastal aquifers, seawater would replace the water pumped from the slant wells, as discussed in Section 4.4, Groundwater Resources. The continuous replacement of water would keep the pore spaces between the grains filled with water, further supporting the granular structure. Consequently, the soil structure above the slant wells would be unable to subside as a result of pumping and there would be no impact from subsidence impacts associated with the subsurface slant wells. Thus, this area would not be susceptible to subsidence and no revisions were made in response to this comment.

CEMEX-7 EIR/EIS Figure 4.2-5, which shows the liquefaction potential, shows that the area where the well heads of the slant wells would be constructed on the CEMEX site is an area of moderate liquefaction potential. The risks from liquefaction are high in sandy areas with shallow groundwater (e.g., Castroville Pipeline and Source Water Pipeline portions within the Salinas River floodplain). The well heads would be set back from the beach behind the sand dunes, where the depth to groundwater would be deeper, thus reducing the risk (see Impact 4.2-4). In addition, as discussed in Section 4.2.4, Approach to Analysis, the proposed project components would undergo a final geotechnical investigation and CalAm would implement all geotechnical recommendations in design and construction of the project to resist damage from seismic shaking. Because the slant wells would not be located in an area with high liquefaction potential, they would not be expected to experience

damage from liquefaction. The secondary risk to the existing CEMEX structures resulting from liquefaction impacts affecting the slant wells would be very low.

CEMEX-8 Mitigation Measure 4.2-10, Slant Well Abandonment Plan, has been revised in response to this comment, to require that the slant well abandonment plans be prepared and implemented in coordination with the property owner.

CEMEX-9 In response to the comment, the discussion of Impact 4.3-9 under "Subsurface Slant Wells" (see Draft EIR/EIS page 4.3-116) has been revised as follows:

> As shown in Figure 4.3-2, the subsurface slant wells and associated structures would be located within or adjacent to the 100-year coastal flood hazard area. The subsurface slant wells would be constructed at the western terminus of the CEMEX access road and just south of the CEMEX settling ponds. The ~~E~~electrical control cabinet at each well site (Figure 3-3a) would be a single-story structure 16 feet long by 7 feet wide. Any flood flows associated with 100-year coastal flooding diverted by the electrical control cabinet would be diverted to the sandy areas immediately surrounding the cabinet, ~~still~~ within the CEMEX active mining area, and would be temporary in nature, ~~and~~ highly localized in extent, and would not affect other properties or structures or otherwise interfere with CEMEX operations. The wellheads and supporting structures would extend at a maximum height of 2 feet above the ground surface and would not impede or redirect flood flows in the area. Therefore, the impact would be less than significant.

CEMEX-10 Impact 4.2-10 assess impacts related to coastal erosion patterns, beach erosion, and bluff retreat following implementation of the project and considers such hazards within the context of sea level rise as a predicted environmental condition that could adversely affect certain components of the project sometime in the future. Impact 4.3-11 focuses only on the long-term impacts related to exposure of people or structures to a significant risk of loss, injury, or death from flooding due to sea level rise. As discussed in detail under Impact 4.3-11, because the subsurface slant wells would be constructed underground (and are not designed for human occupancy) and designed to withstand inundation, these facilities would not be subject to a significant risk of damage, injury, or loss from flooding due to sea level rise. Impacts on the CEMEX active mining area related to coastal flooding and inundation of project components is discussed in detail under Impact 4.3-9 (see also response to comment CEMEX-9).

CEMEX-11 As the commenter correctly notes, Applicant Proposed Measure 4.4-3 has been proposed by CalAm. The EIR/EIS determination under Impact 4.4-3 is less than significant, and the Lead Agencies have not recommended mitigation to reduce this impact. However, Applicant Proposed Measure 4.4-3 would be incorporated into the Mitigation Monitoring and Reporting Plan (MMRP), which would be approved

concurrently with the MPWSP or an alternative. Thus, the Lead Agencies would be responsible for enforcing this measure, including approval of the expansion of the regional groundwater monitoring program as contemplated by Applicant Proposed Measure 4.4-3.

The CEMEX production well, also referred to as the "South Well," is currently the only active production well at the site; however, it cannot be accessed for monitoring. The "North Well" collapsed and is no longer in use (Villalobos, 2017). Groundwater conditions beneath the CEMEX site would be monitored continually after MPWSP start-up using CalAm's monitoring well clusters 1, 3, and 4. Groundwater Monitoring Well 3-D and 4-D are screened in the 400-Foot Aquifer (similar to the South Well) and thus conditions in the 400-Foot Aquifer would be continually monitored through CalAm's monitoring program, even if the South Well is not accessible. If excessive drawdown is identified in Monitoring Wells 3-D and 4-D, it would be expected that a similar response would be occurring in the South Well. Response to South Well pumping has also been observed in the Monitoring Well 4-S and 4-M. Moreover, if well yields decrease substantially in the South Well, it would be an additional indicator of excessive drawdown caused by the slant well pumping. Applicant Proposed Measure 4.4-3 has been revised to clearly state that wells in the 400-Foot Aquifer will be monitored and conditions will be corrected under the measure if the wells are found to be adversely impacted by MPWSP pumping. Thus, the Applicant-proposed measure includes monitoring conditions in the 400-Foot Aquifer and applies to wells screened in that aquifer, as stated in Applicant Proposed Measure 4.4-3. Ameliorative actions under this measure would be triggered if drawdown exposes the well screens, damages the well, and/or decreases yield in a production well. This includes wells screened in the 400-Foot Aquifer. These triggers represent the performance standard within Applicant Proposed Measure 4.4-3 given that action would be taken to address and alleviate project effects if any of the triggers occur.

CEMEX-12 See response to comment CEMEX-11.

CEMEX-13 Text in EIR/EIS Section 4.4.5.2 regarding the allowable dredge pond depth and the underlying geologic materials has been updated to reflect the information provided in this comment. This information does not change any of the impact conclusions in the EIR/EIS.

CEMEX-14 Applicant Proposed Measure 4.4-3 is not mitigation for a significant impact, and is not intended to nor does it address potential drawdown effects on vegetation. See response to comment CURE-Owens-19 in Section 8.6.2 regarding the source of the water available to dune plants, which do not rely on groundwater in the aquifers intersected by proposed slant well screens.

CEMEX-15 In addition to the analysis presented in Impact 4.4-3 of the EIR/EIS, details on the potential effects of pumping on the CEMEX dredge pond are provided in EIR/EIS Appendix E3, Section 2.4.5.3. As shown in Table 3.1 of EIR/EIS Appendix E2, the CEMEX dredge pond was not represented in the 2015 version of the North Marina Groundwater Model ($NMGWM^{2015}$) but was represented in the 2016 version of NMGWM ($NMGWM^{2016}$, which informed the EIR/EIS analysis) as constant head cells in Layer 1 (ocean) to represent the effect of the dredge pond. Moreover, the initial head of the dredge pond was not represented in $NMGWM^{2015}$ but was in $NMGWM^{2016}$ as active cells with initial heads equal to mean sea level. Therefore, the $NMGWM^{2016}$ did not necessarily model the effects of the proposed slant well pumping on the dredge pond specifically, because the active cells representing the dredge pond behave the same as the active cells representing the ocean since the dredge pond is tidally influenced. As stated in the comment, the EIR/EIS analysis considered the CEMEX model simulation completed in September 2014 and based on that, hypothesized that full scale MPWSP pumping could result in additional lowering of the dredge pond water levels, but added that when compared to daily tidal fluctuations, the decline in surface water levels from slant well pumping would be masked by the consistent recharge and tidal influence of the ocean.

As discussed in the EIR/EIS in Section 4.4.4.1, Subsurface Investigations, and in Impact 4.4-3, CalAm installed a pressure transducer in the dredge pond at the beginning of the Test Slant Well long-term pumping test and data were collected from April 2015 to October 2015. The dredge pond was breached on October 28th, 2015 and the transducer was eventually buried. Transducer data show that dredge pond levels may have been affected by test slant well pumping as evidenced by the slight increase (about 1 foot) in pond levels that occurred when the pump was turned off on June 5, 2015 (see Appendix E-3, Figure 2.1). The data also show, however, that tides and dredge operations influence pond levels and that under non-pumping conditions, pond levels fluctuate as much as 2 feet. Water levels are maintained in the dredge pond because it is hydraulically connected to the ocean through the sand and occasional breaches during storms. Consistent with the findings in the EIR/EIS, water level fluctuations due to dredging and tides would have a much greater effect on dredge pond water levels than the MPWSP slant well pumping. As stated in the EIR/EIS (Impact 4.4-3), the impact would be less than significant because, while there may be slight changes in dredge pond levels from MPWSP pumping, the magnitude of change would not interfere with recharge or inhibit mining operations primarily because the dredge pond is hydraulically connected to the ocean and constantly recharged by ocean water. Since the dredge pond is located within the 1-foot drawdown, and the Applicant proposed measure includes the area within the 1-foot drawdown (plus one mile), the dredge pond could be included in the groundwater monitoring program. However, the sand mining operation at CEMEX will be closed by 2020, the dredge mining operations will cease and the pond will be restored. See Master Response 14, CEMEX Settlement Agreement.

The text in the EIR/EIS has been updated to discuss the full set of dredge pond data collected between April and October 2015.

CEMEX-16 The mitigation measures for biological impacts that are listed in the EIR/EIS and that are of concern to the commenter – Mitigation Measures 4.6-1c through 4.6-1h – are all avoidance and minimization measures and all address activities that would be occurring inside the project area boundary, as delineated on EIR/EIS Figure 3-3a. As described in Master Response 14, CEMEX Agreement, CEMEX has granted an easement to CalAm for the wells and the pipelines that are proposed on the CEMEX property. As noted in Section F(3)(e) of the easement option, "CalAm shall minimize the impact to the Greater CEMEX Property by confining its activities to the footprint within the Option Property." As noted in Section F(3)(f) of the easement option, "To the extent CalAm is required to perform remediation activities in connection with its activities, CalAm shall be able to use the property subject to the Permanent Easements to fulfill any such obligations." Compliance with Mitigation Measures 4.6-1c through 4.6-1h would not interfere with any CEMEX pre-existing mining operations, reclamation activities, or access. In implementing the mitigation measures, CalAm would be obligated to comply with and limited to its rights under its agreements with CEMEX on use of the CEMEX land.

Subsequent to the publication of the Draft EIR/EIS, the CCC, the California State Lands Commission, and the City of Marina reached an agreement with CEMEX in July 2017 to end the sand mining operations. As a result of the July 2017 Settlement Agreement, the property will no longer be owned by CEMEX by 2020, and the deed restriction placed on the property as a result of the Settlement Agreement must preserve the open space and habitat values of the property, and must reflect that improvements to provide low-impact passive recreation, public access, and public education, removal activities, and activities to restore native habitat will be consistent with existing easements or other rights of record; see Master Response 14, CEMEX Settlement Agreement. Mitigation Measure 4.6-1n is the Habitat Mitigation and Monitoring Plan (HMMP) and it shall be implemented at all areas where special-status species habitat or sensitive natural communities will be restored, created, or enhanced to mitigate for project impacts either prior to, concurrently with, or following project construction and its implementation. Mitigation Measure 4.6-1n would outline measures to be implemented, depending on the mitigation requirements, to restore, improve, or re-establish special-status species habitat, sensitive natural communities, and critical habitat. To that end, CalAm's HMMP may or may not focus the restoration activities on the CEMEX property, but the sand mining operations would have ceased, and CEMEX would no longer be the property owner.

In response to this comment, Mitigation Measure 4.6-1c has been revised to clarify that existing access roads within the CEMEX site will be returned to their existing use.

CEMEX-17 As described in the Draft EIR/EIS, a final wetland delineation report has not been verified by the U.S. Army Corps of Engineers (USACE), Regional Water Quality Control Board (RWQCB), and California Coastal Commission (CCC). A wetland delineation report, based on some of these field surveys, has been prepared and is referenced in the Final EIR/EIS. In the absence of a verified wetland delineation by the USACE, RWQCB, and CCC, the Draft EIR/EIS conservatively assumes that any wetland or water feature mapped during field surveys conducted for the proposed project, mapped in the U.S. Fish and Wildlife Service (USFWS) National Wetland Inventory (NWI), and mapped in the wetland delineation report is potentially jurisdictional. The wetland delineation report would need to be approved by the agencies to determine the limits of jurisdictional wetlands and waters within the project area. In response to this comment, the text in Section 4.6.1.6, Wetlands and Other Waters has been revised to clarify these assumptions. See the response to comment MCWD-134 in Section 8.5.2 for the revised text.

CEMEX-18 As described on Draft EIR/EIS page 4.15-21, in its cultural resources investigation and evaluation for the test slant well, SWCA determined that the Lapis Sand Mining Plant was a Historic District eligible for listing in the National Register of Historic Places and the California Register of Historical Resources under Criteria A/1 (association with an important event) and Criteria C/3 (architectural merit). The SHPO concurred with this recommendation, see EIR/EIS Section 7.1.3, and the Lead Agencies defer to the SHPO's concurrence.

The proposed Source Water Pipeline would be installed within the boundaries of the Historic District; however, the buildings and structures that contribute to the district are outside of the direct and indirect APE for the proposed project. Therefore, no further consideration of the architectural components of this resource was deemed necessary for the proposed project. Since publication of the Draft EIR/EIS, the SHPO concurred with a finding of No Adverse Effects to Historic Properties for the proposed project, see EIR/EIS Section 7.1.3.

CEMEX-19 As discussed in EIR/EIS Section 4.17, Mineral Resources, although mining operations would experience minor disruptions during project construction, access for mining vehicles would continue during construction, access to the dredge pond would continue during construction, and mining operations would continue throughout project construction. Also, as stated on Draft EIR/EIS page 4.17-8, "since CEMEX facility operators mine sand from the dredging pond, which is continuously replenished by sand that is washed over the berm, the siting of the subsurface slant wells in the CEMEX active mining area would not interfere with sand mining activities or adversely affect the availability of mineral resources for future recovery." For those reasons, Section 4.17 supports the conclusion that construction-related impacts would be less than significant.

As discussed on Draft EIR/EIS pages 4.9-24 and 4.9-25 in Section 4.9, Traffic and Transportation, Mitigation Measure 4.9-1 (Traffic Control and Safety Assurance Plan) has been developed for the project as a whole and applies to all project components and associated construction activities. Mitigation Measure 4.9-1 includes several requirements that would be applicable to the CEMEX access road, including maintaining alternate one-way traffic flow past the construction zone where possible, restoring roads and streets to normal operation by covering trenches with steel plates outside of normal work hours or when work is not in progress, and complying with roadside safety protocols to reduce the risk of accidents.

In addition, Mitigation Measure 4.9-6 applies to all proposed facilities and associated construction activities and requires that CalAm repair roads damaged by project-related construction vehicles to a structural condition equal to that which existed prior to construction activities.

The following text addition has been made in Section 4.17, Mineral Resources, Impact 4.17-1, under the Impact Conclusion heading:

> For a discussion of mitigation measures that would apply to all project components related to traffic control and safety, as well as roadway rehabilitation, see Section 4.9, Traffic and Transportation, Impacts 4.9-1 and 4.9-6.

8.6.7 Responses to Comments from Citizens for Just Water

CJW-1 This EIR/EIS was prepared by the CPUC as the CEQA lead agency, and Monterey Bay National Marine Sanctuary (MBNMS) as the NEPA lead agency; see Master Response 1, EIR/EIS Authorship. See also Master Response 2, Source Water Components and Definitions, and Master Response 3, Water Rights.

CJW-2 EIR/EIS Section 4.4.1 presents the setting/affected environment for groundwater resources, and the proposed project's consistency with the Sustainable Groundwater Management Act (SGMA) is presented in Section 4.4.2.2. As summarized in Section 4.4.2.2, SGMA became effective January 1, 2015, and gives local agencies the authority to manage groundwater in a sustainable manner. A Groundwater Sustainability Plan will be prepared by the local groundwater agency that describes how users of groundwater within the basin would manage and use groundwater in a manner that can be sustainably maintained during the planning and implementation horizon without causing undesirable results. SGMA defines undesirable results as follows:

- Chronic lowering of groundwater levels indicating a significant and unreasonable depletion of supply;
- Significant and unreasonable reduction of groundwater storage;
- Significant and unreasonable seawater intrusion;
- Significant and unreasonable degraded water quality, including the migration of contaminant plumes that impair water supplies;
- Significant and unreasonable land subsidence that substantially interferes with surface land uses, and;
- Depletions of interconnected surface water that have significant and unreasonable adverse impacts on beneficial uses of the surface water

A summary of the analyses to address each undesirable result identified in SGMA has been added to Final EIR/EIS Section 4.4 in Impacts 4.4-3 (groundwater supplies and recharge) and 4.4-4 (groundwater quality) under the subheadings "Consistency with Regulatory Requirements." Based on those discussions, the project would not result in any of the six undesirable results cited in SGMA; therefore, the proposed project would be consistent with SGMA, and SGMA would not restrict the project's ability to pump groundwater as proposed. See also Master Response 6, Sustainable Groundwater Management Act.

MCWD supplies would not be affected by the proposed project; see EIR/EIS Table 4.4-10, Master Response 2, Source Water Components and Definitions, and Master Response 3, Water Rights, Section 8.2.3.7, and Master Response 8, Project Source Water and Seawater Intrusion. Furthermore, the text prepared by the Lead Agencies (not the proponent) on Draft EIR/EIS page 4-37 is neither self-serving,

because the Lead Agencies do not represent the interests of the Applicant, nor gratuitous, because NEPA requires the analysis of beneficial as well as adverse impacts. The assertion is substantiated by the EIR/EIS text that follows the quote provided in the comment: "Regarding the former [seawater intrusion], groundwater modeling shows that the proposed project would retard the advance and limit the ultimate inland extent of seawater intrusion. With respect to the latter [water surface elevations in the 400-Foot Aquifer], by returning in-lieu desalinated water to the CCSD, the proposed project would provide recharge benefits to groundwater levels in the 400-Foot Aquifer." This supports the conclusion on Draft EIR/EIS page 4.4-37 that, ". . . the proposed project would not conflict with the SGMA."

CJW-3 The topic of water rights is not typically addressed in an EIR/EIS. It is a legal matter that is rarely relevant to the question of whether a proposed project being evaluated under CEQA or NEPA would generate impacts on the environment. The issue of water rights is addressed in this EIR/EIS in Section 2.6 as a matter of project feasibility. See also Master Response 3, Water Rights, specifically Section 8.2.3.2 regarding the sequence of approvals vis-s-vis water rights. As noted, there is no state or local agency with authority to approve CalAm's water rights for the MPWSP. As stated on page 35 of the State Water Resources Control Board (SWRCB) Final Review of CalAm's MPWSP (EIR/EIS Appendix B2), "No permit is required by the State Water Board to acquire or utilize appropriative groundwater rights."

CJW-4 As noted in EIR/EIS Table 3-1, "The slant wells would draw water from groundwater aquifers that extend beneath the ocean floor (the Dune Sands Aquifer and the 180-Foot-Equivalent Aquifer of the Salinas Valley Groundwater Basin) for use as source water for the MPWSP." As explained in Section 3.2.1.1, "Each well would be screened for approximately 400 to 800 linear feet at depths corresponding to both the Dune Sand Aquifer and the underlying 180-Foot-Equivalent Aquifer of the Salinas Valley Groundwater Basin." See also Figure 4.4-3; Master Response 2, Source Water Components and Definitions; Master Response 3, Water Rights; and Master Response 4, The Agency Act and Return Water.

CJW-5 EIR/EIS Section 4.4.1.3 presents the Groundwater Enhancement Programs in the SVGB that are described by the commenter. EIR/EIS Section 4.4.5.2 found impacts on the groundwater basin resources, and therefore, impacts to these enhancement projects, to be less than significant.

CJW-6 See Appendix E2, Section 5.1, which states: "the slant wells will be screened in both the Dune Sand Aquifer and 180-FT Aquifer." See also quoted text in response to comment CJW-4. The existing MCWD 300-afy desalination plant is located 1-mile south of the test slant well, and has not been operational for at least a dozen years due to corrosion of the pipes and pumps.

EIR/EIS Section 4.4.4 presents the approach to analysis while Section 4.4.5 presents the direct and indirect effects of the proposed project on groundwater resources, and concludes the impacts would be less than significant. The analysis is supported by groundwater modeling that is described in Appendix E2. As described in Applicant Proposed Measure 4.4-3, the cost and responsibility for mitigating the unlikely effects of increased salinity or lowered groundwater levels would fall on CalAm, and not the well owners or ratepayers of MCWD.

See also Master Response 8, Project Source Water and Seawater Intrusion.

CJW-7 See Master Response 11, CalAm Test Slant Well. Specifically, Section 8.2.11.2 describes the City of Marina's review process and clarifies that the city declined to adopt its *Draft Initial Study and Mitigated Negative Declaration for the California American Water Slant Test Well Project.* Section 8.2.11.2 also describes the California Coastal Commission CEQA review process for the test slant well and Section 8.2.11.3 describes the NEPA review process. In response to this and other similar comments, footnote 2 in the Executive Summary (and other locations where similar text appears in the EIR/EIS) has been revised to clarify these agencies' actions and processes regarding consideration of the test slant well.

CJW-8 The EIR/EIS does, in fact, identify key differences between the MPWSP and the prior Coastal Water Project in Sections 1.4.1 and 1.4.2. However, differences between the MPWSP and the prior project, or between the EIR/EIS and the prior Coastal Water Project EIR are not pertinent to the current CEQA/NEPA analysis, which analyzes the impacts of the proposed MPWSP described in Chapter 3, against the existing environmental setting, or baseline conditions.

CJW-9 See response to comment PWN2-38 in Section 8.6.17 and Master Response 10, Environmental Baseline under CEQA and NEPA. The HWG prepared a separate baseline report for the test slant well, as described in Master Response 11, CalAm Test Slant Well, Section 8.2.11.4. It is referenced in EIR/EIS Section 4.4 as Geoscience, 2015b; the April 20, 2015 report titled *Baseline Water and Total Dissolved Solids Levels Test Slant Well Area* was prepared by the HWG in response to Special Condition 11 of the CDP, and continues to be publicly available at: https://docs.wixstatic.com/ugd/28b094_bd1db648e7b44f32a9676dfc7bf71989.pdf

CJW-10 See Master Response 9: Electrical Resistivity Tomography (ERT) and Airborne Electromagnetics (AEM).

CJW-11 See Master Response 11, CalAm Test Slant Well, Section 8.2.11.8, and response to comment Marina-11 in Section 8.5.1. In addition to the slant wells discussed in Master Response 11, Santa Cruz rejected subsurface intakes because of the lack of sand cover over bedrock (Kennedy/Jenks Consultants, 2011).

Monitoring of the slant test well at CEMEX demonstrates that the salinity impacts are very localized. The EIR/EIS provides modeling results of the proposed production slant wells that indicate they would also increase salinity locally at the CEMEX site, but would retard further inland encroachment of seawater. See Draft EIR/EIS Section 4.4.5.2 at page 4.4-77 and Appendix E2 Section 5.4 at page 40 and Master Response 8, Project Source Water and Seawater Intrusion. Uncertainty is addressed in EIR/EIS Appendix E2 Section 6.

CJW-12 EIR/EIS Section 4.4.5 presents the direct and indirect effects of the proposed project on groundwater resources, and concludes the impacts on the SVGB would be less than significant and water supplies would not be affected by the proposed project. See Master Response 8, Project Source Water and Seawater Intrusion, as well as responses to comments MCWD-168 and MCWD-170 in Section 8.5.2.

8.6.8 Responses to Comments from Coalition of Peninsula Businesses

CPB-1 See the discussion of "Supply Provided by the Desalination Plant" in Section 8.2.13.3 of Master Response 13, Demand (Project Need) and Growth.

CPB-2 See the discussion under "Comments Urge Higher Demand Number" in Section 8.2.13.2 of Master Response 13.

CPB-3 EIR/EIS Table 2-4, CalAm Monterey District Water Supplies with Proposed MPWSP, shows the amount of water supply available for other uses after meeting service area demand. Other uses would include CalAm's return water obligation. While the precise quantity of Salinas Valley Groundwater Basin return water that will be needed initially, until the wells equilibrate, and how much that will change over time is not currently known, groundwater modeling conducted for the EIR/EIS assessed a range of return water scenarios between 0 and 12 percent. See the discussion under "Supply available for other use" in Master Response 13, Section 8.2.13.3 . See also Master Response 4, The Agency Act and Return Water.

CPB-4 The demand numbers shown in Chapter 2 indicate system demand – not consumption by water users – and thus include non-revenue water. As discussed in EIR/EIS Section 2.5.3.3., the SWRCB's 2009 cease and desist order (CDO) requires CalAm to reduce non-revenue water in the Monterey District, and for the last three years for which data were available (2013 through 2015), the reduction in system losses exceeded the target established in the CDO.

CPB-5 The EIR/EIS evaluates the desalination plant as proposed by CalAm in its application for project approvals, and as updated by subsequent testimony and amendments (i.e., a 9.6 mgd plant). Consideration of a larger desalination plant than currently proposed is not within the scope of this EIR/EIS. See also the discussion under "Comments Urge Higher Demand Number" in Section 8.2.13.2 and "Supply Provided by the Desalination Plant" in Section 8.2.13.3 of Master Response 13.

CPB-6 An expansion of the proposed MPWSP would require additional evaluation by the Lead Agencies; however, at this time, no such project change has been proposed.

CPB-7 The peer review by LBNL was conducted on the 2015 version of the North Marina Groundwater Model ($NMGWM^{2015}$), which both LBNL and HydroFocus independently determined to be deficient in the simulation of the Ford Ord area and the Dune Sand aquifer. As part of the HydroFocus review of the $NMGWM^{2015}$ and revision that resulted in the 2016 version ($NMGWM^{2016}$), available geologic reports from the area were reviewed. HydroFocus determined the need to include the A-Aquifer and the Fort Ord-Salinas Valley Aquitard independent of the LBNL review, and the $NMGWM^{2016}$ implements this revision. See Master Response 12, The North Marina Groundwater Model (v. 2016), for more information.

CPB-8 The discussion of water supply and growth for each of the alternatives appears in EIR/EIS Section 5.5.21.2. This section provides details on the source of water and return water for each of the alternatives that include water from the GWR Project (i.e., Alternatives 5a and 5b). See also Master Response 13 for a detailed discussion on water supply and growth related to the proposed project under various scenarios and supply from the GWR Project. But the comment that the now-approved Water Purchase Agreement (WPA) allows for less than expected GWR water production for essentially two or three year periods, is unclear. The WPA approved by the CPUC in September 2016, includes a Water Availability Guarantee at Section 13, that speaks to CalAm's allotment of 3,500 afy from the GWR project, and CalAm's right to draw on reserve water[1] in the event the MPWMD fails to deliver CalAm's allotment in any given year, in order to meet the Water Availabilty Guarantee.

[1] Reserve water is the quantity of water delivered annually to the Seaside Basin in excess of CalAm's annual allotment of 3,500 afy, minus the quantities of reserve water previously drawn upon to satisfy CalAm's annual allotment.

8.6.9 Responses to Comments from DeepWater Desal, LLC

DWD-1 The DeepWater Desalination Project is undergoing a separate environmental review process. See Master Response 15, Alternative Desalination Projects – Status, Information Sources, and Cumulative Scenario. As noted in EIR/EIS Section 5.4.5, "The evaluation of this alternative in this EIR/EIS is based on information available publically, information provided by MBNMS, and the independent judgement of the analysts using the best available information. More detailed analyses of the DeepWater Desal Project will be forthcoming in the separate EIR/EIS and will be based on technical studies that were not available at the time this EIR/EIS was being prepared. The approach to analysis of the impacts of the DeepWater Desal Project in this EIR/EIS is intended to be reasonable so as not to over- or under-state impacts, but also draws conservative conclusions where information is currently unavailable."

Throughout Chapter 5, Alternatives Screening and Analysis, the analysis of Alternative 3 impacts clearly indicates that some conclusions are conservative because not enough information is available to conclude that impacts would be less than significant or that mitigation would be effective in reducing impacts to less than significant. However, the MPWSP EIR/EIS necessarily includes significance determinations in the analysis of the environmental impacts of this potential alternative, as required by CEQA Guidelines Section 15126.6(d) and 40 CFR 1502.16.

DWD-2 The MPWSP EIR/EIS does not analyze a "scaled-down" version of the DeepWater Desal Project (Monterey Bay Regional Water Project or MBRWP), either as Alternative 3 or as a cumulative project in combination with other alternatives. Rather, the EIR/EIS analyzes the DeepWater Desal Project in the form and scope proposed by the DeepWater Desal proponent. As described in EIR/EIS Section 5.4.5, the description of Alternative 3 "includes the construction and operation of a screened open ocean intake system, a seawater desalination facility, a co-located data center, and associated components to provide up to 25,000 afy of potable water and data transmission and storage services." Because project alternatives must meet most of the basic project objectives, the EIR/EIS must evaluate a description of Alternative 3 that would serve the same Monterey District demand that the MPWSP is proposed to serve. However, because product water from Alternative 3 would exceed this demand, the balance is proposed to serve other areas. For example, as was stated on Draft EIR/EIS page 5.4-34, "The DeepWater Desal proposal includes product water pipelines to supply three different areas: the Monterey Peninsula; Castroville and Salinas; and North Monterey and Santa Cruz Counties. It is assumed that up to an additional 25 miles of product water pipelines could be constructed to accommodate the product water that would not serve the Monterey Peninsula." Similarly, when analyzing the DeepWater Desal Project in the cumulative scenario relevant to other alternatives, the analysis assumes the project would be constructed as proposed by DeepWater Desal, LLC.

DWD-3 The EIR/EIS does not consider the DeepWater Desal Project in the context of the MPWSP only as an "either/or" situation. The DeepWater Desal Project is considered as a choice instead of the MPWSP (thus, as an "either/or" choice) in Alternative 3, but the EIR/EIS also addresses the DeepWater Desal Project as a cumulative project that could be built in addition to the MPWSP.

As described in Master Response 15, Section 8.15.2.3, and as explained in more detail below, the DeepWater Desal Project is proposed by DeepWater Desal, LLC as a regional project that would serve customers in CalAm's Monterey District service area as well as customers in Salinas and Santa Cruz County. The DeepWater Desal Project is best understood as an alternative to the MPWSP because it is a desalination plant being separately proposed to meet the same project objectives of the MPWSP. However, the DeepWater Desal Project is also considered in the cumulative impacts analysis because the project proponent has indicated that it intends to proceed even if another desalination plant is selected to serve the Monterey District service area since it would provide water to other areas outside the CalAm service area. Therefore, the EIR/EIS considers two reasonably foreseeable scenarios that include development of the DeepWater Desal Project:

1) Development of the DeepWater Desal Project as an alternative to the MPWSP (serving CalAm's Monterey District service area and customers in Salinas and/or Santa Cruz County). This regional project is Alternative 3, and it is described in EIR/EIS Section 5.4.5 and is analyzed in Section 5.5.

2) Development of the DeepWater Desal Project as a separate project *in addition to* the MPWSP or another alternative that would serve CalAm's Monterey District service area; see Project No. 34 in EIR/EIS Table 4.1-2. In this case, the impacts of the DeepWater Desal Project are considered in the cumulative scenario since the provision of water to Santa Cruz County and the City of Salinas would be a reasonably foreseeable project in addition to the MPWSP. A scenario in which the MPWSP, as well as the DeepWater Desal Project may be constructed, is addressed in the cumulative analyses of the proposed project in EIR/EIS Chapter 4; scenarios in which the DeepWater Desal may be constructed in addition to other alternatives are addressed in the cumulative scenario relevant to all other alternatives in Section 5.5; see EIR/EIS Table 5.5-1.

DWD-4 The Lead Agencies acknowledge that DeepWater Desal, LLC does not propose a scaled-down version of the DeepWater Desal Project. As described below, the statement on Draft EIR/EIS page 5.3-16, "This analysis assumes a version that has been scaled down to meet the needs of the 9.6 mgd project proposed by CalAm," refers specifically to Intake Option 9 and not to the DeepWater Desal alternative (Alternative 3).

See introductory text in EIR/EIS Section 5.3, Alternatives Development, Screening and Evaluation Process, which describes the process of screening alternative components to those proposed by CalAm – including intake, outfall, and desalination plant options. As stated therein, "Components that are considered to be the least environmentally

damaging are then combined into "whole" alternatives in Section 5.4." As described in response to comment DWD-2, the EIR/EIS does not analyze a scaled-down version of the DeepWater Desal Project. Rather, Section 5.3 of the EIR/EIS evaluates component options (options for intake, outfall, and desalination plant locations) for various factors to determine which options are carried forward. Some of the intake and outfall options screened in Section 5.3 are considered because they are similar to options proposed by other projects and proponents, including DeepWater Desal. See EIR/EIS Section 5.3.2 for a description of this component development and screening process.

Section 5.3.3 pertains only to intake options (i.e., that may be combined with a desalination plant, an outfall facility, distribution pipelines, and other project components into a "whole" alternative). As described in Section 5.3.3.9, Intake Option 9 was carried forward into the development of Alternative 2, and is not part of the DeepWater Desal alternative (Alternative 3).

Similarly, Section 5.3.4 pertains only to outfall options (i.e., that may be combined with other components into a "whole" alternative). As stated therein, "only the proposed use of the existing [MRWPCA] outfall was carried forward in the development of the "whole" alternatives."

DWD-5 Table 5.3-1, Intake Option Screening Results, and Section 5.3.3.9, Intake Option 9 – Screened Deep-water Ocean Intake at Moss Landing, have been revised as suggested in this comment for clarity. Note that the description of the intake pipeline diameter of 36-inches is consistent with the description of Alternative 2 in Section 5.4 (see Table 5.4-1) and therefore, does not alter the impact analysis of Alternative 2. Note also that Intake Option 9 is not relevant to the description of Alternative 3 (the DeepWater Desal Project), and is only relevant to the Lead Agencies' process of creating other alternatives by combining components as described in Section 5.3.

DWD-6 Table 5.3-2, Outfall Options Screening Results and Section 5.3.4.7, Outfall Option 7 – New Outfall at Moss Landing, have been revised as suggested in this comment. However, note that Outfall Option 7 was screened out from further evaluation in Section 5.3.6.1 and is not included in any of the alternatives analyzed in detail. Therefore, these revisions do not alter the impact analysis. Note that the referenced sentence on Draft EIR/EIS page 5.3-16, "This analysis assumes a version that has been scaled down to meet the needs of the 9.6 mgd project proposed by CalAm," refers specifically to Intake Option 9 and not to the DeepWater Desal alternative (Alternative 3).

DWD-7 The suggested change has been made in Section 5.4.5.1.

DWD-8 The suggested change has been made in Section 5.4.5.1.

DWD-9 As explained in EIR/EIS Section 3.2.1, Source Water Intake System, the proposed slant wells would extend west beneath the seafloor. The EIR/EIS explains in

Impact 4.2-4 that "In comparison to aboveground structures, underground pipelines, and buried structures are generally less susceptible to liquefaction damage because they are embedded in compacted backfill that can tolerate more seismic wave motion." Pipelines are relatively narrow and flexible structures able to accommodate some movement. In addition, the susceptibility to the potential for damage from liquefaction decreases with the increasing depth of the slant wells further out under the ocean. Finally, as explained in EIR/EIS Section 2.4, Available Supplies, and as listed in Table 2-4, CalAm does have other available water supplies in the event that damage to the slant wells requires a temporary shutdown for repairs. Therefore, a public health emergency due to the shutdown of the slant wells is unlikely.

The commenter provided the results of a recent liquefaction study of the DeepWater Desal Project area that indicates the potential for liquefaction at the location of the Alternative 2 and/or Alternative 3 intake infrastructure is relatively low. However, as explained above, the potential for damage due to liquefaction at the proposed slant well location is similarly relatively low. Therefore, the requested revision – "reduced impact related to liquefaction" – was not made in response to this comment.

DWD-10 EIR/EIS Table 5.3-6 has been revised to indicate that the preliminary environmental impacts comparison of Desalination Plant Site Option 3 for surface water hydrology and water quality would be "Similar" to the proposed project desalination plant site. To clarify, as stated on Draft EIR/EIS page 5.3-54, among the alternative desalination plant sites considered in the screening of alternative components, "only the Charles Benson Road site was carried forward for development of whole alternatives." Thus, Desalination Plant Site Option 3 was not incorporated into alternatives developed specifically for the proposed MPWSP. However, because this site is the location of the proposed DeepWater Desal plant, it is evaluated in detail under Alternative 3 in EIR/EIS Section 5.5.3.6, which evaluates surface water hydrology and water quality impacts of Alternative 3. This analysis acknowledges that "impacts related to flooding and flood risks, including those from tsunami and sea level rise, would result in a slightly reduced level of impact compared to the proposed project due to the inland location of the desalination facility and data center;" therefore, no revisions were made to the analysis of Alternative 3 in response to this comment.

DWD-11 EIR/EIS Table 5.3-4, Intake Options Evaluation – Preliminary Environmental Impact Comparison, in Section 5.3.6.1, Evaluation Results for Intake, Outfall and Desalination Plant Options, has been revised as requested in this comment. Note that this revision is consistent with detailed analysis of Alternative 2 (which incorporated Intake Option 9) in Section 5.5.16.5, which explains that operation and siting of the intake system would have no impact on agricultural resources.

DWD-12 The second sentence of the quoted text from Table 5.3-4 on Draft EIR/EIS page 5.3-32 is not specific to construction impacts. No change has been made in response to this comment. Detailed analysis of Alternative 2 (which incorporated Intake Option 9) is provided in Section 5.5.

DWD-13 It is not currently known whether feasible mitigation strategies would be available to address the stated impingement and entrainment impacts. Thus, no change is warranted in response to this comment. Detailed analysis of Alternative 2 (which incorporated Intake Option 9) is provided in Section 5.5.

DWD-14 EIR/EIS Section 5.5.1 presents an overview of the approach to the alternative impact analysis. The results of the evaluation of the proposed project on marine biological resources are summarized in Section 5.5.5.2; the operational and facility siting impacts of Alternative 3 (DeepWater Desal) using the same evaluation criteria that were applied to the proposed project are presented in Section 5.5.5.6. An alternatives impact summary is presented in Table 5.6-1 and conclusions on marine biological resources impacts are summarized on Draft EIR/EIS pages 5.6-10 and 5.6-11. While each impact statement often included analysis of several components that would contribute to the impact being analyzed, the impact conclusions in the EIR/EIS were drawn only for each impact statement. For example, Impact 4.5-4[1] for Alternative 3 considered the permanent loss of seafloor, entrainment, ability to effectively mitigate, brine salinity, and other Ocean Plan constituents including polychlorinated biphenyls (PCBs), and temperature. The conclusion for Impact 4.5-4 for Alternative 3 was determined to be significant and unavoidable because of the 16,700 square feet of permanent loss of seafloor habitat, the uncertainty of the efficacy of mitigation for entrainment impacts on marine resources, the potential for salinity to exceed 2 parts per thousand (ppt) beyond the brine mixing zone (BMZ), and an increase in temperature of the discharge. Since an impact conclusion was not drawn for each component within the impact statement, and no independent conclusion was drawn for the severity of the potential entrainment impact, no changes to the significance conclusions for Alternative 3 have been made in response to this comment.

While the Lead Agencies appreciate the presentation of the 2004 CA Coastal Commission's Coastal Act Report, the approach to fisheries management plans and the extensive discussion of proportional mortality, the EIR/EIS does not rely on the cited 2004 quote for the threshold of significance for entrainment impacts. Rather, the analysis, as required by CEQA and NEPA, compares the potential impacts of the proposed project (and alternatives) against baseline conditions and the No Action alternative respectively, to determine if the proposed project would "result in a substantial adverse effect, either directly or through habitat modifications . . . on any species, natural community, or habitat ... ." See CEQA Guidelines Appendix G Environmental Checklist Form, Section IV(a). The analysis in EIR/EIS Section 5.5.5.6 relies on the 2016 Ocean Plan acknowledgment that seawater is habitat and recommends using Area of Production Forgone (APF) to estimate mitigation. During operations, the DeepWater Desal Project would draw 55 mgd of habitat as source water, which represents a reduction in habitat. The impact conclusion in Section 5.5.5.6 relied on the likelihood of Alternative 3 to effectively

[1] Have a substantial adverse effect, either directly or through habitat modification . . .on any marine species, natural community, or habitat . . . during operations.

compensate for the loss of habitat, and as noted in Section 5.5.5.6, ". . . residual impacts may remain due to the uncertainty of the efficacy of the mitigation." See also response to comment DWD-15.

DWD-15 CEQA requires an EIR to include sufficient information about each alternative to allow meaningful evaluation and comparison. NOAA's NEPA implementing policy, "Policy and Procedures for Compliance with the National Environmental Policy Act and Related Authorities," requires the decision maker to use the "best available scientific information and analysis to present the environmental effects of the proposed action and alternative(s) in comparative form, providing a clear basis for choice among the options." (NOAA 2017) EIR/EIS Section 5.1.1.1 notes that if an alternative would cause one or more significant effects not caused by the proposed project (in this case, entrainment at the screened open water intake), the significant effects must be disclosed but in less detail than the significant effects of the project. EIR/EIS Section 5.1.1.2 notes that NEPA requires agencies to provide substantial and detailed treatment to each alternative in the analysis, and impacts of the alternatives should be presented in comparative form in order to sharply define the issues and provide a clear basis for choice to the public and the decision-makers. What is presented in Section 5.5.5.6 on Draft EIR/EIS page 5.5-122 is an impact that is unique to the alternatives proposing screened open water intakes, and the estimated APF is provided as a general indication of the order of magnitude of each project's potential effect that would not also be caused by the proposed project. The impact conclusion was based on the fact that although mitigation is required, "residual impacts may remain due to the uncertainty of the efficacy of the mitigation" (Draft EIR/EIS page 5.5-122), consistent with 40 CFR 1508.27(b)(5) which requires a NEPA lead agency to consider "The degree to which the possible effects on the human environment are highly uncertain or involve unique or unknown risks" in its assessment of impact intensity.

With respect to the use of preliminary information prior to finalization of the Tenera Report to support the EIR/EIS conclusions, MBNMS is currently reviewing the Tenera Intake Assessment and Addendum (Tenera, 2016), in coordination with the California Coastal Commission, in the context of its role as Lead Agency for the separate NEPA analysis of the DeepWater Desal Project application. At this time, it is premature to conclude that this most recent report supports a conclusion that entrainment impacts would not be significant. Moreover, as discussed in EIR/EIS Section 5.5.5.6, the consideration of potential operational impacts from Alternative 3 was not limited to analysis of the potential ETM/APF, but also included consideration of updated brine discharge modeling as well as potential temperature increase to receiving waters from the brine discharge. Although the separate DeepWater Desal Project CEQA and NEPA analysis, when completed, may include more detailed conclusions that differ somewhat from those presented here for Alternative 3, the Lead Agencies for the MPWSP are obligated to make conclusions based on the best available information to support the necessary comparison among alternatives. Therefore, no changes have been made in response to this comment.

DWD-16 Until such time as the Lead Agencies confirm the feasibility analysis and SWRCB provides a determination of consistency with Water Code 13142.5(b) on the intake, "Alternative 3 may be inconsistent with MBNMS Desalination Guidelines with regard to its open water intake and lack of a combined discharge", as concluded in EIR/EIS Section 5.5.5.6. No changes have been made in response to this comment. Also, see added text in EIR/EIS Section 6.4 regarding this alternative's consistency with MBNMS Desalination Guidelines.

DWD-17 The comment does not dispute the facts presented in the EIR/EIS, but points out that the "circumstances required for this situation include the data center using no water for cooling, a Davidson current, and the desalination plant undergoing start-up activities." As noted in the Draft EIR/EIS on page 4.2-49, "such exceedances are based on worst-case model simulations and may not occur under actual operational conditions," in agreement with this assessment. The Lead Agencies note that such potential worst-case exceedances are not the basis for the conclusion in Section 5.5.3.6 that Alternative 3 would have a less-than-significant impact with mitigation. Rather, the significant impact conclusion is based on the absence of a monitoring and reporting plan, which is in conflict with applicable plans and policies.

Further, the comment notes that the DeepWater Desal Project now proposes a modification of the discharge louvers, with more jets that would result in no modeled exceedance outcomes as explained in Jenkins' update to the Brine Dilution Analysis for the DeepWater Desal Project (2017). That update describes a discharge design with 14 discharge jets as compared to the five jets proposed in the project description information that is the basis for the analysis of Alternative 3. No additional information on this revised project design change has been submitted to the MPWSP Lead Agencies, and no other analysis has been undertaken to address this change. Although salinity impacts may be reduced compared to the five-jet design, construction-related impacts and permanent impacts related to this revised design also may change. In the absence of additional information about this revised proposal, and because salinity impacts already are considered less than significant, no changes have been made to the Draft EIR/EIS in response to this comment.

DWD-18 In response to this comment, the last paragraph of "Facility Siting Impacts" in Section 5.5.3.6 has been revised as follows:

> ~~In addition to physical impacts, Alternative 3 may be inconsistent with~~ The MBNMS Desalination Guidelines (NOAA, 2010)~~, with regard to its lack of a combined discharge compared to the proposed project, which would use an existing outfall. One of the guidelines~~ state: "project proponents should investigate the feasibility of diluting brine effluent by blending it with other existing discharges." Although a combined discharge currently is not proposed for Alternative 3, the DeepWater Desal Project proponent is investigating the feasibility of diluting brine effluent by blending it with Moss Landing Power Plant cooling water through a combined discharge. If proposed by DeepWater

Desal, the separate EIR/EIS for the DeepWater Desal Project will evaluate this option in detail, but it is not included as part of Alternative 3.

DWD-19 In response to this comment, the Lead Agencies reviewed the conclusion that Alternative 3 would have a significant and unavoidable contribution to significant cumulative impacts related to salinity and other Ocean Plan constituents and found that this conclusion statement was in error. Text in the last paragraph of Section 5.5.3.6 has been revised as follows:

> The most recent amendment to the Ocean Plan (SWRCB, 2016b) reflects the SWRCB's process of adapting to the need to regulate discharges from desalination projects. Ocean Plan water quality objectives are incorporated into NPDES permits in the form of specific water quality requirements. As discussed above, under some circumstances, Alternative 3 discharges occasionally c~~w~~ould exceed the 2 ppt salinity significance threshold by 0.15 ppt, and could exceed Ocean Plan water quality objectives for PCBs. Because proponents of the DeepWater Desalination Project have not proposed a monitoring and reporting plan that demonstrate~~d~~s methods of compliance with the Ocean Plan objectives that are protective of beneficial uses, and feasible mitigation strategies have not yet been identified, Alternative 3 in combination with other cumulative projects c~~w~~ould result in significant ~~and unavoidable~~ cumulative impacts on ocean water quality and Alternative 3 would have a cumulatively considerable contribution to such effects ~~(*significant and unavoidable*)~~. However, with the implementation of a monitoring plan consistent with Ocean Plan requirements that defines clear performance standards and feasible corrective actions linked to the defined performance standards substantially similar to **Mitigation Measures 4.3-4 and 4.3-5** (but revised specific to the Alternative 3 project final design and defined operating conditions), the contribution of Alternative 3 could be reduced to a level that is less than significant because it would comply with Ocean Plan requirements (*less than significant with mitigation*).

Additionally, the summaries of impacts in Table ES-1 and Table 5.6-1 have been revised to indicate that this impact (4.3-C) would still be increased compared to the proposed project, but would be less than significant with mitigation, rather than significant and unavoidable. The above revision does not affect the consideration of Alternative 3 compared to the proposed project and other alternatives because the relative impact of Alternative 3 remains increased compared to the other alternatives.

DWD-20 As noted in the description of Alternative 3 in Section 5.4.5.1, "the Castroville Pipeline, the Pipeline to CSIP Pond, and the operational components related to delivering water to CCSD would not be implemented" for this alternative. Alternative 3 would require 6.5 miles of product water pipeline between the desalination plant and the CalAm distribution system; the 25 miles of additional pipeline are assumed to be to the north of the Alternative 3 desalination plant. As noted in Table 5.4-1, Alternative 3 would have a total of 48 miles of pipelines; this

total accounts for the product water pipelines that differ from the proposed project. No changes have been made in response to this comment.

DWD-21 The Draft EIR/EIS on page 5.5-121 discusses additional construction activities associated with Alternative 3 beyond those cited in the comment (e.g., anchor chains on construction barges used during placement of both intake and discharge structures would pose temporary obstructions, temporary disturbance to and possible loss of soft substrate habitat or function), which "could cause altered behavior (altered foraging and swimming patterns) in some special status fish, marine mammals and sea turtles." No changes have been made in response to this comment.

DWD-22 At this point in the planning and review process for the DeepWater Desal Project, the Lead Agencies cannot substantiate that any constraint on local and/or regional power transmissions caused by MBRWP would be mitigated before interconnection. No changes have been made in response to this comment.

DWD-23 See response to comment DWD-3.

DWD-24 See response to comment DWD-2.

DWD-25 Receipt of the four attachments to the DeepWater Desal letter is acknowledged. Where the letter has made specific reference to these attachments in comments DWD-1 through DWD-24, specific responses have been provided.

8.6.10 Responses to Comments from Ecological Rights Foundation, the Center for Biological Diversity, and Our Children's Earth Foundation

ERF-1 See responses below for specific discussions of revisions made to the EIR/EIS. Per CEQA Guidelines Section 15088.5, "New information added to an EIR is not "significant" unless the EIR is changed in a way that deprives the public of a meaningful opportunity to comment upon a substantial adverse environmental effect of the project or a feasible way to mitigate or avoid such an effect that the project's proponents have declined to implement." Furthermore, "Recirculation is not required where the new information added to the EIR merely clarifies or amplifies or makes insignificant modifications in an adequate EIR." Likewise, under NEPA regulations at 40 CFR 1502.9(c), a supplement to an EIS is required if there are significant new circumstances or information relevant to environmental concerns and the impacts of the proposal. The questions raised by the commenter, and any revisions that have been made to the Draft EIR/EIS in response, are not significant in a way that would require recirculation of or supplement to the Draft EIR/EIS because they provide additional clarifications, and do not change any of the impact determinations, previously discussed in the Draft EIR/EIS.

ERF-2 Regarding the CEQA and NEPA baseline generally, see EIR/EIS Section 4.1.3 and Master Response 10, Environmental Baseline under CEQA and NEPA, which explains that since the CPUC issued its NOP in 2012, the Lead Agencies have developed or received new data on some of the resource areas, so they have updated the baseline data as appropriate. EIR/EIS Table 4.3-5 presents concentrations over varying time periods for the contaminants of concern for impacts on water quality and marine organisms and the associated discussion describes how such concentrations relate to and are considered in the impact analyses for project operations. Regarding the need for additional water quality data to fully describe baseline conditions and to assess impacts, EIR/EIS Section 4.3.1 and Appendix D3 present detailed baseline water quality information specific to Monterey Bay, including site-specific water quality data for the area surrounding the MRWPCA outfall diffuser, sufficient for assessing the potential impacts from implementation of the MPWSP. The list of references used in the preparation of Section 4.3 includes Central Coast Long-term Environmental Assessment Network (CCLEAN) data referenced in the comment from 2011 and 2014, as well as CCLEAN data from 2012, 2013, and 2016.

Regarding environmental monitoring conducted as part of mitigation to comply with the Ocean Plan and how such obtained information relates to the project baseline in regards to assessing impacts from implementation of the project, see response to comment Marina-41 in Section 8.5.1, which explains that surveys conducted as part of Mitigation Measure 4.3-4 do not constitute deferral under CEQA of either a characterization of baseline conditions or the analysis of potential impacts from implementation of the proposed project or alternatives.

ERF-3 The EIR/EIS uses the ABA Consultants 1999 report to help identify and characterize the benthic community occurring at the study site. The report reflects monitoring and sampling taken between 1977 and 1994, and although the sampling methodology may have changed over time and has some limitations described by the commenter, the information is sufficient and is the best available to provide overall observations of the condition of the benthic community. But the EIR/EIS impact analysis did not rely on the conclusions of that report regarding potential effects of the MRWPCA wastewater discharges, which are not the subject of the impact analysis in this EIR/EIS. As described in EIR/EIS Section 4.5.1.4, the EIR/EIS also relies on video of the benthic community surrounding the MRWPCA outfall taken during routine maintenance in 2014, and the conditions documented are similar to those summarized in, and confirm, the ABA Consultants report.

ERF-4 See response to comment ERF-2 and Master Response 10, Environmental Baseline under CEQA and NEPA.

ERF-5 This comment uses several terms including need, objectives, proposed project, and proposed action, in ways that are inconsistent with their definitions and uses in the EIR/EIS, and references Draft EIR/EIS pdf page 3 ("Dear Reviewer" letter), and Section ES.3.3 and ES.3.2 (Executive Summary), while the objectives are provided in Section 1.3, Project Objectives and Purpose and Need. The project purpose (and need for the project) is presented in EIR/EIS Section 1.3 and begins by explaining the MPWSP is **needed** to replace existing water supplies that have been constrained by legal decisions affecting the Carmel River and Seaside Groundwater Basin water resources. As a result of the constrained supply situation, nine (9) primary **objectives**, and six (6) secondary **objectives**, of the proposed project are clearly listed in EIR/EIS Section 1.3.1 (and in Section 5.1.2.1), including the demands the **proposed project** intends to meet.

EIR/EIS Section 3.1 explains that the project (and Alternative 5a, the Environmentally Superior/NEPA-Preferred Alternative with GWR, see EIR/EIS Section 5.6) is proposed to produce approximately 10,750 afy to develop a new water supply for the Monterey District service area, and the proposed MPWSP desalination plant would have a rated capacity of 9.6 million gallons per day (mgd). See also Footnote 1 in EIR/EIS Section 3.1.

EIR/EIS Section 2.3 describes the project demand assumptions that were proposed by the Applicant as the basis for the MPWSP's proposed capacity, including demands of existing customers (Objective 4), legal lots of record (Objective 6), and tourism under recovered economic conditions (Objective 7). EIR/EIS Section 6.3 evaluated, determined and disclosed how much of the proposed project capacity would be utilized for existing customers and how much would be available for growth.

EIR/EIS Section 5.4 describes alternatives to the proposed project, and each alternative is evaluated for its ability to meet project objectives; see EIR/EIS Sections 5.4.2.4, 5.4.3.4, 5.4.4.4, 5.4.5.4, 5.4.6.4, 5.4.7.4, and 5.4.8.4.

ERF-6 Impacts on marine species during MPWSP operations, as a result of the potential impingement of organisms or through the accumulation of fine particulate material on the seafloor, are evaluated in detail in EIR/EIS Section 4.5.5.2. The analysis examined the speeds of wave-induced and ambient ocean currents, and the velocity of water being drawn through the seafloor to the slant wells to determine the probability of impingement of organisms and particulate material against the seafloor. The EIR/EIS concludes that swimming speeds of invertebrate plankton substantially exceed the estimated vertical infiltration rate for the MPWSP slant wells (see Table 4.5-8) by several orders of magnitude. Therefore, no impingement from slant well operations is expected to occur.

The impingement of organic matter on the seafloor is also addressed in Section 4.5.5.2 and the EIR/EIS concluded that normal wave generated water velocities at the seafloor locations of the slant wells is predicted to be 8 to 20 times greater than that required for fine-grained material to accumulate on the seafloor over the subsurface slant wells. As a result, there would be no potential for the impingement of fine organic matter on the seafloor or changes to soft substrate habitat.

The screened portion of the slant wells that would be located within MBNMS (below Mean High Water, see EIR/EIS Figure 3-3a) would be within the intertidal and nearshore habitats as described in EIR/EIS Section 4.5.1.2, which are characterized by sandy beaches subject to daily tidal changes. Various invertebrate animals live in the sand and in wracks of decaying seaweed and other detritus, while market squid (*Doryteuthis (Loligo) opalescens*) inhabit the pelagic habitat in Monterey Bay but return to shallower nearshore areas (in water depths between 18 to 55 meters or 59 to 180 feet) to spawn on sand and mud sea floor habitats. Because the depth ranges for squid spawning is much deeper than the intertidal zone where slant wells would be located, potential impacts on market squid from slant well pumping would not be a reasonable conclusion.

ERF-7 The EIR/EIS extensively assesses the potential concentration of the brine discharge within the Brine Mixing Zone (BMZ) (Section 4.3.5.2, Surface Water Hydrology and Water Quality) that was in turn used to assess the potential effects on marine biological resources inhabiting the Project Study Area and the BMZ. The Coanda Attachment and hypoxia are discussed on Draft EIR/EIS page 4.3-83, and the EIR/EIS concludes that it would not occur because the plume would be affected (influenced and further diluted) by ocean currents and waves (which generate horizontal and vertical movement) after contact with the seafloor, and therefore, would not follow and travel along the seafloor "like Saran Wrap."

An extensive analysis of brine discharge impacts on marine biological resources, including special-status species (EIR/EIS Impact 4.5-4), considered increased salinity/brine concentrations as well as potential toxicity from any concentrated contaminants in the brine discharge. The analysis determined that as a result of dispersal and dilution of the brine discharge by the outfall dispersion jets, the reasonable worst-case brine-only discharge would not exceed 1.6 parts per thousand (ppt) over ambient by the time it reaches the seafloor (see Table 4.5-12). Furthermore, as illustrated in Tables 4.5-9, 4.5-10, and 4.5-11, the documented salinity concentrations at which toxic effects have been shown to occur in marine organisms is an order of magnitude greater than the projected 1.6 ppt over ambient salinity at the seafloor or within the BMZ. Laboratory research performed by Dr. Carol Reeb demonstrated that salinity concentrations greater than 50 ppt are needed to affect market squid egg hatching, and the projected salinity concentration from the project brine discharge is estimated to be 35.23 when it reaches the seafloor (see EIR/EIS Impact 4.5-4). See response to comment Reeb-7 in Section 8.7.20, and Marina-67 in Section 8.5.1.

As for whether the infiltration rate of the slant well intakes was or should have been considered in the brine discharge modelling, as shown in EIR/EIS Figure 4.3-7, the BMZ and outfall jets are located about 2 miles downslope from the location of the slant well intakes and would not be affected by the slant well intakes (or vice versa).

ERF-8 The EIR/EIS explains in Impact 4.5-4 under the subheading, Potential Effects of Elevated Salinity, that in all cases, the Ocean Plan salinity limit of 2 ppt would be met at the edge of the ZID, the length of which ranges from approximately 10 to 39 feet for the dense discharge scenarios, which is well within the regulatory limits of the BMZ (100 meters or 328 feet from the diffuser). This subsection of the EIR/EIS assesses the potential salinity concentrations within the ZID and the BMZ and describes the potential effects on both hard and soft substrate taxa and marine organisms inhabiting the water column itself.

The EIR/EIS evaluates the water-column salinity at the point of discharge that would exceed 2 ppt and concludes that for the worst-case brine-only discharge scenario modeled (which only could occur during the dry season months of April through October in any given year), 1,100 cubic feet of water is anticipated to exceed 2 ppt and would be located above the seafloor (see EIR/EIS Figure 4.3-10). Thus, the modelling reflects that nowhere near 27-acres of the BMZ would exceed 2ppt. The small volume of water that would be greater than 2 ppt above ambient salinity would not come into contact with any hard-substrate organisms inhabiting the ballast rock anchoring the outfall or benthic fauna located on the sea floor. Consequently, benthic communities near the outfall would not be affected by the increased salinity brine discharge. Additionally, the water area around each diffuser (estimated at 2 feet by 8 feet) is a small area for any of the marine mammals referenced by the commenter to spend any substantive time occupying in order for any detectable or documentable impact to occur. See also response to comment Marina-67 in Section 8.5.1.

Finally, even if the estimated 27-acre BMZ where to exceed 2 ppt as permitted under the Ocean Plan, which modeling, as explained above, indicates would not likely occur, when compared to the overall project study area, 27-acres represents an infinitesimally small fraction of the MBNMS and California coast.

ERF-9 The Southern California Coastal Water Research Project (SCCWRP) report cited in the comment was prepared prior to the State Water Board Resources Control Board (SWRCB) amending the Ocean Plan and establishing State regulations concerning desalination brine discharges; see the Draft Substitute Environmental Document prepared for the Ocean Plan Amendment (SWRCB, 2015, at Section 8.7.1, Background: Effects of Saline Discharges on the Marine Environment). The Science Advisory Panel (Roberts et al. 2012) recommended, based on the studies of the effects of brine discharges, that the maximum salinity increase at the edge of the zone of initial dilution (also referred to as the mixing zone) should be no more than 5 percent above ambient background. Even though natural background salinity varies throughout California, and by season, salinity is generally close to 34 ppt as a state-wide average (average Monterey Bay salinity is 33.5 ppt). The Science Advisory Panel recommended that salinity vary by no more than five percent at the edge of the ZID. For most California coastal waters, this translates to an increase of 1.7 ppt (rounded up, 2 ppt) above ambient background (Roberts et al. 2012). Additional review of salinity effects on marine life (Foster et al. 2013) found that salinity increases less than 2 to 3 ppt were protective of most marine life.

The Science Advisory Panel further recommended that the salinity objective should be based on the most conservative species. The reports by Phillips et al. (2012) and Roberts et al. (2012) provide the basis to develop a receiving water limitation for California's ocean waters. Studies showed that red abalone was most sensitive to elevated salinity, with a lowest-observed-effect concentration (LOEC) at 35.6 ppt (2.1 ppt above Monterey Bay background salinity of 33,500 mg/L). Since salinity toxicity studies were not done for all organisms in the California marine environment, the 2 ppt limit may be overly conservative for some species, but not conservative enough for others. However, the majority of the studies on elevated salinity showed that effects were not seen below 2 to 3 ppt above natural salinity. (Roberts et al. 2012).

It is understood that a 5 percent increase above pre-project ambient salinity levels would result in a smaller BMZ. However, as the commenter clearly stated, the 2 ppt threshold for the BMZ is what the SWRCB has established as State regulatory limit in the Ocean Plan Amendment. Whether or not the 2 ppt is greater than the 5 percent by 17 percent is not relevant to the analysis however, because while this EIR/EIS did use 2 ppt above ambient as the threshold of significance, none of dense plume scenarios modeled would exceed 1.61 ppt or 4.8 percent (see EIR/EIS Table 4.3-13) above ambient salinity (33,500 mg/L) at the edge of the ZID, which would meet the 5 percent threshold.

ERF-10 As described in detail in EIR/EIS Section 4.3.5.2, the assessment of impacts and regulatory compliance related to the discharge of brine via the existing MRWPCA outfall

diffuser is based on model analyses that incorporate conservative (i.e., worst-case) assumptions regarding effluent and receiving water density, dilution and mixing dynamics (assumed zero ocean currents), and concentrations of water quality constituents. These conservative assumptions were applied to ensure the results of the impact assessments are appropriately cautious. The results of the model analyses were further assessed against both the regulatory requirements (Section 4.3.2) and the significance criteria (Section 4.3.3) related to operational discharges, representing a rigorous standard for analyzing potential impacts. The consideration of all regulatory standards, requirements, and performance thresholds (described in detail in Section 4.3.2), included specific recent (2016) amendments to the California Ocean Plan for avoiding and/or minimizing potential adverse impacts on marine life associated with desalination facility operations. Such amendments to the Ocean Plan were based on the findings of the SCCWRP (see response to comment ERF-9), which evaluated methods of brine disposal and monitoring strategies. The Ocean Plan amendments were further assessed as part of a SWRCB Substitute Environmental Document and staff report (SWRCB, 2015), providing the rationale for how implementing such measures reduce potential environmental impacts from desalination facilities.

The model analyses conducted for this EIR/EIS to determine dilution and mixing, the results of which were subsequently utilized to determine compliance with Ocean Plan water quality objectives for salinity and other constituents, was conducted in a manner consistent with the recommendations in the SWRCB's technical report on discharges from desalination plants (described in detail in EIR/EIS Appendix D1 and discussed in Section 4.3.5.2 under Impacts 4.3-4 and 4.3-5). Also presented in detail in Appendix D1 are the results of a comprehensive literature review and incorporation of peer reviewed methodologies, assumptions, and results into the assessment of operational impacts. The extensive model analyses assessed, in part, the hydraulics of the outfall, which includes horizontally oriented diffuser ports, as well as dilution and mixing of operational discharges with receiving waters under a range of discharge scenarios and ocean conditions. As described under Impact 4.3-4, two separate analytical methodologies were employed to provide redundancy in the analysis and confirmation of the results characterizing dilution; both methods are consistent with the regulatory approach recommended by the SWRCB for analyzing brine discharges. Further, in response to public comments relating to concerns over the model analyses, and at the request of MBNMS, the model analyses underwent peer review (see Impact 4.3-4).

While impacts related to water quality from operational discharges have been determined to be less than significant based on the comprehensive and detailed model analyses, additional monitoring and reporting will further ensure that discharges will comply with the Ocean Plan as well as comply with MBNMS guidelines for operation of desalination facilities that are protective of the beneficial uses (including aquatic wildlife and habitat) of Monterey Bay. Furthermore, Mitigation Measure 4.3-4 would ensure that water quality and biological monitoring data considers impacts on marine resources and that all collected data is assessed against defined performance standards and that corrective actions are implemented in the case that performance standards are not met. Corrective

actions to be implemented in the case that performance standards are not met are detailed in Mitigation Measure 4.3-5 (Implement Protocols to Avoid Exceeding Water Quality Objectives), which includes retrofitting the existing outfall diffuser to include inclined diffuser jets positioned at the optimum angle to achieve maximum dilution.

Finally, EIR/EIS Section 4.13.5.2 identified the potential for the proposed project to increase corrosion of the MRWPCA outfall and diffuser as a result of brine discharge. Based on studies provided by the MRWPCA (E2 Consulting Engineers, 2015), Impact 4.13-5 determined the proposed project could accelerate corrosion of a nearshore portion of the offshore segment, as well as the land segment, of the outfall. The EIR/EIS concludes the impact could be significant and includes Mitigation Measures 4.13-5a and 4.13-5b, which would apply to the offshore segment and the land segment, respectively. Impact 4.3-5 in EIR/EIS Section 4.3.5 and Mitigation Measure 4.3-5 have been revised to reflect the concern that the existing outfall diffuser end gate may need to be modified in order for operational discharges from the proposed project to comply with Ocean Plan and NPDES permitting requirements. See responses to comments MRWPCA-2 through MRWPCA-6 in Section 8.5.9 for further discussion related to suitability of the outfall diffuser to discharge brine.

ERF-11 See Final EIR/EIR Section 5.3.2, which was revised to clarify that alternative brine disposal options were considered but rejected as infeasible. Also, the article in the July 16, 2015 edition of the Monterey County Weekly authored by Kera Abraham and referred to by the comment letter in Footnote 15, acknowledges there are "major hitches" with extracting salt from the desalination brine; not the least of which is that the salt extraction plant would cost even more to build than the desalination plant itself, and the natural gas needed to power it would cost about $1,200 per acre foot. Furthermore, the proposed project would generate approximately 14 mgd of brine that would need to be shipped in 10,000-gallon tanker trucks, resulting in 1,400 truck trips a day, or approximately 1 truck trip every minute of every day. Alternative 5a, the Environmentally Superior Alternative would result in less brine, but would still generate approximately 9 mgd of brine, resulting in 900 truck trips per day.

See responses to comments MCWD-168 and -170 in Section 8.5.2.

ERF-12 The laboratory results of the water quality testing that is referred to in the comment is presented in Appendix G of Appendix C of EIR/EIS Appendix E3. The low concentrations of volatile organic compounds identified in the groundwater samples from the soils borings at CEMEX represent analytical laboratory surrogates. Surrogates are compounds similar in chemical composition to the analytes of interest and added into environmental samples prior to preparation and analysis as part of the quality control protocols. They are used to evaluate extraction efficiency and matrix interference on a sample-specific basis. While they are included in the laboratory quality control sheets and may appear as a low concentration detection, these compounds were not detected in the water samples and are not present in the groundwater.

EIR/EIS Section 4.4.5.2 includes Impact 4.4-4: Violate any groundwater quality standards or otherwise degrade groundwater quality during operations. Impact 4.4-4 addresses impacts associated with existing groundwater remediation systems, and discusses how the slant well pumping could effect the migration of the contaminated groundwater located to the southeast, in the Former Fort Ord (see EIR/EIS Section 4.7.1.1). The EIR/EIS determined that the radius of influence of pumping in the Dune Sand and 180-FTE Aquifers is expected to extend close to, but not overlap with, the contaminant plumes associated with the ongoing cleanup at the former Fort Ord. However, it is remotely possible that the radius of influence could reach and affect the contaminant plumes. Implementation of Mitigation Measure 4.4-4 would prevent the significant and unreasonable degradation of water quality due to the migration of contaminant plumes that impair water supplies.

ERF-13 As discussed in Section 4.7, Hazards and Hazardous Materials, the CEMEX sand mining facility has no records of hazardous materials releases and does not have any underground storage tanks for fuel or oil.

ERF-14 Although the GeoTracker website still lists the Fort Ord OU1 plumes sites as open, review of the documents indicates that groundwater monitoring is no longer occurring and the sites are awaiting regulatory agency closure upon destruction of wells and treatment systems (GeoTracker, 2017; Central Coast Regional Water Quality Control Board, 2016).

ERF-15 Adverse impacts on the water quality of receiving ocean waters and on marine resources from operational discharges are comprehensively assessed in EIR/EIS Sections 4.3.5 and 4.5.5, respectively. The analysis of impacts from operational discharges presented in Section 4.3.5.2 assesses compliance with numeric water quality objectives prescribed in the California Ocean Plan (described in detail in Section 4.3.2), including chlorine and chlorine residuals that result from the use of sodium hypochlorite (see Table 3-1) as part of standard drinking water supply disinfection. Further, as presented in detail in Appendix D3, for all operational discharges, dechlorination of potable water supplies will occur such that the total chlorine residual will be below detection and thus, below the Ocean Plan water quality objective.

ERF-16 The EIR/EIS fully discloses the potential for special status species, including fully protected State species, to occur in the study area in Sections 4.5.1.3 (Special Status Marine Species) and Section 4.6.1.10 (Sensitive Terrestrial Biological Resources in the Study Area). The Brown pelican is identified in Table F-1 in EIR/EIS Appendix F as a California fully protected species with a low potential to occur in the project area. The Brown Pelican may well roost in MBNMS, but Table F-1 explains that suitable roosting habitat does not exist in the project area; see response to comment Marina-66 in Section 8.5.1. And while the Brown pelican may forage in ocean waters in the vicinity of the MRWPCA ocean outfall and the subsurface slant wells, Brown pelicans do not breed locally.

California Fish and Game Code Section 4700 is addressed in EIR/EIS Section 4.5.2.2, which states, the MPWSP components proposed for the marine environment would be consistent with Fish and Game Code Sections 3503, 3511, 4700, 5050, and 5515 because their construction and operation are not expected to result in the take or possession of any State protected species.

The commenter is correct in stating that the Pacific right whale, the northern elephant seal, and the southern sea otter are fully protected mammals as designated by the state of California. The Pacific right whale, the northern elephant seal and the Southern sea otter are listed in EIR/EIS Table 4.5-2 as special status species with a potential to occur in the study area. The potential project effects on all marine mammals are evaluated in Impact 4.5-4 in EIR/EIS Section 4.5.5, which concludes that the proposed project operations would have a less than significant impact from salinity and other Ocean Plan constituents (via bioaccumulation) on special-status species that frequent the study area. Furthermore, Impact 4.5-4 concludes that impacts due to shear stress caused by the brine discharge would be limited to plankton, because motile organisms would be able to avoid turbulence in the immediate vicinity of the brine discharge; the impact would be less than significant because of the small percentage of plankton abundances potentially affected. Because there is little risk that benthic infauna and macrofauna populations would decline due to impingement, shear stress, and increased salinity, impacts are not anticipated on fish, marine mammals (such as the Southern sea otter and California gray whale), seabirds, and other species. The acknowledgement that the above-listed species are fully protected results in no change to the EIR/EIS analysis or conclusions of impacts on these species, which already were identified as being protected by the Federal Endangered Species Act, and the Marine Mammal Protection Act. See also EIR/EIS Section 7.1.1.

EIR/EIS Section 4.5.1.3 identifies Dungeness crab as a valued commercial species in Monterey Bay that typically resides within hard rock habitat. Proposed project operations would not affect hard rock habitat. In its assessment of potential effects of increased salinity and other Ocean Plan constituents on marine communities, Impact 4.5-4 considered all marine species, including crab species, and concluded that project operations would have a less than significant impact. Salinity would be 1.6 ppt above ambient or less at the edge of the ZID (see EIR/EIS Table 4.3-13) which is well below the tolerance level of the crab species. See also response to comment ERF-9.

Finally, the EIR/EIS thoroughly discusses the potential toxic effects of elevated brine discharge, as well as the potential physical effects of the brine discharge itself (see Draft EIR/EIS pages 4.5-54 through 4.5-66).

ERF-17 The background on the Federal Endangered Species Act (FESA) and western snowy plover are noted, and are consistent with descriptions in the EIR/EIS. Regarding the assertion that the EIR/EIS did not adequately analyze project impacts on snowy plover, see responses to comments ERF-18 through ERF-21, which provide greater specificity. Also note that since MBNMS is a federal Lead Agency under NEPA, FESA

consultation with the USFWS will occur under Section 7, not Section 10 and an HCP would therefore, not be required. See also response to comment ERF-21.

ERF-18 In regard to the comment that sea level rise and erosion linked to climate change will also contribute to reduction of plover habitat, see the response to comment Point Blue-3 in Section 8.6.15; sea level rise and ongoing coastal erosion act in concert to move beach profiles inland, such that average beach width is anticipated to be maintained in this location. See EIR/EIS Figures 4.2-7 and 4.2-8 which show the anticipated beach profiles over time, and see also EIR/EIS Appendix C2. As the bluff erodes, it maintains the beach width, as described in Impact 4.2-10.

Contrary to the commenter's assertion, the EIR/EIS evaluates the impacts of operational and maintenance activities on western snowy plover in Section 4.6, and acknowledges that the repeated disturbance associated with ongoing periodic maintenance of slant wells would result in the permanent loss of up to 6 acres of snowy plover habitat.

Mitigation Measure 4.6-1d does not limit mitigation to "restoration actions beyond the Project site." This measure does not specify that mitigation would occur off-site. In response to this comment, Mitigation Measure 4.6-1d has been revised to clarify that compensation may occur on-site or off-site. In this context, "on-site" may refer to adjacent areas within the CEMEX property that could be restored (see Master Response 14, CEMEX Settlement Agreement); however, on-site restoration of the permanently impacted habitat (such as between maintenance activities) would result in repeated re-occurrence of maintenance-related disturbance of restored habitat and, potentially, individual plovers. Therefore, no on-site (i.e., within the permanently impacted area) restoration is recommended. Impact 4.6-6 describes that implementation of multiple mitigation measures, including Mitigation Measure 4.6-1d, would reduce impacts to less than significant as fully described in Impact 4.6-1. See also EIR/EIS Section 7.1 for a discussion of Lead Agency consultation with USFWS.

ERF-19 The EIR/EIS provides an analysis of noise impacts on snowy plover in Section 4.6. As stated in Impact 4.6-6, the noise generated from the well pumps would be less than the ambient noise of the combination of CEMEX operations, crashing waves, and Highway 1 traffic. The comment incorrectly describes the characterization of ambient noise at the project site as a cumulative impact analysis; rather, this combination of existing noise sources represents the current total ambient noise. As explained in Impact 4.6-6, since ambient noise levels at the CEMEX active mining area include noise generated from heavy machinery and mining vehicles associated with the CEMEX operations (85 dBA at 50 feet), crashing waves at the Pacific Ocean (57 dBA at 300 feet), and vehicle traffic along Highway 1, the 66 dBA attenuated noise level from pump operations would be less than the combination of these existing sources. Since the attenuated noise from the pumps would not exceed ambient noise levels, the pumps would not be expected to impact migratory birds or other special-status wildlife at the site. Therefore, although pump operations may generate some low-level

increased noise, this would not be above ambient noise levels at the project site under existing conditions, and would not significantly impact western snowy plover.

Despite this less-than-significant conclusion, as reiterated in response to comment ERF-18, the EIR/EIS has assumed that the entire 6-acre maintenance area around the well heads would be permanently lost because of disturbance associated with ongoing periodic maintenance at the well heads. Therefore, it is assumed that since no suitable habitat would be available at "significantly closer than 50 feet away from the well pumps," that snowy plover would also not be closer than 50 feet from the wellhead. This habitat impact would be reduced to less than significant through implementation of several mitigation measures, including compensation at a 3:1 ratio for permanent impacts as described in the revised Mitigation Measure 4.6-1d in the Final EIR/EIS.

ERF-20 The EIR/EIS did not fail to analyze the potential impacts on western snowy plover from the vibrations caused by the well pump. EIR/EIS Section 4.12.14 explains that operation of the Project would not involve equipment that would produce ground borne vibration; therefore, no impacts related to excessive ground borne noise levels would occur in connection with Project operations. Since operation of the well pumps would not produce ground borne vibration, there would be no impact on western snowy plover.

In response to this comment, the following text has been added to the Subsurface Slant Wells section in Impact 4.6-6:

> As described in Section 4.12.14, Evaluation Criteria in Section 4.12, Noise and Vibration, operation of the proposed project would not involve equipment that would produce ground borne vibration. Since operation of the well pumps would not produce ground borne vibration, there would be no impact on western snowy plover from such vibration.

ERF-21 Habitat Conservation Plans (HCPs) are developed by permit applicants in support of an incidental take permit application pursuant to section 10(a)(1)(B) of the ESA for projects with no federal nexus. Because there is a federal nexus related to this project, any take authorization sought would be pursuant to ESA Section 7, and therefore, a HCP is not prepared. Rather, the action federal agency (MBNMS) would prepare a biological assessment and the USFWS and NMFS would either respond with a letter of concurrence (where no adverse effects are expected) or with a biological opinion that would support an incidental take statement (which gives take authorization).

A Biological Assessment, which evaluates the project's impacts on federally listed species, has been prepared in support of Federal Endangered Species Act Section 7 consultation between the ONMS and USFWS. See EIR/EIS Section 7.1.

ERF-22 The EIR/EIS in Impact 4.5-C explains that the five-mile coastal geographic area was chosen because beyond this area, other projects would be too distant from the MPWSP

to result in any combined salinity or elevated brine constituent plumes, or to combine in any other way that may cause a cumulative effect on marine biological resources. Unlike other environmental stressors or impacts, such as air emissions, the impacts on marine resources are not wide-scale or mobile, and are instead localized. To interact or accumulate, a five-mile area of analysis is more than adequate for the nature of these particular stressors and impacts. For example, the largest possible size for the BMZ would be 27 acres, or .04 square miles.

ERF-23 The approach to the cumulative analysis is presented in EIR/EIS Section 4.1.7.1, which explains that for each resource or issue considered in this chapter, the cumulative effects analysis identifies the relevant geographic area and time period within which cumulative effects could occur and then considers existing conditions (which are the combination of the natural condition and the effects of past projects) and describes the effects of other past, present and reasonably foreseeable future projects in combination with the effects of the proposed project. This approach is consistent with CEQ regulations which define a cumulative impact as an "impact on the environment which results from the incremental impact of the action when added to other past, present and reasonably foreseeable future actions" and emphasizes that "cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time." As described in Section 4.1.7, cumulative effects may arise from single or multiple actions and may result in additive or interactive effects.

Brine impacts result in small, localized, less than significant impacts on benthic communities in only the worst case scenarios. Therefore, the appropriate scale for assessing cumulative impacts for brine discharges is to examine the potential for other projects within a five-mile coastal area that may also result in benthic impacts, or other projects where brine plumes or their impacts, while individually minor, may have additive or incremental impacts. In the case of the cumulative analysis for Alternatives 5a and 5b, the potential for cumulative effects of GWR combined with the MRWPCA recognizes the interactive cumulative effect, which required detailed modelling to account for changes in buoyancy and dispersal of contaminants when the brine discharge is added to GWR effluent.

As for the commenter's concern about improperly limiting the cumulative impacts analysis of construction impacts geographically, the excerpted statement was part of a longer statement in the Draft EIR/EIS on page 4.5-67: "With the exception of DeepWater Desal and People's Project, all of these projects are either built (No. 47), not reasonably foreseeable in its current configuration (No. 31), or projected to have very localized construction impacts." Since CEQA Guidelines Section 15130 states that "the focus of analysis should be on the cumulative impact to which the identified other projects contribute, rather than on attributes of the other projects that do not contribute to the cumulative impact," the statement is characterizing the level of construction impacts of the other projects and is, therefore, consistent with CEQA and NEPA.

ERF-24 The EIR/EIS did not exclude the Sand City Desalination project. The plant is already constructed and has been in operation since 2010, which means it is a "past project" and as noted in Footnote 2 in EIR/EIS Section 4.1.7.2, while a cumulative analysis includes past, present and reasonably foreseeable future projects, the category of past projects is captured within the existing setting, or baseline, against which impacts are judged throughout the EIR/EIS, including the cumulative analysis. The two new wells that are proposed at the Sand City plant (see EIR/EIS Table 4.1-2) will allow the plant to operate as designed: the brackish source water would result in brine that is discharged into Monterey Bay at lower than or equal to the ambient ocean salinity.

ERF-25 See response to comment ERF-22. The Bay Avenue Outfall Project would be located almost 8 miles south of the MRWPCA outfall and would be outside of the geographic scope of the marine biological resources cumulative impact analysis. The Bay Avenue outfall project would reduce (Phase 1) and ultimately eliminate (Phase 2) discharges of storm water from the City of Seaside to Monterey Bay.

ERF-26 See Master Response 15, Alternative Desalination Projects – Status, Information Sources, and Cumulative Scenario, Section 8.2.15.3, which reiterates the explanation provided in EIR/EIS Section 4.1.7 regarding the consideration of the People's Project in the cumulative context. Master Response 15 also clarifies the status of the People's project and associated CEQA/NEPA review.

ERF-27 See Master Response 15, Alternative Desalination Projects – Status, Information Sources, and Cumulative Scenario.

ERF-28 The cumulative impact discussion for marine biological resources (EIR/EIS Section 4.5.6) explains that the cumulative projects listed in Table 4.1-2 that are located within the geographic scope and whose impacts could overlap with those of the MPWSP include Test Slant Well (No. 47), RUWAP Desalination Element (No. 31), and RUWAP Recycled Water Element (No. 35). In addition, it is expected that either the DeepWater Desal Project (No. 34) or The People's Moss Landing Desal Project (No. 57), but not both, would be constructed and operated in the reasonably foreseeable future. With the exception of DeepWater Desal and People's Project, all of these projects are either built (No. 47), or not reasonably foreseeable in its current configuration (No. 31).

Since the test slant well (No. 47) is a past project, it was considered in the evaluation of the proposed project, as explained in response to comment ERF-24. The RUWAP Desalination Element (No. 31,) see Table 4.1-2) was not considered directly in the cumulative scenario for marine biological resources, but it was considered in the EIR/EIS Section 4.3 discussion on discharges and outfall capacity; see response to comment Marina-117 and -156 in Section 8.5.1. The RUWAP Desalination Element (No. 31) was also considered in the cumulative scenario for effects on groundwater resources; see EIR/EIS Section 4.4.6 and response to comment MCWD-155 in Section 8.5.2.

The RUWAP Recycled Water Element (No. 35) would reduce wastewater flows to the MRWPCA ocean outfall. The impacts that would result from a range of brine with wastewater flows were evaluated for the proposed project under Impact 4.5-4 (see Table 4.5-12) and for Alternative 5a (the Environmentally Superior Alternative) in Section 5.5.3.8 (see Table 5.5-3). Therefore, since the RUWAP Recycled Water Element (No. 35) was considered in combination with the proposed project (and alternatives), and the impacts of the test slant well was considered in the analysis of the proposed project analysis (and alternatives), the cumulative analysis included the impacts of the combination of these reasonably foreseeable identified projects.

ERF-29 The third paragraph in EIR/EIS Section 4.5.6 explains that the RUWAP Recycled Water Element (No. 35) would reduce wastewater flows to the MRWPCA ocean outfall. The impacts that would result from a range of brine with wastewater flows were evaluated for the proposed project under Impact 4.5-4. The paragraph draws a conclusion on level of impact, and does not improperly terminate any consideration; but to clarify, the last sentence of this paragraph has been revised as follows:

> Therefore, t~~T~~he cumulative scenario that would result from the RUWAP Recycled Water Element in combination with the proposed project would be within the range of brine with wastewater flows that were analyzed under Impact 4.5-4; that impact was determined to be less than significant.

The potential effects of impingement, elevated salinity (and hypoxia), other brine contaminants, and shear stress resulting from the range of brine with wastewater flow discharge scenarios (combinations of wastewater and brine discharge), are discussed in EIR/EIS Section 4.5.5.2. For each of the potential impacts, (salinity, other contaminants, and shear stress) all of the various discharge scenarios were considered.

The EIR/EIS explains that if the discharge plume between the diffuser port and the edge of the ZID on both sides of the outfall were to settle on the seafloor (which the model results indicate it would not), approximately 0.0042 to 0.0163 percent of the suitable spawning area south of Monterey Submarine Canyon would be unsuitable for squid spawning. That potential impact was considered to be less than significant. See response to comment Marina-67 in Section 8.5.1.

ERF-30 As stated in Section 4.1.7.1, "Where the analysis finds that the cumulative effects of past, present and future projects would be significant and adverse, the analysis then identifies whether the proposed project's contribution to the overall adverse effect would be of a considerable nature such that the project's contribution to cumulative effects in that area is deemed significant." Thus, the cumulative analyses in the EIR/EIS do not dismiss cumulative impacts solely because project impacts are less than significant. Each of the cumulative impact discussions in Impact 4.5-C specifically describe why the project would not contribute at all to cumulative impacts (e.g., because the project would result in *no impact* or because the project's impacts *could not* combine with the impacts of other projects due to distance or other factors), or why

the cumulative impact to which the project could contribute would not be significant, or why the project's contribution to a potentially significant cumulative impact would not be considerable (e.g., because the project would comply with standards below which incremental project impacts are not considered significant in a cumulative context).

ERF-31 CEQA Guidelines Section 15130(a)(1) states that "an EIR should not discuss impacts which do not result in part from the project evaluated in the EIR." And, while cumulative effects analysis must consider the additive or incremental effects of individually minor effects, the proposed project must have at least an individually minor effect that is one that could accumulate or interact with other minor effects. The EIR/EIS explains in Section 4.5.6 that the MPWSP does not propose any in-water construction activities that are expected to result in disturbance or effects on marine biological resources. For instance, underwater construction noise would be less than the ambient noise, and there would be no other projects in the vicinity that would generate underwater construction noise. The EIR/EIS does explain the potential for a risk of spills associated with the slant well drilling but it also explains that any discharge of clarified water to the ocean would be in compliance with Ocean Plan Water Quality standards, and that NPDES permit requirements already consider and prohibit cumulative effects on the receiving water.

ERF-32 There are no other reasonably foreseeable projects that would contribute to the salinity impact. See also responses to comments ERF-26 and ERF-28 and Master Response 15, Alternative Desalination Projects – Status, Information Sources, and Cumulative Scenario.

ERF-33 The 2012 Science Advisory Panel, chaired by Dr. Philip Roberts, is included as a reference to the EIR/EIS (SWRCB, 2012a). The recommendations from that panel were later incorporated into the 2016 amendment to the California Ocean Plan (SWRCB, 2016). It is the Ocean Plan that sets the regulatory limit of the BMZ. As explained in the EIR/EIS and as modeled by Dr. Philip Roberts in EIR/EIS Appendix D1, the edge of the ZID represents the near field mixing zone that is influenced by the dynamics of the discharge, while the area between the edge of the ZID and the BMZ at 100 meters (328 feet), represents the far field where the ocean turbulence effects the plume dilution. As explained in response to comment ERF-8, the ZID for the proposed project would extend approximately 10 to 39 feet from the diffuser for the dense discharge scenarios modeled (see EIR/EIS Table 4.3-13) and salinity at the edge of the BMZ for those same scenarios would range between 1.3 and .01 ppt above ambient, within the range of natural ocean salinity changes. The DeepWater Desal point of discharge would be located almost 5-miles north from the proposed project's BMZ, at a depth of 100 feet in the Monterey Submarine Canyon; therefore, it is highly unlikely the plumes from the two projects would merge.

The plume from the proposed project's dense discharges would not attach to the seafloor (see response to comment ERF-7), and the lack of dissolved oxygen (hypoxia) would not be an issue for the MPWSP, at a project-specific level or in a cumulative

context, because oxygen would be supplied to the discharged plume by ambient seawater entrained during turbulent mixing and dilution. See also EIR/EIS Section 4.3.5.2.

ERF-34 The EIR/EIS analyzed in detail the project-level and cumulative impacts of greenhouse gas emissions by quantifying construction and operational emissions and comparing them to thresholds that apply to both project-specific significance determinations as well as determinations regarding the significance of contributions to cumulative impacts. As explained in Impact 4.11-C, the evaluation of GHG emissions impacts is inherently a cumulative impact analysis, and as a result, if MPWSP construction and operations emissions exceed numeric thresholds or conflict with AB 32 Scoping Plan Measures, the MPWSP would not be considered consistent with the State's GHG reduction goals and the associated impact would be cumulatively considerable. All of the climate change-related effects discussed in Section 4.11.1.1 stem from global, cumulative greenhouse gas emissions levels.

Furthermore, as discussed in response to comment USEPA-4, Mitigation Measure 4.11-1 has been revised to ensure that the MPWSP would result in net zero indirect operational greenhouse gas emissions from electricity consumption. With implementation of this revised measure, project-level greenhouse gas impacts – and by definition, the project's contribution to cumulative greenhouse gas impacts – would be reduced to below applicable numeric thresholds and would be less than significant. See Final EIR/EIS Section 4.11 for a revised discussion of the significance greenhouse gas emissions following implementation of this mitigation measure.

ERF-35 EIR/EIS Section 6.3, Growth Inducing Impacts, provides much of the information reiterated in this comment, in particular in Section 6.3.1, Introduction, and 6.3.3, Regulatory Framework, which provides the basis for the analysis. See Master Response 13, Demand (Project Need) and Growth, Section 8.2.13.1, regarding demand assumptions and Section 8.2.13.3 regarding the water that the project would provide for growth and the impacts of growth, including the impacts of cumulative water projects.

ERF-36 Project water supply available to serve additional development would be allocated to jurisdictions or reserved by MPWMD. The impacts of growth within the service area jurisdictions have been analyzed in the jurisdictions' general plan CEQA documents; these are the impacts of growth that would be supported, to some degree, by the proposed project, as described in EIR/EIS Section 6.3. More specific analysis of hypothetical specific projects that could be supported by project water supply would be speculative. See also Section 8.2.13.2, Growth Inducement, in Master Response 13.

ERF-37 The EIR/EIS analysis of the proposed project determined that impacts on marine life specific to the MPWSP's proposed intake and brine discharge systems would be less than significant. The MPWSP's consistency with the MBNMS Desalination Guidelines, including those listed in the comment, is discussed in EIR/EIS Section 6.4. The project need is discussed in Section 1.3, project background is discussed in

Section 1.4, water supply is discussed in Chapter 2, and alternatives are analyzed in full in Chapter 5. The Monterey Peninsula Water Conservation and Rationing Plan is addressed in Section 5.4.2.3. As described therein, the No Project Alternative would trigger actions under this plan, and the impacts of these actions would be a result of the No Project Alternative (see Section 5.5.20.3). The Monterey Peninsula Water Conservation and Rationing Plan is addressed in Section 5.4.2.4 and in Appendix K, and is considered in the impacts assessment under the No Action Alternative.

8.6.11 Responses to Comments from Fort Ord Recreational Users

FORU-1 The purpose of the slant wells, as explained in EIR/EIS Table 3-1 is to draw water from groundwater aquifers that extend beneath the ocean floor (the Dune Sands Aquifer and the 180-Foot-Equivalent Aquifer of the Salinas Valley Groundwater Basin) for use as source water for the MPWSP Desalination Plant. Section 4.4.1.4 explains that the proposed slant wells would draw water from the Dune Sand Aquifer and the 180-FTE Aquifer from about 30 feet below msl to 200 feet below mean sea level. See Master Response 2, Source Water Components and Definitions, which clarifies terms, as well as Master Response 8, Project Source Water and Seawater Intrusion, Sections 8.2.8.1 and 8.2.8.2, which discuss the source water capture zone.

FORU-2 See Master Response 3, Water Rights, Section 8.2.3.7, Effect on Marina Coast Water District, as well as Master Response 8, Sections 8.2.8.1 and 8.2.8.2, which discuss the source water capture zone. Marina Coast Water District's (MCWD) need for water supplies for the redevelopment of the Former Fort Ord is discussed in EIR/EIS Section 4.1.7.2. Project 31 (Regional Urban Water Augmentation Project Desalination Element) in Table 4.1-2 describes the three-party water supply planning agreement between MCWD, Fort Ord Reuse Authority, and the Monterey Regional Water Pollution Control Agency. EIR/EIS Section 4.4.6 addresses the cumulative impacts associated with the proposed project and Project 31 on groundwater resources.

FORU-3 See Master Response 8, which clarifies the hydrogeology and water quality characteristics of the source water capture zone, and Impacts 4.4-2 and 4.4-4 in EIR/EIS Section 4.4.5.2. Additionally, Master Response 2, provides clarification on the definitions of terms used to describe source water. As item 3 in this comment notes, the purpose of moving the proposed slant wells inland was related to coastal erosion, and not water source; see coastal erosion impact analysis and related mitigation in Impact 4.2-10 in EIR/EIS Section 4.2, Geology, Soils, and Seismicity.

FORU-4 See Master Response 3, Water Rights, Section 8.2.3.5.

FORU-5 EIR/EIS Chapter 5 provides a comprehensive evaluation of alternatives: Sections 5.1.1 and 5.1.2 describe the guidelines for alternatives analysis under CEQA and NEPA; Section 5.2 presents and discusses other water supply alternatives that were considered, but not carried forward for detailed evaluation; Section 5.3 describes the process employed to develop, screen and evaluate potential alternative components, and develop whole alternatives for analysis; Section 5.4 describes a No Project/No Action Alternative and five action alternatives; Section 5.5 presents the impact analyses of the No Project/No Action Alternative and the five action

alternatives, and; Section 5.6 identifies the environmentally superior/preferred alternative(s) and the NEPA agency preferred alternative.

FORU-6 See response to comment FORU-2.

FORU-7 EIR/EIS Sections 2.6 and 3.2.3.7 explain that the portion of the water drawn from the subsurface slant wells that is determined to be groundwater originating from the Salinas Valley Groundwater Basin (SVGB), would be delivered to Castroville Community Services District (CCSD) as desalinated water in lieu of CCSD pumping an equivalent amount of groundwater. See Master Response 4, The Agency Act and Return Water.

FORU-8 See Master Response 3, Section 8.2.3.5, for a discussion of whether the MPWSP would cause harm to other groundwater users. See EIR/EIS Section 4.4.5.2, Impact 4.4-4, and Master Response 8 for discussion of the MPWSP's impact on seawater intrusion.

FORU-9 There is ample background information regarding the interconnection between the 180-Foot, 400-Foot, and deeper aquifers of the SVGB, which is based on numerous hydrogeologic studies in the SVGB region; see EIR/EIS Section 4.4.1.2. Graphical representation of the underlying hydrostratigraphy is presented in Figure 4.4-3, which is based on numerous soil borings and groundwater monitoring wells. Master Response 8, Section 8.2.8.1 provides supplemental information regarding the slant wells and the capture zone of source water. Master Response 7, The Deeper Aquifers of the Salinas Valley Groundwater Basin, provides additional information on the deeper aquifers (including the "900-Foot Aquifer" referred to in the comment).

FORU-10 Regarding baseline reporting for groundwater conditions, see Section 8.2.11.4 of Master Response 11, CalAm Test Slant Well. Regarding the groundwater modeling used to assess potential impacts of project pumping, including peer review of the 2015 version of the model prepared by CalAm's consultant, and the 2016 version of the model prepared by a consultant to the Lead Agencies, see Master Response 12, The North Marina Groundwater Model v. 2016. The project's impacts on groundwater quantity and quality are discussed in Section 4.4, Groundwater Resources, Impacts 4.4-3 and 4.4-4.

FORU-11 Master Response 9, Electrical Resistivity Tomography (ERT) and Airborne Electromagnetics (AEM), describes how ERT technology relates to and has been addressed in the Final EIR/EIS.

FORU-12 Regarding the Santa Barbara studies and the Dana Point well, see Master Response 11, Section 8.2.11.8. Santa Cruz rejected subsurface intakes because of the lack of sand cover over bedrock (Kennedy/Jenks Consultants, 2011). See also response to comment Marina-11 in Section 8.5.1. On the issue of outages and

interruptions, see Master Response 11, Section 8.2.11.5 and responses to comments Baer-29 and Baer-30 in Section 8.7.1 and Beech2-13 in Section 8.7.2.

The Draft EIR/EIS at page 3-15 explains that the site-specific field data collected during the pilot test well program are intended to inform the final design of the subsurface slant wells, the overall source water intake system, and the MPWSP Desalination Plant treatment system. The Draft EIR/EIS used the test slant well data in the groundwater modeling (see Master Response 11, Section 8.2.11.6, and Appendix E2, Section 4.2). The use of this EIR/EIS and how other issues that have been established in the record of this proceeding (including but not limited to economic, social, and need) will be used in decision making by the Lead Agencies, is explained in EIR/EIS Section 1.5.4.

FORU-13 See response to comment FORU-2.

FORU-14 EIR/EIS Section 4.8.1.2 explains the proposed desalination plant would be located in unincorporated Monterey County. Section 4.20, Socioeconomics and Environmental Justice, addresses potential construction-related and operational socioeconomic and environmental justice impacts on Marina, which is identified as a minority and low-income population. The Desalination Plant would not result in operational air quality emissions that would exceed any of the thresholds derived from applicable air quality plans. Additionally, as stated on Draft EIR/EIS page 4.14-38, mature trees along Charles Benson Road would screen or block views to the MPWSP Desalination Plant from the south and west. Long-term noise and traffic impacts associated with the Desalination Plant also would be minimal, even when considered in combination with existing and planned sources of noise and traffic; see EIR/EIS Sections 4.9.5 and 4.12.6.

FORU-15 No proposed project facilities would be located within Marina State Beach or within Fort Ord Dunes State Park. See Section 8.4.3 for comments from the California Department of Parks and Recreation. These comments, and responses to these comments, address potential impacts on central dune scrub at Fort Ord Dunes State Park related to construction of the Transmission Main. Coastal retreat is anticipated to occur independent of the MPWSP; it is a baseline condition that will continue regardless of the proposed project, and the EIR/EIS analysis indicates the MPWSP would not impact, accelerate, or exacerbate the rate of coastal erosion, as explained in Section 4.2, Impact 4.2-10 (see Draft EIR/EIS pages 4.2-68 through 4.2-72).

FORU-16 The effect of the proposed project on MCWD is explained in Master Response 3, Water Rights, Section 8.2.3.7. EIR/EIS Section 4.1.5, Project Consistency Analysis, describes the process undertaken in the Draft EIR/EIS to analyze the proposed project's consistency (or potential conflicts) with applicable general plans, specific plans, and regional plans, including Local Coastal Plans.

FORU-17 The Lead Agencies acknowledge the commenter's request for denial of EIR/EIS certification and project approval. This comment will be considered during the agencies' decision making process; see EIR/EIS Section 1.5.4.

References

Kennedy/Jenks Consultants, 2011. scwd2 Seawater Desalination Intake Technical Feasibility Study. Prepared for scwd2 Desalination Program, September. http://www.scwd2desal.org/documents/Draft_EIR/Appendices/AppendixH.pdf.

8.6.12 Responses to Comments from Just Water

JW-1 EIR/EIS Section 2.6 addresses water rights. See also Master Response 3, Water Rights.

JW-2 The commenter states that there is inadequate proof of "no harm" to the basin from seawater intrusion. EIR/EIS Section 4.4.5.2 presents the analysis of potential impacts of the proposed project on groundwater resources in the Salinas Valley Groundwater Basin, and concludes that impacts would be less than significant. See also EIR/EIS Section 2.6, as well as Master Response 3, Water Rights, Section 8.2.3.5 which addresses potential harm or injury to users in the basin, and Master Response 7, Deeper Aquifers of the Salinas Valley Groundwater Basin.

JW-3 The proposed project would not take groundwater from the Marina Coast Water District. See EIR/EIS Section 2.6, as well as Master Response 3, Water Rights, Section 8.2.3.7, Effects on Marina Coast Water District, and Master Response 8, Project Source Water and Seawater Intrusion.

JW-4 The comment is unclear about what "regional justice" is and how the proposed project "ignores" it "for a sustainable and protected water source." Environmental justice is addressed in EIR/EIS Section 4.20, Socioeconomics and Environmental Justice. Impacts on the Salinas Valley Groundwater Basin are addressed in Section 4.4.5.2. See also Master Response 3, Water Rights, Section 8.2.3.5 which addresses potential harm or injury to the basin; Master Response 8, Project Source Water and Seawater Intrusion as well as Master Response 6, The Sustainable Groundwater Management Act.

8.6.13 Responses to Comments from Land Watch Monterey County

LWMC-1 Return water percentages are discussed in the EIR/EIS Section 4.4.4.2 and a description and explanation of the return water percentages and the calculation of those percentages are provided in Master Response 4, Agency Act and Return Water, Section 8.2.4.3. By November 2015, just as preparation of the Draft EIR/EIS was beginning, the test slant well at CEMEX was extracting water that was reported by the Hydrogeologic Working Group (HWG) to be in the range of 29,400 mg/L (see Table 3 in Geoscience, 2016), or 12 percent of ocean water salinity (33,500 mg/L), suggesting 12 percent was a reasonable upper limit.

LWMC-2 The MPWSP would **not** be able to meet all of the project objectives under the 12 percent return water scenarios. Table 5.2 in EIR/EIS Appendix E2 indicates 3,242 afy would be required for a 12 percent return water scenario in 2012 and 2073 for the proposed project at CEMEX and for Alternative 1 (Slant Wells at Potrero Road); 2,085 afy of return water would be required for the 6.4 mgd desalination plant (Alternatives 5a and 5b).

EIR/EIS Table 6.3-4 presents water supplies and demands during the Seaside Groundwater Basin replenishment period for the proposed project with 6 percent and 12 percent return water obligation and EIR/EIS Section 6.3.5.1 explains that the available supply would meet existing service area demand and water entitlements, and demand associated with the existing hospitality industry (12,845 afy), with a surplus of 209 or 1,829 afy, depending on the return water obligation. The table also compares available supply with the total 14,275 afy demand that the MPWSP is proposed to meet. Assuming a 6 percent SVGB return water obligation, there would be enough water to meet existing and anticipated demand. But assuming a 12 percent return water obligation, supplies would **not** be able to fully meet anticipated demand.

LWMC-3 CalAm's entire Monterey District includes more than the main distribution system and the Bishop, Hidden Hills, and Ryan Ranch satellite systems. CalAm's Monterey District includes the Monterey main distribution system and five satellite systems located along the Highway 68 corridor, as stated in EIR/EIS Section 2.2.1, Existing Water System. As stated in Section 2.2.1, two of these small systems, the Toro and Ambler systems, would not be served by the project and therefore, were not included in the project supply and demand assumptions. CalAm's Monterey District also includes two satellite systems located farther north and east of the project area (the Ralph Lane system north of Salinas and Chualar system to the east in the community of Chualar) that also are not included in the project. Only the main system and the three satellite systems that would be served by the MPWSP are included in the smaller population figure cited in this comment.

LWMC-4 See Master Response 3, Water Rights, Section 8.2.3.1.

LWMC-5 See response to comment USEPA-4 in Section 8.3.5 for revised text of Mitigation Measure 4.11-1. Implementation of this revised measure, including the preparation and approval of a GHG Emissions Reduction Plan that ensures the approved project's operational electricity use would result in net zero GHG emissions, would reduce impacts related to greenhouse gas emissions to less than significant. Revised Mitigation Measure 4.11-1 includes an option for the purchase of offsets (among several options for reducing or offsetting greenhouse gas emissions).

LWMC-6 Because of the return water obligation, the proposed project would not produce enough surplus to justify a smaller project; see response to comment LWMC-2. See also response to comment LWMC-5; with the revisions to GHG Mitigation Measure 4.11-1, and the related revision to the conclusion of Impact 4.11-1 (incremental contribution to climate change from GHG emissions) to less than significant with mitigation, the EIR/EIS does not identify a significant impact for any resource that would require inclusion of a downsized alternative as mitigation. See also response to comment Surfrider-6 in Section 8.6.19.

LWMC-7 See the discussion of lots of record in Master Response 13, Demand (Project Need) and Growth in Section 8.2.13.2, Demand Assumptions, and response to comment LWMC-6.

LWMC-8 See the discussion under "Water Available for Growth" in Master Response 13, Section 8.2.13.4.

LWMC-9 See the discussion of "Other approaches to estimating future water demands" in Master Response 13, Section 8.2.13.2, Demand Assumptions. Regarding the EIR/EIS use of MPWMD's estimate of water demand associated with general plan growth, see the discussion of "Water Available for Growth" in Master Response 13, Section 8.2.13.4. Reliance on the CEQA documents prepared for jurisdictions' general plans to characterize the impacts of growth that would be supported by project water supply is appropriate because general plans and related adopted plans and policies would guide the development decisions of any jurisdictions receiving project water. Project water not otherwise needed or reserved would be allocated to jurisdictions pursuant to MPWMD's allocation process, which is yet to be determined for the MPWSP. More specific information about where or how this water would be used is not currently available. Therefore, more specific analysis of the impacts of future projects that could be supported by project water supply would be speculative.

See also response to comment LWMC-2; assuming a 6 percent SVGB return water obligation, there would be enough water to meet existing and anticipated demand, and there could be a surplus of between 209 and 1,829 afy, not the 2005 stated in the comment. This is consistent with the expectations in the General Plans, and the environmental consequences of this planned growth – whether it would be 836 or 7,316 (or 8,020) new dwelling units – have been largely addressed in the general plan CEQA reviews as well as in other, project-specific documentation. Some of the

identified indirect effects of growth are significant and unavoidable; others are significant but can be mitigated; see EIR/EIS Appendix J2.

LWMC-10 See the discussion under "Water Available for Growth" in Master Response 13, Section 8.2.13.4.

LWMC-11 See Master Response 3, Water Rights, Section 8.2.3.8, Effect of Annexation Agreement.

LWMC-12 As stated in EIR/EIS Section 4.4.4.3, the State Water Resource Control Board (SWRCB, 2013, see EIR/EIS Appendix B2) reviewed the proposed MPWSP and provided specific investigation and modeling recommendations to demonstrate the project would not harm or cause injury to other legal water users. One of the three possible categories of injury that could result from the MPWSP was, "a reduction in groundwater elevations that require users to expend additional pumping energy to extract water from the basin." This criterion was not included in the evaluation criteria (significance thresholds) applied to the CEQA/NEPA analysis of groundwater resource impacts because while CEQA/NEPA does not require an EIR/EIS to consider costs, the additional energy required to lift the water an additional foot in the handful of wells that may be affected would be insignificant. The active wells that may be susceptible to drawdown because they would be located within the slant well capture zone, are shown in EIR/EIS Table 4.4-10. The foreseeable injuries identified by the SWRCB, that overlying groundwater users could experience are presented and discussed in the EIR/EIS Sections 2.6.1 and 4.4.4.3 and Master Response 3, Section 8.2.3.5.

LWMC-13 A significant reduction in well yields due to lower groundwater levels is defined as a substantial reduction in the volume of groundwater that a user is able to withdraw from the production well, and would apply equally to the proposed project and to the cumulative scenario. This is directly related to the degree of drawdown that the well would experience from MPWSP pumping. As discussed in the EIR/EIS Section 4.4.5.2, Impact 4.4-3, the neighboring wells that could be impacted by the MPWSP slant wells are projected to experience drawdown between 1 and 5 feet under current sea level conditions and less following several years of project operation as sea level rises (see EIR/EIS Figures 4.4-14 and -15). The projected additional drawdown in neighboring groundwater wells affected by MPWSP pumping is not expected to impact well yield. However, if a substantial reduction in well yield is observed and found to be a consequence of MPWSP slant well pumping, Applicant Proposed Measure 4.4-3 would provide an interim water supply and would require CalAm to begin developing a mutually agreed upon course of action to repair or deepen the existing well, restore groundwater yield by improving well efficiency, provide long term replacement of water supply, or construct a new well.

LWMC-14 As discussed in the EIR/EIS Section 4.4.6, the cumulative analysis considers the cumulative projects **(Table 4.1-2)** that are within the geographic scope and involve

construction, development and use of a large yield production well. The only project of this type was the Granite Ridge Water Supply Project (No. 33), which the analysis determined would not combine with the effects of the MPWSP because these two projects are far enough apart and in different aquifer systems. The analysis also considered those projects that have the potential to pump groundwater and create a cone of depression that could possibly coalesce with the area of pumping influence of the MPWSP. Of those projects, the only pertinent project would be the Regional Urban Water Augmentation Project (RUWAP) Desalination Element (No. 31). The other projects in this category would likely use municipal supplies and not attempt to develop a water supply that depends on private groundwater extraction from either the 180-Foot Aquifer or 400-Foot Aquifer, which are impacted by seawater intrusion where these cumulative projects are located. If other projects did privately extract groundwater for supply, it would be from the deeper aquifers (also sometimes referred to as the 900-Foot Aquifer). The MPWSP would not extract groundwater from the deeper aquifers and the 2016 version of the North Marina Groundwater Model ($NMGWM^{2016}$) projected that there would be no response in the deeper aquifers from MPWSP pumping; see Appendix E2.

As discussed in EIR/EIS Section 4.4.5.2 and further clarified in Master Response 8, Source Water and Seawater Intrusion, Section 8.2.8.4, the MPWSP slant wells would draw water at the coast from a capture zone, which would over time be recharged by seawater. The projected influence of the MPWSP wells is discussed in EIR/EIS Section 4.4.5.2 and shown graphically on Figures 4.4-13a through 4.4-16. The capture zone and the relationship to the cone of depression is shown in Master Response 8, Figures 8.2.8-1 and 8.2.8-2. The relationship between the cone of depression and the capture zone is shown on Figure 8.2.8-3. In essence, the capture zone and the associated groundwater response from the MPWSP slant well pumping would be confined to a localized area adjacent to the coast that, other than a minor drawdown response inland from the coast, would not extend to such a degree that it influences groundwater conditions in the inland regions of the SVGB. For that reason, the project would not have a cumulatively considerable contribution to impacts on water supplies or the advancement of seawater intrusion.

Cumulative projects that currently pump groundwater from the SVGB, or those that could in the future, are located outside the MPWSP area of pumping influence but the geographis scope of the cumulative analysis extended further inland, beyond the influence of the MPWSP groundwater pumping to consider other regional groundwater production projects. There were no cumulative projects within the area of MPWSP pumping influence or within the larger area of the geographic scope. As discussed in the EIR/EIS Section 4.4.5.2, Impact 4.4-4, the MPWSP would not exacerbate seawater intrusion, and MPWSP brackish groundwater/seawater extraction from the coast would be expected to retard future inland migration of the seawater intrusion front. The $NMGWM^{2016}$ projected the groundwater response under current sea level and after 63 years accounting for sea level rise. The $NMGWM^{2016}$ projected

that the area of influence from MPWSP pumping would eventually decrease because of higher sea levels at the coast.

LWMC-15 CEQA and NEPA do not make a distinction between cumulative impacts that are adverse or beneficial when determining what projects are necessary to consider in the cumulative analysis. The cumulative analysis presented in the EIR/EIS Section 4.4.6 identifies what projects, when combined with the MPWSP, would have a cumulative effect, either adverse or beneficial, on groundwater resources. In this case, the groundwater projects that were identified are those with region-wide effects that would also improve SVGB conditions. Furthermore, whether or not the beneficial cumulative impacts are mentioned as part of the analysis has no bearing on and does not change the overall impact conclusions. The proposed project would draw brackish groundwater and seawater from the coastal terrace deposits and Monterey Bay, and not from aquifers inland from the coast where other users are extracting groundwater for municipal, agricultural, and industrial uses. The MPWSP impacts on groundwater resources would be localized and would not extend beyond the area of influence of the slant well pumping, which is delimited, for the sake of the analysis, by the -1-foot drawdown contour. However, the EIR/EIS did conclude that the project would not exacerbate and would retard seawater intrusion, which is a regional beneficial effect. See EIR/EIS Section 4.4.5.2, Impact 4.4-4.

LWMC-16 The geographic scope of the groundwater resources cumulative analysis in the Salinas Valley Groundwater Basin was established to adequately encompass the 180/400-Foot Aquifer in the western portion of the Pressure Area and more than fully encompasses the area of influence from the MPWSP pumping. The maximum projected extent of influence from slant well pumping is shown in the EIR/EIS Figures 4.4-13a and 4.4-13b and in Master Response 8, Source Water and Seawater Intrusion, Figures 8.2.8-1 and 8.2.8-2. The geographic scope extends an additional 4 miles inland from the furthest projected inland extent of the MPWSP cone of depression and includes the entire north-south extent of the western Pressure Area and the entire Seaside Basin. This is appropriate due to the nature of the groundwater response from the MPWSP. The maximum projected MPWSP area of pumping influence (cone of depression) would only extend at most 4.5 miles inland and the actual capture zone would be located at the coast in an area containing brackish to saline groundwater, which is recharged directly by seawater in the Dune Sand and 180-Foot Aquifer. From a hydrogeological perspective, the geographic scope of the cumulative groundwater analysis is not arbitrary but is based on established hydrogeologic boundaries and an adequate inland distance to ensure that other regional projects that could combine cumulatively with MPWSP would be considered.

LWMC-17 The conclusion that the MPWSP's contribution would not be cumulatively considerable is based on the hydrogeologic setting and the groundwater response to slant well pumping. As explained in EIR/EIS Section 4.4.5.2 and further clarified in Master Response 8, Section 8.2.8.4, the effects to the underlying aquifers from slant well pumping would be confined to the coast where the groundwater is brackish to

saline and where the slant well capture zone is constantly recharged by seawater infiltrating through coastal terrace deposits. The effects of MPWSP pumping would not extend far enough inland to cumulatively contribute to the depletion of SVGB groundwater supplies or the violation of groundwater quality standards.

LWMC-18 As stated in the final paragraph of Section 4.4.6 (Impact 4.4-C), "Because the MPWSP combined with the possible RUWAP desalination element would not result in a significant adverse cumulative impact and may have beneficial consequences, and the Salinas Valley Water Project Phase II and the Interlake Tunnel would have beneficial effects, the cumulative effect of these four possible projects on groundwater resources would be less than significant." This summarizes the above discussion that outlines in greater detail the expected beneficial cumulative impacts resulting from the proposed project and projects in the cumulative scenario.

LWMC-19 The MPWSP would not contribute to the depletion of groundwater supplies or the degradation of groundwater quality in the inland aquifers of the Pressure Area because the source water to the MPWSP would be the brackish to saline groundwater extracted from a coastal capture zone, which would initially be recharged by ambient, heavily brackish to saline groundwater and eventually by seawater. The project would not draw fresh groundwater from inland sources. As discussed in Master Response 4, Agency Act and Return Water, Section 8.2.4.1, CalAm has proposed to satisfy the Agency Act by annually calculating (based on water quality sampling from the slant wells) the percentage of supply water that originated in the SVGB as fresh water (i.e., the fresh water component of the brackish water drawn by the slant wells that originated in the SVGB). CalAm would then "return" to the SVGB that same amount of water by providing desalinated product water to the Castroville Community Service District (CCSD) in lieu of its pumping an equal amount of groundwater. The return water component of the MPWSP would recharge the 400-Foot Aquifer because of the reduced pumping by CCSD. The return water is not considered mitigation for the depletion of groundwater from inland regions of the SVGB. The projected 1- to 5-foot change in groundwater levels due to slant well pumping, as determined by the NMGWM[2016] would be a minor drawdown localized within the area of influence of the slant well pumping. Of the past, present, and foreseeable projects considered for the cumulative analysis, the only potential project near the area of influence that would contribute to the drawdown of groundwater levels is the RUWAP Desalination Element (No. 31). As stated in EIR/EIS Section 4.4.6, the MPWSP and a desalination project at MCWD, would not deplete the basin groundwater supply and could have a combined beneficial effect because the capture zone for inland flowing seawater would expand to the south and would retard the inland advance of the existing seawater intrusion front.

LWMC-20 See responses to comments LWMC-14, LWMC-17, and LWMC-19. The MPWSP would not contribute to the declining groundwater levels in the SVGB and would not contribute to overdraft elsewhere in the SVGB. However, the project could

provide a benefit in that it would reduce groundwater pumping in the CCSD service area, return water to the 400-Foot Aquifer, and contribute to retarding the advance of seawater intrusion.

LWMC-21 In regard to the comment's footnote 7, see response to comment LWMC-12. Responses to comments LWMC-14, LWMC-17, LWMC-19 address the concerns expressed in this comment.

LWMC-22 See Master Response 8, Source Water and Seawater Intrusion, Section 8.2.8.1 and 8.2.8.2 for additional clarification regarding the difference between the capture zone and the cone of depression. Water would not be drawn into the wells from the inland edge of the cone of depression. Groundwater currently flows landward from the inland extent of the capture zone to the inland edge of the cone of depression (see Figure 8.2.8-3). Drawdown of less than 1 foot could indeed extend farther than the -1-foot contour used to delimit the zone of MPWSP pumping influence, but a water level decline of less than 1 foot would not be considered a measurable or substantial drawdown, and would likely not be distinguishable from seasonal variations in groundwater levels.

LWMC-23 The MPWSP would not contribute to the depletion of a groundwater supply because under steady state conditions, the proposed slant wells would draw over 95 percent of the required feedwater from Monterey Bay. See responses to comments LWMC-14, LWMC-17, LWMC-19, and LWMC-22. See also Master Response 4, The Agency Act and Return Water, Section 8.2.4.3 as well as EIR/EIS Appendix E3.

8.6.14 Responses to Comments from Pebble Beach Company

PBC-1 As described in EIR/EIS Section 2.3.3.1, water entitlements totaling 380 afy were granted by the MPWMD to the Pebble Beach Company and the other fiscal sponsors of the wastewater reclamation project; the wastewater project saves substantially more water than the water entitlements represent. Because MPWMD has issued water permits associated with this entitlement, counting the total amount of the entitlements along with existing water demand would double count some water use associated with the entitlements. For the reasons discussed in Section 2.3.1.3, the EIR/EIS analysis assumed that of the 380 afy, entitlements totaling about 325 afy would not be reflected in existing service area demand; this amount was included with existing demand and other demands the MPWSP is proposed to meet. In response to this comment and comments from MPWMD, as well as the SWRCB's recognition of the Pebble Beach water entitlements in the CDO, the discussion of Pebble Beach water entitlements in the EIR/EIS has been revised to show that the remaining Pebble Beach entitlements are considered existing service area demand that CalAm is obligated to serve with or without the project. The Chapter 2 discussion of the Pebble Beach entitlements has therefore been moved from the aforementioned Section 2.3.3.1 to Section 2.3.1.3 of the Final EIR/EIS and other associated text revisions have been made throughout the EIR/EIS.

PBC-2 See response to comment PBC-1.

PBC-3 See response to comment PBC-1. Revisions to Section 6.3 recognize that the entitlements represent an existing obligation by CalAm to serve the associated properties, with or without the proposed MPWSP; that lack of water is not an obstacle to their development; and that water for these entitlements would therefore not be growth-inducing. These revisions do not affect the overall significance conclusions in Section 6.3.

PBC-4 In response to this comment and recognition that neither MPWMD nor Monterey County have the authority to reassign the water entitlements or reallocate the associated water supply, the second paragraph under "Assumptions Regarding Allocation and Use of MPWSP Water Service Capacity" in Section 6.3.5.1 has been deleted. These revisions do not affect the overall significance conclusions in Section 6.3.

8.6.15 Responses to Comments from Point Blue Conservation Science

Point Blue-1 In response to this comment, the following text revisions have been made in the "Subsurface Slant Wells" discussion in Impact 4.6-1 in EIR/EIS Section 4.6.5.1:

> The beach north and south of the site is subject to ~~relatively little~~ some disturbance from humans or dogs~~, and~~; however, birds can ~~readily use~~ access these areas during construction.

and,

> Construction activities may temporarily displace birds that typically winter along the beach near the western portion of the Source Water Pipeline. ~~However, there is abundant, relatively undisturbed h~~ Habitat is available~~, located~~ on the beach and in the dunes north and south of the project area ~~that is available~~ for wintering use during construction.

Point Blue-2 Draft EIR/EIS (page 4.6-136 in Impact 4.6-1) acknowledges that impacts on western snowy plover habitat are anticipated to be significant. Additionally, Draft EIR/EIS text has been revised to clarify that impacts would occur on both nesting and wintering western snowy plover habitat. See also response to comment CURE-Owens-13 in Section 8.6.2.

Point Blue-3 CEQA and NEPA require that potential project impacts be analyzed compared to existing (baseline) conditions (see Master Response 10, Environmental Baseline under CEQA and NEPA, for further discussion). Based on these existing conditions, which include ongoing coastal erosion, the Draft EIR/EIS (page 4.6-136, Impact 4.6-1) acknowledges that impacts on western snowy plover habitat are anticipated to be significant. See EIR/EIS Appendix C2 for an analysis of projected beach profiles under potential future conditions; both sea level rise and ongoing coastal erosion were considered and act in concert to move beach profiles inland, such that average beach width is anticipated to be maintained in this location; see EIR/EIS Figures 4.2-7 and 4.2-8 which show the anticipated beach profiles over time. As the bluff erodes, it maintains the beach width, as described in Impact 4.2-10.

Point Blue-4 Mitigation Measure 4.6-1d in EIR/EIS Section 4.6 requires restoration of temporarily impacted habitat and compensation for permanent loss of habitat. This measure has been revised to include performance standards to ensure that the restoration and compensation areas meet certain standards relative to the condition of the impacted area. The newly added performance standards require that native vegetation cover be at least 70 percent of baseline, and that no net increase in invasives occurs. These are consistent with Point Blue's recommendations. These

compensation requirements would be described in the Habitat Mitigation and Monitoring Plan (HMMP) required in Mitigation Measure 4.6-1n. See Final EIR/EIS Section 4.6 for the revised Mitigation Measure 4.6-1n. The HMMP will describe the restoration and compensation requirements for impacts on all special-status species and sensitive habitats as described in Mitigation Measures 4.6-1d, 4.6-1e, 4.6-1f, 4.6-1h, 4.6-1m, 4.6-1o, and 4.6-2b. Each of these measures describes the restoration and compensation requirements, including performance standards for each species. Restoration and compensation requirements will be specific to each species, although some requirements may overlap.

Point Blue-5 Based on consultation with USFWS, Mitigation Measure 4.6-1d in EIR/EIS Section 4.6 has been revised to no longer include an option to contribute funds to an existing restoration program because this would not likely be a feasible option that would approved by local jurisdictions and regulatory agencies; therefore, the recommendation to require that such a restoration program be located in an area where recreational impacts on plovers are adequately managed no longer applies to this measure. Nonetheless, in response to this comment, the measure has been revised to ensure that the Habitat Mitigation and Monitoring Plan (as described in Mitigation Measure 4.6-1n) will include measures to manage recreational activities to benefit western snowy plover.

Point Blue-6 The revised Mitigation Measure 4.6-1d specifies a 3:1 compensation ratio. This ratio has been revised for consistency with permitting application documents, which specify a 3:1 compensation ratio, which is assumed to be the minimum that USFWS will require to compensate for permanent impacts.

8.6.16 Responses to Comments from Public Trust Alliance

PTA-1 The issues raised in this comment are discussed in Master Response 13, Demand (Project Need) and Growth, under the headings "Existing Annual Service Area Demand," "Supply Assumptions," and "Water Available for Growth."

PTA-2 The EIR/EIS does not ignore the analysis prepared by MPWMD with respect to hospitality sector rebound demand. See response to comment MPWMD-59 in Section 8.5.7 for a discussion of MPWMD's range of results, of which 194 afy is the lowest, and the EIR/EIS' consideration of this analysis.

There are two distinct ways in which the EIR/EIS uses estimates of demand to analyze the project. The first is to evaluate the project *as proposed by CalAm* to determine its potential environmental effects, including potential growth-inducing effects. As noted in Section 2.3.2.1, which describes CalAm's estimate as part of the basis for sizing the project as proposed, the MPWMD's direct testimony to the CPUC in February 2013 concluded that CalAm's estimate of demand related to tourism rebound (i.e., 500 afy) was reasonable. However, that section of the EIR/EIS also acknowledges that this estimate may be too high, and refers readers to the analysis of growth inducement in Section 6.3. As discussed in EIR/EIS Section 6.3.5.1, in addition to considering MPWMD's analyses of commercial sector demand, the EIR/EIS preparers conducted an independent analysis that included several comparisons, and concluded that the increased demand associated with economic recovery of the hospitality industry could be closer to 250 afy, and thus assumed that the remaining 250 afy of CalAm's estimate of 500 afy could in fact be available for new development, rather than recovery. Thus, in its analysis of the potential impacts of the project as proposed, the EIR/EIS does not rely solely on CalAm's estimates of demand. The estimates used in the growth inducement analysis are supported by substantial evidence including MPWMD's analysis and the independent analysis undertaken for the EIR/EIS.

The second way the EIR/EIS uses demand estimates is to determine whether feasible alternatives exist that would meet most of the basic objectives of the project, which requires an analysis of the reasonableness of – and assumptions supporting – those objectives. As discussed in Master Response 13, Demand (Project Need) and Growth, Section 8.2.13.5, a sensitivity analysis was conducted to determine if using 250 afy instead of 500 afy, in addition to other adjustments in demand, could support the approval of a smaller desalination plant than proposed. Further, as also discussed in Master Response 13, additional analysis prepared for this Final EIR/EIS suggests that 500 afy is a reasonable estimate of increased demand that could occur under a fully recovered economy at existing commercial businesses, industries, and institutional/public sector uses. Regarding elasticity of demand, as used in the EIR/EIS the term occupancy rates refers to the occupancy levels or use rates (e.g., the relative proportion of occupied to unoccupied lodging rooms or restaurant seats at visitor-serving businesses), not the prices of rooms ("room rates") or restaurant meals.

PTA-3 See the discussion of Table 13 water rights under the heading "Supply Assumptions" in Master Response 13, Demand (Project Need) and Growth. Note also that 12,270 afy was used to represent demand of existing customers, as discussed in Master Response 13 under "Existing Annual Service Area Demand." The EIR/EIS does not assume that demand would be higher in wet years than in normal water years; an extended rainy season in wet years can reduce outdoor irrigation needs, reducing water demand for that purpose. The basis for the assertion that "the DEIR does incorporate increased demand during wet years" is unclear. However, following the end of a drought, some relaxation of voluntary, temporary (behavioral) conservation efforts could lead to somewhat higher demand than during a drought. Operation of the ASR system is predicated on water being available for storage in wetter periods or years for use in dryer periods or dryer years. Although the SWRCB's CDO currently requires CalAm to use any Carmel River water diverted to ASR storage within the same year so that available ASR water is used to reduce unlawful diversions from the Carmel River, when CalAm is no longer unlawfully diverting Carmel River water (e.g., following implementation of a new water supply project such as the MPWSP), CalAm will be allowed to manage carry-over storage for greater flexibility in operating the ASR system. The ASR system could then be used to store water over a period of years for use in dry years

PTA-4 See responses to comments MCWD-168 and MCWD-170 in Section 8.5.2.

PTA-5 EIR/EIS Section 6.4, Project Consistency with Monterey Bay National Marine Sanctuary Desalination Guidelines, states that the guidelines are *non-regulatory guidelines* (italicized for emphasis) developed to help ensure that any future desalination plants in the Sanctuary would be sited, designed, and operated in a manner that results in minimal impacts on the marine environment. The consistency assessments included in Section 6.4 are meant to assist the Superintendent of MBNMS with decision-making concerning the special use permit and permit authorizations and any terms or conditions that may be necessary to ensure that MBNMS resources are protected. Response to comment Marina-151 in Section 8.5.1 addresses maximization of wastewater recycling. Regarding mitigation of greenhouse gas emissions, see responses to comments PTA-11 and PTA-12, and regarding the comment about sea level rise and potential erosion, see response to comment PTA-6, below.

PTA-6 As summarized in Section 4.2.1.3 of the EIR/EIS and described in more detail in Appendix C2, Analysis of Historic and Future Coastal Erosion with Seal Level Rise, the sea level rise projection used to assess the proposed project is based on the 2013 state guidance. NRC (2012) projects an upper range of sea level rise of 66 inches by 2100.

The comment's reference to "the Assessment Report from the IPCC from 2016" is unclear, and no specific citation is provided in the letter. The International Panel on Climate Change (IPCC) 2014 report is the IPCC's Fifth Assessment Report. The IPCC

is currently working on its sixth Assessment Report, which is scheduled for completion in 2022. As per the IPCC's press release of April 28, 2017: "[Assessment Report] 6 will assess scientific findings that have been published since the IPCC's last comprehensive report, the Fifth Assessment Report (AR5), which was completed in 2014" (IPCC, 2017). The Lead Agencies are not aware of and were unable to locate an IPCC Assessment Report from 2016 that has bearing on this comment.

EIR/EIS Figure 4.3-1 shows "Surface Water Resources in the Project Area" and does not reference sea level rise. Rather, Figure 4.3-3, "Areas Subject to Sea Level Rise in the Project Area," shows areas subject to sea level rise in 2100, referencing a 2009 report by The Pacific Institute cited in Section 4.3, Surface Water Hydrology and Water Quality.

The summary of the IPCC Fifth Assessment Report on Draft EIR/EIS page 4.3-15 is revised to clarify that the report actually states that up to 7 meters is potentially possible over a millennium or more (not by 2099) and that realizing this amount of sea level rise would require near-complete collapse of the Greenland ice sheet (which is dependent upon the amount of future warming and not certain to occur). Some of this qualification was included in the Draft EIR/EIS's footnote 16 on page 4.3-15. This statement has been revised in the Final EIR/EIS, as follows:

> The more recent Assessment Report predicts mean sea level could, depending on future emissions, ~~to~~ rise by up to 7 meters (23 feet) over a millennium or more, assuming near-complete loss of the Greenland ice sheet ~~globally by 2009~~ (IPCC, 2014, p. 12).~~16~~

The associated footnote 16 has been deleted to avoid repetition.

One of the citations on Draft EIR/EIS page 4.3-15, the National Research Council (NRC) *Sea-Level Rise for the Coasts of California, Oregon, and Washington: Past, Present, and Future* (2012), was and remains the latest available federal study of the sea level science and projections specific to the west coast. The findings from this report were adopted by California as official state guidance (California Ocean Protection Council, 2013). Therefore, the EIR/EIS's use of the sea level rise projections from the NRC (2012) study was consistent with current state guidance and adopted best available science at the time of its publication (see below regarding recent updates to state guidance).

As indicated by the three references for sea level rise predictions in EIR/EIS Section 4.3.1.4 (i.e., IPCC, 2014; NRC, 2012; and Pacific Institute, 2009), there is a range of sea level rise projections, and these projections continue to be updated in response to new observations and scientific analysis. For all sea level rise projections, the uncertainty increases as more distant future times are considered. Thus, the difference between 2100 sea level rise projections of 55 inches (Pacific Institute, 2009) and 66 inches (NRC, 2012) is probably best viewed as reflecting inherent uncertainty about the future. These two projections are based on different information and

assumptions, and due to uncertainty, it is not possible to say one particular projection of sea level rise, particularly when considered to the nearest inch, is "best." This uncertainty stems from the unknowable future greenhouse gas (GHG) emissions and the climate's response to these scenarios.

Since the preparation of the Draft EIR/EIS, new scientific studies of sea level rise projections have been released. In preparation for the 2018 updates to the state's sea level rise guidance (California Ocean Protection Council, 2017), California agencies reviewed the latest sea level rise projections (Cayan et al., 2016; Griggs et al., 2017). These recent studies confirm that the expected range of sea level rise by 2100 is within a range of 3 to 6 feet, similar to the NRC (2012) projections of 17 to 66 inches cited in the Draft EIR/EIS. In addition to the expected range, the studies acknowledge that an extreme sea level rise scenario, resulting from rapid ice sheet loss, cannot yet be ruled out, and could result in sea level rise of nearly 10 feet by 2100. Although current science cannot resolve the likelihood of this extreme scenario, these recent studies do provide new assessments in the form of probability estimates for projected sea level rise. For the highest GHG concentration scenario, Cayan et al. (2016) estimates that 2100 sea level rise has a 50 percent probability of exceeding 4.5 feet and 0.5 percent probability of exceeding 8.6 feet. Similarly, Griggs et al. (2017) estimates that 2100 sea level rise has a 50 percent probability of exceeding 2.5 feet and 0.5 percent probability of exceeding 5.9 feet. Note that both these cases are for the scenario in which GHG emissions continue to rise through 2100, and therefore represent no or little reduction in present-day emission trends. If GHG emissions are reduced, as proposed in the international Paris Agreement of 2015, GHG concentrations and hence sea level rise will likely be less.

With respect to the specific instance of sea level rise analysis as applied to the MPWSP in Figure 4.3-3, this figure is intended to indicate the regional extent of potential coastal hazards by 2100. To do so, the figure includes the available regional coastal hazard mapping, which is from the Pacific Institute (2009). At the time of the Pacific Institute study, the upper range of sea level rise was projected to result in 55 inches by 2100. Since the hazard zones in this figure are for 2100, and are based on the upper range of sea level rise projections, this figure adequately represents the potential coastal flooding facing the MPWSP project.

For the trajectory that arrives at 66 inches by 2100 (NRC, 2012), the projected sea level rise by 2060 is 28 inches (Table 4, Appendix C1). This 28 inches of sea level rise is used in the coastal erosion analysis in Appendix C2. In the coastal erosion analysis, sea level rise is not only assumed to increase mean water levels, but also to accelerate sand dune erosion faster than historic erosion rates and to bring the potential erosion from the 100-year storm event further inland. In its review of the coastal erosion analyses in Appendix C2, another coastal engineering firm found the approach of Appendix C2 to be reasonable and the resulting erosion predictions to be conservative in their predictions of maximum possible landward erosion extents (Sea Engineering, 2014).

As discussed above, the amount of sea level rise used to assess potential impacts is consistent with the upper end of the projected sea level rise range. Therefore, the EIR/EIS does not underestimate the degree to which structures may be exposed to erosion and flooding.

The slant wells would be buried underground, and therefore not subject to surface flooding. The well head vaults would be located above 30 feet NAVD as shown in Figures 4.2-7 and 4.2-8. The present-day base flood elevation for the 100-year coastal event, including wave run-up, is 18 to 21 feet NAVD (FEMA, 2017). Therefore, the well head vaults would not be exposed to coastal flooding hazard for the upper range of projected sea level rise, which is 28 inches or 2.3 feet by 2060.

The potential coastal erosion, including accelerated erosion due to the upper range of projected sea level rise and 100-year storm events up to 2060, was mapped horizontally and vertically. As shown in Figure 4.2-7, the test well head vault may be exposed to erosion at 2060 in the event of a 100-year storm event. As shown in Figure 4.2-8, the well head vaults for the main set of slant wells are not expected to be exposed to erosion at 2060 even for the upper range of sea level rise and a 100-year storm event. As per Mitigation Measure 4.2-9, Slant Well Abandonment Plan, coastal erosion would be monitored by CalAm annually, and when any of the slant wells may be exposed within 5 years, CalAm would be required to prepare a plan for abandoning the threatened wells. The threatened wells would be abandoned according to well destruction standards and regulatory permitting requirements. Sea walls would not be used to adapt the slant wells to coastal erosion.

As noted by Cayan et al. (2016) and Griggs et al. (2017), the possibility of an extreme sea level rise scenario that exceeds the upper range of expected projections cannot yet be ruled out. Under an extreme scenario, sea level rise could reach 9.3 feet by 2100 (Griggs et al., 2017). In the event that this scenario comes to pass, most of the sea level rise would occur in the second half of the 21st century. Therefore, even for the most extreme (and therefore very unlikely) sea level rise scenario, the main wells are not likely to face erosion during most or all of their functional lifespan, and if exposure does become likely to occur, Mitigation Measure 4.2-9 would address this.

PTA-7 See the discussion under “Impacts of Growth” in Master Response 13.

PTA-8 See the discussion under “Water Available for Growth” in Master Response 13.

PTA-9 CEQA Guidelines Section 15126.2(a) requires analysis of the significant environmental impacts of a project and Section 15126.2(d) requires consideration of a project’s growth-inducing impacts. Chapters 4 and 5 of the EIR/EIS evaluate the environmental impacts of the MPWSP and MPWSP alternatives, respectively, including the direct growth-inducing impacts of project construction and operation, while Section 6.3 evaluates the indirect growth-inducing impact of the water supply provided by the project. Therefore, Section 4.8.5 evaluates the effects of project construction and

operation (e.g., construction and operation of the slant wells, desalination plant, pipelines and related infrastructure) on land use and recreation consistent with the significance criteria provided in Appendix G of the CEQA Guidelines and NEPA guidance, relying on and consistent with conclusions in EIR/EIS Section 4.19 regarding the project's potential direct growth-inducing impact, while as shown in Table 6.3-9, growth indirectly induced by the project water supply would result in significant traffic, land use, and recreational impacts. These separate conclusions regarding direct and indirect impacts are not contradictory, and are addressed in separate sections of the EIR/EIS because the cause of growth inducement (i.e., direct employment vs. water supply) differs substantially and merits separate, in-depth discussion. The significant traffic, land use, recreational, and other impacts described in Section 6.3 that were identified in the General Plan CEQA documents of jurisdictions that would be served by the project are the basis for the EIR/EIS's conclusion that the project's indirect growth inducing impact would be significant and unavoidable.

PTA-10 See the discussion under "Impacts of Growth" in Master Response 13.

PTA-11 Subsequent to the release of the Draft EIR/EIS, Greenhouse Gas (GHG) Emissions Mitigation Measure 4.11-1 has been revised to include a net zero indirect operational GHG emissions requirement for project-related electricity use (see response to comment USEPA-4 in Section 8.3.5 for specific revisions to this measure, and Impact 4.11-1 discussion in Final EIS/EIR Section 4.5.11 for revised discussion based on this measure). The first item identified in the revised measure's emission reduction loading order is for CalAm to obtain renewable energy from on-site solar photovoltaic (PV) panels and/or from the adjacent Monterey Regional Waste Management District (MRWMD) landfill-gas-to-energy (LFGTE) facility. Any remaining indirect emissions associated with electricity use would be off-set through procurement of renewable energy from off-site sources, procurement and retirement of Renewable Energy Certificates, and/or procurement and retirement of carbon offsets.

PTA-12 As described in EIR/EIS Section 4.18.5.2, the analysis of project-related operational energy demand considers the change in total system-wide demand with the project compared to baseline system-wide energy consumption. Thus, the analysis does not "assume that none of the existing supplies and operations would be ongoing," rather, it properly analyzes the change compared to baseline (baseline consumption is not attributable to the project and therefore is not a project impact). The comment is unclear regarding which significance criterion is alleged to have been disregarded; all evaluation criteria listed in Chapter 4 have been evaluated as described in individual resource sections. With respect to Mitigation Measure 4.11-1 for GHG impacts, see response to comment PTA-11. Revisions to this measure include enforceable performance standards and a suite of feasible options for achieving such standards, and do not constitute deferral of mitigation.

PTA-13 The comment does not specify the source of "CARB's mandates to employ less energy intensive water infrastructure;" however, EIR/EIS Section 4.11.2.2 describes CARB's action measure W-3: Water System Energy Efficiency, from the Climate Change Scoping Plan. With this measure, CARB has set a 20 percent energy use reduction target from 2006 levels. The GHG Emissions Reductions Plan that would be implemented pursuant to Mitigation Measure 4.11-1 would include a commitment by CalAm to incorporate all available feasible energy recovery and conservation technologies; or, if CalAm finds that any of the technologies will not be feasible for the project, the Plan shall clearly explain why such technology is considered to be infeasible. This provision of the mitigation measure is consistent with the intent of CARB's Measure W-3; however, as explained in Impact 4.11-3, the CPUC cannot substantiate that the proposed project's electricity use would be reduced by 20 percent. As described in response to comment PTA-11, above, Mitigation Measure 4.11-1 has also been revised to include a net zero indirect operational GHG emissions requirement for project-related electricity use, which is consistent with the comment's recommendation to obtain or produce onsite sufficient renewable power to reduce emissions below the 2,000 metric tons CO_2e per year threshold.

PTA-14 The California Constitution is not a plan or policy against which the project must be judged. Nonetheless, it is not expected that the project would be inconsistent with Article X, Section 2 of the Constitution, which states in pertinent part:

> [T]he general welfare requires that the water resources of the State be put to beneficial use to the fullest extent of which they are capable, and that the waste or unreasonable use or unreasonable method of use of water be prevented, and that the conservation of such waters is to be exercised with a view to the reasonable and beneficial use thereof in the interest of the people and for the public welfare.

There is no basis to conclude that use of seawater, with an incidental amount of brackish water, is a waste or unreasonable use of water. Indeed, the development of the new water source can be characterized as a reasonable and beneficial use of water. See Master Response 3, Water Rights, for additional discussion.

8.6.17 Responses to Comments from Public Water Now

8.6.17.1 Responses to Comments from Public Water Now – Letter 1

PWN1-1 The California Energy Commission is not listed in EIR/EIS Table 3-8 (Anticipated Permits and Approval) because they do not have any permit authority over the proposed MPWSP. The discussion of the planned retrofit of the once-through cooling system at Moss Landing Power Plant, and the cumulative effects of the retrofit for each alternative in Chapter 5.4 that include an open water intake at Moss Landing, was not omitted, but is discussed for these alternatives as follows:

- Alternative 2 in Section 5.5.5.5 on Draft EIR/EIS page 5.5-120,
- Alternative 3 in Section 5.5.5.6 on Draft EIR/EIS page 5.5-125, and
- Alternative 4 in Section 5.5.5.7 on Draft EIR/EIS page 5.5-128.

For clarification, the planned retrofit of the once-through cooling system at Moss Landing Power Plant has been added to Table 4.1-2 and Figure 4-1 as cumulative project No. 60, and the text in Section 5.5.5 been revised to acknowledge that the planned retrofit by the power plant would not offset the significant adverse cumulative impact attributable to entrainment and impingement at the Moss Landing alternatives that propose to use screened open water intakes. However, because the MPWSP would result in no impingement or entrainment of fish or invertebrate species (as discussed on Draft EIR/EIS pages 4.5-52, 4.5-53, and 4.5-68), the planned retrofit of the once-through cooling system at Moss Landing Power Plant is not included in the cumulative impact analysis for the MPWSP.

This clarification results in no changes to the conclusions regarding the cumulative effects of the MPWSP or alternatives.

PWN1-2 The Sustainable Groundwater Management Act (SGMA) is discussed in the Draft EIR/EIS Section 4.4.2.2 on page 4.4-37. See also Master Response 6, The Sustainable Groundwater Management Act.

PWN1-3 The comment is not clear regarding what authority the CPUC may claim as superior to local governments, or what other materials may have been omitted that could support other options. See response to comment PWN1-2 and Master Response 6 regarding the relationship of the SGMA to the project.

8.6.17.2 Responses to Comments from Public Water Now – Letter 2

PWN2-1 The water supply challenges facing the Monterey Peninsula have been documented in the Draft EIR/EIS in several places. Section 1.3 (Project Objectives and Purpose and Need), describes the overdrafting of the Carmel River and the Seaside Basin, SWRCB Order 95-10, and the Monterey County Superior Court Adjudication; the order and the adjudication are further discussed in Section 2.2.3 and Section 2.2.4, respectively. The MPWSP objectives, and purpose and need, are discussed again in

the alternative analysis at Section 5.1.2.1. CalAm's history of proposing water supply projects in response to these challenges, including the New Los Padres Dam and Reservoir, the Carmel River Dam and Reservoir, and the Coastal Water Project (and the North Marina Project and the Regional Project) are discussed in Section 5.2.

PWN2-2 The conflict of interest issue is discussed in the Draft EIR/EIS in Section 1.4.3, which notes that the CPUC made the groundwater data files available for public review, and the CPUC employed the Lawrence Berkeley National Laboratory to conduct an independent evaluation of that data. The results of that evaluation were provided in Appendix E1. See also Master Response 5, The Role of Hydrogeologic Working Group (HWG) and its Relationship to the EIR/EIS, which addresses this issue among other issues related to this group.

PWN2-3 See Master Response 2 regarding source water components and definitions. The proposed slant wells are described in Draft EIR/EIS Section 3.2.1.1 and are shown on Figures 3-3a and 3-3b, including a table with lengths of proposed well casing above and below mean high water. See also Table 3-2, which shows the lengths of permanent slant wells seaward of mean high water.

PWN2-4 See Master Response 11 regarding the test slant well. Specifically, Section 8.2.11.2 describes the City of Marina's review process and that the city declined to adopt its *Draft Initial Study and Mitigated Negative Declaration for the California American Water Slant Test Well Project.* Section 8.2.11.3 describes the California Coastal Commission CEQA review process for the test slant well. In response to this and other similar comments, footnote 2 in the Executive Summary (and other locations where similar text appears in the EIR/EIS) has been revised to clarify these agencies' actions and processes regarding consideration of the test slant well.

PWN2-5 The impacts from the MPWSP on the groundwater resources of the Salinas Valley Groundwater Basin (SVGB) are not ignored. Potential impacts on groundwater resources in the SVGB, as well as water rights related to other users of the basin, are clearly identified as an area of controversy in the Executive Summary. The impacts of the proposed project on the groundwater elevations in the SVGB, and the area that is the MCWD Service Area, are presented as drawdown contour maps in the Draft EIR/EIS and are discussed in Section 4.4, Groundwater Resources. See also Master Response 14, CEMEX Settlement Agreement, regarding impacts on future water supply.

PWN2-6 The Draft EIR/EIS concludes in Section 4.4.5 (Direct and Indirect Effects of the Proposed Project) that impacts on the groundwater basin would be less than significant and the water resources of the MCWD and the City of Marina would not be jeopardized. The Applicant Proposed Measure described at the end of Impact 4.4-3 recognizes the long-term nature of the proposed project and the need to provide continued verification that the project would not contribute to lower groundwater levels in nearby wells within the SVGB. So, as part of the project, CalAm proposes to work

with the Monterey County Water Resources Agency to expand the existing regional groundwater monitoring program to include the area where groundwater elevations are anticipated to decrease by 1 foot or more plus 1 mile, and to make whole any pumper who is affected by project pumping, including MCWD. This Applicant Proposed Measure is detailed in the Draft EIR/EIS at page 4.4-74.

PWN2-7 See response to comment PWN2-3.

PWN2-8 The Draft EIR/EIS explains in Section 5.3.1.1, SWRCB and the California Ocean Plan, that the SWRCB prefers subsurface intakes, but allows surface water intakes where subsurface intakes are not feasible or economically viable. A citation to the Ocean Plan, which defines terms, was provided in that section (Draft EIR/EIS page 5.3-2). However, for clarification, the definition of "feasible" from the Ocean Plan is provided as a revision in Final EIR/EIS Section 5.3.1.1, as follows:

> Section 13142.5 of the California Water Code requires new or expanded coastal industrial facilities, including desalination plants, to use the "best available site, design, technology, and mitigation measures feasible" to minimize the intake and mortality of marine life. The SWRCB prefers subsurface intakes, but allows surface water intakes where subsurface intakes are not feasible or economically viable. For the purposes of Water Code Section 13142.5(b) and implementation of the Ocean Plan, "feasible" means "capable of being accomplished in a successful manner within a reasonable period of time, taking into account economic, environmental, social, and technological factors" as defined in Appendix I of the Ocean Plan. (SWRCB, 2016)

Because this definition of "feasible" is the same as that used under CEQA, this revision causes no change in the consideration of which alternatives are feasible in the EIR/EIS. The Draft EIR/EIS presents the CEQA requirements for alternatives analyses and provides a citation to CEQA Guidelines Section 15126.6 and the corresponding definition of "feasible" in Section 5.1.1.1 (Draft EIR/EIS pages 5.1-2 and 5.1-3).

In Section 5.2, Alternatives Not Evaluated in Detail, ". . . projects were determined to be politically, legally, economically, or technically infeasible." In Section 5.3, Alternatives Development, Screening and Evaluation Process, the Draft EIR/EIS explains in Footnote 6 that, "NEPA requires alternatives to be reasonable, or feasible, which could include consideration of whether the alternative is capable of complying with regulations governing desalination plants in order to receive the required regulatory approval."

PWN2-9 See Master Response 5, which addresses two separate conflict of interest issues related to Geoscience and Dennis Williams, and clarifies the role of the HWG in relation to this EIR/EIS. See also response to comment PWN2-2.

PWN2-10 EIR/EIS Section 1.3.1.1 describes the three federal actions that may be taken by MBNMS on the proposed project, including authorization of a Coastal Development Permit to be issued by the City of Marina for CalAm to drill into the submerged lands of the Sanctuary to install a subsurface source water intake system. It does not address the approval process that was appealed to the CCC following the City of Marina's denial of the Coastal Development Permit (CDP) for the test slant well. See response to comment PWN2-4.

PWN2-11 Footnote 4 in the Draft EIR/EIS qualified the word "pipeline" in one of the federal proposed actions that MBNMS will take on the proposed MPWSP: "issuance of a special use permit to CalAm for the continued presence of a pipeline conveying seawater to a desalination facility." If the pipeline(s) did not extend seaward of the mean high water line, MBNMS would not require this permit. Regarding the location of slant well screens and the nature of source water for the MPWSP, see Master Response 2. As to the issue of water rights, please see Draft EIR/EIS Section 2.6, as well as Master Response 3, Water Rights.

PWN2-12 Footnote 5 on Draft EIR/EIS page 1-8 compares the North Marina Project, not the MPWSP, to the Coastal Water Project. For clarity, the footnote has been revised as follows:

> "The key differences between ~~this~~ the North Marina Project alternative . . ."

PWN2-13 The project setting and background discussion in Draft EIR/EIS Section 1.4 provides context about a project that is no longer under consideration. For clarity, the sentence has been revised as follows: "It included vertical ~~seawater~~ intake wells on coastal dunes located south of the Salinas River and north of Reservation Road." Regarding definitions and composition of source water for the MPWSP, see Master Response 2.

PWN2-14 In addition to being available at the CPUC in San Francisco, the Draft EIR/EIS was available for review at these locations in the project area:

- MBNMS, 99 Pacific Avenue, Building 455a, Monterey
- Castroville Public Library, 11160 Speegle Street
- Marina Public Library, 188 Seaside Avenue
- CSU Monterey Bay Library, 100 Campus Center, Seaside
- Seaside Public Library, 550 Harcourt Avenue
- Carmel Valley Public Library, 65 W. Carmel Valley Road
- City of Marina Community Development Department, 209 Cypress Avenue
- City of Seaside Community Development Division, 440 Harcourt Avenue
- MCWRA, 890 Blanco Circle, Salinas
- MPWMD, 5 Harris Court, Monterey
- MRWPCA, 5 Harris Court, Monterey

The Draft EIR/EIS also was made available online at http://www.cpuc.ca.gov/Environment/info/esa/mpwsp/comms_n_docs.html and at www.regulations.gov/#!docketDetail;D=NOAA-NOS-2016-0156. Information about the availability of the document to review in person or online was provided in public notices for the availability of the Draft EIR/EIS. All supporting documents referenced in the Draft EIR/EIS were made available online at https://drive.google.com/drive/u/2/folders/0B63ty1hxcSNhV2JvMU15UW9VcHc, also accessible via https://tinyurl.com/MPWSPRefs. This link was provided on the CPUC website for the project.

The Coastal Water Project (CWP) is no longer under consideration and the Final EIR for that project is relevant to the MPWSP only in the context of background on projects that preceded the current application. Therefore, print copies of the CWP Draft and Final EIR (2009) are available for public review at the CPUC in San Francisco, with prior arrangements. Additionally, the commenter requested a copy of the CWP Final EIR on September 20, 2016, and a CD was immediately provided to the commenter by US Mail.

PWN2-15 Draft EIR/EIS, Section 1.4.1 introduces the Coastal Water Project, while Section 1.4.2 introduces the MPWSP and explains how it is different from the Coastal Water Project. The commenter does not provide evidence to support the opinions and judgements expressed in the comment. Water rights are addressed in Master Response 3, and a significant and unavoidable impact with respect to inconsistency with the City of Marina's Local Coastal Land Use Plan was identified in Draft EIR/EIS Section 4.6, Terrestrial Biological Resources.

PWN2-16 See response to comment PWN2-4 and Master Response 11.

PWN2-17 Regarding the use of per capita demand to estimate overall service area demand, see the discussion "Other approaches to estimating future water demands" in Section 8.2.13.1 of Master Response 13, Demand (Project Need and Growth). The comment cited Draft EIR/EIS Section 2.3.3.2, Hospitality Industry Rebound, which addresses changes in demand at hospitality-related businesses that could occur under an improved economy, not residential or dwelling unit water use. An increase in demand at such businesses would result from increased occupancy rates at area businesses absent any physical expansion. Therefore, the approach taken in the Draft EIR/EIS to assess the effects of the recession – by reviewing changes in commercial sector water consumption before and since the recession started – was an appropriate and reasonable approach to gage the effect of the recession and thereby the degree to which water consumption could increase under an improved economy. For clarification, the discussion of the comparisons of commercial sector water consumption presented in the Draft EIR/EIS has been expanded in this Final EIR/EIS (see Section 6.3.5.1 of Final EIR/EIS). In response to a comment by MPWMD, the analysis of commercial sector water consumption before and since the recession started was expanded to include the industrial and public authority

sectors. See the discussion in Section 8.2.13.1 of Master Response 13, associated with economic recovery, for more information.

PWN2-18 See response to comment LWMC-4 in section 8.6.13, which explains that CalAm's Monterey District includes more than the main distribution system and the Bishop, Hidden Hills, and Ryan Ranch satellite systems, resulting in the different descriptions of service population.

PWN2-19 Draft EIR/EIS Section 2.3.4 presents information from CalAm's Monterey District Urban Water Management Plan for informational purposes, as stated on Draft EIR/EIS page 2-15. The Management Plan, not the Draft EIR/EIS, assumed a rate of 115 gallons per capita per day for purposes of estimating future water demand while the Draft EIR/EIS used historical water use for the estimates of peak demand. The Management Plan estimate of per capita demand was provided as insight into CalAm's expectations regarding population growth and water demand in the Monterey District. Note also that Appendix K describes the residential per capita water usage in the area reported to the state during the drought emergency, not gross per capita usage presented in the Management Plan. Regarding the suggestion to use residential per capita water use to estimate the project's growth inducing impact, refer to the discussion of "Other approaches to estimating future water demands" in Section 8.2.13.1 of Master Response 13.

PWN2-20 The comment is unclear as to the source of the "theory that MPWSP wells will draw more groundwater toward the pumping locations." As described in the cited reference and explained in Draft EIR/EIS Section 2.5.1, the MPWSP wells would draw less groundwater over time, not more, as evidenced by the increase in salinity measured in the test slant well and reported in the publicly available Test Slant Well Monthly Monitoring Reports.

PWN2-21 CalAm would not be allowed to return water to a customer of the MCWD service area because MCWD has exclusive rights to water service within this area. Although CalAm could deliver return water directly to MCWD, as described in the Draft EIR/EIS in Section 2.5.1, the decision to provide the return water to the CCSD was a result of a June 2016 Settlement Agreement by several parties to the proceeding. CEQA Guideline Section 15126.6(f)(3) states that an "EIR need not consider an alternative . . . whose implementation is remote and speculative."

PWN2-22 Water districts and facilities that provide drinking water to residents and businesses in the project area are presented in Draft EIR/EIS Section 4.13.1.4 and include MCWD, CalAm, Seaside Municipal Water System, and the CCSD. While the slant wells and some pipelines would be located in the City of Marina, Draft EIR/EIS Section 3.1 explains the project area extends from Castroville in the north to the City of Carmel in the south, the desalination plant would be located in unincorporated Monterey County, and pipelines would be located in Marina, Seaside, Sand City, Monterey, and Carmel. The SWRCB and the water rights discussion in the Draft

EIR/EIS Section 2.6 focuses on what "harm" may be caused by proposed project pumping regardless of jurisdiction. To that end, known active supply wells within the vicinity of the proposed MPWSP slant wells are identified in Table 4.4-10 (including the MCWD wells), their impacts on groundwater are discussed in Section 4.4.5.2, and their location relative to project-induced drawdown is shown on Figure 4.4-15, Figure 4.4-15, and Figure 4.4-16.

Regarding water rights and related questions of project feasibility, see Master Response 3. The issue of ratepayer liability is outside the scope of CEQA and NEPA requirements; however, as described in Draft EIR/EIS Section 1.5.4.1, the CPUC decision to grant or deny a Certificate of Public Convenience and Necessity for the project (i.e., project approval) would follow a process after certification of the EIR during which the Commission will consider any other issues that have been established in the record of the proceeding, including but not limited to economic issues, social impacts, specific routing and alignments, and the need for the project. Therefore, comments regarding ratepayer liability are relevant to and will be considered as part of that proceeding.

PWN2-23 The Draft EIR/EIS evaluated returning water to CCSD as well as returning water to the CSIP. Consistent with CEQA Guidelines Section 15126.6(a), an EIR "need not consider every conceivable alternative", as explained in Draft EIR/EIS Section 5.1.1. See also response to comment PWN2-21 and Master Response 4 regarding the Agency Act and return water.

PWN2-24 As explained in the Draft EIR/EIS Appendix A (Notice of Preparation and Notice of Intent Scoping Report) introduction, the CPUC formally began the process of determining the scope of issues and alternatives to be evaluated in the Draft EIR (a process called "scoping") when it issued a Notice of Preparation (NOP) of an EIR for the proposed project on October 10, 2012. In accordance with Section 102(2)(C) of NEPA, the NOAA Office of National Marine Sanctuaries published a Notice of Intent (NOI) to prepare an EIS for the proposed project on August 26, 2015 (80 Fed. Reg. 51787). MCWD submitted comments on the NOP/NOI on October 10, 2015, as detailed in Appendix A at page A-28. The Lead Agencies subsequently contacted MCWD during the preparation of the Draft EIR/EIS in December 2015 and again in March 2016, seeking information about MCWD's proposed plans for desalination or another water supply project, as well as groundwater data from their monitoring wells near Reservation Road. Information from that response is included in EIR/EIS Table 4.1-2 at Project No. 31, Regional Urban Water Augmentation Project (RUWAP) Desalination Element, and is referenced in the table as MCWD, 2016. The MCWD did not have a representative on the HWG because they were not a signatory to the Settlement Agreement that established it.

PWN2-25 See Master Response 11 regarding the test slant well and further modeling; specifically, see Section 8.2.11.5 regarding results of the long-term pump test and Section 8.2.11.6 regarding the use of test results in further modeling. See Master

Response 5 regarding the HWG. The Lead Agencies do not have jurisdiction over this group or the duration of its work.

PWN2-26 The quoted text refers to evidence evolving "throughout" the proceeding; the decision completes the proceeding. See Master Response 11 regarding the use of test slant well data and Master Response 3 regarding water rights. Regarding ratepayer liability, see response to comment PWN2-22.

PWN2-27 The cited text refers to Draft EIR/EIS Section 4.4. As described on Draft EIR/EIS page 4.4-50, the exact quantity of water to be returned annually would vary and would be determined each year using a mathematical formula. For groundwater modeling and impact analysis purposes in the EIR/EIS, it is estimated that somewhere between 0 and 12 percent of the source water withdrawn for the project would comprise water originating from the inland aquifers, and thus would be returned to the basin. However, the model cannot predict the return water percentage of a given future year, because the model uses historic hydrology, and predicts what would happen if history repeated itself. See also Master Response 4 regarding the Agency Act and return water.

The discussion of causing "no harm" to SVGB water users was provided in Draft EIR/EIS Section 2.6.2, and clarification is provided in Master Response 3, regarding water rights.

PWN2-28 See Master Response 5, Sections 8.2.5.2 and 8.2.5.3, as well as response to comment PWN2-27.

PWN2-29 See Master Response 3 regarding water rights, which explains that the feasibility studies related to establishing water rights are separate from the CEQA/NEPA evaluation process.

PWN2-30 See response to comment PWN2-21 and Master Response 4 regarding the Agency Act and return water.

PWN2-31 See response to comment PWN2-3 regarding Draft EIR/EIS information on well locations and Master Response 2 regarding source water components and definitions, including discussion of the placement of well screens relative to the seafloor and groundwater aquifers. See also Master Response 3 regarding water rights.

PWN2-32 The Draft EIR/EIS Section 3.2.1.1 explains that, "Each well would be screened for approximately 400 to 800 linear feet at depths corresponding to both the Dune Sand Aquifer and the underlying 180-Foot-Equivalent Aquifer of the Salinas Valley Groundwater Basin." Table 3-2 provides the length of permanent slant wells seaward of the 2020 Mean High Water line, and that is illustratively shown in Figure 3-3b. The portion of each well that is not seaward of MHW is therefore, landward of the sea. Nothing in this response triggers a need for recirculation per CEQA Guidelines Section 15088.5. See also Master Response 2.

PWN2-33 See response to comment PWN2-32.

PWN2-34 Draft EIR/EIS Figure 3-3a shows both the City of Marina boundary and the Mean High Water (MWH) line at 2020. They are, in fact, different lines. All of the wells would be located within the City of Marina, and their authority over the MPWSP is described in Draft EIR/EIS Section 1.5.4.3. Because some portion of the wells would extend beyond MHW, MBNMS also has authority over the MPWSP, which is described in Draft EIR/EIS Section 1.3.2.

PWN2-35 See response to comment PWN2-4.

PWN2-36 Table 3-2 presents the uncertainty of the effects of coastal retreat relative to the proposed slant wells in 2020, depending on what factors may (or may not) occur. Figure 3-3b is an illustrative cross sectional view of the subsurface slant wells, and also includes a table of well lengths, but only presents the Table 3-2 offshore lengths labeled as 2020 MHW. The comment does not explain what does not line up between the table and figure, and why they do not represent the facts. See also the analysis of historic and future coastal erosion with sea level rise in Appendix C2 of the Draft EIR/EIS.

PWN2-37 See Master Response 11 regarding the test slant well; specifically, see Section 8.2.11.8, New Technology, which discusses the use of slant wells, and Section 8.2.11.9, Slant Well Angle, which discusses the proposed change in drilling angle. Regarding ratepayer liability, see response to comment PWN2-22.

PWN2-38 This response addresses two separate issues mentioned in the comment: CEQA and NEPA baseline, and baseline conditions related to the test slant well and its results. There was no specific report on the CEQA and NEPA baseline; it is integrated into the EIR/EIS. See Master Response 10, Environmental Baseline under CEQA and NEPA.

The HWG prepared a separate baseline report for the test slant well, as described in Master Response 11. It was referenced in the Draft EIR/EIS Section 4.4 as Geoscience, 2015b and continues to be publicly available at: https://docs.wixstatic.com/ugd/28b094_bd1db648e7b44f32a9676dfc7bf71989.pdf

PWN2-39 See Section 8.2.11.9 of Master Response 11.

PWN2-40 Section 4.4.6 includes consideration of the RUWAP Desalination Element (No. 31) in the analysis of cumulative groundwater impacts (see Draft EIR/EIS page 4.4-89).

PWN2-41 See Master Response 11 regarding the test slant well. Specifically, Section 8.2.11.5 describes the long-term pump test. The text cited in the comment does not, nor is it intended to suggest that pumping of the test slant well has been continuous since April 2015.

PWN2-42 The cited statement is true and is provided in the context of Coastal Act policies related to public works facilities (in the Draft EIR/EIS section titled "Public Services and Utilities"). The California Coastal Act Section 30260 encourages coastal-dependent industrial uses to locate within existing sites, as the proposed slant wells would be located within the existing CEMEX site and the Alternative 1 slant wells would be located within an existing parking lot. The Draft EIR/EIS explains consistency with the Marina Local Coastal Land Use Plan (LCLUP) in Section 4.6.2. Specifically, in Table 4.6-4 on page 4.6-105, this issue is summarized as follows: "Installation of the subsurface slant wells, Source Water Pipeline, new Desalinated Water Pipeline, and new Transmission Main, and maintenance of the subsurface slant wells would occur within special status species habitats (including wetlands and including those defined as primary and secondary habitat in the City of Marina LCLUP). This issue is addressed further in Impacts 4.6-1, 4.6-2, 4.6-3 4.6-4, 4.6-6, 4.6-7, and 4.6-8. Mitigation measures are provided to reduce or avoid impacts on special-status species habitats. However, as described in Impact 4.6-4 at page 4.6-223 and -224, construction of these facilities, and maintenance of the subsurface slant wells, would be inconsistent with the City of Marina LCLUP, a significant and unavoidable impact."

PWN2-43 Draft EIR/EIS Section 4.13 evaluates the potential impacts on public services and utilities resulting from implementation of the MPWSP. The Marina LCLUP does not contain policies specific to the topic of public services and utilities. Consistency with the City of Marina LCLUP is discussed in Section 4.6, Terrestrial Biological Resources, and in other sections as relevant to specific policies in the LCLUP. See also response to comment PWN2-42.

PWN2-44 See response to comment PWN2-8.

PWN2-45 The MBNMS Desalination Guidelines indeed recommend that "desalination plant proponents should pursue collaborations with other water suppliers and agencies currently considering water supply options in the area to evaluate the potential for an integrated regional water supply project. This should include an evaluation of other potential desalination locations and alternatives, as well as other forms of water supply." (NOAA, 2010, Section D.1) The Desalination Guidelines explain that the regional desalination approach "would include consideration of alternative water supply strategies, adjacent jurisdictions, potential for co-locating desalination discharges with discharges from other facilities to minimize impacts, as well as a comprehensive analysis of both site-specific impacts of each proposed plant, and the cumulative impacts associated with having multiple facilities in a region. These impacts would include both potential direct environmental impacts, as well as indirect impacts, such as increased population growth that would be facilitated by providing additional water supplies to a region."

This EIS/EIS describes how the process leading to the proposed MPWSP has been consistent with the spirit of this guideline. As explained in EIR/EIS Section 5.2.1,

CalAm proposed the MPWSP as the result of a multi-year planning effort, during which various entities have proposed several options intended to meet the water supply needs of the Monterey Peninsula. Since the SWRCB issued Order 95-10, CalAm and the MPWMD collaborated to develop ASR Phases 1 and 2; CalAm is working with the City of Sand City in the operation of the Sand City Desalination Plant; and CalAm, the Monterey Peninsula Regional Water Authority (MPRWA, which includes the cities within the Monterey District), and MRWPCA and MPWMD (the partners in the Pure Water Monterey GWR Project), have been working together to promote and support the GWR Project.

CalAm and MCWD were partners on the Regional Project, a CPUC-approved alternative to the Coastal Water Project, described in EIR/EIS Section 1.4.1. EIR/EIS Section 5.2, Alternatives not Evaluated in Detail, describes attempts to develop alternative water supply projects based on greater collaboration with other water suppliers and agencies that have not been successful; Section 5.2.4 explains how the CalAm-MCWD public-private partnership resulted in continuing and ongoing litigation, and how CalAm ultimately withdrew its support for the Regional Project and reapplied to the CPUC for a CPCN for the MPWSP. EIR/EIS Section 5.3 screened and evaluated 13 intake options, seven outfall options, and three desalination plant options for the MPWSP. Sections 5.4. describes two desalination plant alternatives (Alternative 3, the DeepWater Desal Project, and Alternative 4, the People's Project) that would rely on different owners/operators, as well as Alternatives 5a and 5b, that would rely on collaboration between CalAm, and MRWPCA, and MPWMD in order to collectively meet the project objectives. See also response to comment MCWD-188 in Section 8.5.2.

Throughout the current proceeding at the CPUC (Proceeding A.12-04-019), CalAm and several dozen other parties to the proceeding have collaborated over the years on issues such as project sizing, project financing, and alternatives, including the relationship between desalination and the use of recycled water (see EIR/EIS Sections 1.1, 2.1, 2.4, and Project No. 59 in EIR/EIS Table 4.1-2 and EIR/EIS Section 2.5.3.1). CalAm has entered into at least three draft settlement agreements over the years with various parties to the proceeding, including MPWMD, MRWPCA, MCWRA, MPRWA, and CCSD, that address among other things: effects of the proposed project on groundwater resources (see Master Response 5), Salinas Valley Return Water (see EIR/EIS Sections 2.5.1 and 4.20.2.3), and brine discharge monitoring (see EIR/EIS Section 4.3.5.2).

MBNMS continues to recommend that CalAm pursue collaborations with other water suppliers, agencies, and communities regarding regional water supply solutions and will consider past and ongoing collaboration in its decision-making for this project.

PWN2-46 Per capita water use is one, but not the only, or necessarily the optimal, method of estimating future water demands in an area. See response to comment PWN2-19 and the discussion of "Other approaches to estimating future water demands" in Master

Response 13, Section 8.2.13.1. The comment is unclear regarding what data support the claim that one acre-foot per year would support five families; however, the assumptions used in EIR/EIS Section 6.3 are supported by substantial evidence, as cited and explained therein.

PWN2-47 See Master Response 11 regarding the test slant well. Specifically, Section 8.2.11.5 describes the long-term pump test and provides a definition of "long-term" for the purposes of this test.

PWN2-48 See Master Response 11 regarding the test slant well. Specifically, Section 8.2.11.4 describes how the HWG established baseline water and Total Dissolved Solids (TDS) levels in the monitoring wells per Special Condition 11 of the CDP prior to commencement of the long-term pump test.

PWN2-49 See response to comment PWN2-2 and Master Response 5 (Section 8.2.5.5).

PWN2-50 See response to comment PWN2-2 and Master Response 5 (Section 8.2.5.5).

PWN2-51 The conflict of interest issues are addressed in response to comment PWN2-2 and in Master Response 5, Section 8.2.5.5. The HWG members are presented in Master Response 5, Section 8.2.5.2.

PWN2-52 The document cited in the comment, Draft EIR/EIS Appendix C3 at page 50, reports the average salinity for the central California coastal region was calculated at 33.6 psu based on historical salinity measurements. The difference in near-shore salinity was compared for the period 1950-1976 and 1977-1999 and very little variation was found, demonstrating that the estimated salinity is representative of baseline.

As explained in Draft EIR/EIS Section 4.3.1.3, near-shore surface salinities vary from 33.2 psu to 34.0 psu. Streams and rivers can locally affect salinity, but even during flood conditions, when freshwater inputs to Monterey Bay peak (e.g., from the Salinas River), the salinity of Monterey Bay surface waters does not fall below 31 psu.

As reported in Draft EIR/EIS Appendix D1, monthly measurement of conductivity-temperature-depth were made over the MRWPCA outfall, as well as north, south, and west of the outfall, over a two-year period and are displayed in Table 1 of Appendix D1. The denominator, like ocean salinity, changes with the seasons and could range from 33.34 psu to 33.89 psu.

PWN2-53 This comment addresses Special Condition 11 of the test slant well CDP, which in and of itself is not the subject of the MPWSP Draft EIR/EIS. The baseline report is cited in Draft EIR/EIS Section 4.4 as Geosciences, 2015b. See also response to comment PWN2-38 and Master Response 11.

PWN2-54 See response to comment PWN2-21.

PWN2-55 See Master Response 9, Electrical Resistivity Tomography (ERT) and Airborne Electromagnetics (AEM), which describes ERT and its application to this EIR/EIS.

PWN2-56 See Master Response 9, which describes the relationship of available ERT data to modeling.

PWN2-57 See Master Response 9.

PWN2-58 The comment is based on language from Appendix I2, Component Screening Results – Component Options Not Carried Forward, specifically from Intake Option #12 – Subsurface Slant Wells at Reservation Road on p. I2-11. This intake option was eliminated, and is therefore not part of the proposed project. Regarding potential impacts related to MCWD's provision of water service and the location of the proposed project's slant wells, see response to comment PWN2-5.

PWN2-59 Appendix J1 presents an analysis of the consistency of the MPWMD's 2006 estimate of future water needs within CalAm's service area, with growth projections anticipated in the general plans of the jurisdictions within CalAm's service area. MCWD is not in CalAm's service area and therefore, not included in either the future water forecast, or the analysis of growth policies. The comment provides no evidence that the MPWSP may interfere with MCWD plans; see response to comment PWN2-6. The MCWD plans are not considered irrelevant to the EIR/EIS; the RUWAP Desalination Element (No. 31) is listed as a potential cumulative project in Draft EIR/EIS Table 4.1-2, and potential cumulative impacts on groundwater resources are described in Draft EIR/EIS Section 4.4.6 at page 4.4-89.

PWN2-60 Draft EIR/EIS Appendix G2 is an analysis of CO2 off-gassing from the subsurface intakes and not a discussion of a targeted percentage of seawater in the slant well. The discussion represents the position that water from the test slant well would be a worst case bookend to the analysis, as described on page 5 of Appendix G2; conversely, all seawater would be the "best case" in the context of CO2 off-gassing. The support for the 96 percent used in the analysis is cited on page 5 as GeoScience, 2014b. However, ocean water percentage was not relevant to the analysis. Appendix G2 relied on the average of five water quality sampling events from the test slant well during September 2016, as shown on Table 1 on page 6 of Appendix G2.

PWN2-61 To estimate the concentration of carbon dioxide in the reverse osmosis (RO) concentrate, Appendix G2 modeled the RO process using sampled water quality of the two source waters: the "worst-case" test slant well water, and the "best-case" seawater (see response to comment PWN2-60). It did not use ocean water percentages. ERT data would not be relevant to this analysis since it would not provide any evidence of what is being extracted at the wells. See Master Response 9.

8.6.17.3 Responses to Comments from Public Water Now – Letter 3

PWN3-1 Regarding the feasibility of slant well technology see Master Response 11. As explained in Draft EIR/EIS Section 1.5.4, if the CPUC certifies the Final EIR/EIS, it will then decide whether or not to grant the Certificate of Public Convenience and Necessity (CPCN) for the MPWSP, as proposed or modified. In addition to environmental impacts addressed during the CEQA process, the CPCN process will consider any other issues that have been established in the record of the proceeding, including but not limited to economic issues, social impacts, specific routing and alignments, and the need for the project.

PWN3-2 The baseline report prepared by the HWG is addressed in the response to Comment PWN2-38. The conflict of interest is addressed in response to comment PWN2-2 and Master Response 5.

PWN3-3 This comment is addressed in Master Response 5 and in Master Response 11,

PWN3-4 This comment is addressed in Master Response 5.

PWN3-5 CalAm's March 14, 2016, amended application to the CPUC and MBNMS (Exhibit H to the amended application, cited in the Draft EIR/EIS Section 5.4 as CalAm, 2016), describes the permanent slant wells as being screened for "approximately 400 to 800 linear feet at depths corresponding to both the Dune Sand Aquifer and the underlying 180-Foot Equivalent Aquifer of the Salinas Valley Groundwater Basin." See also response to PWN2-32. As described in Draft EIR/EIS Section 4.4.1.2 on page 4.4-6, the Dune Sands Aquifer is not a fresh water aquifer; it is directly influenced and controlled by seawater and most of the water has been intruded by seawater and is considered saline to brackish. Increased seawater intrusion or loss of source water would cause harm, but the Draft EIR/EIS found neither condition would occur as a result of the proposed project. See response to comment PWN2-6 and Master Response 3 regarding water rights.

PWN3-6 See response to comment PWN3-5.

PWN3-7 The conflict of interest is addressed in response to comment PWN2-2 and Master Response 5.

PWN3-8 For a discussion of the definition of feasible, see response to comment PWN2-8. For a discussion of the feasibility of slant well technology, see Master Response 11, CalAm Test Slant Well.

Installation and long-term maintenance cost estimates for the proposed slant wells are based on both the test slant well at CEMEX and the well at Dana Point. Regarding ratepayer liability, see response to comment PWN2-22. Regarding the Sustainable Groundwater Management Act (SGMA), see Master Response 6.

The SWRCB drives the CDO deadlines with input from the community. That process is not under the control of the Lead Agencies.

The history of water supply projects in response to SWRCB Order 95-10 and the Seaside Groundwater Basin adjudication are described in EIR/EIS Section 1.4 as well as Section 5.2.

EIR/EIS Chapter 5 includes an extensive alternatives analysis that considered Ranney wells (see EIR/EIS Sections 5.3.3.5, 5.3.3.11, and 5.3.3.13). Section 5.3.6.1 concludes on page 5.3-30 that Ranney wells do offer an opportunity to replace slant well technology at either the CEMEX or the Potrero Road site if necessary. The DeepWater Desal project and the People's Project were both evaluated as alternatives to the MPWSP in EIR/EIS Section 5.5. See also Master Response 15, Alternative Desalination Projects – Status, Information Sources, and Cumulative Scenarios.

Regarding the operation of the test slant well, MCWD has no permit authority over the slant well tests; regardless, the environmental review of the operation of the test slant well pursuant to its existing permits is outside the scope of this EIR/EIS; see Master Response 11, Sections 8.2.11.2 and 8.2.11.3.

The lead agencies' purpose in a CEQA and/or NEPA analysis is to assess the environmental impacts of a proposed project and to consider alternatives to the project. An EIR/EIS does not assess the "leadership" of the project proponent. Further, the cited statement from the Settlement Agreement about CalAm's position on the feasibility of the proposed project is not relevant to the analysis in the EIR/EIS, in which the Lead Agencies address both the feasibility of and the full range of environmental impacts of the project as proposed using independent judgment. As noted in EIR/EIS Section 1.5.4.1, in addition to the environmental impacts addressed during the CEQA/NEPA process, the CPUC will consider any other issues that have been established in the record of the proceeding, including but not limited to economic issues, social impacts, specific routing and alignments, and the need for the project.

8.6.18 Responses to Comments from Salinas Valley Water Coalition and Monterey County Farm Bureau

SVWC/MCFB-1 The comments regarding the Return Water Settlement Agreement are acknowledged. The Draft EIR/EIS analyzes impacts of the proposed project based in part on the implementation of this settlement agreement.

SVWC/MCFB-2 This comment describes the presence of seawater intrusion and various efforts to date to address this issue, but does not comment on the Draft EIR/EIS. The information presented in the EIR/EIS is consistent with this comment.

SVWC/MCFB-3 See EIR/EIS Section 2.6, Water Rights, and Master Response 3, Water Rights. With respect to localized water quality changes, see Master Response 8, Project Source Water and Seawater Intrusion.

SVWC/MCFB-4 As explained in EIR/EIS Section 2.6, Water Rights, and Master Response 3 Water Rights, the EIR/EIS employs the criteria set forth in the SWRCB Report to reach the determination of whether it appears feasible that CalAm would possess water rights for the project. The commenter opines that the return water component of the project is required in order for CalAm to have such water rights. As noted in Master Response 3, the return water element of the project is proposed by CalAm; thus, consideration as to whether CalAm would have water rights without that project component is unnecessary.

SVWC/MCFB-5 The comment in support of the approval of the Return Water Settlement Agreement is acknowledged.

SVWC/MCFB-6 The EIR/EIS correctly concludes in Impact 4.4-4 that the seawater intrusion front would migrate back toward the ocean, a less-than-significant impact. The increase in salinity would only occur in the capture zone near the coast at the CEMEX site; areas outside the capture zone would not be affected. See Master Response 8, Section 8.2.8.2, which discussed this issue further. In addition, implementation of the Return Water Settlement Agreement is part of the proposed project, not a mitigation measure. See Section 2.5.1 of the EIR/EIS for further discussion of the Return Water Settlement Agreement.

SVWC/MCFB-7 This comment does not relate to the EIR/EIS, but will be considered by the Lead Agencies during their decision-making processes for this project.

8.6.19 Responses to Comments from Surfrider Foundation

Surfrider-1 Responses to specific comments regarding compliance with the California Environmental Quality Act (CEQA) and National Environmental Policy Act (NEPA), and the adequacy of the Draft EIR/EIS, are provided below, where the commenter provides enough specificity to allow a substantive response. With respect to compliance with MBNMS policies and regulations, the Draft EIR/EIS described compliance with MBNMS policies and regulations where applicable in resource-specific discussions and in the discussion of compliance with MBNMS Desalination Guidelines in Section 6.4. Footnote 2 of the comment states that the EIR/EIS contains an incomplete discussion of the requirements necessary for a national marine sanctuary to authorize prohibited activities, such as the discharge of brine concentrate. The EIR/EIS explains the process for making decisions on prohibited activities in detail in Section 1.3.2, and MBNMS is ensuring that National Marine Sanctuaries Act requirements are being closely followed. Regarding the comment on 15 CFR 922.49(a)(1) which requires the project applicant to notify the Director of the Office of Ocean and Coastal Resource Management, or a designee, within 15 days of the date of filing of the application for an authorization, the Applicant filed a permit application with MBNMS in 2015 and has continued to keep both agencies apprised on application processing. The authorizations relevant to the MPWSP are described in EIR/EIS Section 1.3.2 and include authorizations of a Coastal Development Permit and a National Pollutant Discharge Elimination System (NPDES) permit or other discharge authorization. This section of 15 CFR 922.49 does not pertain to CalAm's application to the CPUC.

Surfrider-2 See response to comment USEPA-4, in Section 8.3.5, which describes the revised mitigation measure for greenhouse gas emissions, and see Final EIR/EIS Section 4.11.5 for the revised significance conclusions of less than significant with mitigation with respect to the proposed project's GHG emissions impacts. Revised Mitigation Measure 4.11-1 meets the CEQA criteria for mitigation as outlined in the comment. Subpart b specifies a performance standard that governs implementation of this measure: that CalAm must achieve net zero operational GHG emissions. With respect to practical considerations that preclude the development of specific measures at the time of project approval, Subpart a requires that CalAm retain a qualified professional to prepare and submit a GHG Emissions Reduction Plan to the Lead Agencies that quantifies GHG emissions and identifies feasible energy recovery and conservation technologies. Although the EIR/EIS has quantitatively estimated GHG emissions from the proposed project, further project design would refine these estimates, necessitating this quantification step prior to construction. Additionally, Subpart b requires that CalAm achieve the net zero operational GHG performance standard by implementing offsetting procedures in a specified loading order. The exact use of these procedures cannot be known at this time due to the uncertainty of the total availability of the various

sources specified in the measure, such as energy from the adjacent landfill-gas-to-energy (LFGTE) project. Finally, substantial evidence supports the conclusion in the Final EIR/EIS that the mitigation, as carried out based on the performance standards and loading order specified, will be feasible and will be effective in achieving the net zero operational GHG emissions standard, which will ensure that total project GHG emissions are below identified thresholds of significance. Based on the Final EIR/EIS GHG emissions estimate, the project would need to reduce or offset approximately 6,885 metric tons of CO_2-equivalent GHGs per year, and this would be feasible based on a combination of on-site or adjacent renewable energy sources, renewable energy sources that are procured from PG&E or another provider, Renewable Energy Certificates, and Carbon Offsets. As stated in Table 4.1-2 (see Project No. 58), about half of the MPWSP Desalination Plant operational energy requirements could be met with renewable electricity generated at the LFGTE facility, leaving approximately half of the annual operational emissions to be offset by other means. There are many different types and adequate numbers of carbon offsets currently available that can be purchased for the project (CARB, 2017).

Surfrider's suggested list of measures that could reduce the project's GHG emissions includes several measures relating to building and landscape efficiency. Although all of these measures will be considered and several of these measures are likely to be incorporated into project design as required by Subpart a of Mitigation Measure 4.11-1. Building and landscape-related energy consumption accounts for a relatively small portion of the operational energy demands of the proposed project – the operational energy associated with pumping, desalinating, and delivering water and disposing of brine accounts for the majority of operational electricity demands, which in turn account for the majority of operational GHG emissions. The recommendation to require installation of solar photovoltaic (PV) panels on-site has been incorporated into revised Mitigation Measure 4.11-1. The recommendations related to construction vehicle efficiency are addressed in Mitigation Measures 4.18-1 (Construction Equipment and Vehicle Efficiency Plan).

Surfrider-3 See response to comment USEPA-4, in Section 8.3.5, and Surfrider-2, which address the issue of requiring CalAm to purchase offsets as one part of a strategy to achieve net zero GHG emissions from operational electricity use. The strategy outlined in revised Mitigation Measure 4.11-1 would reduce or offset emissions regardless of whether operational electricity is sourced from in-state or out-of-state generation. Note that Assembly Bill 398, signed into law on July 25, 2017, extends the California Cap and Trade program to 2030.

Surfrider-4 The commenter is correct that Draft EIR/EIS page 4.2-45 states that an analysis of the effects of the existing environment on the project "is provided for information purposes." However, in both the project-level and cumulative analyses, the EIR/EIS provides a thorough and complete analysis of coastal hazards related to

sea level rise and coastal erosion and the effects of such changes on the project facilities. EIR/EIS Section 4.2.4.5 explains the approach to the coastal retreat analysis, the extensive coastal retreat study conducted, and the fact that CalAm had already responded to that study by moving the proposed location of 9 out of 10 of the proposed slant wells (all but the one that is to be converted from the existing test slant well) to a location further from the coast so as not to become exposed during the project life. Impact 4.2-10 examines the effects of the projected long-term coastal retreat and sea level rise *on the project* and how that effect on the project could exacerbate or accelerate coastal erosion. Thus, the EIR/EIS does in fact comprehensively evaluate the impacts of the existing and projected environmental conditions on the project. (We note, however, that the legal cases cited by the commenter deal with a requirement to address the impacts of coastal erosion on residents and users, not on utility infrastructure). The analysis concludes that the well casings and concrete wellhead vault of the converted test slant well could become exposed during the life of the project, possibly accelerating or exacerbating natural processes. This is classified as a significant impact of the project (and therefore, is not treated as merely informational). Mitigation Measure 4.2-10 is included to ameliorate this impact. Furthermore, though the analysis forecasts that only the converted test slant well could likely be affected by coastal erosion and retreat, the mitigation measure is proposed for all 10 of the project slant wells. Similarly, Impact 4.2-C finds that the project would result in a cumulative impact on increased scour and erosion resulting from projected sea level rise. Mitigation Measure 4.2-10 is proposed to reduce the project's contribution to that cumulative effect to a less than significant level. Also, see response to comment Marina-36, in Section 8.5.1.

As to the project's contribution to sea level rise based upon greenhouse gas emissions, see responses to comments USEPA-4, in Section 8.3.5, and Surfrider-2. With the revisions described therein, the proposed project's contribution to the primary and secondary adverse effects of global climate change would be negligible and likely well within the sea level rise projections employed in the coastal retreat study upon which the impact analysis of the EIR/EIS was based.

Surfrider-5 EIR/EIS Section 4.2.4.5 describes the Coastal Retreat Study (Appendix C2), which examined coastal processes and the likelihood for the slant wells and their wellheads to become exposed on the beach. The study estimated coastal retreat both laterally (using coastal erosion hazard zones) and vertically (using coastal profiles). Because of the anticipated rate of coastal retreat, the originally proposed locations of the slant wells were relocated further inland specifically to avoid being exposed and accelerating or exacerbating erosion (see Draft EIR/EIS page 4.2-69, not page 4.2-60).

EIR/EIS Figures 4.2-7 and 4.2-8 present the erosion profiles and envelopes for the test slant well and the production wells, respectively. The wellhead of the test slant well is shown to be at 30 feet (NAVD) above mean sea level and just behind

(inland of) the "2060, 100-Year Storm Event" line; the other nine wells would be located further inland of the "2060, 100-Year Storm Event" line.

To ensure that the slant wells would not accelerate or exacerbate coastal erosion and dune retreat, Mitigation Measure 4.2-10, Slant Well Abandonment Plan, requires CalAm to monitor the rate of coastal retreat and to remove the sections of well casing and pipelines prior to potential exposure, to a depth of 5 feet below the 2060, 100-year lower profile envelope as determined by the Coastal Retreat Study or as directed by any permit condition. Based on projections of sea level rise and coastal retreat, abandonment procedures are anticipated to begin sometime after 2040 for the converted test slant well and after 2060 for the other nine slant wells, but would occur as needed based on monitoring required under Mitigation Measure 4.2-10. The implementation of this mitigation measure would eliminate, not merely reduce any erosion impact, by ensuring the slant well(s) would be removed prior to exposure. Mitigation Measure 4.2-10 has been revised to include how a timeframe for well abandonment should be established.

EIR/EIS Section 4.2.4.5 explains that the most important variables in the coastal erosion model are the historic erosion trend, backshore toe elevation, and the total water level. In this region, where beaches have historically been controlled in part by sand mining, the study assumed there would be no changes to existing sand mining practices. Consistent with the Federal Emergency Management Agency (FEMA) Pacific Coast Flood Guidelines, the potential for shoreline retreat caused by sea level rise and the impact from a large storm event was estimated using a geometric model of dune erosion and applied with different slopes to make the model more applicable to sea level rise. Instead of predicting storm-specific characteristics and response, the method assumes that the coast would erode or retreat to a maximum storm wave event with unlimited duration and is a conservative approach to estimating the impact of a 100-year storm event.

As shown on Appendix C2 Figure 1 and Figure 3(d), the location of profile 4a (test slant well) and 4b (other wells) are just north and south of the CEMEX access road, respectively. Note 3 in EIR/EIS Figures 4.2-7 and 4.2-8 explains the "profile is located immediately south of the CEMEX Pacifica Lapis sand mining *plant*," (emphasis added) and not south of the sand mining *area* as claimed in the comment. That same Note 3 acknowledges that data is not available to quantify the uncertainty in beach and dune erosion related to sand mining activities, and that "[t]he potential for fluctuations in beach width associated with sand mining were not considered in this analysis." That is because the analysis included the historic sand mining practices in the historic rates of erosion and assumed there would be no changes to existing sand mining practices. As a result of using this and other conservative assumptions in the analysis,[1] the potential magnitude of erosion at

[1] As noted by Sea Engineering in its peer review of the Coastal Retreat Study, "Based on our professional judgment, the ESA study (2014) represents a worst-case scenario developed by a very conservative approach" (Sea Engineering, 2014).

CEMEX was very likely over-estimated, not under-estimated as asserted by the comment, especially considering the anticipated closure of the sand mining operations in 2020, resulting from the July 2017 Settlement Agreement between CEMEX and the California Coastal Commission (see Master Response 14, CEMEX Settlement Agreement). Regardless, the commenter expressed concerns about extreme climate and storm events (discussed above), and provided suggested modifications to Mitigation Measure 4.2-10; the suggested text about 100-year storm events has been incorporated into Mitigation Measure 4.2-10.

The well abandonment required under Mitigation Measure 4.2-10, Well Abandonment Plan, would use standard procedures provided in Bulletin 74, California Well Standards, as required by the City of Marina Municipal Code Section 13.12.100. The secondary environmental impacts resulting from abandoning the well(s) have been added to the discussion of Mitigation Measure 4.2-10 and would be less than significant with implementation of the same mitigation measures relevant to the proposed project and discussed in the EIR/EIS. The time required for permitting of well abandonment is anticipated to be on the order of a few months at most, well within the proposed 5-year timeframe provided for in the mitigation measure, especially since the installation of replacement wells would not be part of that process. As discussed in response to comment Marina-37, replacement wells, if pursued, would be a new project that would be developed decades in the future and would be subject to a subsequent CEQA analysis.

Surfrider-6 As explained in CEQA Guidelines Section 15126.6, an EIR shall include alternatives that would avoid or substantially lessen any of the significant effects of the proposed project. With the revision to GHG Mitigation Measure 4.11-1 (see response to comment Surfrider-4), and the related revision to the conclusion of Impact 4.11-1 (incremental contribution to climate change from GHG emissions) to less than significant with mitigation, the EIR/EIS has not identified a significant unavoidable impact for any resource that would require a downsized alternative as mitigation. Specifically, Impact 4.3-4 (degrade ocean water quality from increased salinity), Impact 4.3-5 (degrade ocean water quality from brine discharges), and Impact 4.4-4 (degrade groundwater quality) were all determined to be less than significant with mitigation while Impact 4.4-3 (deplete groundwater supplies or interfere substantially with groundwater recharge) was determined to be less than significant.

Chapter 5, Alternatives Screening and Analysis, provides detailed descriptions of two reduced-sized alternatives (Alternatives 5a and 5b, see Sections 5.4.7 and 5.4.8, respectively) and Section 5.5 presents an analysis of the environmental impacts of Alternatives 5a and 5b. Under CEQA and NEPA, an alternative need not be analyzed unless it would meet most of the basic objectives of or the purpose and need for the project. See CEQA Guidelines Section 15126.6(a) and 40 CFR 1502.13 and 1508.9(b). The primary objective of the proposed project is to supply in a timely manner a certain quantity of water for CalAm customers, such that a

smaller desalination plant than those considered in the EIR/EIS (including Alternatives 5a and 5b, which pair a smaller desalination plant with a water purchase agreement from the approved GWR Project) would not meet the basic project objectives. However, see Master Response 13, Demand (Project Need) and Growth, concerning demand and supply assumptions and the possible consideration of alternate scenarios in which lessened demand would allow for a smaller desalination plant. The Lead Agencies will consider all evidence in the record concerning demand and supply prior to acting upon the project, and may conclude that a smaller desalination plant (or some other alternative) would indeed satisfy the basic objectives of the project.

Surfrider-7 See Master Response 13, Demand (Project Need) and Growth, in particular, the discussion of demand assumptions in Section 8.2.13.1 and the discussion of Water Available for Growth in Section 8.2.13.3. Also see response to comment Surfrider-6.

Surfrider-8 The EIR/EIS did not identify a significant unavoidable impact for any resource that required a downsized alternative as mitigation, and as described in response to comment Surfrider-6, any alternative considered must meet the basic project objective with respect to water supply. The discussion of Revised CDO Stage 3 Conservation Measures and Stage 4 Rationing under the No Project Alternative in Section 5.4.2.1 represents a worst-case scenario of severe water rationing, and not a reasonable alternative to the proposed project. The EIR/EIS does consider the potential for the Pacific Grove Local Water Project to provide up to 125 afy of non-potable supply that would offset the need for project supply in Section 2.5.3.1. As stated therein, "In 2013, CalAm and several other parties asked the CPUC to approve a settlement agreement on plant sizing and operations. The Settling Parties agreed that the Pacific Grove project would be a valuable part of a comprehensive solution to water issues in CalAm's Monterey District when integrated with the MPWSP, the GWR Project, and ASR." The EIR/EIS does also consider the potential for the Pebble Beach Recycled Water Project Phase II to offset the need for project supply in Section 2.5.3.2. See also Master Response 13, Demand (Project Need) and Growth, and response to comment MCWD-168, in Section 8.5.2.

Surfrider-9 As noted in the comment, impacts related to water quality from operational discharges have been determined to be less than significant based on the comprehensive and detailed model analyses performed and presented in EIR/EIS Section 4.3, Surface Water Hydrology and Water Quality, and Appendix D. Mitigation Measure 4.3-4 includes a provision requiring CalAm to monitor impacts on marine biological resources even if the discharge meets established salinity and effluent standards.

Surfrider-10 Mitigation Measure 4.3-4 would ensure that monitoring would be conducted for salinity levels, benthic community health, aquatic life toxicity, and hypoxia, and that the monitoring program would be consistent with the requirements detailed in

Appendix III of the Ocean Plan. The performance standards required by Mitigation Measure 4.3-4 for benthic community health incorporate by reference those defined in the Ocean Plan, and represent, in part, a narrative-based standard. The standards are defined in Chapter III of the Ocean Plan (Part 4 (a)) and in Appendix III (Part 8), with definitions of terms provided in Appendix II. In this context, a statistically significant change also is defined in the Ocean Plan. Degradation occurs if there are significant differences (defined as a statistically significant difference in the means of two distributions of sampling results at the 95 percent confidence level) in any of three major biotic groups, namely, demersal fish, benthic invertebrates, or attached algae. Other groups may be evaluated where benthic species are not affected, or are not the only ones affected. See EIR/EIS Section 4.3.2.2 for a discussion of the Ocean Plan Monitoring Requirements.

Surfrider-11 See Master Response 15, Alternative Desalination Projects – Status, Information Sources, and Cumulative Scenario.

Surfrider-12 New information that has been added to the Draft EIR/EIS in response to comment Surfrider-5, as well as comments by others, has been added to amplify or clarify the data within the Draft EIR/EIS. The new information does not change the environmental impacts than were shown in the Draft EIR/EIS, nor indicate that there are feasible alternatives or mitigation measures available that the project proponent declines to implement that would minimize significant effects.

8.6.20 Responses to Comments from Water Ratepayers Association of the Monterey Peninsula

8.6.20.1 Responses to Comments from Water Ratepayers Association of the Monterey Peninsula – Letter 1

WRAMP1-1 See Master Response 3, Water Rights.

WRAMP1-2 See Master Response 8, Source Water and Seawater Intrusion, Sections 8.2.8.1, 8.2.8.2, and 8.2.8.3 for clarification of the source water for the proposed MPWSP slant wells and Master Response 11, CalAm Test Slant Well, for additional information on water quality in the test slant well.

WRAMP1-3 See Master Response 4, Agency Act and Return Water, and Master Response 3, Water Rights.

WRAMP1-4 See Master Response 4, Agency Act and Return Water, and Master Response 8, Source Water and Seawater Intrusion.

WRAMP1-5 The elevated sodium chloride concentrations in the groundwater extracted from the test slant well over the period of pumping are undeniably a result of seawater intrusion from the Monterey Bay. See Master Response 11, Test Slant Well for additional information on test slant well water quality, and Master Response 8, Source Water and Seawater Intrusion, Section 8.2.8.2, for water quality data within the MPWSP slant well capture zone.

WRAMP1-6 See response to comments MCWD-HGC-3 and -5 in Section 8.5.2.2 for a response regarding water quality conditions, specifically related to TDS and sodium chloride concentrations, in the MPWSP area and the purported "freshwater" flows that are interpreted as protection against seawater intrusion. Master Response 4, Agency Act and Return Water, Sections 8.2.4.1 and 8.2.4.2, provide additional explanation on return water.

WRAMP1-7 See Master Response 4, Agency Act and Return Water, which provides a detailed description of the Agency Act, return water, and the ocean water percentage calculation. No field data are reported in Appendix E2 of the 2017 MPWSP Draft EIR/EIS relevant to the percentage of groundwater extracted from the Dune Sand Aquifer (represented by part of Model Layer 2) and the 180-Foot Aquifer (represented by part of Model Layer 4). Page 28 of Appendix E2 describes three different assumed percentages of the groundwater extracted from Model Layer 2 and Model Layer 4. The assumed percentages are based on (1) well construction and model geometry; (2) well construction, model geometry, and modeled hydraulic conductivity; and (3) Geoscience calibration of a different model to test slant well pumping data.

WRAMP1-8 Master Response 4, Agency Act and Return Water, provides a detailed description of the Agency Act, return water, and the ocean water percentage calculation.

WRAMP1-9 Receipt of the attached petition for writ of mandate is acknowledged. The respondents to the petition objected to the petition and, in March 2017, the Superior Court of Monterey County dismissed the action without leave to amend. The Superior Court's order was not appealed.

WRAMP1-10 See Master Response 4, Agency Act and Return Water.

WRAMP1-11 The purchase of water from the DeepWater Desal Project or the People's Project is analyzed as Alternatives 3 and 4, respectively, in Chapter 5 of the EIR/EIS.

8.6.20.2 Responses to Comments from Water Ratepayers Association of the Monterey Peninsula – Letter 2

WRAMP2-1 Three independent runs using different MODFLOW executables produced the same output (model-calculated water levels) and confirm that the model-calculated water levels were not modified. Neither HydroFocus nor LBNL conducted post-processing of model output after running MODFLOW other than plotting the results using Excel software. The model-calculated water levels from three independent MODFLOW runs all agreed. See Master Response 12, The North Marina Groundwater Model (v. 2016), for more information.

8.6.20.3 Responses to Comments from Water Ratepayers Association of the Monterey Peninsula – Letter 3

WRAMP3-1 See response to comment WRAMP2-1.

8.6.20.4 Responses to Comments from Water Ratepayers Association of the Monterey Peninsula – Letter 4

WRAMP4-1 See Master Response 4, Agency Act and Return Water, which provides a detailed description of the return water and the calculations necessary to determine the ocean water percentage.

WRAMP4-2 See Master Response 2, Source Water Components and Definitions, for clarification of the terms used to describe source water (e.g., "groundwater"). See also Master Response 3, Water Rights; Master Response 4, Agency Act and Return Water; and Master Response 8, Source Water and Seawater Intrusion, for a comprehensive explanation of the water rights associated with the MPWSP, return water, and the source water quality in the capture zone of the proposed MPWSP slant wells.

WRAMP4-3 See Master Response 8, Source Water and Seawater Intrusion, and Master Response 12, The North Marina Groundwater Model (v.2016), and response to comment WRAMP1-7.

WRAMP4-4 See responses to comment WRAMP1-6 and Master Response 8, Source Water and Seawater Intrusion, Section 8.2.8.1 and 8.2.8.2.

WRAMP4-5 The issue of ratepayer liability is outside the scope of CEQA and NEPA requirements; however, as described in Draft EIR/EIS Section 1.5.4.1, the CPUC decision to grant or deny a Certificate of Public Convenience and Necessity for the project (i.e., project approval) would follow a process after certification of the EIR during which the Commission will consider any other issues that have been established in the record of the proceeding, including but not limited to economic issues, social impacts, specific routing and alignments, and the need for the project. Therefore, comments regarding ratepayer liability are relevant to and will be considered as part of that proceeding.

Esteemed Regulators,

Enclosed are my comments related to the MPWSP DEIR. They are divided into 3 major sections which are delineated by **Bold Centered Titles**. In my opinion, the problems of this project make it infeasible. The EIR needs to be *recirculated* to address the gaps and errors highlighted here, and evolving technologies discussed by others elsewhere. (**1.** ERT to determine "baseline" groundwater conditions in the Coastal Aquifers of the Salinas Valley Groundwater Basin and… **2.** Source water ocean intake screening systems that have evolved in the last 5 years since this project first began.) Baer-1

As the deadline has been extended, I may have more to say by March 29, 2017

Thank you for your time and attention. This is an enormous undertaking for everyone involved.
Regards,
Michael Baer ~Long term resident of Monterey, abutting the jewel known as Monterey Bay

Established Groundwater Rights

The Monterey Peninsula's long and difficult experiences in attempting to develop new and reliable water sources to create a sustainable supply for now and future generations has been complicated and arduous. CalAm Water has been no friend to the residents in this process, leading us down several ill-conceived dead ends which we are still paying for to the tune of tens of millions of dollars, often referred to as stranded costs. Baer-2

The current DEIR is another lengthy document which obfuscates many of the real issues and omits or downplays several key areas despite its cumbersome 4,000 pages. It is easy to get lost, overwhelmed and numbed by the minutiae of all the complex details within it. Much of the technical analysis in the supporting Appendices is only discernable to experts, which neither concerned citizens nor CPUC Commissioners are truly capable of interpreting.

Let's be frank. Cal Am has over-drafted our public resources in their relentless drive for profits. They have been stealing from the Carmel River two to four times the amount that they are legally allocated year after year for decades. They have also taken more than their allocated share from the Seaside Aquifer Basin, and have water debts to repay there too. Baer-3

These water debts, or thefts depending on your orientation, are now proposed to be repaid through the MPWSP and specifically the desalination plant at the Cemex site, where the source Baer-4

water is another theft from another river basin's coastal aquifers. Cal Am has no rights in the Salinas Valley River Basin, yet they propose stealing 25 million gallons per day, which will significantly impact the neighbors who hold the overlaying legal water rights, including AgLand Trust and Marina Coast Water District.

These arguments have been put before you, the CPUC, throughout the process that began in 2012. They have been put before the CCC since 2014. Now they are before the MBNMS as well.

Yet they are ignored. . .

Establishing water rights should be the first order of business in determining the feasibility of capital expenditures in the hundreds of millions of dollars, yet the DEIR freely admits that these issues will be determined after the project is approved.

Baer-4 cont.

Question

How can ignoring the fundamental issue of groundwater rights (or lack thereof) be considered responsible oversight by lead agencies with tens of millions of upfront expenditures required to prepare the DEIR?

Can you appreciate the fundamental error of the cart before the horse approach here? It points directly to feasibility and is surely to end in lengthy litigation, likely causing CalAM to miss the CDO deadlines, exposing the Peninsula to severe penalties in rationing, potential fines, and stranded costs of another failed water project.

Once again, we beseech you, The Regulators: Please consider the whole picture behind this ill-conceived project, and put the horse back before the cart as we strive to develop sustainable water supplies in our region.

Issues with the Hydrogeological Working Group (HWG)

(note: Questions for ESA are in **bold**)

Baer-5

The HWG is a group of hydrogeologists who are the scientists in the field, taking data from the test slant well and surrounding monitoring wells to measure and record the intake efficiency of the slant well and its impacts on the surrounding groundwater. *The DEIR concludes that the impact to the surrounding groundwater is insignificant.* The role that the HWG plays in reaching that conclusion is occluded. The following pages will highlight some of the issues with this group and their role and relevance (or lack thereof) to the DEIR.

Baer-6

1. Inconsistencies relevant to the HWG

DEIR Executive Summary, p.14 ES-14

"The HWG was a result of an August 2013 Settlement Agreement between CalAm and 16 parties whereby CalAm agreed their hydrologist and technical team would work with the Salinas Valley Water Coalition's and Monterey County Farm Bureau's assigned hydrogeologists, and other technical experts designated by CalAm. The HWG developed a work plan in order to reach agreement about the studies, well tests, fieldwork, modeling, monitoring, and other data

analyses that is needed to assess and characterize whether and to what extent the proposed operation of the MPWSP may adversely affect the SVGB and the water supply available to legal water users thereof."

DEIR Footnote 34, Section 2, p 35
"The HWG is composed of experts representing myriad parties in the CPUC proceeding *with diverse interests related to the Basin, including but not limited to* the Monterey County Farm Bureau, the Salinas Valley Growers Association (sic - it is in fact the SV Water Coalition) and CalAm" (italics mine)

Baer-6 cont.

Comments
The two quotes above from the DEIR document are inconsistent, and this is no small matter. Thorough examination of the reports listed on the HWG website at http://www.watersupplyproject.org/test-well reveals that *only* CalAm, MC Farm Bureau, and SVWC experts comprise the HWG. Three organization representing two interest groups (Salinas Valley farmers and the applicant) can hardly be categorized as "myriad," "diverse", or "including but not limited to." For the record, I made verbal comments on the lack of diversity of the HWG at the September 2014 Marina City Council hearings that suspended the permit request.

Add to that fact, that CalAm's chief hydrogeologist on the HWG is Dennis Williams, President of GeoSciences, and an international slant well patent holder with obvious incentives for a particular and successful result from the testing. Although omitted in the background discussions of this DEIR, Dr. Williams' conflicts of interest remain a primary cause for the recirculation of the original document, along with the decision to combine the CEQA/NEPA work. An excerpt from that July 9, 2105 ALJ ruling (page 3) for the Application 12-04-019…

Baer-7

"The Commission's Energy Division issued the Draft EIR in April 2015. Comments on the Draft EIR were due on July 13, 2015. Energy Division has now determined that it is appropriate to further extend the comment period on the Draft EIR to September 30, 2015. We may take additional actions as described below. We do these things for three important reasons.

First:
We have learned that one of our sub-contractors, an entity called Geosciences, also has a contractual relationship with Cal-Am, the MPWSP's proponent, and that Geosciences's contract with Cal-Am pertains to the MPWSP; and that the President of Geosciences holds one or more patents related to slant well technology that Cal-Am might or could use in the construction of the MPWSP…"

Baer-8

Although the PUC chose to distance their relationship from GeoSciences, Mr. Williams remains on the HWG with his conflicts of interest unresolved, collecting the weekly data and filing the monthly reports for the CDP with the Executive Director of the CCC. This situation makes the entire test well analysis suspect as a result of the work of two special interests, and one private conflict of interest, who do not have the best interests of entire community at heart.

Baer-9

Questions

Can you provide documented evidence that experts of other parties "representing diverse interests related to the Basin" beyond the 3 mentioned above, were involved in the data collection, analysis, or other work of the HWG? Baer-10

Why was Dr. Williams allowed to remain on the HWG, once his personal conflicts of interest were revealed? How is this consistent with objective scientific practices? Baer-11

DEIR 4.4 p 4

"The HWG developed a collaborative plan of investigation to assess the hydrogeologic conditions in the project area. The draft work plan provided a phased approach to progressively investigate the hydrogeology and the potential effects of the project on aquifers from the use of subsurface slant wells for obtaining feedwater supply. The final work plan incorporated comments and recommendations by members of the HWG, and covered the investigative steps needed to evaluate the project impacts (Geoscience, 2013c). The final work plan became the hydrogeology investigation roadmap and resulted in the implementation of the fieldwork and modeling efforts described in the approach to analysis, Section 4.4.3.2." Baer-12

Comment

Section 4.4.3.2 does not exist. Section 4.4.3 ("Evaluation Criteria" 4.4 p41) makes no mention of the HWG. Section 4.4.5.2 "Operations Impacts and Mitigation Measures" exists, but likewise makes no reference to HWG.

Question

Where is the evidence of the actual work of the HWG within the DEIR document? Baer-13

2. Deeper examinations into the work of the HWG

DEIR Section 4.4 p42 "Test Slant Well"

"Special Condition 11 of the Coastal Development Permit, "Protection of Nearby Wells," requires the MPWSP HWG to establish baseline water and TDS levels prior to commencing the long-term pumping tests (Geoscience 2015b). The long-term pumping test began in mid-April 2015, and results are available at http://www.watersupplyproject.org/#!test-well/c1f1l."

Neither the background material in the executive summary of the DEIR, nor elsewhere in the document, relays the historical storyline of how the CCC CDP #A-3-MRA-14-0050, Dec 8, 2014, and the subsequent amended version CCC CDP #A-3-MRA-14-0050-A1 came to be. The narrative below is intended to further inform the decision makers. Baer-14

The story…

The original application for a CDP was submitted to the City of Marina, as the Cemex site is within their city limits. After nearly 10 hours of deliberation over two consecutive days in September of 2014, the Council and Mayor voted 3-2 to suspend the application, ruling that the

prepared negative declaration was insufficient under CEQA law for the requested permit, and that a full EIR would have to be prepared to reconsider the application. CalAM chose instead to appeal the decision before the California Coastal Commission at their November 2014 meeting in Half Moon Bay, CA.

Baer-14 cont.

A crucial part of the appeal was that the test well was experimental, and temporary, and therefore did not require an EIR. The Marina City Council decision was overturned, and the permit was approved with stipulations including special condition 11 mention above and attached in its entirety at the end of this section. The permit also included a provision that at the end of the test slant well period, the well would be decommissioned, cut off 40 feet below the surface of the beach, filled with cement and capped, as the slant well being defined as experimental and temporary was a contingency of avoiding the EIR process.

Baer-15

Baer-16

Today, the slant well is planned as a production well. The CCC has yet to raise objection to this violation of its permit terms.

The permit was awarded and signed on Dec 8, 2014 and construction was completed by late March 2015. With less than 2 months of baseline testing at the monitoring wells for groundwater and TDS levels (wholly insufficient to determine seasonal or historical trends) the slant well "long term test" began on April 22, 2015. By June 5 the pumping was voluntarily halted as the water table had dropped near the threshold level proscribed in special condition 11. The Executive Director of the CCC was consulted and convinced that the decline in water table was due to seasonal precipitation or agricultural pumping trends and that the slant well had not impacted the basin.

Baer-17

An amended permit was applied for and approved on Oct. 6, 2015, and the pumping resumed on October 27. The amended permit required monthly reports to the ED of the CCC (instead of "periodic" ones in the original permit). New language was added to special condition 11 to reflect the addition of "seasonal and regional trends", rather than fixed values as thresholds at the monitoring well. The amended permit language is referenced at the end of this section.

Within that document, I have highlighted in yellow that the HWG is directed by the CCC to *identify* groundwater and TDS regional trends so they may compare that information to the collected data to calculate the impact.

In order to identify regional trends, one would presume that groundwater withdrawal pumping logs would be necessary to identify how much groundwater was pumped from the basin, or nearby sub-basin, by the farmers in the region. This has not been reported by the HWG.

Baer-18

In order to identify seasonal trends, one would presume that rainfall totals would not only be collected, but analyzed to see how they might impact both groundwater and TDS levels at MW4s and MW4-m. This has not been reported by the HWG.

Baer-19

In order to identify historical seawater intrusion, specifically at the Dunes Sand and 180 ft aquifers (which is where the threshold monitoring wells MW4-S and MW4-M identified in the permit collect their data), one would presume that a baseline of well data in the coastal aquifer region prior to well pumping would be necessary to establish the baseline for the historical seawater intrusion trend. This has not been reported by the HWG. Baer-20

Yet HWG throughout their thousands upon thousands of pages of monthly well data, neither establish nor discuss in detail any method by which they determined or measured regional, seasonal or historical trends. Baer-21

Each monthly report sent by the HWG to the Executive Director per the terms of the permit have a brief paragraph with little or no change from month to month stating that the test slant well (pumping over 90 million gallons per month if run continuously) has zero impact on groundwater level or quality. Here is an example:

HWG Monthly report 15 to Executive Director of the CCC, 5.3.2, page 11
http://www.watersupplyproject.org/test-well

"From April 2015 through January 2017 the TDS concentrations in MW-4M followed a regional slightly increasing trend (see Figure 3-3). However, the slightly increasing trend occurred consistently during both non-pumping and pumping periods, and therefore likely represents seasonal climate changes or regional pumping, and a continuation of historical seawater intrusion."

Baer-22

Questions

Where are the agricultural pumping records to establish regional pumping trends?

How do you justify using seawater intrusion maps that show the margin of intrusion many miles inland (threshold 500mg Cl/L) as a method to explain historical seawater intrusion trends at the coast where no baseline was ever established? Baer-23

How do you define a "regional slightly increasing trend"? Isn't it true that the table 2 of the HWG monthly report #15 (p.44) shows an increase in TDS at MW4-m from 17,500 ppm on 4/2/15 to 22,600 (mean) ppm on 1/11/17 an increase of over 29% in 21 months? How can you characterize that substantial increase as "slightly increasing"? Baer-24

Looking for clarifying answers in 2016

In the late fall of 2015 and winter of 2016, myself and a couple of other citizen colleagues deeply concerned with the lack of transparency and inability to get answers from CalAm or the HWG about the slant well protocols and data began to ask the permitter of the CDP, the California Coastal Commission, to provide such answers. I submit the following excerpted email for the record. Submitted on or about February 15, 2015 from myself to Tom Luster, permit Baer-25

liason at the California Coastal Commission. No reply was ever forthcoming, and after a few attempts I gave up trying …

Questions for the HydroGeologic Working Group of the MPWSP slant well test project permit #A-3-MRA-1410050-A1

1. Who, *specifically*, reports the data to montereywatersupply.org website, the public website required by permit #A-3-MRA-1410050-A1 ?

2. Why was the laboratory water quality sampling tests suspended between July 29 and December 19, 2015?

3. Who takes the weekly hand samples for conductance and water depth at MW4? Why are those results not posted on montereywatersupply.org?

4. How are "regional trends" determined? Is there data to substantiate "regional trends" as real and quantifiable? Who at the CCC reviews the rationale for determining "regional trends"? Why is this information not available on montereywatersupply.org?

5. Why does the language of permit #A-3-MRA-1410050-A1 indicate "minimal effects at the monitoring well" when Table 2 in the monthly reports indicate that the TDS threshold was exceeded in early May, 2015 after less than three weeks of continuous pumping?

6. Why was the well not suspended on May 6, 2015 as required by the original permit in effect for exceeding 2000ppm of rise in TDS?

7. MPWSP Technical Memorandum "Baseline Water and Total Dissolved Solids (TDS) Levels Test Slant Well Area" submitted to HWG and dated 4/20/15 shows a table 2 with a MW4 baseline reading of March 6 as 17,900, and April 2 and 17,500. This document was submitted to establish the baseline at all the wells in the project, right?

8. Doesn't the decline in TDS levels from March to April, 2015 indicate that seawater intrusion was in a state of reversal before the slant well began pumping? Why or why not?

9. How can it be verified that the slant well has been running at 2000gpm "24/7" since pumping resumed on or about October 27, 2015. Who measures the volume of water pumped at the well head? How is it determined. Why are those results not posted on the website?

10. Table 2 indicates an Electrical Conductance reading at MW4-M of 27,250 (EC), for April 22, 2015, yet the conductance graph plots that point at very near, apparently slightly above, 30,000 (EC). This has the effect of increasing the baseline by 1,870ppm TDS, and flattening the visual appearance of the curve. How do you (HWG) explain what appears to be a simple point plotting error?

Baer-25 cont.

Appendix to this section

CCC Amended CDP for Test Slant Well, October 6, 2015 Appendix 2 of HWG monthly reports

Coastal Development Permit amendment A-3-MRA-14-0050-A1 , -Page 3

SPECIAL CONDITIONS

This **Special Condition** modifies **Special Condition 11** as initially imposed by the Commission in Coastal Development Permit A-3-MRA-14-0050. Standard Conditions 1-5 and Special Conditions 1-10 and 12-17 of that permit shall remain in full force and effect**. Special Condition 11** now requires:

"Protection of Nearby Wells, PRIOR TO STARTING PROJECT-RELATED PUMPING TESTS, the Permittee shall install monitoring devices at a minimum of four wells on the CEMX site, within 2000 feet of the test well, and one or more offsite wells to record groundwater and salinity levels with the wells and shall provide to the Executive Director the baseline groundwater and Total Dissolved Solids ("TDS") levels in those wells prior to commencement of pumping from the test well.

The Permittee, in coordination with the Hydrogeological Working Group shall identify groundwater elevation trends and TDS level trends in the groundwater basin resulting from regional influences such as groundwater withdrawals, rainfall events, increases or decreases in streamflow contributions, and other influences. During the project pumping test, the Permittee shall, at least once per day, monitor groundwater and TDS levels with the monitoring wells in person and/or with electronic logging devices. The Permittee shall post data collected from all monitoring wells on a publicly available internet site at least once per week and shall provide all monitoring data to the Executive Director upon request.

The Hydrogeology Working Group shall review data from the monitoring wells and prepare a monthly report that shall be submitted to the Executive Director that documents the groundwater elevation trends and the TDS level trends resulting from regional influences. If during the pumping tests, data collected from Monitoring Well-4S ("MW4-S") or Monitoring Well-4M ("MW4-M") during any weekly monitoring period show either a decrease in groundwater levels that exceeds an identified decrease in regional groundwater level trends by 1.5 feet or more or show an increase in TDS levels that exceeds an identified increase in regional TDS level trends by two thousand parts per million or more, the Permittee shall immediately stop the pumping test and inform the Executive Director. The Hydrogeology Working Group shall examine the data from monitoring Well 4 if the pumping test is stopped due to either of these causes.

If, based on the above review of monitoring data, the Executive Director or the Hydrogeology Working Group determines that the pumping test caused, at MW-4S or MW4-M, either a decrease in groundwater level of 1.5 feet or more or caused an increase n TDS levels of two thousand part per million or more in excess of identified regional trends, then the Permittee

shall not re-start the pumping test until receiving an amendment to this permit, otherwise the Executive Director will allow the pumping test to resume."

Performance and Maintenance of Slant Wells

Performance

As has been repeated by many citizens in many public comment letters and public forums before the CPUC about the MPWSP since 2012, there are no seawater intake production slant wells for desalination plants functionally operating anywhere in the world. That fact raises the question of how reliable this novel system will be in delivering source water to the plant over decades of use. This issue should be a highest priority item; the reliability of source water intake is fundamental to the feasibility of the project. When it comes to a desal plant, if you do not have a reliable intake for source water, you don't have anything. Baer-26

The public record does contain one previous similar slant well effort, also developed by GeoSciences. However, that project fails to provide any confidence in slant well performance, as the slant well production efficiency declined from 95% in 2006 to 52% in 2012, before being shut down.

(for a review of that project's slant well performance, see :http://www.mwdoc.com/filesgallery/SL_1_Step_Test_Comp._FINAL_TM_Geoscience_12_09_2012.pdf) Sections 2.5 to 3.3 are the pertinent sections on well efficiency in that report.)

That project, at Doheny Beach in Dana Point, California, is currently mothballed as too expensive and unreliable. Concurrently, GeoSciences has moved its ongoing experimental technology to MPWSP at Cemex. Baer-27

Here is the confounding thing: A search of the MPWSP DEIR under the terms "slant well performance", "slant well yield" or "slant well efficiency" provides zero hits.

There appears to be no discussion or analysis of the slant wells' long term performance expectations. Baer-28

Question

How can the DEIR be considered valid and thorough without this crucial piece of the puzzle, slant well performance expectations, even receiving a mention in the DEIR?

There is another aspect to performance (or lack thereof) that shows up in the HWG monthly reports for the project's CDP with the CCC. *There have been numerous interruptions* to the so-called continuous pumping test. A table has been compiled and the data from that table is below: Baer-29

Data on Pumping Interruptions of the slant well from HWG monthly report #15, p 3

1/19/2016 11:10 AM 1/20/2016 8:51 AM 22 hours PG&E power interruption
1/22/2016 11:53 PM 1/24/2016 11:01 AM 35 hours PG&E power interruption
1/30/2016 2:50 AM 1/30/2016 11:08 AM 8 hours PG&E power interruption
1/31/2016 3:29 PM 2/1/2016 11:20 AM 20 hours PG&E power interruption
2/12/2016 2:43 AM 2/12/2016 10:51 AM 8 hours PG&E power interruption
3/1/2016 8:30 AM 3/2/2016 1:40 PM 29 hours Discharge line repairs
3/4/2016 10:10 AM 5/2/2016 1:22 PM **1,419 hours** Discharge line repairs
5/17/2016 11:59 PM 5/18/2016 2:35 PM 15 hours PG&E power interruption
5/25/2016 1:28 PM 5/25/2016 5:21 PM 4 hours PG&E power interruption
6/3/2016 7:45 AM 6/3/2016 9:08 AM 1 hour PG&E power interruption
7/8/2016 6:12 AM 7/8/2016 7:17 AM 1 hour PG&E power interruption
7/14/2016 10:21 AM 7/14/2016 11:36 AM 1 hour PG&E power interruption
8/13/2016 11:32 AM 8/16/2016 7:29 PM 80 hours PG&E power interruption
10/3/2016 7:55 PM 10/5/2016 6:23 PM 46 hours PG&E power interruption
12/24/2016 9:18 AM 1/11/2017 9:23 **AM 432 hours** PG&E power interruption & discharge line repair
1/20/2017 7:42 PM 1/25/2017 2:43 PM **115 hours** PG&E power interruption

Baer-29 cont.

The most striking thing about the table is what is not in it. Recall that the continuous long term pumping test began on April 22, 2015, but the table only includes data from 2016. The longest shut down from the table above, 1419, hours, is roughly 60 days in duration. But in 2015, besides the few short-term delays of a couple days or less**,** *there was a lengthy shut down from June 5, 2015 to October 27, 2015 roughly 144 days or about 3456 hours*.

It is but another example of the sloppy science conducted with omissions tending to be clustered around events that are not helpful to a successful outcome of the "experiment."

Questions

Why does the table of interruptions not include the data from April 22, 2015 through the end of that calendar year?

Why was the pumping interruption information omitted from the DEIR? How does the numerous and sometimes lengthy interruptions to slant well pumping interfere with the experimental integrity? Why is there no discussions of the impacts of interruptions to the test well either within the DEIR or the HWG reporting?

What will be done to strengthen and ensure the safety of the power supply? What happens to our water supply with lengthy outages? How long does it take to restart the desalination process after a lengthy power outage? Given the huge power demand for the desal production plant, is it feasible to have fuel based generators as back up? Where is this scenario discussed in the DEIR?

Baer-30

One final note on this topic. Power outages are inevitable. Just this week (February 17-24, 2017) heavy winter storms knocked out power around the Peninsula for several thousands of PG&E customers, some for more than 3 days. The fact that slant well performance receives no mention, discussion or analysis within the DEIR document is *very disconcerting*.

Baer-30 cont.

Maintenance

Since slant wells are functioning nowhere in the world, it raises the question of maintenance. The six-year study at Dana Point does not appear to have resolved the questions of protocols for effectively maintaining slant well efficiency. The link referenced above does examine the issues of physical, chemical and biological clogging of the wellscreens, but the report is theoretical. From the document, it doesn't appear they have actually field-tested how to clean and maintain a slant well.

It is with some relief, that a search of the DEIR for MPWSP does provide hits on slant well maintenance. It is reported that slant well maintenance would occur about every 5 years and take up to 18 weeks to complete on all 10 proposed wells. Further …

Baer-31

DEIR, Chapter 4.3, Page 111 and elsewhere…

"As described in Chapter 3, Description of the Proposed Project, mechanical brushes would be lowered into the slant wells to mechanically clean the well screens. If chemical cleaning products are needed for maintenance, only environmentally inert products would be used. However, the effluent produced during slant well cleaning could carry sediment or other contaminants that, if discharged directly to the beach area, could adversely affect water quality in Monterey Bay."

Questions

Doesn't the sediment in the effluent originate from the Monterey Bay and Salinas Valley Groundwater Basin? Why would that be a contaminate to the beach?

What other contaminants might be introduced in the maintenance process and where would they originate? What are the environmentally inert products? Have they successfully been used to clean slant well screens?

Baer-32

Is there any evidence or documentation of a seawater intake slant well for desalination ever being successfully maintained?

What happens if scrubbing the screens from ***inside* the well and/or applying inert chemical agents fails to clean the "gunk" accumulating on the ***outside*** of the screen intake system?**

Baer-33

These questions must be resolved, and I ask that the DEIR be ***recirculated***.

Respectfully submitted,

Michael Baer

DEIR/DEIS, MONTEREY PENINSULA WATER SUPPLY PROJECT

Public Comment

Thank you for the opportunity to comment on this very large Draft EIR/EIS, which has immense implications for the Monterey Peninsula environment, and for those of us who are Cal-Am ratepayers. I should be grateful to receive your answers to the questions below.

My first submission is on the following topic:

Beech-1: Required Decommissioning of Test Slant Well

The DEIR/DEIS states "The existing test slant well would be converted into a permanent well" (p.3-7 footnote 3, *et al*). However, Cal-Am is not at liberty to do this, since under both the original (#A-3-MRA-14-0050 dated 8-Dec-14) and the revised permits granted by the California Coastal Commission, Cal-Am has signed an undertaking to accept all the conditions, including decommissioning of the test slant well, and posting of a one million dollar bond to ensure that this is carried out. A significant consequence of characterizing the test well as a temporary structure was that it was asserted that it was "adequately mitigated", so no environmental review was required for the test well, and none was carried out. Beech1-1

Q1: Would the conversion to a permanent well be a CEQA and/or NEPA violation, and hence require revision of the project proposal to exclude this conversion? Beech1-2

Q2: Has it not been, and is it not now, erroneous to allow testing to proceed without environmental review, since the impact is not limited to temporary visual and hazardous aspects of the pump, but also includes permanent effects such as: Beech1-3

(CEQA) potential lowering of water level in the aquifers, and salt water intrusion;
(CEQA and FEMA) extraction from the aquifers, and discharge of that water through the pollution treatment outflow pipe into Monterey Bay;

in the course of up to two years of test pumping of millions of gallons per day?

Q3. Would not an environmental review of the Test Slant Well proposal have revealed, or would it not now reveal, the serious environmental harm likely to ensue in pumping from groundwater aquifers, and call instead for testing of true subocean intake of seawater? Beech1-4

To bring some science into this, and quantify the effects:

Q3: How many acre-feet will have been pumped in total out of the 180 foot and Dune Sand aquifers, say through March 1, 2017? Beech1-5

Q4: What have been the true environmental impacts already, say at Monitoring Well 4, on water level relative to an actual baseline, and on salinity as estimated via conductivity and total dissolved solids, with any regional trends based on hard data? Beech1-6

Even if the test slant well is indeed decommissioned, there is disturbing evidence (identified in the letter below) that there was already an intention, when the permit was signed and an EIR was avoided, to later convert the test well into a backup well in the production system. Beech1-7

Q5. In order to uphold the integrity of the CEQA and NEPA processes, and avoid setting a bad precedent, doesn't this reinforce the case for insisting that the undertaking to decommission the test well must be honored, with possibly some reprimand to the applicants for manipulation of the processes, and even for any demonstrated harm to the environment during testing? Beech1-8

To any suggestion that Cal Am would actually be saving ratepayers money by making the conversion to a backup well, there are two major answers – that the amount saved would be trivial compared to the harm done by condoning the gaming of the system; and that if Cal-Am were seriously interested in saving ratepayers money, it would not have withdrawn from the previous Regional Project, and we could by now have already been using cheaper desalinated water, purchased by Cal-Am from a plant owned and operated by Marina Coast Water District, with vast Federal funding. Beech1-9

Some more details are included in the letter below to Mr. Traylor of the local CCC Enforcement Office. For reasons that they have been unwilling to state, the CCC, having assigned the issue Case # V-3-16-0032, has not been prepared to pursue it. My public records request to CCC produced no documents directly bearing this case number, and the issue appears to have been quietly dropped. Please investigate whether there was some conflict of interest due to CCC staff having assisted in the preparation of this faulty CDP permit (and, indeed, also in the preparation of its revised version after the testing was suspended as soon as it appeared to be failing). Beech1-10

However, my questions to you are not about why CCC chooses not to enforce conditions in its permits, but about whether CEQA and NEPA requirements have been satisfied, on which subjects you have the expertise and the vested authority and obligation to answer. Beech1-11

With thanks for your attention,

David Beech

Santa Cruz, CA 95060

From: David Beech

Permit Violation re Decommissioning of Cal-Am Test Slant Well
Coastal Development Permit #A-3-MRA-14-0050

Dear Mr. Traylor,

This letter is to notify you formally of an apparent permit violation concerning the decommissioning of the Cal-Am Test Slant Well, whose Permit \was approved at the CCC November 2014 meeting, and revised in October, 2015, after a halt in testing. The issue only came to my attention by accident in January when I was researching the facts on the slant well project to present at an informational community outreach meeting in Carmel, and looked at the map for the intended production system.

Executive Summary

1. The Test Slant Well Permit requires that the test well be decommissioned on completion of testing.
2. Consequently, as a temporary structure, the test well escaped CEQA requirements, such as an Environmental Impact Report.
3. The Findings in the original permit recommendation already make a contradictory mention of possibly not decommissioning the test well.
4. Cal-Am has subsequently issued an RFP for construction of the production wells, and accepted a bid, including use of the test well as one of two backup wells.
5. CCC investigation and action are requested regarding this permit violation.

1. Decommissioning Required by Permit

In the documentation of permit A-3-MRA-14-0050, the decommissioning of the test well is mentioned in the one-sentence description of the project (p.1),

Details of the mandatory ("shall") decommissioning are given in Special Condition 6, para. 2 (p.6), and the posting of a $1,000,000 bond "to guarantee the Permittee's compliance" is required in Special Condition 17 (p.12). (When was this bond in fact posted?)

2. **Escaping CEQA Review**

In the FINDINGS AND DECLARATIONS (http://www.coastal.ca.gov/meetings/mtg-mm14-11.html, item 15a) section V. CALIFORNIA ENVIRONMENTAL QUALITY ACT (p.63), the summary (without any supporting detail), refers to the "seventeen special conditions necessary to avoid, minimize, or mitigate these [significant adverse environmental] impacts." Special Conditions 6 and 17, cited above, were thus a factor in the Commission's finding that "the proposed project, as conditioned, has been adequately mitigated and is determined to be consistent with CEQA." If SC 6 is not honored, this finding would need to be revisited.

3. **Contradictory Findings**

Unaccountably, there is discussion in FINDINGS AND DECLARATIONS IV.A. (p.16) regarding the "long-term use of the well, including converting the well to use as a water source for the separately proposed MPWSP." This directly contradicts the commitment to decommissioning of the test well, which was a factor in the CEQA mitigation. As a discussion of what "these Findings …do not authorize", it does not have any force in this document to override the "shall" commitment and the Bond requirement for the decommissioning described above. The full paragraph in FINDINGS is as follows:

"The proposed project evaluated herein is for construction and operation of a test slant well only. These Findings, and any coastal development permit issued pursuant to these Findings, apply only to the proposed test slant well and its associated monitoring wells and do not authorize development that may be associated with long-term use of the well, including converting the well to use as a water source for the separately proposed MPWSP. Any such proposal will require additional review and analysis for conformity to relevant Local Coastal Programs and the Coastal Act and will be conducted independent of any decision arising from these Findings. Further, the Commission's decision regarding these Findings exerts no influence over, and causes no prejudice to, the outcome of those separate future decisions."

It is disturbing that someone, at least, was already, at the time of the original permit commitment to decommission the test well, thinking in terms of the Permittee later walking away from the commitment. Can any Commission Staff Member shed light on this? Who introduced this material? Are there working documents in the Commission's files that can help resolve this issue of good faith in the adoption of the original permit?

4. Map Showing Converted Test Well

Cal-Am has subsequently issued an RFP for construction of the production wells (ahead of approval of the test results), where the test well was explicitly allowed to be "converted into a production well." A bid from Boart Longyear was accepted, including use of the test well as a backup well in the production system. The map below is taken from the official documentation of the project at http://www.watersupply.org under

PROCUREMENT, 1. Source Water Slant Wells RFP, Contract Drawings. The converted test well is seen slanting down from top center, labelled EXISTING TEST SLANT WELL (STAND-BY 1).

5. CCC Investigation and Action Requested

Investigation and appropriate CCC action are requested in light of the above permit violations. In order to penalize the apparent intent to mislead, and to effect the required decommissioning of the test well, since the existing SC 6 and 17 have failed to "guarantee" this, some stronger action appears to be required, possibly with the Commission's Enforcement Unit recommending to the Executive Director rescission of the permit, in addition to tracking that the decommissioning is actually carried out before the specified deadline date of February 28, 2018.

Respectfully submitted,

David Beech,

DEIR/DEIS, MONTEREY PENINSULA WATER SUPPLY PROJECT

PUBLIC COMMENT BEECH-2

Thank you for the opportunity to make a few more concise comments on this very large Draft EIR/EIS, which has enormous implications for the Monterey Peninsula environment, and for those of us who are Cal-Am ratepayers. I should be grateful to receive your answers to my questions on the topics below.

Slanted Description of Slant Wells

Right from the start of the project, there has been considerable ambivalence as to:

(a) whether, or to what extent, the slant well intake was ocean water; and
(b) under what surface exactly the slanted screened intakes were "subsurface".

This Draft EIR/EIS perpetuates misleading terminology, possibly to make the project appear more closely aligned with true subocean intake than in fact it is.

Q1: Under what definition of "Seawater" do you assert that the project has a "seawater intake system" (heading of section 3.1 and content of 3.1.1, page 3-7)?

Although the precise content of Total Dissolved Solids (TDS) in seawater has to take account of factors such as location, depth, and temperature (see National Oceanic and Atmospheric Administration documents online), a first approximation to a scientifically acceptable definition close to the Cemex site would be in some specified TDS range close to 35,000 mg/L.

Beech2-1

Q2: Is it not true that the recorded intake TDS during the slant well testing has always been significantly below the acceptable range for seawater?

Q3: Can you show any evidence that the intake TDS of the production slant wells will fall within the range defined for seawater? Beech2-1 cont.

Also in 3.1.1, it is stated:

"The seawater intake system would include 10 subsurface slant wells at the coast (eight active and two on standby at any given time) that would draw seawater from beneath the ocean floor for use as source water for the MPWSP Desalination Plant."

Q4. What evidence can you present that the intake water is drawn from "beneath the ocean floor?" Beech2-2

Q5. Given that the pumping is through screens that are potentially partly or largely under dunes inland of the mean high water mark (where the project description does not exclude the possibility that some screening in the Dune Sand Aquifer may even be above sea level), are you claiming that all of the intake water originated under the ocean floor? Beech2-3

Other aspects of the placement of the slant wells will be discussed shortly.

Again in 3.1.1, it is stated:

"When compared to vertical wells, slant wells allow for a substantially increased screen length in the target water source, resulting in higher production rates."

Given that an experimental slant well of appropriate dimensions would cost approximately $11 million, versus a tried-and-trusted vertical well to the same depth that would cost approximately $1 million (as planned in the Regional Project from which Cal Am withdrew), this immediately raises a major question:

Q6. Why was a vertical well not also constructed nearby for direct comparison of performance and reliability? Beech2-4

Since the use of hitherto unsuccessful slant well technology is perhaps the second weakest part of the proposal being evaluated (after the absence of water rights), please also answer these questions:

Q7. What evidence is there that increased screen length would in practice reliably result in higher production rates when compared to vertical wells?

The output of a well is largely determined by the power of its pump, and nearby (and worldwide) vertical wells have reliably sustained high production rates for many years. Beech2-5

Moreover:

Q8. Since the planned operation of the production slant wells is at "approximately 2,100 gallons per minute (gpm) per well" (p. 3-15), is it not true that this output, or more, is commonplace, with proven reliability and economy, for vertical wells, and thus any theoretical (but contested) higher production rate for slant wells is not even needed? Beech2-6

To examine the production slant wells more closely, we move ahead to Table 3-2 (p. 3-16), and pursue the theme of slanted presentation.

Q7. Since you have replaced the Mean Sea Level used in the test well permit description by Mean High Water, could you please also add a column computed using Mean Low Water?

The zone between MHW and MLW would not normally be described as "offshore", but rather as being, as in Doc Ricketts' enduring title, "Between Pacific Tides". The term "offshore" tends to be defined by dictionaries as "some distance out to sea", and to use it as beginning at the Mean High Water mark is surely misleading.

Beech2-7

Then again, the length of the production wells is to be "approximately 900 to 1,000 feet", but the calculations assume the maximum length, despite the fact that the test slant well had a permit up to 1000 feet, but was actually built only to 724 feet, so 1000 feet for the production wells is by no means guaranteed.

Beech2-8

Q8. Could you please clarify the assumptions made in the tables and in the text, including explanation of the limited accuracy and relevance of the +env and storm numbers?

Beech2-9

In fact, the figure on p.3-13 probably gives a better impression of the true state of affairs, maybe when the tide is fairly well out.

Q9. Is it intentional that all of the wells on the p.3-13 map stop short of the Marina City Boundary, which thus limits the extent to which the wells would be subocean, or perhaps of concern to the National Marine Sanctuary?

Beech2-10

Also there is considerable freedom in the placement of the screens on the well casing of the production wells, where the actual intake occurs. On p 3-15, it is stated that "Each well would be screened for approximately 400 to 800 linear feet at depths corresponding to both the Dune Sand Aquifer and the underlying 180-Foot-Equivalent Aquifer of the Salinas Valley Groundwater Basin.

Q10. Could you please confirm that a correct understanding of this is that all intake water would be drawn from the Dune Sand Aquifer and/or the underlying 180-Foot-Equivalent Aquifer of the Salinas Valley Groundwater Basin?

Beech2-11

Discrepancies between Test Slant Well and Production Slant Wells

There must be serious concern, in such previously uncharted territory, that the production slant wells differ substantially from the test slant well, to be drilled at an angle of 14 degrees to the horizontal instead of 19 degrees, and being approximately 900 to 1,000 feet in length instead of 724 feet. The concern is heightened by the fact that there appeared to be reliability problems with the test well, with frequently interrupted testing.

Beech2-12

Q11. For how many days out of how many actual calendar days has the test well produced water, and at what rate? Beech2-12 cont.

Q12. What lessons have been learned from the test that can give confidence that improved design of the production wells will overcome problems experienced with the test well? Beech2-13

Q13: Why was the slant angle changed to 14 degrees? Beech2-14

Q14: If this project is approved, would subsequent design changes be allowed without further review, as problems were discovered during construction, i.e. would this unprecedented project be a continuation of an experiment, only on a scale ten times as large, with ratepayer money irretrievably committed? Beech2-15

Q15: How have you estimated the cumulative effects of 8 closely-situated active production wells as compared to 1 test well, for example on the sustainability of the intake volume from the aquifers, lowering of aquifer levels, seawater intrusion, and relationship of the cones of depression? Beech2-16

Rationale for Carmel Valley Pump Station

The Carmel Valley Pump Station is described in Section 3.2.3.6, as follows:

"The Valley Greens pressure zone, in Carmel Valley south of the Segunda Reservoir, does not have sufficient hydraulic head to fill the existing Segunda Reservoir, which is located at the southern end of the existing Segunda Pipeline. The proposed Carmel Valley Pump Station, with a pumping capacity of 3 mgd (2,100 gpm), would provide the additional pressure needed to fill Segunda Reservoir."

Q16: Why is filling the Segunda Reservoir in Carmel Valley, at the end of a pipeline conveying water over the hill to Seaside, a necessary part of distributing desalinated water that passes through Seaside already? Beech2-17

The Monterey Peninsula Water Management District has an agenda item for their 2/22/17 meeting to approve a modified Addendum to the PWN/GWR EIR, related to the Monterey Pipeline which is also a crucial part of the distribution of desalinated water as covered in this DEIR/EIS. Since the supporting documentation (Exhibit 2-A) http://www.mpwmd.net/wp-content/uploads/Feb-22-2017-Board-Mtg-Agenda-and-Packet.pdf describes (bottom p.15) the intent to significantly increase the pumping of Carmel Valley water for ASR purposes, and to distribute it by a different route, the following CEQA question arises: Beech2-18

Q17. Doesn't the above significant change require a Supplemental EIR?

Harmful Postponement of Resolution of Water Rights Issues

Section 2.6 on Water Rights begins: Beech2-19

"The topic of water rights is not one typically addressed in an EIR/EIS. It is a legal matter that is rarely relevant to the question of whether a proposed project being evaluated under CEQA or NEPA will generate impacts on the environment. Here, however, the issue of water rights is addressed as one of project feasibility."

Not being an attorney, I will here, without prejudice, opt out of any legal discussion of the merits of the substance of this section. But I do wish to exhaust my administrative remedies by making a meta-level request, related to the possibility that it is eventually determined that this project is infeasible due to Cal Am's lack of water rights.

To expend so much time and energy on designing and evaluating a complex system, before determining that an essential precondition could be satisfied, appears to have been to put the cart before the horse. It was a very poor business decision that would not, in my opinion, have been made by a company putting its own money at risk.

If the project is found infeasible, then, together with many other people, I will have been harmed by having to bear the inflated stranded costs of a failed project, and by having spent countless hours (in my case, from late 2014 to the present) in trying to avert this wastage. I have also driven hundreds of miles to Coastal Commission meetings in Half Moon Bay. Morro Bay, and Santa Rosa, in order to alert CCC to these issues, being limited to a few minutes of Public Comment since CCC had ignored requests to make the issues an agenda item for discussion and potential action.

Beech2-19

Those stranded costs would be unnecessarily high due to the decision by Cal-Am, supported by others including but not limited to CPUC, MBNMS, ESA and CCC, to not resolve water rights issues before proceeding with detailed design, testing, and EIR preparation and processing.

Q17, Could you please respond with a recommendation that the parties above adopt an appropriate undertaking to indemnify all those harmed as described, in the event that the project is found infeasible due to lack of water rights?

The plight of the suffering ratepayer in dealing with the priesthood of water agencies is well captured in the New Yorker cartoon overleaf.

Respectfully submitted,

David Beech

Cal-Am Residential Ratepayer
Monterey, CA 93940

"Except for the actual sacrifice, all this is largely symbolic."

When the CCC board members were shown this, they laughed politely, and allowed the sacrifice to continue.

DEIR/DEIS, MONTEREY PENINSULA WATER SUPPLY PROJECT

PUBLIC COMMENT BEECH-3

Thank you for the opportunity to make a few more concise comments on this very large Draft EIR/EIS, which has enormous implications for the Monterey Peninsula environment, and for all those of us who are Cal-Am ratepayers. I should be grateful to receive your answers to my questions on the topics below.

Selection of Alternatives

A search of the DEIR/EIS reveals no mention of the substantial 2011 report on alternatives prepared for Cal-Am by RBF Consulting.
https://www.scribd.com/document/68554233/Technical-Memorandum-RBF-Consulting
This appeared to be an outstanding piece of work in the technical analysis. Even though some of the pros and cons, and cost comparisons, would need to be revisited after the passage of more than 5 years, it appears to be a more diligent study than presented in this DEIR/EIS.

Q1. Was the above 2011 report studied as part of the selection process? If not, why not?

In particular, alternative 9, to divert winter runoff of surface water from the Salinas River from above the rubber dam via the treatment plant into the Seaside Aquifer, deserves renewed attention, and I shall return to this under Superior Alternative below.

Beech3-1

Evaluation of Alternatives

The dismissal of some alternatives appears to be on rather slender grounds, but I will not linger over details here, as I am hurrying towards a constructive alternative proposal.

Beech3-2

I will only ask about diligence in obtaining sufficient information to make evaluations of serious potential alternatives to the proposed project at comparable depth, as required by CEQA and NEPA. For example:

Q2. How much contact was there, in order to improve understanding and seek additional information, between the DEIR/EIS team and the lead agencies and/or proponents of the following:

(a) The People's Project;
(b) DeepWater Desal;
(c) Cal-Am Desal Project?

Beech3-2 cont.

Superior Alternative

The *prima facie* case for including consideration of Salinas River winter surplus diversion as a component of a superior solution is very clear.

It is generally accepted that an average of as much as 250,000 acre-feet of fresh surface water (not groundwater) is lost from the mouth of the Salinas River into Monterey Bay in the winter rainfall season – where diversion of a mere 10,000 acre-feet would be enough to deal with all near-to-medium term problems addressed by this DEIR/EIS.

Beech3-3

Diversion of substantial quantities of this water (including for municipal use) is already allowed by State Permit 11043 approved in 1952, and modified some years later to slightly reduce the permitted maxima as punishment to Monterey County for making no use of the permit. However, the quantity allowed is still ample, although some refinements of the permit would likely be necessary. The prognosis for those refinements should be very good, given that their approval is decided by the State Water Board (under their surface water powers) – the very body that has been pressing this area since 1995 to come up with an environmentally friendly solution to the water supply deficiency.

Beech3-4

There seems to be a local political opinion that the Salinas Valley farmers would never agree to this diversion, but if their position is that no one else can touch Salinas River surface water; even where they have no use for it themselves and it is running out into the ocean, this is a desperately weak position which could hardly survive in front of the various regulatory bodies that oversee the best interests of the whole community.

Beech3-5

This should rather be a time for the whole of Monterey County to work together to solve the County's water problems. An example would be to share the costs of the Interlake Tunnel, if there can be shared benefit. Already the farmers are due to benefit hugely from Pure Water Monterey, since much of their toxic waste water will be cleaned for them, and much of the resulting clean water will be returned to them at a knockdown price. So the least to be expected in return is that they do not obstruct residential use of water at a season and a location where the farmers have no use for it.

Beech3-6

Beech3-7

Returning therefore to the technical and economic feasibility of what we might call Aquifer Storage and Recovery (Salinas River) – ASR(SR) – the next step would be to set engineers to work to develop a detailed proposal. I would just note two other things:

(1) Although the Advanced Treatment Plant for Pure Water Monterey is nearby, and has been designed to facilitate a modular extension to double its capacity, it may be much cheaper to use simplified treatment instead, if the surface water from the river is dramatically cleaner than the mix of source water currently planned for Pure Water Monterey. But the delivery pipe from the treatment plants to the Seaside Aquifer should in any case be sharable. Beech3-8

(2) If it turns out (as I, using only common sense, expect) that some of the water sources for Pure Water Monterey prove too toxic to be cleaned in any cost-effective way, or even at all, then some ASR(SR) water could replace that lost input. Beech3-9

If the engineering design is successful, the close relationship of ASR(SR) to PWM suggests that an efficient approval process would be to propose ASR(SR) in a Supplemental EIR for PWM. Beech3-10

The Cal-Am Desal Project appears to be facing possibly insuperable obstacles,

Q3. Do you agree that it is at least prudent at this point to begin to think outside the box, and minimize delays in the event of failure of the present proposal? Beech3-11

Q4: Do you see merit in the initial sketch of ASR(SR) above? Beech3-12

Plan C

Since I believe Plan B has already come and gone, this section will propose ASR(SR) in the context of a comprehensive Plan C.

The portfolio approach would be continued, this Superior Alternative Project being comprised of:

(i) One or more desalination plants as needed
(ii) Existing Aquifer Storage and Recovery (Carmel River)
(iii) Pure Water Monterey
(iv) Aquifer Storage and Recovery (Salinas River) Beech3-13

Items (i) and (iv) are the only ones that need work, and development of (iv) does not appear problematic, especially if processed as a Supplemental EIR for PWM. (There is a recent precedent for overlapping EIRs, with the Monterey Pipeline being moved from the Desal EIR to the earlier PWM EIR as a shared component.)

Q5: Does Plan C satisfy your criteria for serious consideration as a Superior Alternative?

Resolution of the Desal Alternatives

Only the quandary of the imperfectly synchronized EIRs for the Cal-Am, People's, and DeepWater desal projects would then remain to be resolved. It appears ridiculous to proceed with independent unsynchronized reviews that could produce contradictory evaluations and recommendations. Beech3-14

Q6: Do you agree that some thinking outside the box is required here, or do CEQA and NEPA indicate how such a situation should be handled?

For example, given some reasonable deadline for issuance of the other DEIR/EISs, should all desal proposals have a common end date for receipt of public comments, so that at least the public can make a properly informed appraisal of the related (possibly competing) projects? Then some combined analysis of these comments and development of responses and recommendations seems to be called for. Beech3-15

Although the present DEIR/EIS is the first of the three to appear; it is quite likely to attract by far the most comments, so that the other two projects could catch up after the shared final date for public comment, with the Final EIR/EIS dates converging. Beech3-16

Q7: How do you propose to resolve the above issues for the desal proposals?

Recirculation of this DEIR/EIS, possibly including Plan C

Q8: Do you agree that in light of the severity of the many well-informed objections you have received – and in light of the low probability of successful minor amendments to answer all these objections – it is necessary to make major amendments and recirculate the DEIR/EIS? Beech3-17

Q9: Will you kindly give full consideration to recommending Plan C above? Beech3-18

Q10: Will you also, after consulting Cal-Am, give full consideration to recommending termination of their current Desal Project (with its spiraling potentially stranded costs), in favor of the desal component (i) of Plan C being satisfied by reasonably well-synchronized reviews of the DEIRs for the People's Project and DeepWater Desal? Beech3-19

Indeed, Cal-Am's agreement to termination of their staggering project sooner rather than later would accelerate the ultimate solution, win them friends, and improve their long-term prospects for remaining the water purveyor to the Monterey Peninsula.

DEIR/DEIS, MONTEREY PENINSULA WATER SUPPLY PROJECT

PUBLIC COMMENT BEECH-4

Thank you for the opportunity to make more comments on this very large Draft EIR/EIS, which has immense implications for the Monterey Peninsula environment, and for all those of us who are Cal-Am ratepayers. I should be grateful to receive your answers to my questions on the topics below.

I apologize for the length and level of detail of this submission. Unfortunately this is necessary in order to adequately address certain major issues raised in the 3700 pages of the DEIR/EIS, which themselves contain much essential detail!

Purpose of Test Slant Well

The following surprising statement of the purpose of the test slant well is found on p. 3-2:

To inform the final design of the subsurface slant wells and the MPWSP Desalination Plant treatment system, and to collect geologic and hydrogeologic data needed for Federal, state, regional, and local permits for the full-scale project, CalAm built a test slant well at the same location as the seawater intake system for the proposed Project. CalAm currently is operating the test slant well as a pilot program to collect data. Construction of the test slant well and operation of the pilot program was covered under separate environmental review.[2]

Yet the original Project Description for the test slant well was as follows:

Project Purpose
The project would allow Cal-Am to gather technical data related to the potential hydrogeologic and water quality effects that would result from using similar wells at or near this site to provide water for the proposed Monterey Peninsula Water Supply Project. If the data collected from this proposed test well demonstrates that this well design and location would provide the necessary amount of water and not cause unacceptable adverse effects, Cal-Am may choose to apply for additional coastal development permits to convert the test well to a production well and/or construct additional similar wells, subject to certification of an Environmental Impact Report ("EIR") by the California Public Utilities Commission, which is preparing the document for the above-referenced water supply project.

This was the basis on which the California Coastal Commission granted the test well permit. https://documents.coastal.ca.gov/reports/2014/11/W14a-s-11-2014.pdf

Beech4-1

Separating out the conversion of the test well, which was addressed in my earlier comments Beech-1, we focus here on the intended production wells, i.e.

If the data collected from this proposed test well demonstrates that this well design and location would provide the necessary amount of water and not cause unacceptable adverse effects, Cal-Am may choose to apply for additional coastal development permits to … construct additional similar wells …

Q1: If you do not have adequate grounds for limiting the purpose as being "to inform the design" and "to collect data", omitting any mention of evaluation of the "well design and location", will you please amend the DEIR/EIS to be consistent with the permitted project description?

Beech4-1

Q2: Do the planned production wells, at slant angle of 14 degrees instead of 19 degrees, and of length between 900 and 1000 feet instead of 724 feet, qualify as sufficiently "similar" for test results to be confidently extrapolated to justify a project slated to cost hundreds of millions of dollars and to be an indispensable part of the water supply for decades?

As a footnote to a footnote, we return to footnote 2 referenced above at the end of the extract from DEIR/EIS p. 3-2, which reads as follows:

[2] In October 2014, Monterey Bay National Marine Sanctuary finished its NEPA review of the construction of the test slant well and the operation of the pilot program. In November 2014, the City of Marina and the California Coastal Commission completed their CEQA review.

After considering my comments in Beech-1 on the avoidance of an EIR due to the undertaking to decommission the test slant well, you may agree that some less misleading footnote is required. I have not checked the NEPA and City of Marina materials, but you will know whether they had similar dependencies on the temporary nature of the test well.

Beech4-2

Q3: Will you please clarify in footnote 2 the nature of the NEPA and CEQA reviews, and the reason why no EIR/EIS was deemed to be required for the test well, despite the environmental impact of pumping of millions of gallons out of the aquifers and into Monterey Bay during testing?

Beech4-3

HWG and Conflict of Interest

The Hydrogeologic Working Group (HWG) was set up by CPUC to play a pivotal role in the data collection, reporting, and evaluation of the slant well test. Yet it appears to be dominated by Dr Dennis Williams (holder of slant well patents) and his company (GeoSciences) on whose letterhead most of the reports have been published.

Dr Williams was previously removed from his position as representing CPUC in the HWG, after it was pointed out that there was a conflict of interest in his evaluating the technology that he was designing and promoting. However, he has still remained as an

Beech4-4

active member of HWG, whereas there is little evidence of the other members participating beyond (usually) signing their names on the periodic reports.

Q4: Is this not still a conflict of interest that fatally undermines the credibility and value of the HWG reports?

Beech4-4 cont.

To illustrate the unnerving fragility of evidence derived from the slant well testing, we move to a small sample of the reported data. It is important to understand that this is not a new investigation, but that several concerned residential rate-payers have been raising these issues with Coastal Commission staff, and thus (as requested) indirectly, or occasionally directly, with HWG members, ever since the testing began. Our cries have fallen on deaf ears.

Unscientific Test Well Reporting and Evaluation

Testing under Original Permit

Probably as good a first example as any arose early in the testing, when Cal Am voluntarily suspended pumping as the water level was dropping fast. Fingers were pointed at farmers for having been responsible, yet no data were produced, and no log data from nearby farm wells were even sought – unscientific!

Then examination of the reported levels at Monitoring Well 4 suggested that the level had previously already fallen by more than one inch below the baseline, which should have automatically triggered a condition in the permit to cease pumping, pending CPUC review. This led to claims that the baseline was not actually a number, but was a discussion in a technical report, and hence no numerical calculation was needed or carried out. In my frustration, I sent 12 simple questions to CCC staff, appended below as Exhibit 4-A.

Having received no direct reply at the time, and since these questions are fundamental to an evaluation of the scientific integrity of the testing, I ask the following:

Beech4-5

Q5: Could you please obtain answers to these questions from the HWG, and publish them in your response?

I emphasize that an answer from CCC staff would not suffice, since it is their previous treatment of technical questions that is being challenged. In this whole section, I am counting on the professional reputation of the DEIR/EIS team to guarantee answers that live up to the scientific standards required by CEQA and NEPA.

In an email dated 2/16/2016 to CCC staff, I raised the following question:

==========

Question about Permit Compliance

1. Under what provision of the permit was the permittee allowed to voluntarily suspend pumping?

   This is not a trivial question, since in a stress test, the patient is not usually allowed to step off the treadmill when things don't seem to be going too well, take a rest during the most severe part (summer dry season, continued drought), and wait for easier conditions (heavy rainstorms) and an easier setting of the treadmill on resumption (regional trends in Special Condition 11), and finally delay the resumption voluntarily by claiming repairs were needed to the treadmill (well pump).

   The purpose of the test is to determine the most accurate prognosis for the patient, not to find a way to "pass".

Beech4-5 cont.

==========

The (correct) reply was that the permit did not preclude voluntary interruption of testing, and, as far as I know, this reply is also correct under the revised permit.

Q6: Has it not been a serious scientific (and engineering) flaw in the test well permits that they have not insisted on almost continuous operation of the test well, in order to provide evidence of reliability (and maintainability, which seems to have been almost totally neglected)?

This sketchy testing would not matter so much in a small project, but we are looking here at a project with a base sticker price of $320M, which could easily creep up to around the $1 Billion mark as a total cost to ratepayers after finance charges, corporate taxes and annual 9.9% profits are added in. That would be an average of about $25,000 for each of the approximately 40,000 Cal Am ratepayer connections in the Monterey Peninsula area.

Beech4-6

Then problems with the unproven technology during construction (hardly unforeseen) could lead to endless cost overruns, when the project had proceeded so far that there was no turning back, and the contractor could call the tune.

Beech4-7

Consider what happened to the repairs to the Bay Bridge after the Loma Prieta earthquake, where the original estimate of $250 Million was said to have grown to $6.5 Billion, i.e. by a factor of 26.
http://www.citylab.com/politics/2015/10/from-250-million-to-65-billion-the-bay-bridge-cost-overrun/410254/
If that happened to the Cal Am Desal Project, ratepayers would be on the hook for an average of about $650,000 each over 20 or 30 years.

Q7: Who could afford that?

To the reply "That could never happen here", a realistic response would be "Well, maybe not quite as badly, but what incentive does Cal Am have to keep the cost down? In fact, there is even an incentive to increase the cost of the newly acquired assets, on which their annual 9.9% profit, guaranteed by CPUC, is calculated."

Beech4-8

Q8: Is it time to terminate the apparently failing Cal Am Desal Project due to inadequate testing, rather than continuing to harm the environment and throw good money after bad? Beech4-8 cont.

Q9: In case you might consider responding to Q8 that it is not within your remit to answer it, I ask: Do CEQA and NEPA require that an EIR/EIS always makes a positive recommendation in support of the project under review, or is it possible to recommend denial of approval on grounds of insufficiently mitigated impact on the environment, and/or (particularly relevant to apparently unscientific testing) insufficient evidence that the production system would have insignificant environmental impact? Beech4-9

In support of my suggestion in Q8, I append below as Exhibit 4-B a letter I wrote on 17 January, 2016 to respected former Executive Director of CCC, Dr Charles Lester, making a similar request after he told me that he was supporting the Cal Am project because they had told him the intake was "in the surf zone". Since I walk on the beach at Spanish Bay and observe surfers and the surf zone almost every week, I can assure you that this description by Cal Am was very far from the truth. Beech4-10

I did not receive any reply from Dr Lester, nor was the issue placed on any CCC agenda.

Weaker Revised Permit

After the voluntary suspension of testing mentioned above, CCC issued a revised permit with testing conditions weakened in at least two ways:

(1) Observed water levels and TDS levels were to be adjusted by taking account of "regional trends";
(2) Each report set a new baseline for comparison of water levels and TDS levels.

Regarding the regional trends, I have been unable to find any use of hard data as to what they are. It seems to have been sufficient to dismiss unfavorable readings as "due to regional trends", without any numerical computation. Beech4-11

Q10: Has the way that regional trends have been used in the periodic reports failed to satisfy the scientific standards required by CEQA and NEPA?

The shifting baseline was quite difficult to notice in the way it was introduced in the revised permit. The complete explanation is appended as Exhibit 4-C, but the essence of it is that it provides a loophole so large that "it would be possible to have a 1.4 feet drop in level each week for a year, i.e. a drop of over 70 feet, without raising a threshold event (stop pumping and notify Executive Director). Similarly, the TDS levels could rise 1,900 ppm each week for only 10 weeks from around 22,000 ppm to 41,000 ppm, which is beyond the high end of seawater concentrations, and into brine territory, without raising a threshold event."

In the email of Exhibit 4-C, I suggested to Mr Luster that it must be an editorial mistake, but he (and, I believe, HWG) continued to use the loophole interpretation, thus making the thresholds (designed to protect neighboring land from harm due to the testing) almost certain never to be reached.

Q11: Is not the loophole interpretation of the shifting baseline scientifically absurd?

Q12: Given the conflicted nature of HWG, have you accepted their reports without question, or have you checked on their scientific credibility?

Q13: What interpretation of the revised baseline definition have you used?

Beech4-11 cont.

Disconnect between Data and Findings

The hundreds of pages of indigestible instrument data in the weekly and monthly test well reports have presumably been used in some way, but I have not found any explanation of how this is done. For example in reducing the data recorded at 5-minute or 15-minute intervals to single points on a summary graph, one might use the mean for the day, the median, an arbitrarily selected value, or none of the above.

Q14: How is the instrument data used to plot the graphs?

Beech4-12

Q15: How is the vital salinity graph (apparently hand drawn, and without visible means of data support), computed?

Beech4-13

Respectfully submitted,

David Beech

Cal-Am Residential Ratepayer
Monterey, CA 93940

EXHIBIT 4-A

Questions for the HydroGeologic Working Group of the MPWSP.

1.Who, specifically, reports the data to montereywatersupply.org website, the public website required by permit #A-3-MRA-1410050-A1 ?
2. Why was the laboratory water quality sampling tests suspended between July 29 and December 19, 2015?
3. Why was the laboratory water quality sampling test taken on or about December 20, 2015 as indicated on conductance graph MW4 not reported in monthly monitoring report #2, released January 13, 2016?
4. Who takes the weekly hand samples for conductance and water depth at MW4? Why are those results not posted on montereywatersupply.org?
5. How are “regional trends” determined? Is there data to substantiate “regional trends” as real and quantifiable? Who at the CCC reviews the rationale for determining “regional trends”? Why is this information not available on montereywatersupply.org?
6. Why does the language of permit #A-3-MRA-1410050-A1 indicate “minimal effects at the monitoring well” when Table 2 in the monthly reports indicate that the threshold was exceeded in early May after only two weeks of continuous pumping?
7. Why was the well not suspended on May 6 as required by the permit for exceeding 2000ppm of rise in tds?
8. MPWSP Technical Memorandum “Baseline Water and Total Dissolved Solids Levels Test Slant Well Area” submitted to HWG and dated 4/20/15 shows a table 2 with a MW4 baseline reading of March 6 as 17,900, and April 2 and 17,500. This document was submitted to establish the baseline at all the wells in the project, right?
9. Doesn’t the drop in tds from March to April indicate that seawater intrusion was in a state of reversal before the slant well began pumping? Why or why not?
10. Will Monthly monitoring report # 3, due this week, contain table 2, the data table with the Laboratory results for TDS at MW4M and MW4S, that currently appear in Monthly reports #1 and #2. Will it be updated to reflect the results of the laboratory water quality sampling events on or about Dec 20, 2015 and January 26, 2016?
11. What is the most current TDS reading at MW4M?
12. How can it be verified that the slant well has been running at 2000gpm “24/7” since pumping resumed on or about October 27, 2015. Who determines the volume at the well head? How is it determined? Why are those results not posted on montereywatersupply.org?

Termination of Cal Am Slant Well Test

Dear Dr Lester,

1 Introduction

I write to notify you of a severe problem with the Cal Am Slant Well Test at the Cemex site in Marina, CA, for which CCC granted a permit at their November 2014 meeting (renewed in October 2015 after a halt in testing).

In fact, I aim to demonstrate that the newly-discovered problem is so severe that CCC should rescind that permit. After various serious problems already reported by others, I submit that a "killer" has now surfaced, as shown in boldface below.

Please confirm that submission of this letter is sufficient notice to become part of the public record, and for the issue to be investigated and acted upon by CCC.

Otherwise, please indicate what other formalities are required to achieve this.

2 Executive Summary

- The slant well concept was introduced to CCC as an ecologically-friendly way to draw ocean water from Monterey Bay for desalination

- The design was altered in a bait-and-switch manner until just before permit approval, such that **the test well no longer has subocean intake, but now draws entirely the brackish water of the already overdrafted 180 foot aquifer beneath the beach and dunes of Marina**

- **The eight intended production wells are similarly located**

- **With the abandonment of subocean intake, there is absolutely no good reason to employ the exceedingly risky and expensive slant well technology to draw water from beneath the beach and dunes**

- CCC should rescind the testing permit before any more ratepayer money is spent on this wasteful and deceptive project

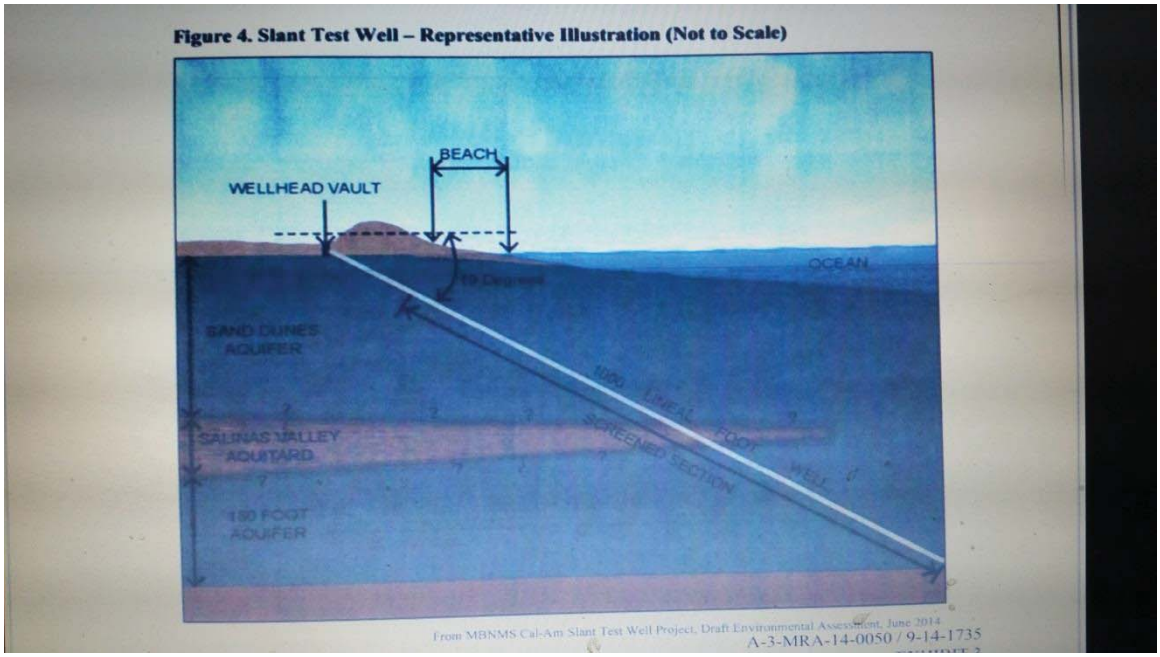
- CCC should encourage the competing People's Project and DeepWater Desal, both using a genuine seawater intake at Moss Landing, to submit their DEIRs as soon as possible, and request any CCC permits necessary

2. Precise Location of Test Slant Well

At the December 2015 CCC meeting in Monterey, I spoke briefly in initial Public Comment to alert the Commission to the fact that the Cal Am test slant well did not have subocean intake, but was now "subsurface" at the shoreline. In your Director's Report, Dr. Lester, you were kind enough to refer to this, and said that you had been assured that although the well had been shortened, the intake was "in the surf zone".

This led me to search the official documentation accessible on line, to discover the more precise facts that I am reporting in this submission.

The first illustration I encountered was Exhibit 3 of the package that Commissioners would have seen in deciding the Appeal and granting the test well permit in November 2014.



This gives an immediate impression that the well extends way under the OCEAN as it says (barely legibly, even in the original – see http://documents.coastal.ca.gov/reports/2014/11/W14a-s-11-2014.pdf). This illustration, besides being "Not to Scale", was not kept up to date with the text of the permit, so it says along the well bore "1000 LINEAL FEET", and, given the position of the original WELLHEAD VAULT at 450 feet inland from mean sea level, the well length is exaggerated to look as though it is over 2000 feet. This would not matter so much were it not for the fact that most of the Coastal

Commissioners, with their almost impossible reading load, would have formed their main impression from this picture. Probably most CalAm customers still think this is roughly the slant well that is being tested – it was only a few months ago that I personally began to discover that it was not.

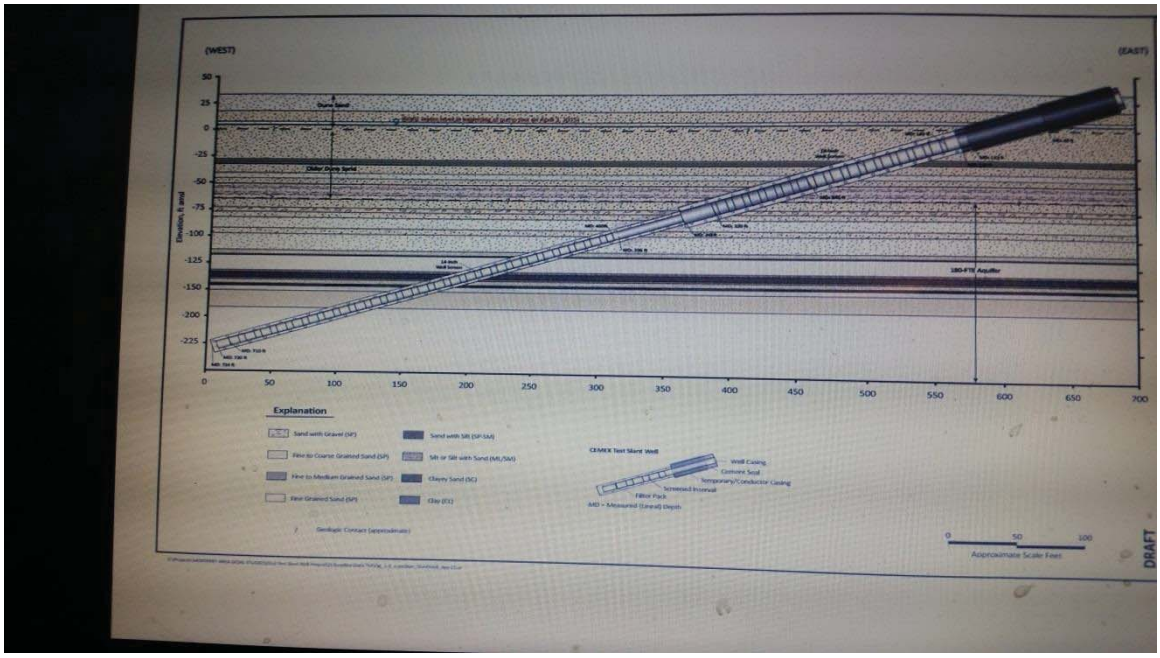
In addition to the textual changes of the well length, which resulted in a test well of 724 lineal feet as built, the following change was introduced at the last moment in the Addendum to the staff report
http://documents.coastal.ca.gov/reports/2014/11/W14a-s-11-2014.pdf

Page 2, Project Description: "The test wellhead would be located approximately ~~450~~650 feet inland of mean sea level at an elevation of about 25 feet."

This apparently trivial change brought the whole well 200 feet further inland.

Seen in cross-section, the actual test well is shown below:

http://documents.coastal.ca.gov/reports/2015/10/Tu15a-10-2015.pdf
EXHIBIT 2



Note that the horizontal length of the well is shown as less than 700 feet, consistent with the following calculation:

Test well bore length = 724 feet (reduced from 1000 feet)
Horizontal distance = 724 x cosine 19 degrees = 724 x 0.9455 = 685 feet
Horizontal distance from wellhead to mean sea level = 650 feet (increased from 450 feet)

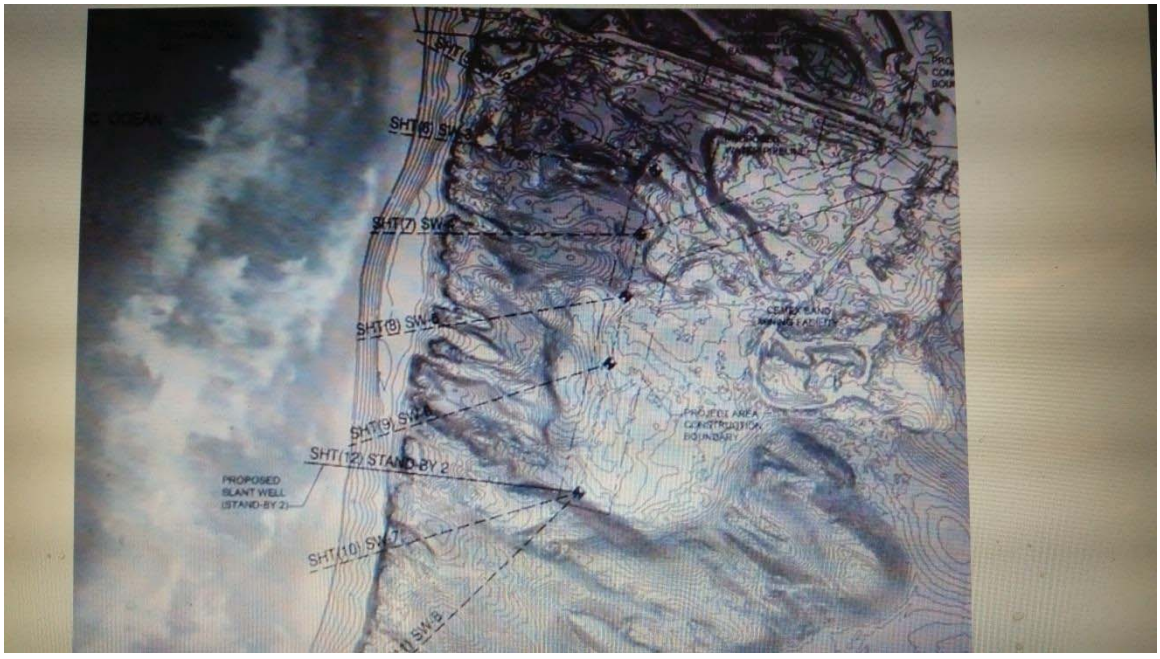
Therefore, end of well = 685 – 650 = **35 feet beyond mean sea level**

THIS IS NOT UNDER ANY SURF ZONE

From the above cross-sectional schematic, it is clear that **the screened intake extends (in this approximate diagram) from top to bottom of the 180 foot aquifer, beneath the beach and dunes, rather than being subocean.**

I was surprised to discover on www.watersupplyproject.org , under PROCUREMENT, that Cal Am has already completed the RFP process and signed contracts for slant well drilling, desalination, and transport pipelines, long before slant well testing is complete, let alone project approval. But you must be already aware of this, and of the alteration of the slant angles from 19 degrees to 14 degrees, without any apparent testing of the latter,

The following illustration of the 8 production wells confirms that the wells are intended to stop far short of the surf zone.



3. Disappearance of Any Need for Slant Wells

In making these progressive changes to the location of the test slant well, **CalAm appears to have shot itself in the foot**, since the only justification for experimenting with that technology was the hope that it would provide ocean water with less potential impact on marine life than open-ocean intake, Now that the source water is from a simple aquifer under land, there is no reason to enter the realm of the high risk and high cost of slant well experiments, and every

reason to terminate the testing before it becomes even more costly to ratepayers (including the new prospect of the evaluation being double-checked by the use of supercomputers at the Lawrence Berkeley Lab. – at whose expense?)

That is not to say that Cal Am should plan instead to drill vertical wells at the Cemex site, since there is no need for anyone to be making extensive demands on the already-overdrafted 180 foot aquifer, which is apparently protected by a 1975 California Supreme Court decision. Moreover, Cal Am should not be rewarded for yet another failed and potentially ruinous project, by being allowed to start over, and again prioritize profit over successful production of water.

Fortunately, there are better solutions awaiting the encouragement of the California Coastal Commission.

4 Additional Reasons for Termination of Testing

If other reasons for termination are needed, you are probably aware that several submissions have been made to the CCC and/or CPUC on other serious problems with the slant well testing, including conflict of interest, data tampering, scientific incompetence, and delay in producing source data as ordered by ALJ Weatherford. I support all of those complaints, for the reasons that have been given by others, and I \need not repeat them.

5 Recommended Way Forward for CCC

The two projects at Moss Landing, the People's Project and DeepWater Desal, are making good progress towards their DEIRs, and both plan seawater intake. One or both of them could become suppliers of desalinated water to Cal Am, with the potential for being publicly owned and more cheaply financed. Both have goals more consistent with those of CCC for the Central Coast than does Cal Am. For example, the People's Project would be cleaning up much of a disused industrial site, and reusing existing infrastructure with existing rights.

After 20 years of failing to meet the CDO, it is time for Cal Am to step aside from attempted production and allow someone else to succeed. It would be timely for the CCC to encourage rapid progress in this direction, and emerge from an unfortunate interlude of seemingly being misled by Cal Am.

EXHIBIT 4-C

On 2/16/2016 8:43 AM, David Beech wrote:
Hello Tom,

I saw your reply to Michael Baer that you saw no permit violation on 1/29/16 because it was your reading of the October 2015 revision of Special Condition 11 that it meant the Monitoring Well 4 decreases of water level, or increases of Total Dissolved Solids, were to be compared to the previous week, and not (as previously) to the baseline at the start of testing.

I know you sincerely believe this, but it must be a mistaken reading, for two reasons.

1. It conflicts with the overview of changes given in the October permit, which states:

"Cal-Am's proposed amendment would modify Special Condition 11. The primary modification would keep the same numerical groundwater and salinity thresholds as previously approved, but would provide that they be compared to regional trends rather than be based on a static value at a single location. This modification is in recognition of monitoring data collected from early 2015 until the present that show the pumping test resulted in minimal effects at the monitoring well that were not evident at more distant monitoring sites, and that those minimal effects could readily be distinguished from other regional influences, such as municipal and seasonal agricultural groundwater pumping, that were causing much greater changes. The proposed modification specifically acknowledges these regional influences and direct the HWG and the Executive Director to consider them in their analyses. Other proposed changes to Special Condition 11 would provide additional clarity to the condition language (e.g., referring to "groundwater" rather than "water")."

Note that the "comparison to regional trends" is the only "primary modification" cited, and yet comparisons week-over-week could make a much bigger substantive difference to when a threshold is reached. And the last sentence speaks only of "increase in clarity" and not anything substantive.

So it appears that the SC11 wording is just an editorial mistake - the two major inserts should both end "compared to pre-pump test conditions". The logical alternative, that this major substantive change was slipped in without mention as a primary modification, is unthinkable, raising serious ethical issues.

2. The loophole that your reading of SC11 introduces is so large that it almost completely vitiates the threshold tests, providing virtually no protection to neighboring wells.
For example, it would be possible to have a 1.4 feet drop in level each week for a year, i.e. a drop of over 70 feet, without raising a threshold event (stop pumping and notify

Executive Director). Similarly, the TDS levels could rise 1,900 ppm each week for only 10 weeks from around 22,000 ppm to 41,000 ppm, which is beyond the high end of seawater concentrations, and into brine territory, without raising a threshold event. (The Table 2 in the report for Week 40 that I referred to yesterday to get an approximation for the baseline has vanished overnight - what is going on?)

Do you agree that this was an editorial mistake, to be corrected as I suggest?

In view of the urgency due to possible ongoing rapid seawater intrusion, could you please send me TODAY (a) the official baseline figures for MW4 water level and TDS level, and (b) the HWG calculations of water level and TDS, adjusted for regional trends on 1/29/16?

Many thanks,

David

March 2, 2017

To:

Mary Jo Borak, CEQA Lead California Public Utilities Commission c/o Environmental Science Associates 550 Kearny Street, Suite 800 San Francisco, CA 94108	Karen Grimmer, NEPA Lead Monterey Bay National Marine Sanctuary 99 Pacific Avenue Building 455a Monterey, CA 93940

DEIR/DEIS, MONTEREY PENINSULA WATER SUPPLY PROJECT

PUBLIC COMMENT BEECH-5

Thank you for the opportunity to continue to comment on this very large Draft EIR/EIS, which has immense implications for the Monterey Peninsula environment, and for all those of us who are Cal-Am ratepayers. I should be grateful to receive your answers to my questions below.

I should like to take advantage of the newly extended comment period by submitting my fifth set of comments, which will be mercifully short although requesting decisive action.

Expedited Termination of Cal Am Desal Project

The extension of the comment period will give the Lead Agencies and the DEIR/EIS team a chance to review comments already received. What will likely become clear to many of you is that this is a project that has been on life support for too long already, and that it is time to pull the plug.

Also, to switch to a marine metaphor, when a project has been torpedoed, it can go down very quickly to its subsurface grave. I have seen an even larger project in the computer industry dead in the water within a week, once the fatal flaws of its experimental technology were demonstrated to top management. Any company with its own money at stake knows there are times when it has to cut its losses. Since Cal-Am does not have this pressure, it falls to the Lead Agencies for the EIR and the EIS to make timely decisions to cut the community's losses, in order to avoid being negligent of their duties.

Beech5-1

Q1: Will the CPUC and/or the MBNMS expedite whatever action is necessary to terminate the Cal Am Desal Project?

Not only would an early decision put a cap on stranded costs, it would accelerate a solution by necessitating immediate work on a superior alternative.

Q2: Will the CPUC and/or the MBNMS immediately encourage development of a superior alternative, such as an expanded portfolio that includes the new component Aquifer Storage and Recovery (Salinas River)?

(Please see summary of "Plan C" in earlier Beech-3 comments, and the start on an engineering specification for alternative 9 in the RBF 2011 Technical Memorandum "Cost Analysis of Water Supply Alternatives" https://www.scribd.com/document/68554233/Technical-Memorandum-RBF-Consulting pp.14-16.)

Beech5-2

With positive answers to Q1 and Q2 above, the talents of valued consultants such as ESA would be much more profitably applied to constructive groundwork for a superior alternative than in attempting to defend an indefensible status quo. Indeed, if those positive answers were available by the revised comment deadline, the task of honest and scientific response to comments would be immensely simplified and abbreviated. This may seem a tight schedule, but 4 weeks is four times as long as it took the company I mentioned earlier to finally kill a project and reassign, I believe, about 2,000 people.

Q3: Can positive answers be secured to Q1 and Q2 by March 29, 2017, or shortly thereafter?

Beech5-3

The simplest way to secure positive answers to all the above questions would be if Cal-Am itself made the call, via whatever are the correct and most time-efficient processes. If the present project is seen as doomed to failure sooner or later, the timing of its replacement becomes a calculation of the public relations benefit and the long-term role of the company in the Monterey Peninsula (and potentially Marina and Fort Ord) areas. In the light of DEIR/EIS comments received, "sooner" could now be seen by Cal-Am as the best choice.

"Sooner" termination of the current Cal Am Desal Project could also result in "very much sooner" delivery of water from replacement projects, which would use conventional technology and be less exposed to the glacial delays likely from well-founded litigation against the Cal Am project (if approved).

Q4: Is it correct that under CEQA law (and NEPA law), termination of a project, whether voluntarily by the applicant or due to denial or disapproval by the lead agency, removes any need to continue work on the EIR (and EIS)?

Beech5-4

If the answer to Q4 is positive (confirmed e.g. by *Las Lomas Land Co. v City of Los Angeles 2009*), an early termination could result in even greater savings in the costs of the EIR and EIS themselves. Although this would result in some loss of future revenue to the consultants processing this document, they have already received much more income than expected, thanks to the lengthy revision and recirculation as a Draft EIR/EIS!

From the point of view of the lead agencies, CPUC especially, they may feel that they have been very tolerant of Cal-Am since the end of the Regional Project, paying out more

and more rope as they wait for a project that is legitimate, environmentally acceptable, and technologically proven ready for 24x7 operation, besides – a distant fourth – being as economically beneficial to the ratepayers as it is to Cal-Am. What the lead agencies must be seeing at this moment, if they are honest, is that Cal-Am has let them down, offering a project that fails on all four counts. Instead of paying out more rope, now is the time for the lead agencies to haul Cal-Am out of this foray into the water supply business, and look, first. to the People's Project and DeepWater Desal for desalinated water, and, second, to Monterey County agencies like the Monterey Regional Water Pollution Control Agency (already well advanced with design and permitting as the lead agency for Pure Water Monterey) for diverted surface water and more recycled water.

The above discussion should establish that I am seeking an accelerated viable solution, and not further delay, which would be intolerable for a community thirsting for a solution after a series of failed Cal-Am projects (and after the company's withdrawal from a viable solution, the Regional Project, which could have actually been delivering desalinated water by now).

There is a feeling in the community that the lead agencies wish to approve the Cal Am project because they consider it the only game in town likely to succeed, despite Cal Am's none-for-plenty record, and evidence presented to you in Public Comments, that suggest the contrary -- that it might be the least likely to succeed.

Q5: Do you regard the Cal Am Desal Project as the only game in town that is likely to succeed? Beech5-5

Q6: Having studied Public Comments received to this Draft EIR/EIS, do you now see evidence therein that causes you to lower your ranking of the Cal Am Desal Project, and to rate more highly the People's Project and DeepWater Desal, and to give encouraging consideration to an additional ASR(Salinas River) Project? Beech5-6

Finale: Long-term Needs

Finally, it may not have been obvious why I limited the benefit of ASR(Salinas River) in Beech-3 to the "short-to-medium term", when the runoff from the Salinas River could easily satisfy long-term needs. The reason is that expansion of the facility would eventually be gated by the estimated 53,000 acre-foot storage capacity of the Seaside Aquifer. Long-term needs beyond this could be satisfied by increased use of desalinated water, and/or a new reservoir, depending on community wishes and economic factors, to be decided many years in the future.

Respectfully submitted,

David Beech (Cal-Am Residential Ratepayer, Monterey)

David Beech
Letter 6

Dear DEIR/EIS Team,

Please insert the following after the Q6 paragraph in my earlier submission Beech-5:

Thought of the Moment (seen on the internet today)

No matter how far you have gone on the wrong road, turn back. -Turkish proverb

Q7: Do you agree, having reviewed many critical public comments, that this wisdom may be applicable to the Cal-Am Desal Project?

Beech6-1

Respectfully submitted,

David Beech (Cal-Am Residential Ratepayer, Monterey)

MPWSP DEIR Public Commentary

Commentary on Monterey Peninsula Water Supply Project (MPWSP) DEIR by Kathy Biala, resident of Marina, Citizens for Just Water ("Just Water") - 02.23.17

Respectfully Submitted to:

California Public Utilities Commission c/o Environmental Science Associates 550 Kearny Street, Suite 800 San Francisco, CA 94108	Karen Grimmer, NEPA Lead Monterey Bay National Marine Sanctuary 99 Pacific Avenue, Building 455a Monterey, CA 93940

Pg/Section	Cited text	Comments/Questions	
2.6.2 Project Water Rights pg. 2-35	***#1. Topic: Water rights as justification of "No Harm".*** Pg. 2-35 As noted above, CalAm extraction of seawater does not require water rights. The question presented is thus whether Basin water rights holders would be **injured or harmed** by virtue of withdrawal from the Basin of any amount of water that is not purely seawater. The extensive groundwater modeling conducted for this EIR/EIS and discussed in detail in the Groundwater Resources section and in **Appendix E2** is different from that conducted for the 2015 Draft EIR on the MPWSP. **As explained in Chapter 4.4, Groundwater Resources, the modeling is specifically targeted to isolating the change in groundwater levels that would be generated by the MPWSP.** ***This modeling, however, cannot project the amount of Basin water that is expected to be drawn into the supply wells*****.**	As the first sentence below the section title of "2.6.2 Project Water Rights", Cal-Am asserts that seawater extraction does not require water rights; this is then followed by the second sentence which speaks of **"injury or harm" as if legal rights to a water source somehow is contingent upon doing no harm**. If this were the case, Cal-Am would have had no rights to the Carmel River and Seaside Groundwater Basin! Does not doing "harm" give an agency water rights? Further, there is the convenient omission that extracting "groundwater" (versus "seawater") ***does*** require water rights! And Cal-Am does plan to extract the groundwater from the Salinas Valley Groundwater Basis. **Does Cal-Am have the legal rights to take water from the Salinas Valley Groundwater Basin? Has this been adjudicated? If not, why has the project been allowed to go forward without the basic issue of water rights not clearly established? Is there any CPUC written process that would allow such a practice of advancing a huge water project for approvals without first producing evidence that water rights exist? Is this legally defensible or does CPUC, in addition to Cal-Am, bear liability should the MPWSP project result in damage to the Salinas Valley Groundwater Basin without definitive water rights in place? At what point in the CPUC administrative process, must water rights be defined and by what agencies? If CPUC concludes that there are no established, definitive water rights of Cal-Am to the Salinas Valley Groundwater, will that end the entire approval of MPWSP? Would a moratorium of all DEIR approvals be in order until CPUC water rights processes are completed?** Further, the whole notion of harm (as distinct from legal water rights) must be evaluated not just at a contained location of the slant well site	Biala1-1 Biala1-2 Biala1-3

Pg/Section	Cited text	Comments/Questions	
		but from the standpoint of impact to a *regional* source of water since the slant wells pull water from the 180' aquifer. We do not doubt Cal-Am's admission that their "***modeling cannot project the amount of Basin water that is expected to be drawn into the supply wells*****".** **But the salient point is that this is precisely the information needed to assess the degree of harm that might occur by collective overdrafting of all aquifers. If the current modeling cannot produce this data of the danger points for overdrafting the Basin, then is it not a compelling reason for some other more comprehensive model to be created that will do so? Is there any legal basis upon which project approvals must be delayed until such basic water rights have been established? If so, will CPUC institute this delay in the DEIR process?**	Biala1-3 cont.
2.6 Water Rights pg. 2-30	***#2. Topic: Degree of likelihood that Cal-Am has water rights.*** The CPUC is not the arbiter of whether CalAm possesses water rights for the project and nothing in this EIR/EIS should be construed as the CPUC's opinion regarding such rights, **except to the extent that the CPUC must determine whether there is a *sufficient degree of likelihood* that CalAm will possess rights to the water that would supply the desalination plant such that the proposed project can be deemed to be *feasible*.**"	**Please clarify on what specific basis will the project be deemed "feasible" based on "sufficient likelihood of possessing water rights"? What specific agencies or legal experts has CPUC sought out to determine if there is "sufficient likelihood" of water rights? If some of these agencies are government agencies, would it not be a conflict of interest for a premature determination to be informally given by CPUC without due process including public hearing and/or independent legal inquiry?** Cal-Am has already spent millions on this project and thereby presents more pressures for approval so that this money will not appear to be "wasted". CPUC must exercise great caution to not allow this factor to influence their decisions regarding this project. The failed Dana Point Doheny slant well resulted in an almost $3M loss among four out of five agencies who opted out but this was deemed preferable to going forward on the project (Minutes of the Joint Board of Directors and Commission Meeting of the Laguna Beach county Water District, March 11, 2014). Money expended is not a background reason to justify DEIR approvals.	Biala1-4
2.6.2 Project Water Rights pg. 2-35	***#3. Topic: Misleading distinctions made between "brackish" water versus "fresh, potable water".*** **Due to decades of seawater intrusion in the area, any Basin water extracted by the supply wells would be brackish water, which is a combination of ocean water and water that originated from the inland aquifers of**	**Cal-Am asserts: "Due to decades of seawater intrusion in the area, any Basin water extracted by the supply wells would be brackish water".** According to Hydrogeologist Curtis Hopkins, "**CalAm's 2014/15 modeling inaccurately assumes that the entirety of the geographical area of the Salinas Valley Groundwater Basin**	Biala1-5

Pg/Section	Cited text	Comments/Questions
	the Basin. CalAm proposes as part of the MPWSP to return to the Basin (in the manner further described below) the fresh water portion of the brackish source water. **In other words, although the groundwater modeling indicates that the Basin water that could be withdrawn by the supply wells would be brackish and thus not fresh, potable water, the MPWSP would return to the Basin desalinated product water in the amount of the fresh water molecules that make up the withdrawn brackish Basin water. In that the quantity of such fresh water component of the supply water is not currently known, the modeling and the EIR/EIS analysis assess a range of return water between 0 and 12 percent of the source water.**	**contains brackish or high salinity ocean water rather than fresh water**. Recent monitoring data developed for the Test Slant Well (TSW) project demonstrates all of these assumptions are false." (MEMORANDUM to Mr. Keith Van Der Maaten, General Manager, Marina Coast Water District dated January 22, 2016). The presence of a perched layer of fresh water has been identified. Cal-Am states: **"In that the quantity of such fresh water component of the supply water is not currently known, the modeling and the EIR/EIS analysis assess a range of return water between 0 and 12 percent of the source water."** How is it that Cal-Am can openly state the quantity of fresh water components of supply water is ***"not currently known"*** when this information is crucial to the determination of harm? What other methods not currently being utilized can provide more data on this fundamental issue, such that Cal-Am does not have to report a "guess" of return water of "0-12 %"? This is scientifically unacceptable. Cal-Am further concludes that: "…the Basin water that could be withdrawn by the supply wells would be brackish and thus not fresh, potable water…" is a purposely misleading distinction that minimizes the fact that brackish water contains fresh water and is part of a regional subsurface aquifer network. Does CPUC accept such misleading statements? Using brackish water is part of long term strategies of the Marina Coast Water District for developing alternative sources of water as it contains fresh water. It is NOT "un-useable, unwanted water" as Cal-Am suggests. This representation of the value of brackish water needs to be corrected in the DEIR. Further, returning a portion of fresh water to an alternate site in the Basin does not preclude the possibility of extensive, irreversible damage to an already fragile aquifer system. The two are unrelated. Without knowing first what kind of overall impact the MPWSP is likely to have over ***regional*** water sources, offering return water is but a ploy to justify a lack of responsible inquiry. **Is there any scientific evidence that water extracted from Marina and returned to Castroville will "benefit" the water source of MCWD, as Cal-Am claims? Will Cal-Am be expected to do a complete and accurate baseline study of the *regional* aquifer impacts of their project? If not, why not?**

Biala1-5 cont.

Biala1-6

Biala1-7

Biala1-8

Pg/Section	Cited text	Comments/Questions
2.6.2 Project Water Rights pg. 2-37	***#4. Topic: Question whether the slant wells access aquifers versus merely "brackish" water.*** **Pg. 2-37 The entirety of the geographical area of the Basin that would be affected by the project <u>contains brackish water rather than fresh water</u>.** Based on the groundwater modeling and as discussed in the Groundwater Resources section, while **<u>the project may actually improve the Basin's seawater intrusion issue</u> by** slowing the seawater interface line from advancing more inland, **<u>the project is not forecasted to draw any fresh water through the MPWSP source water supply wells over the life of the project</u>.** If indeed no fresh water is withdrawn by the project, then no physical solution in the form of return to the Basin of fresh water (or other off-setting mechanism to alleviate the harm) would be required in order for CalAm to secure and maintain water rights for the project feedwater**.**	Firstly, the statement that "**the geographical area of the Basin that would be affected by the project <u>contains brackish water rather than fresh water</u>" is not true.** According to Hydrologist Curtis Hopkins, "the salinity of seawater up to 8 miles inland is not as assumed by Cal-Am in its modeling and evaluation of return water requirements. **The presence of a perched layer of fresh water was not included in Cal-Am's 2014 modeling."** (MEMORANDUM to Mr. Keith Van Der Maaten, General Manager, Marina Coast Water District dated January 22, 2016). **Will the modeling be revised to include this perched layer of fresh water and will the modeling be reviewed again by objective, independent experts? If the presence of this important perched layer was not known by Cal-Am, what other significant subsurface structures are also not known? Does this significant lapse in Cal-Am baseline data suggest that there could be other significant missing information such that the model is currently invalid?** Secondly, the notion being purported that all "brackish" water has no origins in or links to fresh water aquifers is false. Cal-Am is making the distinction between "brackish/ unuseable" water (pumped from their slant wells) vs potable, fresh water". In the section 2.6.2 (Pg. 127), Cal-Am accurately states **brackish water is "a combination of ocean water and water that originated from the inland aquifers of the Basin".** As a note, an aquifer whether "inland" (Cal-Am's words) or entering the ocean is still the same aquifer. However, Cal-Am continues to focus exclusively on the "unuseable" aspect of brackish water and not on the association of brackish water with fresh water aquifers. This distinction between brackish water as completely different from fresh water is intentionally promoted to support the false claim that "fresh water is not withdrawn by the project" (because it is brackish) and therefore no harm has been done and therefore there is no need to secure water rights. **Is there acceptance by CPUC of such leaps in formulations for dismissal of Cal-Am's need to have water rights? What proof of each part of this formulation has been validated by Cal-Am?** Further, Hydrogeologist Curtis Hopkins, notes that "**monitoring Well-7 is no longer contaminated by high concentrations of seawater** and is likely explained by the changing hydrogeological conditions resulting **from the efforts of MCWD and others to reduce pumping**

Biala1-9

Biala1-10

Biala1-11

Pg/Section	Cited text	Comments/Questions	
		in the area". Responsible curtailing of pumping results in decreases of seawater contamination. Decreases of seawater contamination does NOT occur through massive pumping as would occur in the MPWSP project and which Cal-Am asserts benefits the basin. (MEMORANDUM to Mr. Keith Van Der Maaten, General Manager, Marina Coast Water District dated January 22, 2016).	Biala1-11 cont.
	Pg. 2-37 If the water in the Basin were to become fresher in the future such that the MPWSP supply wells were drawing fresh water from the Basin, then a physical solution (such as the proposed return component of the project, discussed below) would be needed in order for CalAm to maintain rights to the Basin water for the project.	The possibility that drawing fresh water **in the future** somehow ***determines*** MPWSP water rights in the Basin seems preposterous and needs to be challenged. Where is this idea substantiated in any legal precedents?	Biala1-12
		The theory that pumping a large volume of groundwater i.e. 24.1 million gallons per day in the MPWSP project, will slow the advance of seawater intrusion must be proven in peer-reviewed scientific research. Where is the scientific evidence to support such a theory?	Biala1-13
		It should be noted that the MPWSP project intends to pump 27,000-32,000 acre feet of water per year at full capacity whereas the total current pumping of Marina Coast Water District (MCWD) is approximately 2,700-3,800 acre feet per year (one seventh the amount in the proposed MPWSP). Even with MCWD's current pumping, maintaining sustainable water supplies is a regional and ongoing challenge.	Biala1-14
Pg. 1-9 1.4.2 The Monterey Peninsula Water Supply Project	***#5. Topic: False premise of slant wells not accessing fresh water; evidence that slant wells are in 180' aquifer.*** The MPWSP includes the following proposed facilities, all of which are described in detail, and locations shown on figures, in Chapter 3: **A seawater intake system, which would consist of 10 subsurface slant wells (eight active and two on standby) extending offshore into the submerged lands of Monterey Bay at the CEMEX sand mining facility in the City of Marina, and a Source Water Pipeline;**	A "seawater intake system" means that **seawater** is pumped, NOT **fresh water** or **brackish water (that has mixed fresh and seawater);** brackish signifies connection to the freshwater aquifers somewhere along the extent of the aquifer. By pumping brackish water, the MPWSP slant test well is also pumping from fresh water resources. This is a complete misrepresentation of this project as it directly taps into the aquifers currently being used to provide needed water to another region that has water rights to this water, be it fresh or brackish.	Biala1-15
2.6 Water Rights pg. 2-30 Geosciences MPWSP Hydrogeologic Investigation,	The proposed project (MPSWP) and Alternative 5a are designed to take supply water from the ocean via	**The slant wells are, in fact, in the 180' aquifer. This is clearly shown in Appendix E-2. The Cal-Am MPWSP references to brackish water as "unuseable" water attempts to obfuscate the fact that the slant wells are accessing the 180' aquifer, a current**	Biala1-16

Pg/Section	Cited text	Comments/Questions	
Technical Memorandum (TM-1), Summary of Results-Exploratory Borehole **Appendix E-2**	underground slant wells that draw water from the earth underneath the ocean. **Appendix E-2 Geosciences diagrams show slant well in the 180' aquifer of the Salinas Groundwater Basin.**	**source of regional water! Does CPUC agree that the slant wells are clearly drawing water from the 180' aquifer? Why is a percentage of <u>any</u> fresh water to be drawn in MPWSP deemed acceptable? On what basis is this made?**	Biala1-16 cont.
2.6.2 Project Water Rights pg. 2-35 Executive Summary ES-13-14	***#6. Topic: Harm/ injury/water rights.*** **Pg. 2-35** Here, though, the Groundwater Resources section of this EIR/EIS strives to and does in fact effectively and meaningfully analyze two of the three precise concepts of "harm" or "injury" set forth in the Report. **These two criteria *are reduction in the availability of fresh water* and <u>reduction of water quality</u>** . pg. 40 The SWRCB has indicated that for CalAm to appropriate CalAm Monterey Peninsula Water Project groundwater from the SVGB, **<u>the MPWSP EIR/EIS must demonstrate that the proposed project will not harm or cause injury to other basin users</u>** (SWRCB, 2013) and made certain recommendations for further study.	The three precise concepts of **"harm" or "injury" under section Project Water Rights 2.6 are identified as follows:** 1) reduction in the availability of fresh water 2) reduction of water quality 3) reduction in groundwater levels that requires users to spend additional funds to extract water. These issues of harm and injury criteria as listed above **must be applied to the ***<u>regional</u>* **Salinas Valley Groundwater Basin,** as the aquifers are extended across the region, and flow to the ocean, as well as having random, and at this point unknown, connections between the layers through fissures. The pumping of 180 foot aquifer water and the increased impact of regional saltwater intrusion are the key harms for the SVGB stakeholders. Harm and injury cannot be isolated to one part of one aquifer in one limited area. **Have the impacts to the Salinas Valley Groundwater Basin been carefully analyzed with regard to these three "harms"? Will the current modeling provide accurate predictive information of these three harms? Would a comprehensive Electrical Resistivity Tomography regional mapping be beneficial to identification of potential harms to the Salinas Valley Groundwater Basin?**	Biala1-17
2.6.2 Project Water Rights pg. 2-36	***#7. Topic: Water rights and No Harm*.** Pg. 2-36 Applying the thresholds stated above, the analysis **concludes that the MPWSP would not result in a significant impact to groundwater resources.** It would not reduce, or affect at all, the availability of fresh water (only brackish water from the Basin is projected to be drawn into the MPWSP supply); ***would not lower***	There are numerous re-statements claiming general "no harm" without giving specific, scientific data that would support such global claims of "no harm" or "injury". Per Cal-Am's own statements: **"Groundwater Resources, the modeling is specifically targeted to isolating the change in groundwater levels that would be generated by the MPWSP. *This modeling, however, cannot project***	Biala1-18

Pg/Section	Cited text	Comments/Questions	
	groundwater levels in the Basin so as to affect the water supply of any groundwater users or substantially deplete aquifer volume; **and would not alter or reduce groundwater quality.**	***the amount of Basin water that is expected to be drawn into the supply wells*****."** (2.6.2 Project Water Rights pg.127) **Without such information, how can Cal-Am claim that the MPWSP "would not lower groundwater levels in the Basin" or would not substantially deplete aquifer volume? This projective information about the amount of Basin water to be drawn into the supply wells is crucial; how can this vital information be obtained? Would having this information, change the modeling?**	Biala1-18 cont.
2.6.2 Project Water Rights pg. 2-36	***#8. Topic: Test Slant Well decrease in water level drawdown.*** **Pg. 2-36 Due to the long-degraded condition of water in the Basin within the radius of influence (the area within which the project could affect groundwater levels), there are few active wells that could potentially be affected by the project. As discussed in detail in the Section 4.4, Groundwater Resources, there are only three active supply wells with well screens across the Dune Sand Aquifer or 180-Foot Equivalent Aquifer within the area where the project may cause groundwater levels to decrease by more than 1 foot but no more than 5 feet.[35]** These three wells are located at the Monterey Peninsula Landfill and are used for dust control. Given that the well pumps and the screens are set at least tens of feet below the existing groundwater level**, a decrease in the levels of less than 5 feet would not cause injury to this overlying user.** There are four active wells with well screens in the 400-Foot Aquifer. …**Due to the brackish to saline quality of the groundwater within the 400-Foot Aquifer, these wells would not be expected to supply drinking water. The Groundwater Resources section concludes as to all active wells that a water level decline between 1 and 5 feet would not expose well screens, cause damage, or reduce yield in the groundwater supply wells that could be influenced by the MPWSP.** All in all, the project was determined not to result in a significant impact in terms of groundwater supplies either quantitatively or qualitatively. **Thus, it appears reasonable to conclude that the MPWSP would not**	**What is the scientific basis upon which they can assert " a decrease in the (groundwater) levels of <u>less than 5 feet</u> would not cause injury to this overlying user." Where is the scientific proof of this? Over what period of time and under what pumping conditions are they predicting "levels of less than 5 feet"?** An unsubstantiated statement is not sufficient to quell real concerns about the MPWSP causing "no harm". Proving "no harm", in fact, requires the highest standard of scientific review and modeling. The CCC defined excessive decline in water level more than one foot; this was, in fact, exceeded and the test well was stopped. **What levels are currently occurring? What were Cal-Am's reason for the increase in groundwater levels? Was this answer given scrutiny by third party experts? What model or scientific data justified the CCC original parameter of one foot decline in water level? Are those standards still the ones in place and if not, what was the process to modify them such that Cal-Am is now allowed to decrease water levels greater than one foot? How long was the pumping interrupted? Does interrupting the pumping in itself cause an invalidation of the test?** A five foot decrease in levels could be a large difference when applying to a manmade intervention impacting subsurface groundwater tables. Stating that **"it <u>appears</u> *reasonable* to conclude that the MPWSP would not result in harm** …" is not acceptable. Scientific research to answer unknowns is driven by defining "levels of uncertainty" applying scientific parameters. It is unacceptable to make guesses when it "appears" to be favorable; one does not keep moving the target to fit the data, especially when the issue of harm is being addressed. This is another example of sloppy science being employed by Cal-Am. The Electrical Resistivity Tomography would be a more accurate and detailed record of changes in the aquifers that could substantiate or not substantiate Cal-Am's claims. **If CPUC demands proof of Cal-Am's**	Biala1-19 Biala1-20 Biala1-21

	result in harm or injury to the water rights of legal users of water in the Basin in terms of fresh water supply or water quality, two of the Report's three injury criteria relative to the development of legal water rights.	**"no harm" claim, can Cal-Am be compelled to pay for a regional ERT study rather than CPUC merely "taking their word" on such a critical issue?** Further, the assertion that "Thus, **it appears reasonable** to conclude that **injury to the water rights of legal users** of water in the Basin in terms of fresh water supply or water quality…" makes no sense. Water rights are not "injured" or "harmed"; they are violated or not; one has the right or not. The simple question that must be answered is "Does Cal-Am have water rights to the Salinas Valley Groundwater Basin or not?" And this must be determined in a court of law and BEFORE final approvals of this project.	Biala1-21 cont. Biala1-22
Executive Summary ES-5 4.4.4.2 Groundwater Modeling ESA 4.4-43 Pg. 4.4-47 Groundwater Resources, Superposition	**#9*. Topic: Failure to apply accepted standards of scientific research methodologies.*** Executive Summary ES-5 pg. 32 The test slant well is permitted to operate until February 2018 and it is not part of the proposed project being evaluated in this EIR/EIS. If the MPWSP with subsurface slant wells at CEMEX is not approved and implemented, the test well will be removed. **4.4.4.2 Groundwater Modeling ESA-43 pg. 499** Pg. 4.4-43 The applicability or usefulness of the model depends on how closely the mathematical equations approximate the physical system being modeled. For example, models that cover an entire groundwater basin of many square miles may have cells that represent one square mile area each while models designed to evaluate smaller areas have cells representing only 200 square feet. Pg 4.4-47 Groundwater Resources, Superposition	It is entirely with disbelief that Cal-Am seeks DEIR approvals for an untested, experimental slant well technology for which no precedent is in existence and without the full results of a test! **What legal authority is CPUC operating from to potentially approve such a project without knowing the conclusions of a completed test?** The first step in any scientific methodology is observation and description of a phenomenon or group of phenomena. There is so much at risk with the MPWSP i.e. harm to the Salinas Valley Groundwater Basin that is the water source for an entire region. **Given that the accuracy and predictive ability of a model is based upon the understanding of the physical subsurface, how much more accurate is a baseline from 9 monitoring vertical wells of the MPWSP project as compared to the tens of thousands of data points of an Electrical Resistivity Tomography (ERT)?** Further, ERT subsurface imaging can extend further inland as well as reaching depths of 1200 feet versus the limitations of vertical wells presently used in the MPWSP modeling. **What future legal liabilities will there be for intentional disregard of establishing relevant and complete baseline data as the foundation for a model when such information is currently available but not sought?** The second step in any scientific methodology is formulation of a hypothesis to explain the phenomena. What were the hypotheses to be tested by the model? It is not clearly evident in the DEIR. **What were**	Biala1-23 Biala1-24 Biala1-25

Groundwater Modeling	Groundwater Modeling For this project, the NMGWM is converted to a superposition model and only solves for the groundwater changes due solely to the proposed project. These changes are independent of the effects from the other stresses on the basin such as seasonal climate and agricultural pumping trends, other pumping wells, injection wells, land use, or contributions from rivers. By using superposition, the actual effects of only the proposed project can be isolated from the combined effects of all other basin activity. For example, when the NMGWM reports a 1-foot drawdown in a well, it is understood that the one foot of drawdown would be the effect on the basin of the proposed project only. That well may experience greater drawdown due to other stresses, such as drought or other nearby pumping wells, or may experience increases in water levels due to reduced regional pumping or an extremely wet year. But the proposed project's contribution to that drawdown in the well would remain only 1-foot. Superposition is described in **Appendix E2**, Section 5.2.	**the predictions and levels of uncertainty attached to each of these predictions?** It is not clear whether the test well was merely a way to study the effects of pumping or whether it is to apply a model to verify its predictive power of established hypotheses. If the latter, and their hypothesis was to "solve the groundwater changes solely to the proposed project", "independent of the effects from the other stresses on the basin such as seasonal climate and agricultural pumping trends", **why did the model not take into account these factors so that any results obtained would have factored out these impacts and were predicted before the testing?** Note: the water table drawdown exceeded a threshold. Pumping was stopped and then was later attributed to agricultural pumping**. It would be necessary for the model to have studied and precisely calibrated the seasonal agricultural impacts on the Basin. Was this done? Can this be considered a reliable model if such basic transgressions of the scientific modeling principles are present?** Further, a target for saltwater intake from the test slant well was to be 96% but the slant well has yet to reach this (currently at 92-93%) meaning that more fresh water than expected (by the model?) is being pumped by the test slant well. **Again, the hypotheses are not being confirmed and what does this say about the model's validity? Where in the DEIR are the salinity targets in the threshold monitoring well identified and where is the data showing that the targets were not reached? What were the explanations for the target failure and will there be further research by independent scientists to study such variances? As this is a critical data related to the "harm" to the Basin, this data should be highly visible and documented and explained in the body of the DEIR.**
Hydrologic Working Group Monthly Report #14, on April 22, 2016.	Hydrologic Working Group Monthly Report #14, on April 22, 2016. Montoring Well-4 was identified as the "threshold" test well by which salinity was to be measured. Based on the MW-4 showed 17,000 parts (of chlorine) per million but on Dec. 31, 2016 it was reported at 22,000 parts per million, meaning the water pumped was showing more salinity. This represented a 30% increase over the baseline. There are no explanations of this phenomenon yet Cal-Am claims there is no impact to saltwater intrusion. Further irregularities in the HWG reports are: On April 29, 2015 a drop to 19.800 parts per million was recorded (change from the previous report of 20,300 parts per million) and this is recorded on the chart as "Used different analytical method"! A decrease in salinity favors Cal-Am. On Oct. 1, 2016 another decrease in the degree of salinity was reported in the 180 foot aquifer after a	The third step in any scientific methodology is to predict the existence of other phenomena, or to predict quantitatively the results of new observations. Thus far, two instances of predictive ability of this current model has been unanticipated: 1) amount of seawater draw and 2) the greater than 1.5 foot drop in water level at the pumping site. What were the initial targets for salinity increase in the test slant well *as predicted by the model?* As with the greater than 1.5 foot water level drawdown, this model has not verified any reliable predictability as to seasonal or agricultural impacts…a gross weakness of this model. **This model failed to quantify the most obvious and significant impacts in their data before testing began i.e. degree of water level drawdown and**

Executive Summary Es-14	"transducer was replaced". This type of lack of scientific rigor is highly suspect. **Executive Summary pg. ES-14** The Hydrogeologic Working Group (HWG) developed a work plan in order to reach agreement about the studies, well tests, field work, modeling, monitoring, and other data analyses that is needed to assess and characterize whether and to what extent the proposed operation of the MPWSP may adversely affect the SVGB and the water supply available to legal water users thereof. Data from the DEIR reference to Hydrogeologic Working Group (HWG) website, Monthly Report #14; There have a large number of stops and starts of data collection of both short and long durations. A sampling of such interruptions as documented by the HWG records is as follows (Monthly Report #14): **Short durations:** On January 19, 2016 22 hour stoppage but was again turned off 22 hours after restarting. Jan. 22, 2016 stoppage for 35 hours. Jan. 30, 2016 stoppage for 8 hours Jan. 31, 2016 stoppage for 20 hours. Feb. 12, 2016 stoppage for 8 hours. March 1, 2016 stoppage for 29 hours for discharge line repairs. March 4, 2016 stoppage (Figures2-1, 2-2, 2-11 and 3-9); resumed on May 2, 2016 May 17, 2016 stoppage for 15 hours May 25, 2016 stoppage for 4 hours June 3, 2016, July 8, 2016, July 14, 2016 for one hour each. August 13, 2016 stoppage for 80 hours for power interruptions October 3, 2016 stoppage 46 hours Dec. 24, 2016 through Dec. 31, 2016 for storm event.	**the salinity of the water pumped. How is this a valid model?** The modeling has been limited to a small area of the Salinas Valley Groundwater Basin and this represents a significant weakness, as the water source is expansive and can be negatively affected by localized impacts. The predictive power of a model evaluating the MPWSP must be able to predict the impacts of an entire water basin as this is the priority concern for regional stakeholders. **To not include the Basin as a whole is to ignore the true harms of a project such as MPWSP**. The last step in any scientific methodology is that there is ***replication of the predictive performance*** of experimental tests ***by several independent experimenters*** and ***properly performed experiments***. As previously stated, the modeling must be expanded to cover the actual areas to be potentially harmed, i.e. the Salinas Valley Groundwater Basin, not a small portion of this. Although the HGW is composed of a small group of reputable hydrogeologists "familiar with the local region", but does this not speak to a potential bias and possible political influences of these individuals? The interests of Marina Coast Water District which has the greatest to lose if MPWSP causes harm is starkly omitted from HGW membership. **Will CPUC allow members chosen by MCWD on the HGW? Will CPUC mandate the expansion of applicability of test results to the broader Salinas Valley Groundwater Basin area?** The total estimated interruptions as of Dec. 31, 2016 over the previous 20 months demonstrated pumping was interrupted intermittently in excess of 30 weeks (75 interruptions in 1.5 years of test well operation). **How do such interruptions affect the accuracy of the rate of salinity rise? Is this data collection valid? Should the model have included such impacts or anticipated variances in order to be considered a valid model? Does a reset of the slant well test be required from each major interruption of pumping stoppage for whatever reasons?**	Biala1-27 cont. Biala1-28 Biala1-29

Pg/Section	Cited text	Comments/Questions
	Long durations: June 5, 2015 - Oct. 27, 2015 pumping stoppage related to water level decline exceeding thresholds. March 4, 2016 - May 2, 2016 pumping stoppage due to Cal-Am outfall pipe on shoreline exposed due to erosion, and had to be disconnected and moved.	
2.5.4 Assumptions about the Allocation of MPWSP Water Pg. 2-29	***#10. Topic: Future demand needs of not just Cal-Am's customers but of the Salinas Valley, Marina and Ord communities.*** 2.5.4 Assumptions about the Allocation of MPWSP Water Pg. 2-29 As discussed in Section 2.3, CalAm proposes to size the MPWSP Desalination Plant to provide, along with other sources, sufficient supply to meet **service area demand of 14,275 afy. This amount is 2,005 afy more than the 12,270 afy existing service area demand** (shown in Table 2-3), and without Seaside Basin replenishment, it would be 2,705 afy more than existing demand. In addition to meeting existing service area demand, CalAm proposes sizing the plant to meet demand associated with existing Pebble Beach water entitlements, estimated demand associated with the development of vacant legal lots of record and, **if the economy improves, demand from increased water use at existing hospitality businesses.** While such increases in water demand can reasonably be expected, estimating future water demand necessarily entails the use of assumptions about demand factors that cannot be predicted with absolute certainty. (As discussed in Section 2.3.3, MPWMD's review of the factors included in CalAm's estimate produced somewhat different results. For example**, MPWMD's review indicated that supply needed for future development of vacant lots of record may be underestimated and the supply needed for economic recovery of the hospitality industry may be overestimated.)** Moreover, under past and current allocation programs, once a given supply has been allocated to a jurisdiction, whether or not the jurisdiction reserves its allocation for specific uses and at specific levels that CalAm assumed for project sizing	The needs of Cal-Am are thoroughly documented for current and future anticipated needs for the Peninsula; **the demand needs of the Marina and Ord communities must be equally considered as there are also severe concerns that the current water supplies are inadequate for the existing population plus anticipated growth of the Marina and Ord communities*, even without the MPWSP project*.** To devote extensive survey of Cal-Am's customer needs without also documenting MCWD's demand needs of a community with much higher levels of undeveloped properties becomes a mere compounding of critical water supply issues. Solving one entity's water issues by compromising another's has no logic and is unjust. Cal-Am created their present water shortages and MCWD has responsibly managed theirs. The injustice of this may be a future lack of potable water for MCWD which CPUC has willingly enabled, in support of an irresponsible water purveyor over a responsible one. Further, there is an <u>environmental injustice</u> that Cal-Am has progressed this far in the approval processes and blatantly ignores the rights and welfare of Marina, a city of 21,000 with a low income and highly diverse population. Cal-Am assumes that compromising the Salinas Valley Groundwater Basin water supply is inconsequential over the needs of a wealthier, more politically influential jurisdiction. Is a DEIR format structured in such a way that it assumes a request for a project review would be for the same area in which the applicant has jurisdictional rights? There is something extremely amiss when a DEIR structurally ONLY requires evaluation of the applicant's demand needs and potential harm in their "sphere of influence" when the applicant is planning on operating in a completely different jurisdiction**. Will there be a supplement to this DEIR that considers water demand needs, adequacy of water and regional harm to the Salinas Valley Groundwater Basin stakeholders?** All criteria considered and documented for Peninsula stakeholders must be replicated for each city within the Salinas Valley Groundwater Basin.

Biala1-30

	groundwater quality were assessed.	
Ground-water Sources 4.4. Pg. 4.4-43 Pg. 4.4-44	***#13. Topic: ERT regional imaging is currently available but not mandated.*** ***Groundwater Models*** What is a Groundwater Model? **The applicability or usefulness of the model depends on how closely the mathematical equations approximate the physical system being modeled.** Limitations of Groundwater Models Groundwater models simulate aquifer conditions based on a specific set of data that describes parameters such the subsurface characteristics, groundwater flow, and land use. The more robust the data set, the more capable the model will be to accurately simulate subsurface conditions. Given that, and given the fact that these models were calibrated with known data, the level of degree of uncertainty for this analysis is considered tolerable.	What is quite missing is that the impacts of 27,000 acf a year, will have immediate and long term effects on a fragile regional water basin, and the models applied to the project are not concerned with the regional impacts. **Further, the modeling must achieve higher levels of certainty (not "tolerable uncertainty") through the application of Electrical Resistivity Tomography (ERT) technology.** There is no excuse not to apply state-of-the-art, available and affordable methods when the dramatic and possibly permanent negative impact to a region's water supplies is at stake. It is clear that any model's accuracy depends on how much real data it is based upon. (See DEIR quote of "What is a Groundwater Model?". The current model relies on a limited number of vertical wells (sentinel or monitoring wells). Dr. Rosemary Knight's Electrical Resistivity Tomography (ERT) technology generates tens of thousands of data points compared to the hand full of vertical wells. Additionally, the ERT can show subsurfaces of saltwater and fresh water reserves to 1200 feet below the earth's surface compared to the two MCWD wells that reach the 900 foot aquifer. Which should be trusted...a model based upon a comprehensive ERT or a model based on a small number of vertical wells? Which model will give more accurate estimates of uncertainty given the stakes are so high with risking an entire regional water source. **Why is CPUC not mandating an ERT study of the Salinas Valley Groundwater Basin before environmental review approvals?** Why has ERT not been required in establishing the baseline data of saltwater intrusion, the integrity of aquitards and the health of the three levels of aquifers in the Salinas Valley Groundwater Basin? **Can a supplemental section to the DEIR be added that explains the relationship of ERT data to modeling and to establishing levels of uncertainty and creating predictive ability of assessing "harm"?**
Pg. 4.4-28 4.4 Ground-water Resources Seawater Intrusion	***#14. Topic: ERT Reference.*** ***Seawater Intrusion*** Pg. 4.4-28 The current, standard practice for monitoring the inland advance of seawater intrusion involves **TDS analysis of groundwater from a select group of monitoring wells**	**Cal-Am states "The study found that the electrical resistivity readings positively correlated with measured TDS concentrations to a depth of 500 feet in four area groundwater wells."** Why does Cal-Am acknowledge Electrical Resistivity Tomography (ERT) as a tool yet states nothing of its potential value in modeling and its ability to answer the many unknowns about the groundwater in the area they plan to pump from? This is like explaining some of the moving parts of

Biala1-32

Pg/Section	Cited text	Comments/Questions
	that intersect the seawater- intruded aquifers. The TDS concentration data are used to identify the areas of the aquifer intruded by seawater and to plot the leading edge of the inland seawater intrusion front**. The more groundwater wells available in the monitoring program, the better regional seawater intrusion is represented.** Regular annual monitoring data can be used to estimate the rate at which seawater is migrating inland. The MCWRA has been conducting seawater intrusion monitoring for many years using several groundwater wells in the western end of the Salinas Valley. **Geophysics are giving researchers the opportunity to study seawater intrusion using high- resolution, regional scale imaging. The technique, sometimes referred to as Electrical Resistivity Tomography (ERT), can be used to differentiate salty water from fresh water hundreds of feet beneath the ground. Electrical resistivity imaging uses a series of sensors placed along a transect line on the ground surface. An electrical current is applied and the sensors measure the electrical resistance the current encounters as it travels at depth between the sensors. Salty water has a lower resistance than freshwater, due to the higher TDS. The high and low resistivity zones in the subsurface are displayed as a series of colors in a cross section that indicate areas of fresh water, brackish water and seawater.** Pg. 487 Over the past few years, Stanford environmental geophysics researcher **Rosemary Knight** has conducted a study to determine the viability of using electrical resistivity techniques to study seawater intrusion along the coast of the Monterey Bay. Professor Knight's initial survey was conducted along a 4-mile segment parallel to the beach between the cities of Seaside and Marina. **The study found that the electrical resistivity readings positively correlated with measured TDS concentrations to a depth of 500 feet in four area groundwater wells.**	an airplane but omitting the fact that it can fly and transport passengers! (Project Water Rights 2.6.2 Pg. 127) As explained in Chapter 4.4, Groundwater Resources, the modeling is specifically targeted to isolating the change in groundwater levels that would be generated by the MPWSP. *This modeling, however, cannot project the amount of Basin water that is expected to be drawn into the supply wells*. <u>Pg. 114</u> *MPWSP source water would include some brackish groundwater from the SVGB.* The origins of this "brackish groundwater" must be known i.e. where this mixing of fresh and ocean water is occurring and clearly documented. ERT will provide critical information not currently known. **Again, will CPUC mandate such information be clearly identified in the DEIR?** There will be a new peer reviewed professional journal article released very soon by Dr. Knight that describes the capabilities of a more expansive, regional ERT imaging. A finished ERT study of the Salinas Valley Groundwater Basin, using such techniques, must be included in the approval process with adequate time allowed for proper evaluation

		by experts. **Can CPUC require that DEIR approvals not be made until ERT studies have been completed for the SVGB and applied to the current model?**	Biala1-32 cont.
Baseline Conditions 4.1.3 Pg. 4.1-8	***#15. Topic: Groundwater modeling based upon 2012 data is not current and has omissions.*** Pg. 4.1-8 Although the Notice of Intent for the NEPA review contained within this document was issued in 2015**, use of the 2012 baseline is appropriate and reasonable because (i) 2012 is a very recent point in time;** (ii) the CPUC invested considerable resources amassing 2012 background/baseline data for the April 2015 Draft EIR; and (iii**) environmental conditions in the study area have been relatively static such that 2012 conditions remain representative of meaningful baseline conditions.**	Cal-Am asserts the adequacy of data from 2012. It is clear from the Lawrence Berkeley Livermore Laboratory report that potentially crucial "shortcomings" are present. Additionally, according to Hydrogeologist, Curtis Hopkins, **Cal-Am's 2014/15 modeling did not use wells located south of the Salinas River for calibration to compare simulated results with observed groundwater level elevations. Consequently, there cannot be a high level of confidence in their accuracy in the project area because accuracy has not been demonstrated through a comparison of actual data** ((MEMORANDUM to Mr. Keith Van Der Maaten, General Manager, Marina Coast Water District dated January 22, 2016).	Biala1-33
Appendix E-1 Pg. 1045	Lawrence Berkeley Livermore Laboratory Report Pg. 1045 As for our review of the foundation of the groundwater modeling, we find that there are shortcomings in the hydrostratigraphic model and simulation inputs that could potentially change the impact assessments. Chief among these was the absence of the Fort Ord-Salinas Valley Aquitard (FO-SVA), which hydraulically separates the Dune Sand and 180-foot equivalent (180- FTE) aquifers from greater than about 2 km east of the proposed extraction site. *Appendix E1 Lawrence Berkeley National Laboratories peer review Conclusions*	Further, **Cal-Am's 2014/15 modeling assumed the 180-FTE Aquifer was unconfined within the project area. As Cal-Am has acknowledged elsewhere, the Test Slant Well project** data demonstrates this assumption was incorrect. ((MEMORANDUM to Mr. Keith Van Der Maaten, General Manager, Marina Coast Water District dated January 22, 2016).	Biala1-34
		Additionally, Hydrogeologist Curtis Hopkins, notes that monitoring Well-7 is no longer contaminated by high concentrations of seawater and is likely explained by the changing hydrogeological conditions resulting from the efforts of MCWD and others to reduce pumping in the area. Cal-Am's current water proposals do not consider or address any potential harm to protective conditions. (MEMORANDUM to Mr. Keith Van Der Maaten, General Manager, Marina Coast Water District dated January 22, 2016).	Biala1-35
		Will there be any further scrutiny of Cal-Am's data and modeling based upon all the aforementioned discrepancies and omissions, both from the Lawrence Berkeley Livermore Lab and the report by Hopkins Groundwater Consultants?	Biala1-36
Appendix E-1	***#16. Topic: Lawrence Berkeley Livermore National Laboratory report: need for more data on modeling.***	Have all the Lawrence Berkeley Livermore Laboratory recommendations been adequately addressed by Cal-Am? If so, where	Biala1-37

Pg/Section	Cited text	Comments/Questions
Pg. 1043-1056	**2. Conclusions** pg. 1054 Based on this review, LBNL found its simulation results match those in Appendix E2 of the DEIR. Some of the groundwater modeling outputs are reproduced exactly, while others show small differences that can be attributed to computer round-off and cancellation errors. **As for our review of the foundation of the groundwater modeling, we find that there are shortcomings in the hydrostratigraphic model and simulation inputs that could potentially change the impact assessments. Chief among these was the absence of the Fort Ord-Salinas Valley Aquitard (FO-SVA), which hydraulically separates the Dune Sand and 180-foot equivalent (180- FTE) aquifers from greater than about 2 km east of the proposed extraction site.** **Pg. 1054 If there are insufficient data to constrain the position of water levels and the position of the FO-SVA, multiple simulations should be conducted to provide a suite of results that in sum bracket the likely changes resulting from the proposed extraction. This suite of results can be used to determine the maximum capture area, drawdowns, and extraction from beneath onshore, or to provide a probability distribution for those values if probability distributions for the inputs can be established.** **Pg. 1054-1055 The new simulation should be initialized with hydraulic conductivities measured from field data collected in the nearby former Fort Ord. In general these hydraulic conductivities are lower than those previously used to initialize the model and resulting from calibration by the model. The model should also be initialized with larger storativities in the Dune Sand aquifer based upon analysis of field data from the nearby former Fort Ord.**	is this documented? Further, the modeling must be expanded to incorporate as much of the Salinas Groundwater Basin as possible through Electrical Resistivity Tomography; it would seem necessary to then contract with Lawrence Berkeley Livermore National Lab to validate the new model based upon new ERT information. Are there plans to do so? If not, why not?
2.6.2 Project Water Rights	***#17. Topic: Water Rights, Harm and individual compensation***	How is injury to individual well owners because of increased difficulty in pumping due to drawdowns by Cal-Am, to be compared with the injury to the region of pumping significant volumes of water without

Biala1-37 cont.

Biala1-38

Biala1-39

Pg/Section	Cited text	Comments/Questions
Pg. 2-37	Pg. 2-37 Turning to the third of the three injury criteria set forth in the Report – increased pumping costs – as noted above, the water levels in seven potentially active wells could drop by somewhere between 1 and 5 feet, **thus requiring marginally more energy to extract the water from those wells.** As a physical solution to ensure that those well owners continue to enjoy the same measure of water rights as they do prior to MPWSP implementation and thus are not injured, **CalAm could compensate the well owners for any increased pumping costs causally tied to the MPWSP**. Assuming that CalAm were to compensate the owner of these wells for any increased pumping costs sustained due to the MPWSP, the slant wells' operation would not cause injury under the Report's third injury criteria.	knowing, studying and reliably predicting the impacts to the **region's** aquifers? This interpretation of "harm" and "injury" on such a small scale is egregious and serves only to cloud the real issues at hand. **What monetary compensation to MCWD, the City of Marina and Ord communities is Cal-Am prepared to compensate for damages to the Salinas Valley Groundwater Basin stakeholders?** Such mitigation measure must be in writing with details of compensation to all injured parties not merely to "compensate the well owners for any increased pumping costs causally tied to the MPWSP". Such written stipulations for compensation should also include designated amounts for set aside funds. **Can Cal-Am be compelled to commit to such compensation strategies for Marina, the Ord communities and MCWD as they have addressed for other contingencies in this DEIR?**
2.6.2 Project Water Rights Pg. 2-37	***#18. Topic: Water rights, Harm and Cal-Am future "good will" financial support, individual compensation.*** Pg. 2-37 Furthermore, CalAm has proposed a mitigation measure (set forth in Section 4.4, Groundwater Resources as Mitigation Measure 4.4-3) to further ensure that Basin groundwater users are not injured. Working with the Monterey County Water Resources Agency, **CalAm would fund the installation of monitoring wells to expand the County's network of groundwater monitoring wells so as to be better able to monitor on an on-going basis the effect of the project slant wells on groundwater within the radius of influence.** If the monitoring efforts were to demonstrate that the project were affecting any existing neighboring active wells, CalAm would coordinate with the affected well owner and take both interim and long-term steps to avoid harm (possibly including improving well efficiency, providing a replacement water supply and/or compensating the well owner for increased costs). In light of the foregoing, it seems reasonable to conclude that the MPWSP would not cause harm or injury to Basin water rights holders such that CalAm would possess the right to withdraw water from the Basin to produce	If the current modeling that presumably demonstrates "no harm" has been confirmed by Cal-Am, why are ***additional*** groundwater monitoring wells even necessary? The additional monitoring wells to be paid for Cal-Am, under the stated intent of being "better able to monitor on an ongoing basis the effect of the project slant wells on groundwater" suggests that there are some inadequacies of data in their project proposal. **To have *now*, in the present, a comprehensive and accurate assessment of groundwater subsurfaces, would obviate additional *future* installation of monitoring wells. The Electrical Resistivity Tomography will provide a much more accurate and complete baseline today as well as providing comparison for changes from this baseline in the future. If we accept Cal-Am's financial support for "future monitoring wells" that will inherently never be very accurate, why does CPUC not insist on ERT funding now for a baseline and in the future as an ongoing accurate monitoring tool?** It appears that Cal-Am is willing to offer funding for more monitoring wells in the future but they have not offered to fund the Electrical Resistivity Tomography (ERT) that is a more comprehensive, accurate groundwater imaging to understand salt water intrusion as an aspect of "harm". **Monitoring wells are much less accurate in mapping saltwater intrusion than ERT. Why has Cal-Am not been required to pay expenses for current monitoring and the establishment of a baseline via ERT?**

Biala1-39 cont.

Biala1-40

Pg/Section	Cited text	Comments/Questions	
	"developed water" for beneficial use and under the physical solution doctrine.	Further, Cal-Am's offer to "monitor on an ongoing basis the effect of the project slant wells on groundwater within the radius of influence" but this "radius of influence" is defined as a constricted area around the well. **The entire Salinas Valley Groundwater Basin should be defined as "their radius of influence"** but current modeling and limited scope of research suggests otherwise. Why is Cal-Am's envisioned "radius of influence" not defined as the entire Salinas Valley Groundwater Basin since "harm" will be global and devastating to the region?	Biala1-40 cont.
2.6.2 Project Water Rights Pg. 2-39	***#19. Topic: Slant wells will improve groundwater conditions? Claims of MPWSP benefiting each of the aquifers and creating a "no net loss".*** Pg. 2-39 Water is expected to be returned between May and November of the same calendar year as it is withdrawn (see Chapter 3, operating table) such that the senior overlying and prescriptive users would not suffer harm from loss of water**.** As examined by the groundwater modeling and explained in the Groundwater Resources section, **this proposed return water plan would improve groundwater conditions in the 400-Foot Aquifer underlying the CSIP, CCSD and adjacent areas because water levels would increase as a result of in-lieu groundwater recharge, and would benefit each of the aquifers by either reducing the area of influence of the MPWSP or by increasing groundwater levels in other areas.** Since this return option would essentially put the Basin in a "no net loss" position in terms of fresh water quantity and would benefit legal water users by providing fresh water for beneficial use in lieu of Basin pumping, it appears consistent with the Report and enhances the preliminary conclusion that CalAm would likely possess water rights for the project.	The statements that "this proposed return water plan would improve groundwater conditions in the 400-Foot Aquifer" must have clear scientific proof that this is so. The current modeling cannot demonstrate this and if such statements are made repeatedly, scientific evidence must be produced. **Is there any scientific evidence that pumping water from the Marina site but returning a portion of this to Castroville will actually improve groundwater conditions in the area from which the water was pumped? If any claims that water returned in Castroville will benefit the 400' aquifer in the Marina and Ord communities, where is this scientific evidence that this is so? What would prevent the Castroville area from using up any returned water such that it would never reach Marina? Are there any subsurface physical barriers that prevent returned water in Castroville from reaching and replenishing Marina aquifers?** **According to Curtis Hopkins, Hyrdogeologist, "unless a return water method ensures the protective (substrate) conditions (of reduced pumping) in the MCWD area are not harmed, the MPWSP will induce seawater intrusion into the Dune Sand Aquifer (and will exacerbate seawater intrusion in the 180-Foot Aquifer through vertical leakage) in the Northern Marina Subarea and likely result in cumulative impacts to aquifers and wells much further inland."** (MEMORANDUM to Mr. Keith Van Der Maaten, General Manager, Marina Coast Water District dated January 22, 2016). **Will such information be evaluated in the MPWSP project and how does this change the modeling?** Further, Curtus Hopkins states: "…if a greater percentage of	Biala1-41 Biala1-42 Biala1-43

Pg/Section	Cited text	Comments/Questions	
2.6.3 Water Demand, Supplies and Water Rights Pg. 2-39	Pg. 2-39 As examined by the groundwater modeling and explained in the Groundwater Resources section, this proposed return water plan would improve groundwater conditions in the 400-Foot Aquifer underlying the CSIP, CCSD and adjacent areas because water levels would increase as a result of in-lieu groundwater recharge, **and would benefit each of the aquifers** by either reducing the area of influence of the MPWSP or by increasing groundwater levels in other areas. **Since this return option would essentially put the Basin in a "no net loss" position in terms of fresh water quantity and would benefit legal water users by providing fresh water for beneficial use in lieu of Basin pumping, it appears consistent with the Report and enhances the preliminary conclusion that CalAm would likely possess water rights for the project.**	groundwater is pumped than estimated by the model, or if groundwater salinity is increased in the project area, the annual amount of return water required would increase accordingly. **These higher return water volumes are not included in the project's return water estimates**". (MEMORANDUM to Mr. Keith Van Der Maaten[11], General Manager, Marina Coast Water District dated January 22, 2016). Does the current model speak to these possibilities? Are these possibilities addressed in the current model regarding amount of return water? If not, why not? The basis upon the assumed water rights is made upon unscientifically verified claims that the project now "benefits" the groundwater condition. Pumping out massive volumes of water from a groundwater basin and putting back limited fresh water in another location, does not validate the Cal-Am conceived "no net loss" position. This is such a simplistic, almost incredulous explanation and is devoid of any scientific justification. Cal-Am further links this "benefit" to the assumption of water rights in the area.	Biala1-43 cont. Biala1-44
APPENDIX I1 Open-Water and Subsurface Intakes Pg. 1556	***#20. Topic: Subsurface ocean intake Slant Well Technology not successful in U.S. or the world; lack of any study of previous failure at Dana Point.*** Slant Wells Pg. 1556 Slant wells are installed at an angle below the sea floor using vertical well drilling technology. The yield from a slant well depends on the underlying geology. When compared to vertical wells and Ranney wells, slant wells can be screened at greater distances offshore and can result in fewer impacts on coastal groundwater aquifers. Slant wells can be drilled from behind sand dunes or from the active beach area (i.e., between the toe of the dunes and the open ocean). The wellheads can be buried beneath the sand or installed flush with the ground surface. Multiple slants wells can be grouped into clusters to extend from a single "pod." Consistent with the slant wells	This description of slant wells is covered in the appendix regarding intake methods of Open-Water Intakes and Subsurface Intakes, including vertical wells, infiltration galleries, horizontal wells, Ranney wells, and lastly slant wells. **This section on intake methods assumes a casual parity of slant wells with other intake methods when no subsurface ocean intake slant well project has ever been successful in the U.S. or the world.** In fact, a lengthy description of Ranney wells includes examples: Pg. 1555 Examples of Ranney wells in marine environments include three Ranney wells at the Salina Cruz Power Plant in Mexico that draw between 9 and 14 mgd of seawater, and one at the Steinhart Aquarium at the California Academy of Sciences in San Francisco (Hunt, 2008; Feeney, 2013). This is yet another example of truth hiding. **No examples of successful subsurface ocean intake slant well projects can be named but more importantly, the one attempted example has had**	Biala1-45

Pg/Section	Cited text	Comments/Questions
	proposed as part of the MPWSP, it is assumed that construction of each slant well pod (consisting of up to 4 wells) would result in 1 acre of temporary disturbance. Slant wells would require maintenance every 5 years. During maintenance, the wellheads are excavated and exposed, and mechanical brushes are lowered into the wells to mechanically clean the screens. Ground disturbance associated with periodic maintenance is assumed to be similar in extent to construction disturbance (i.e., approximately 1 acre of disturbance for each well pod). Slant well construction and maintenance requirements are described in greater detail in Chapter 3, Project Description. Any intake options that include slant well technology are assumed to be consistent with the slant wells proposed as part of the MPWSP, although the location and number of wells could vary. Ranney Wells Pg. 1555 A Ranney well is a radial well comprised of a vertical caisson (a large diameter shaft where the water is collected from each well and then pumped) extending below the water table from which horizontally placed perforated screens are extended (SGD, 1992). The use of multiple horizontal laterals means that production of each radial well is greater than a single vertical well (Feeney, 2002). A single Ranney well can yield between 0.1 to 25 mgd, which is five to ten times the yield of a vertical well (Hunt, 2008**). Examples of Ranney wells in marine environments include three Ranney wells at the Salina Cruz Power Plant in Mexico that draw between 9 and 14 mgd of seawater, and one at the Steinhart Aquarium at the California Academy of Sciences in San Francisco (Hunt, 2008; Feeney, 2013).**	**no acknowledgement or review by Cal-Am or CPUC.** If an experimental design is being proposed, would not all Dana Point slant well project details be of great interest to CPUC to avoid potential repeat of failure or infeasibility? Would not CPUC wish to include the data from the Dana Point slant well project to compare to the data of the MPWSP test well that ran for 21 months? Should we not be at least curious, let alone scientifically aggressive, in pursuing more information when there is only one documented attempt of such a slant well in the U.S.? The blinders that have been put on to expedite Cal-Am's project is quite astounding and would not be tolerated in any other scientific pursuit. **Any scientific research article begins with an extensive review of literature to give current knowledge of the topic under review. This fundamental practice has been omitted for this untested, experimental technology that has already come with a formidable price tag for the Peninsula ratepayers. Will CPUC require a DEIR addendum with more objective and complete coverage of the true state of subsurface ocean intake slant wells that includes an honest history of the Dana Point Doheny Ocean Desalination Project?** Why has there been no scientific or feasibility studies to compare and contrast the Dana Point slant well project with the MPWSP project? **What are the legal implications for CPUC ignoring previously available information from the abandoned Dana Point slant well project that may have been relevant to issues in the current MPWSP project? Ultimately, four of the five cooperating sponsoring agencies found other preferable ways to procure needed water.**
APPENDIX I1 Open-Water and Subsurface Intakes Pg. 1555		
2.1 Introduction Pg. 2-2	***#21. Topic: Cal-Am as a non-self-regulating, environmentally destructive utility company.***	The history in the project introduction reflects a pattern of repeated violation by Cal-Am of the terms of water extraction until the point of legal mandates being issued, rather than responsible, proactive management of available water sources. Both the Carmel River and the

Biala1-46

Pg/Section	Cited text	Comments/Questions	
Pg. 2-5 2.2.4 Seaside Groundwater Basin Adjudication Pg. 2-8	2.1 Introduction Pg. 2-2 CalAm is proposing **this project to replace part of its existing water supplies, which have been constrained by legal decisions affecting CalAm's diversions from the Carmel River and pumping from the Seaside Groundwater Basin. State Water Resources Control Board (State Water Board) Order 95-10, State Water Board Order 2009-0060 (also referred to as the Cease and Desist Order, or CDO), and the Monterey County Superior Court's adjudication of the Seaside Groundwater Basin in 2006 substantially reduced CalAm's rights to use these two primary sources of supply.** Pg. 2-5 As a result of the adjudication of the Seaside Groundwater Basin (see Section 2.2.4), these satellite systems will lose all of their allocated Seaside Groundwater Basin supplies by 2018. Pg. 2-8 The Decision established a physical solution to basin management that **was intended to reduce aquifer drawdown to the level of the natural safe yield; to maximize potential beneficial uses of the basin**; and to provide a means of augmenting water supply for the Monterey Peninsula. In addition to allocating groundwater rights to the various users, the Decision established an initial "operating safe yield," to be decreased incrementally over time until withdrawals are equal to the identified natural safe yield.[13] Pg. 2-8 By adjudicating the water rights for all users of the basin**, the court intended to protect the basin from long-term damage associated with potential seawater intrusion, subsidence, and other adverse effects that commonly result from overpumping. The Decision identified the "natural safe yield"[12]**	Seaside Groundwater Basin required legal actions (Cease & Desist, reduction in water rights). Cal-Am is being seriously curtailed due to transgressions of their water rights in the Seaside Groundwater Basin and yet they are being allowed to proceed with DEIR approvals in a **non**-Cal-Am water district to which they have no water rights. In all other cases, must projects have confirmation of water rights and permits before proceeding under CPUC? No matter what the perceived needs of an irresponsible purveyor of water may be asserted, this should not allow complete disregard for procedural protocols. **On what legal basis has Cal-Am been allowed to circumvent standard processes of determining water rights in Salinas Groundwater Basin?** **Why has the proven history of Cal-Am's abuse of public resources in areas where Cal-Am has defined water rights, not been considered in allowing them to enter an area in which they have NO water rights?** Even with the privilege of water rights, Cal-Am ignored legal and environmental responsibilities. Trusting that Cal-Am will act in a responsible, ethical and legal manner in a jurisdiction in which they have no legal rights, is simply not reasonable in any manner of thinking. The court intentions to "protect the basin from long-term damage associated with potential seawater intrusion, subsidence, and other adverse effects that commonly result from overpumping" related to the **Seaside Groundwater Basin is the exact same concerns of the Salinas Valley Groundwater Basin**. This is precisely the position of the Salinas Valley Groundwater Basin today ***without*** the impacts of Cal-Am drawing an astronomical volume of 27,000-30,000 acf per year. As a stark comparison, Marina Coast Water District currently pumps only 3,800-4,200 acf per year. There is clear evidence that the Salinas Valley Groundwater Basin is experiencing saltwater intrusion and options to desalinate its own water for its own future may be necessitated. In the meantime, MCWD has engaged in responsible initiatives on conservation, recycling and aquifer replenishment projects that Cal-Am's project will directly mine. like Cal-Am, it plans on internally managing its own water and enact proactive strategies for "natural safe yield". What are the circumstances that necessitated restrictions on Cal-Am to	Biala1-46 cont. Biala1-47

Pg/Section	Cited text	Comments/Questions
E.S.3 CEQA Project Objectives Pg. ES-3		"reduce pumping from the Seaside Groundwater Basin"? Are those not the same, if not more compelling reasons, that the Salinas Valley Groundwater Basin would be subject to? Why is there concern of overpumping in Seaside Basin but not for overpumping in the Salinas Valley Basin when there are already severe concerns with saltwater intrusion? Why does Cal-Am's obligations to their customers take precedence over MCWD's obligations to serve theirs, when Cal-Am is intruding on another district's dwindling water source without water rights to this source? This is completely unjust and unethical.
Pg. 487 Ground-water Sources 4.4 Pg. 4.4-31	***#22. Topic: Comparing the salt water intrusion between Salinas Valley and Seaside Groundwater Basins*** **Salinas Valley Groundwater Basin** Pg. 4.4-31 The SVGB is hydrologically connected to Monterey Bay by ocean outcrops of the 180-Foot and 400-Foot Aquifers a few miles offshore (Eittreim, et. al., 2000; Greene, 1970). The ocean outcrops provide a constant source both of pressure and of direct recharge of seawater, and facilitate the recharge of seawater into those aquifers along the coast when groundwater extraction exceeds natural recharge. As a result, a landward groundwater gradient has developed along the coast and induced groundwater recharge from the ocean since the mid-20th century. Seawater intrusion in the SVGB was first documented in 1946 (DWR, 1946). **The overdraft condition has degraded groundwater quality along the coast within the SVGB**. Before wells extracted water from the Salinas Valley, there was a balance between the seawater in the ocean and the groundwater in the inland aquifers. Surface water within the watershed would infiltrate down into the aquifer, but it would be at a higher elevation than the surface of the ocean. Gravity requires that the difference in elevation forces the freshwater in the inland areas to migrate down and press back against the seawater. **With the development of the Salinas Valley, water supply wells were installed and groundwater was extracted from the aquifer.** This action reduced the weight of water on	It is without a doubt that both Salinas and Seaside Groundwater Basins have similar situations of increasing saltwater intrusion; severe compromises to both water sources are either in the making or are already present. However, Cal-Am bears a direct responsibility to the Seaside Basin stakeholders for assuming an immediate role of pumping from this basin. Cal-Am should not be allowed to repeat their irresponsible practices and claim to be "ameliorating" the Salinas Groundwater Basin when they should be applying positive strategies to the area in which they do have legal water rights. There is no justice in supporting the further spread of saltwater intrusion by Cal-Am in the Salinas Valley Groundwater Basin.

Biala1-47 cont.

Biala1-48

Pg/Section	Cited text	Comments/Questions
	the inland side of the seawater/freshwater interface, creating a pressure imbalance, and resulted in the landward migration of the interface to its current location. **The 2013 estimates of seawater intrusion within the 180-Foot and 400-Foot Aquifers indicate that seawater has intruded to a maximum of approximately 8 miles and 3.5 miles inland, respectively, as inferred from chloride concentrations greater than 500 mg/L**. The seawater intrusion degraded groundwater supplies, requiring urban and agricultural supply wells within the affected area to be abandoned or destroyed (MCWRA, 2001). **Increased degradation of coastal groundwater aquifers led to restrictions on drilling groundwater wells and extracting groundwater from areas affected by seawater intrusion, as discussed in Section 4.4.2, Regulatory Framework. Such restrictions are intended to reduce further inland migration of seawater and reduce the landward advance of the seawater/freshwater interface**. **Seaside Groundwater Basin** **Pg. 487-488 Groundwater pumping from aquifers in the SGB has exceeded recharge and freshwater inflows that caused pumping depressions near the coast, as shown on the groundwater flow maps for both the shallow aquifer zone (see Figure 4.4-7) and the deep aquifer zone** (see **Figure 4.4-8**) (HydroMetrics, 2015). **In addition, seawater intrusion has occurred just north of the SGB in the adjacent 180/400 Foot Aquifer Subbasin of the SVGB,** as discussed above. The boundary between these two basins is a groundwater divide that migrates in response to variations in natural recharge and pumping on either side of the divide. HydroMetrics noted increased chloride concentrations in two wells along the coast, although the concentrations have not yet exceeded drinking water standards. **These conditions all suggest that the SGB could be vulnerable to seawater intrusion.**	**Has Cal-Am engaged in or have plans for any prevention of saltwater intrusion in the Seaside Groundwater Basin? If not, why not?** If Cal-Am's claims of pumping water that benefits the Salinas Valley Groundwater Basin are feasible, why have they not engaged in such "benefits" in the basins in which they currently have water rights?

Pg/Section	Cited text	Comments/Questions
4.4.2.2 State Water Resources Control Board Pg. 4.4-33	***#23. Topic: Applying the same standards to maintain high quality water in both Seaside and Salinas Groundwater Basin.*** 4.4.2.2 State *State Water Resources Control Board (SWRCB) Resolution 68-16 Anti- Degradation Policy* Pg. 4.4-33 In 1968, the State Water Resources Control Board adopted an anti-degradation policy aimed at maintaining the high quality of waters in California through the issuance of Resolution No. 68-16 ("Statement of Policy with Respect to Maintaining High Quality Waters in California"). **The policy prohibits actions that tend to degrade the quality of surface and groundwater.** The Regional Water Quality Control Boards oversee this policy (SWRCB, 1968). The anti-degradation policy states that: **5.** Whenever the existing quality of water is better than the quality established in policies as of the date on which such policies become effective, **such existing high quality will be maintained until it has been demonstrated to the State that any change will be consistent with maximum benefit to the people of the State, will not unreasonably affect present and anticipated beneficial use of such water, and will not result in water quality less than that prescribed in the policies.**	*State Water Resources Control Board (SWRCB) policies:* ***** prohibit actions that tend to degrade the quality of surface and groundwater. * mandate that existing high quality water will be maintained until it has been demonstrated to the State that any change will be consistent with maximum benefit to the people of the State, will not unreasonably affect present and anticipated beneficial use of such water. If the State Water Resources Control Board "prohibits actions that tend to degrade the quality of surface and groundwater, **why have alternative projects to MPWSP not been evaluated on their *impacts to groundwater* resources in the DEIR? Open ocean desalination projects, as opposed to slant wells, do not draw any fresh water/brackish water from any groundwater aquifers.** If both Seaside and Salinas Valley Groundwater Basins will become increasingly salt water intruded, upgrading the quality of **Seaside**'s brackish water (where Cal-Am has water rights) would appear to be in order. Pumping brackish water from another's jurisdiction in which they have no rights, by claiming brackish water is "unusable", and then claiming they are actually improving the groundwater condition, is without merit. Within the *Seaside* Basin where Cal-Am has water rights, there is brackish water that should be restored to a "higher quality" in that same basin just as Cal-Am now proposes to do in the *Salinas* Valley Groundwater Basin.
Table J2-1 pg. 1616	***#24. Topic: Applying the same review and considerations of General Plan growth to both Cal-Am and MCWD customer base.*** **TABLE J2-1 SIGNIFICANT MITIGABLE (S) AND SIGNIFICANT UNAVOIDABLE (U) IMPACTS OF GROWTH IDENTIFIED BY GENERAL PLAN ENVIRONMENTAL IMPACT REPORTS AND MITIGATED NEGATIVE DECLARATIONS IN THE PROJECT AREA** **City of Del Rey Oaks**	The TABLE J2-1 SIGNIFICANT MITIGABLE (S) AND SIGNIFICANT UNAVOIDABLE (U) IMPACTS OF GROWTH IDENTIFIED BY GENERAL PLAN ENVIRONMENTAL IMPACT REPORTS AND MITIGATED NEGATIVE DECLARATIONS IN THE PROJECT AREA) documents give no considerations to the City of Marina which have greatest potential to be negatively affected by the MPWSP project. **Given that the MPWSP proposes to be built in the City of Marina's jurisdiction, should such critical evaluations be applied to Marina and the DEIR be revised to include such reports?** No project approvals should be entertained until such egregious oversights have been corrected with accurate and complete

	chapter. The DeepWater Desalination Project and the People's Project are also addressed in Chapter 5, Alternatives Screening and Analysis	**slant wells reduces any harm to the Salinas Valley Groundwater Basin? If no such evidence exists, why is this reduced alternative the "preferred" alternative? On what basis is Alternative 5a superior to the original MPWSP project when considering harm to the Salinas Valley Groundwater Basin?** If so much attention and urgency was claimed in the full project, how can a reduced project now be acceptable? Does this mean that the urgency was fabricated, or that there are overinflated demand needs or that in the face of valid objections to the project that Cal-Am hopes that reducing the number of slant wells will diminish scrutiny? **What specific reasons does Cal-Am now have for their willingness to support a reduced project?** **Why have all of the options, including MPWSP not been compared as to their impacts to the regional groundwater AND the existence of current water rights? These are the two most fundamental weaknesses of the MPWSP. Will this comparative criteria be added in the DEIR alternative descriptions?**	Biala1-52 cont. Biala1-53 Biala1-54
1.4.4 Revisions Made in This EIR/EIS Pg. 1-11 11//16/16 posting on the	***#27. Topic: Decommissioning the project.*** In October 2014, MBNMS finished its NEPA review of the construction of the test slant well and the operation of the pilot program. In November 2014, the City of Marina and the California Coastal Commission completed their CEQA review. **The test slant well is permitted to operate until February 2018 and it is not part of the proposed project being evaluated in this EIR/EIS.** If the MPWSP with subsurface slant wells at CEMEX is not approved and implemented, **the test well will be removed as analyzed** and approved pursuant to the CEQA and NEPA reviews of the test slant well project. However, if the proposed subsurface slant wells at CEMEX are ultimately approved as part of the proposed project, CalAm would convert the test slant well into a permanent well and operate it as part of the proposed seawater intake system. The conversion and long-term operation of the well has not been covered under previous approvals and is evaluated in this EIR/EIS as part of the proposed project. Municipal Water District of Orange County is accepting bids for the decommissioning of the desalination slant	The Dana Point Slant Well project was abandoned sometime in 2014. But only as of 11/16/16, has a notice for bids to deconstruct their test slant well been posted by the Municipal Water District of Orange County (MCWDO). The MPWSP provisions must specify the time in which such deconstruction take place and this defined timeline should be short. If Cal-Am had to construct 9 more wells, they would work expeditiously, while a removal of one test well could take years. This would be unacceptable. What are the timeframes for deconstruction should this be necessary?	Biala1-55

Letter 2

Commentary on Monterey Peninsula Water Supply Project (MPWSP) DEIR by Kathy Biala, resident of Marina
SUBJECT: Western Snowy Plover, a federally listed threatened species that winters and nests at the proposed MPWSP site.

Respectfully Submitted to:

California Public Utilities Commission c/o Environmental Science Associates 550 Kearny Street, Suite 800 San Francisco, CA 94108	Karen Grimmer, NEPA Lead Monterey Bay National Marine Sanctuary 99 Pacific Avenue, Building 455a Monterey, CA 93940

Pg/Section	Cited text	Comments/Questions	
Section: 4.6-123, Pg. 756	Construction of the nine new permanent slant wells and conversion of the test slant well into a permanent well would disturb approximately 9 acres in the CEMEX active mining area. Construction activities can also result in indirect impacts on special-status wildlife related to disturbance or harassment of individuals. For example, construction noise, vibration, and nighttime lighting can cause special-status birds, bats, and other animals to abandon nests, roosts, or other breeding areas. Artificial lighting during nighttime construction.	It is clear that the population of Western Snowy Plovers (WSP) will be adversely affected by the MPWSP project. If this disturbance will continue for up to 2 years, what is the likelihood that this population impact will be irreversible? What does the science of bird behavior say about return nesting behavior after significant disruption? If not irreversible, over what period of time could the population be restored? ***Will MPWSP utilize the current baseline numbers of WSPs on the Marina coastline that is compiled every year by Point Blue? Based on this baseline, what % decrease of the WSP population will the MPWSP be held to or is it acceptable for the numbers to drop to zero?***	Biala2-1 Biala2-2
Section 4.6-123, pg. 755	T**The beach and foredunes provide important breeding/nesting and wintering habitat for the western snowy plover. Surveys conducted during the 2015 nesting season identified multiple nests along the stretch of beach in the vicinity of the CEMEX active mining area (Page et al., 2015**). Some nests have been found in the vicinity of the CEMEX settling ponds and adjacent to the CEMEX access road (Zander, 2013) and at the location of the northernmost well site. **Nesting has also been documented in the backdunes of the CEMEX active mining area where the subsurface slant wells are proposed (Neuman, 2015).**	In January of this year, the City of Marina passed a resolution designating the Western Snowy Plover as the official City Shorebird, as well as endorsing a C4SM (Citizens for Sustainable Marina) program known as SPARE (Snowy Plover Active Recovery Efforts). Marina takes pride in its natural environment that is home to this federally listed threatened species. To not support the continued WSP population within its jurisdiction is to diminish an aspect of civic pride and the ongoing protection of Marina's unique coastal habitat. In the DEIR Section 2.6.2, Cal-Am has offered to monetarily compensate any well owner who has been impacted by the MPWSP.	Biala2-3
Section 4.6-129	Although birds may be initially disturbed and temporarily displaced during construction, the majority of the site (8 acres) would be returned to pre-construction conditions and birds would be able to utilize the site following construction. Temporary and permanent impacts to plover habitat were described in the previous paragraph.		
2.6.2 Project Water Rights ,Pg. 2-37	**CalAm could compensate the well owners for any increased pumping costs causally tied to the MPWSP**. Assuming that CalAm were to compensate the owner of these wells for any increased pumping	Does Cal-Am have an obligation to offer any type of compensation to the City of Marina or other harmed entities affected by a decline or eradication of a threatened	

Pg/Section	Cited text	Comments/Questions	
	costs sustained due to the MPWSP, the slant wells' operation would not cause injury under the Report's third injury criteria.	bird species on this shoreline? Marina has a rare beach habitat, indeed, where a threatened species is yet observable on its beaches! This was a platform upon which to market and one way to create special identity for the city of Marina.	Biala2-3 cont.
Section 4.6-123, pg. 755 DEIR 4.6-129 to 131 Pg. 761 Section 4.6-130	**Slant well construction would take approximately 15 months to complete, and could take place any time throughout the overall 24-month construction duration for the proposed project.** **However, individual western snowy plovers may also use the entire subsurface slant well construction area for wintering.** **Construction of the slant wells in the CEMEX active mining area could occur year-round.** The nine-acre construction footprint for the subsurface slant wells is located within potential nesting habitat and construction of the nine subsurface slant wells and conversion of the test well to a permanent production well during the breeding season would result in the temporary loss of 8.0 acres (for temporary construction disturbance to areas that would be restored) and permanent loss of 1.0 acre (for new permanent above-ground facilities) of potential wintering habitat. **Construction during the snowy plover wintering season (October 1 through February 28) could directly or indirectly impact individual birds if present within or adjacent to the construction area. Human presence and construction noise and activities can cause roosting plovers to fly and disturb resting or foraging activities. This would be a significant impact.**	In the previous DEIR, it was publically stated that should a nest be discovered during construction, the construction would be stopped (E. Zigas). There is no mention of this intervention except to report that a Lead Biologist will be maintained and perform monitoring duties. What are the specific authorities of this Lead Biologist if a nest is discovered? Will such authorities be documented and if such authority is not heeded, what is the process for appeal? This appeal must be immediate as delaying responsible action would inevitably result in the destruction of the nest with ongoing construction. What are the qualifications of this Lead Biologist and who does this person report to? Is there an unbiased, environmentally oriented board/entity to which the Lead Biologist will report? Without this objective support, this mitigation action is mere "window dressing" to assuage real concerns. Will there be any halting of construction during the WSP nesting period? If not, why not? This temporary cessation of construction was considered for the test slant well and the same considerations are still relevant to the project as a whole. The reasons for unabashed destruction of the environment to build a questionable project that does not have any legal water rights in the region and its current failure to prove "no harm" to the region's sole source of water i.e. the Salinas Valley Groundwater Basin, creates just another devastation to the region for whom no benefits result for Marina and Ord communities.	Biala2-4 Biala2-5 Biala2-6
Section 4.6-131	A full list of special-status species that could be significantly impacted by subsurface slant well construction is provided in Table 4.6-6. Overall, the impact on special-status species during slant well construction would be significant. However, with implementation of Mitigation Measures 4.6-1a (Retain a Lead Biologist to Oversee Implementation of Protective	The DEIR lists mitigation efforts as "…**installing a visual construction barrier** for work conducted adjacent to breeding habitat during the breeding season to reduce human disturbance to plovers, **conducting pre-construction surveys** to determine if plovers are present and	Biala2-7

Pg/Section	Cited text	Comments/Questions	
	Measures), 4.6-1b (Construction Worker Environmental Awareness Training and Education Program), 4.6-1c (General Avoidance and Minimization Measures), 4.6-1d (Protective Measures for Western Snowy Plover), …4.6-1i (Avoidance and Minimization Measures for Nesting Birds), 4.6-1n (Habitat Mitigation and Monitoring Plan), 4.6-1p (Control Measures for Spread of Invasive Plants), 4.12-1b (General Noise Controls for Construction Equipment), and 4.14-2 (Site-Specific Nighttime Lighting Measures), the impacts would be reduced to a less-than-significant level. These measures would reduce impacts on special-status species by designating a lead biologist to oversee and ensure implementation of special-status species protective measures; requiring worker training regarding special-status species potentially present to ensure that workers are aware of special-status species that occur in the project area and the measures to be implemented to avoid, minimize, and/or mitigate impacts**; requiring general measures such as installation of an exclusion fencing to ensure special-status species do not occur within the construction area**, a trash abatement program to ensure special-status species predators are not attracted to the site, and other measures to avoid and minimize impacts on special-status species; requiring specific measures to avoid, minimize, and compensate for impacts on the western snowy plover such as avoiding the breeding season**, installing a visual construction barrier for work conducted adjacent to breeding habitat during the breeding season to reduce human disturbance to plovers**, **conducting pre-construction surveys to determine if plovers are present** and implementing minimization measures to minimize construction impacts on plovers, if present, and compensating for habitat loss to mitigate for temporary and permanent loss of habitat;…	implementing minimization measures to minimize construction impacts on plovers". Will these "pre-construction surveys" be done each day before the start of construction? Or will this be done every week, every month, quarterly and if this type of schedule is followed, is this sufficient monitoring, per the recommendations of disinterested, objective experts in the field? Who will do this and once spotting a nest, what immediate actions will take place? It is ironic that one of the mitigation measures during breeding season is to reduce human disturbance to plovers by "installing a visual construction barrier for work conducted adjacent to breed habitat to reduce human disturbance to plovers". The construction site with plowing of massive sand, trucks, noise, bulldozers, drilling equipment **IS** the major disturbance. This type of mitigation only serves to keep out beach goers from entering the construction area and does little to protect snowy plovers against the assault of heavy equipment moving immediately along the habitat border! This mitigation measure serves only to distract us from the major impacts. "These measures would reduce impacts on special-status species **by designating a lead biologist to oversee and ensure implementation** of special-status species protective measures." If true protective intent hinges solely upon the Lead Biologist, the Lead Biologist's more frequent monitoring with the absolute, unquestioned authority to stop construction or initiate any major mitigation measures must be clearly documented. What are the written authorities of the Lead Biologist to do so? On what legal grounds does this authority stand upon? Can the Biologist determine a more frequent, more random ability to survey the site? Will this report be distributed to state, regional and federal agencies as soon as the Lead Biologist submits them to his/her supervisor to ensure public awareness and transparency of potential threats?	Biala2-7 cont. Biala2-8 Biala2-9 Biala2-10 Biala2-11

Pg/Section	Cited text	Comments/Questions	
Section 4.6-2	Several comments on the Draft EIR concerned use of western snowy plover occurrence data in the vicinity of the proposed subsurface slant wells, status of western snowy plover in the vicinity of this facility, and potential impacts of this facility on plovers. ESA requested western snowy plover occurrence data from Point Blue Conservation Science, but Point Blue Conservation Science was unable to provide this data prior to publication of this EIR/EIS. This EIR/EIS includes additional information and analysis in regards to western snowy plover in Sections 4.6.5.1 (Construction Impacts) and 4.6.5.2 (Operational and Facility Siting Impacts).	There appears to be some limited references to Point Blue publications in this DEIR. Was Point Blue also consulted on the formation of specific mitigation measures? Will they be consulted as to the job description and reporting criteria of the Lead Biologist? Has or will Point Blue be consulted in defining specific, effective ways to mitigate harm to the WSP population in this specific location? Point Blue is the foremost authority of the WSP populations *on the Monterey Bay*; they must be intimately involved in the MPWSP project.	Biala2-12
Section 4.6-2	Some comments expressed **concern about the authority of the Lead Biologist** designated in the mitigation measures presented in the Draft EIR, and the role of that individual relative to the project proponent. This is further described in Section 4.6.5.2 under Mitigation Measure 4-6.1a.	There is very little further detail in this reference so to suggest that there is additional information about the Lead Biologist role is misleading. See above comments for questioning the qualifications, reporting relationships, authority to execute necessary protections, and transparency of the Lead Biologist reporting.	Biala2-13
Mitigation Measure 4.6-6, pg 899	Monitoring of **the Brine Storage Basin** shall include the following: 1. *Monthly Monitoring*: A qualified biologist and/or qualified biological monitor shall regularly survey the Brine Storage Basin at least once per month starting with the first month of operation of the Brine Storage Basin. The purpose of the surveys shall be to determine if the bird deterrents are effective in excluding birds and to assess whether the deterrents serve as a hazard to birds or wildlife. The monthly surveys shall be conducted in one day for a minimum of two hours following sunrise (i.e., dawn), a minimum of one hour mid-day (i.e., 1100 to 1300), and a minimum of two hours preceding sunset (i.e., dusk) in order to provide an accurate assessment of bird and wildlife use of the ponds during all seasons. Operations staff at the MPWSP Desalination Plant shall also report finding any dead birds or other wildlife at the Brine Storage Basin to the Lead Biologist within one day of the detection of the carcass. The Lead Biologists shall report any bird or other wildlife deaths or entanglements within two days of the discovery to CalAm, CDFW, and USFWS. 2. *Quarterly Monitoring*: If after 12 consecutive monthly site visits (described above) no bird or wildlife deaths are detected at the Brine Storage Basin by or reported to the Lead Biologist,	This type of elaborate monitoring program is NOT specified for the WSP main habitats! Where is the "Brine Storage Basin" and what amount of area does this represent compared to the whole of WSP wintering and especially nesting habit area? Should this level of survey not be applied to the areas of the beach and foredunes, identified by Paget: *"The beach and foredunes provide important breeding/nesting and wintering habitat for the western snowy plover. Surveys conducted during the 2015 nesting season identified multiple nests along the stretch of beach in the vicinity of the CEMEX active mining area* (Page et al., 2015). Will monitoring schedules, with even more frequent monitoring visits, be applied to the known significant WSP habitats i.e. on the affected beach and foredunes? It is curious that in this Brine Storage Area, the DEIR states that the Lead Biologist "*may also suggest* adaptive management measures to remedy any problems that are detected during monitoring or modifications if bird impacts are not observed." This does not sound like a duty nor an authority to ensure measures are actually taken. This would apply to the Lead Biologist's role in the main habitat	Biala2-14 Biala2-15

Pg/Section	Cited text	Comments/Questions	
	monitoring can be reduced to quarterly visits. 3. *Biannual Monitoring*: If after 12 consecutive quarterly site visits (described above) no bird or wildlife deaths are detected by or reported to the Lead Biologist, future surveys may be reduced to two surveys per year, during the spring nesting season and during fall migration. *4. Modification of Monitoring Program*: As appropriate, the Lead Biologist shall modify the monitoring program based on information acquired during monitoring, and may also suggest adaptive management measures to remedy any problems that are detected during monitoring or modifications if bird impacts are not observed. CalAm Monterey Peninsula Water Supply Project 4.6-243 ESA / 205335.01 Draft EIR/EIS January 2017	monitoring areas. Will such language be modified to specify this as duties with authorities assigned in the job description of the Lead Biologist? Is a month's time for monitoring sufficient or in a month's time, can a nest be made, eggs laid and the nest be destroyed by construction before the next monthly visit? It is imperative that monitoring not be on an anticipated, regular schedule in order to observe impacts without tampering. This project, if approved, is invested with big money and powerful political influences that could undermine the ability of the Lead Biologist to act ethically and swiftly. This circumstance, no matter how repugnant to some parties this may seem, has had a repeated state and national history that cannot be denied. Will the DEIR mandate that monitoring be on a random basis (in addition to a more frequent, defined schedule) with safeguards for verification of findings?	Biala2-15 cont. Biala2-16 Biala2-17
Mitigation Measure 4.6-6, pg. 899	4. Environmental Setting (Affected Environment), Impacts, and Mitigation Measures 4.6 Terrestrial Biological Resources under Impact 4.6-2, the site is in the Coastal Zone and central dune scrub in this area may be considered primary and secondary habitat under the City of Marina LCLUP. Impacts to central dune scrub would be potentially significant. Additionally, as described under Impact 4.6-2, western snowy plover critical habitat is located approximately 240 feet west of well Site 1. Slant well maintenance at well Site 1 could indirectly impact this critical habitat <u>if worker foot traffic extends beyond the designated construction work area</u>, if trash and debris is left behind following construction, and/or if invasive plant species are introduced or spread at the site. Indirect impacts on critical habitat would be significant.	The area around Cemex dredging pond was, at one time, fenced by the State Park District to indicate sensitive habitat and it was apparent to beach walkers that this did not protect the habitat when immediately behind this fence were truck imprints, moving of sand, and other construction activities! The MPWSP cannot rely on the annually installed symbolic fencing by the State Park District. This fencing marks the nesting habitat for protection against accessing from the beach side. Cal-Am, if concerned about "worker foot traffic" must install another separate fence to demarcate nesting habitat from the landward side. Experts on the WSP must be utilized to identify the specific sensitive habitat zone from both the beach and inland locations.	Biala2-18

Kathy Biala
Letter 3

To: Mary Jo Borak and Karen Grimmer

Dear Ms. Borak and Ms. Grimmer:

The following is my additional public comment regarding the MPWSP DEIR; I have previously submitted two other public comments.

Dr. Ed Thorton has reported that, along the Monterey Bay, the current loss of land mass due to erosion directly attibutable to the CEMEX sandmining operations is approximately 4 feet of shoreline annually. At such a rate due to sandmining activities plus any anticipated sea level rise due to global warming, what is the expected time in which the proposed slant wells will be impacted in terms of becoming situated further out in the ocean? Would this impact the cost of desalination due to the increased salinity of the water being pumped or create the need for the slant wells to be moved further inland to approximate the current equivalent status of the proposed project? It may be that with slant wells further out to the ocean, access to the 180' aquifer may be ameliorated, but if plans to move the slant wells further inland were desired, what approval processes would be required for this additional construction? Does the current DEIR address such possibilities with accurate scientific calculations? If not, why not? Would not another DEIR be necessitated and if such a condition exists, should not this process be clearly expressed in this DEIR so that it is not an assumed extension of any current DEIR approvals? Biala3-1

Please confirm receipt of this email at kbiala@milestonemma.net. Thank you.

Cordially,
Kathy Biala

8.7.4 William Bourcier

Dear Sir,

I have attached a document that addresses the issue of potential greenhouse gas release from subsurface intakes for desalination plants. It specifically addresses information contained in Appendix G2 (Trussel Technologies Technical Memorandum) and compares the GHG releases rates obtained by Trussel with those I previously submitted to an earlier call for public comments on the CalAm DEIR.

To briefly summarize:

(1) The GHG release rates estimated by Trussel are smaller than my estimates because they used a fluid with very low CO2 content relative to the other slant-well fluids

(2) The Trussel estimates do not include release from the RO permeate - which I argue is a bad assumption and detail my argument in my reply. This also lowers their GHG release rate estimates relative to mine.

(3) The method for calculation of GHG release carried out by Trussel and by myself (Bourcier) provides essentially the same rates when using the same starting fluid composition. This verifies the calculational method and confirms that GHG release is an issue that needs to be addressed in regulations controlling desalination feeds.

Sincerely,
William Bourcier

COMMENTS TO TRUSSEL REPORT
William Bourcier
February 23, 2017.

I have reviewed the assessment of carbon dioxide releases from subsurface desalination feeds provided by Trussel Technologies (Appendix G2 – Trussel Technologies Inc. Technical Memorandum, Response to CalAm MPWSP DEIR) and compared their results with the estimates that I provided as comments to the DEIR and California Ocean Plan. Bourcier-1

Our results differ in that I predict larger carbon dioxide releases than estimated by Trussel. In my opinion the values I quoted are more accurate estimates than those reported by Trussel. I believe the following observations and comparisons explain the differences.

1. *The Trussel report ignores all carbon dioxide released from the reverse osmosis permeate*

The Trussel report correctly assumes that the location at which the carbon dioxide release will take place will be affected by the reverse osmosis process. Once the feed fluid is brought to the surface from the well and contacts the atmosphere, it will begin to equilibrate with the atmosphere and release carbon dioxide. Depending on the type of pre-treatment and feed storage methods, much of the degassing may not happen until after the fluid has been subjected to the reverse osmosis (RO) process. In typical sea water RO processing, much of the contained dissolved carbon dioxide will end up in the permeate (vs. the concentrate) as can be seen in Appendix A of the Trussel report. The carbon dioxide in the permeate stream will be released to the atmosphere upon exiting from the RO system. Bourcier-2

However, in the Trussel report it is asserted that this carbon dioxide will **not** be released because prior to distribution of the RO permeate, the permeate will be chemically treated to avoid release of carbon dioxide. Although no more detail is given in the Trussel report, this could be done by adding caustic (NaOH) to the permeate to increase the pH and convert the dissolved carbon dioxide gas into bicarbonate ion. Adding caustic lowers the effective partial pressure of carbon dioxide in the fluid and if added in the right amount (added molal amount of caustic = molal amount of carbon dioxide that would have been released) no carbon dioxide release to the atmosphere will take place. In normal seawater desalination systems a small amount of caustic is commonly added to the permeate in order to avoid corrosion of the distribution system. The caustic is usually added after carbon dioxide degassing in order to reduce the mass of caustic needed. I assert here that caustic addition is the chemical treatment referred to but not specifically identified in the Trussel report. Bourcier-3

The error in this analysis is that no account is taken of the carbon dioxide release ("carbon footprint") which takes place during the production of caustic used to treat the permeate. Caustic is commonly produced using the chloralkali process. The carbon footprint (the amount of carbon dioxide generated and released as a result of production of the caustic) is substantially larger than one mole of carbon dioxide per mole of caustic. In other words, to make enough caustic to neutralize some mass of carbon dioxide in the permeate requires that a much larger amount of Bourcier-4

carbon dioxide be generated during the production of the caustic. This ratio is about 2 for most production facilities (i.e. two moles of carbon dioxide are produced per mole of NaOH) but numbers as low as 1.7 are reported for the most modern chloralkai plants [1].

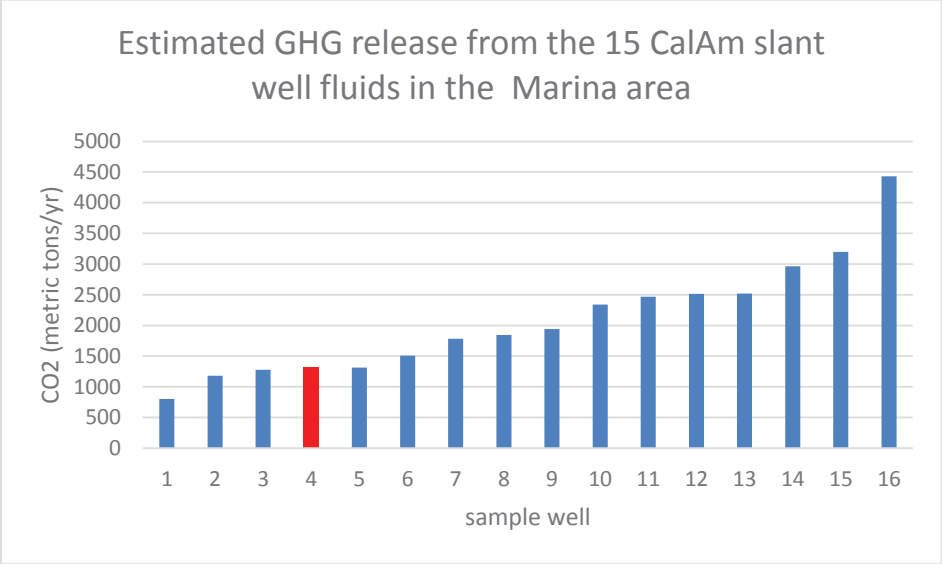
So it is clearly not valid to ignore the carbon dioxide released from the reverse osmosis permeate. Chemical treatment to suppress carbon dioxide release makes the total release of carbon dioxide associated with desalination even greater. In order to minimize total release of carbon dioxide the best approach is to simply allow the carbon dioxide to degas. Other options imply larger CHC releases.

The carbon dioxide that would be released from the permeate and is ignored in the Trussel report needs to be added back to the estimated carbon dioxide release in order to report an accurate and complete carbon dioxide release rate.

Bourcier-4 cont.

2. *In the Trussel report the well fluid composition used to compute the "worst-case" carbon dioxide release is not representative of fluids sampled to date and in fact is nearly the "best-case" scenario*

The well fluid composition used in the Trussel report to compute carbon dioxide release is not representative of the carbon dioxide gas contents of the 15 wells sampled to date in the Marina area as part of the CalAm project. Figure 1 below shows my estimated carbon dioxide release rates along with the fluid studied in the Trussel report (in red). As can be seen, the well fluid



Bourcier-5

Figure 1. Estimated carbon dioxide release rates (metric tons per year) for the 15 well fluid samples reported in the Draft EIR (Appendix G2) and, in red, the fluid composition used in the Trussel study. Estimates are based on 9.6 MGD plant operating at 41% recovery. Average release for all wells is about twice the release of the fluid used in the Trussel analysis.

[1] http://www.eurochlor.org/media/9385/3-2-the_european_chlor-alkali_industry_-_an_electricity_intensive_sector_exposed_to_carbon_leakage.pdf

chosen for their study has among the lowest carbon dioxide contents of the 15 wells sampled. In fact it is the fourth lowest in gas content. The Trussel report having referred to this fluid as being a "worst-case scenario" is simply not true. It is closer to being a best-case scenario. Their estimated release rate of 735 tons/year when corrected for loss from the permeate increases to about 1311 tons/year. This is about one half of the average release rate for all wells sampled to date by CalAm in the Marina area and less than 30% of the largest value.

Bourcier-5 cont.

3. Comparison of methods for estimating carbon dioxide releases

It should be noted that the method I use to estimate carbon dioxide release and the method described in the Trussel report provide very similar carbon dioxide release rate estimates when compared directly. I estimate about 770 tons/yr for the RO concentrate carbon dioxide release vs. 735 tons/yr of release reported in the Trussel report. The small difference between these two numbers can probably be attributed to slightly different thermodynamic data used in the two methods. Note that I used the same correction methods for salinity, temperature, and other factors described in detail in the Trussel report. This suggests that going forward we have an accurate and verified method for estimating GHG releases. What is needed now is validation of the method from an actual feed source.

Bourcier-6

Summary and Recommendations

The Technical Memorandum provided by Trussel Technologies provides verification that carbon dioxide release from subsurface intakes is likely to take place in significant tonnages. For any given fluid composition, the calculated release tonnages calculated by Trussel are very similar to those Bourcier provided in comments to the DEIR and in a later report on the topic. The agreement verifies the method of calculation that both parties (Trussel and Bourcier) used to estimate carbon dioxide release rates.

Bourcier-7

The fact that the carbon dioxide release tonnage estimates provided by Trussel are smaller than those reported by Bourcier is due to two issues: (1) the Trussel estimates ignore any release from the reverse osmosis permeate – which I have argued above to be an unjustifiable assumption; and (2) the Trussel report uses a fluid input composition that has among the lowest carbon dioxide contents of any of the wells sampled to date by CalAm in the Marina area. These two factors are responsible for the difference in estimated carbon dioxide release rates.

Bourcier-8

Bourcier-9

To better clarify the Trussal analysis, I recommend that the report be revised to include a discussion of the method of treatment for the permeate (such that it will not release any greenhouse gases) and specify the chemical additives and their carbon footprint. I would ask that they also include revised calculations that include the carbon footprint of the chemical additives. I also think it would be beneficial to include an analysis of a well composition that is truly a worst case scenario instead of the lower than average carbon dioxide fluid composition that was used in the Trussel report.

Bourcier-10

Bourcier-11

Bourcier-12

In addition, and potentially of far more importance is methane release from the feed solutions. Methane is often found in co-equal amounts with carbon dioxide in pore waters such as those that host the proposed desalination feed sites along the California coast. Because of the much greater greenhouse potency of methane vs. carbon dioxide, methane is of far more concern. Future work to address the issue of GHG release from subsurface feed intakes should include actual measurements of both carbon dioxide and methane in potential desalination feeds. I strongly recommend that measurements of methane from fluids obtained from the currently operating CalAm well be obtained to provide key information needed to better inform policy decisions relating to desalination feed regulations.

Subject: MEMORANDUM FOR: CALIFORNIA PUBLIC UTILITIES COMMISSION (CPUC) AND MONTEREY BAY NATIONAL MARINE SANCTUARY (MBNMS); PUBLIC COMMENT FOR DEIR/DEIS FOR THE MONTEREY PENINSULA WATER SUPPLY PROJECT – A 12-04-019

Date: February 19, 2017

Please accept my comments and questions concerning the CalAm DEIR/DEIS MPWSP – A 12-04-019, as follows:

Re: DEIR, Page 484, 4.4 Groundwater Resources, Seawater Intrusion

The problem with the DEIR stating that there will be no harm to Marina's aquifers, based on a groundwater modeling application, is that such data application utilizes insufficient data, namely, for what is obviously a three-dimensional aquifer, the utilization of point data on salinity, as derived from vertical wells. It mentions but fails to state why electrical resistivity tomography (ERT) was not used to map the aquifer for salinity. This is irresponsible science, in the face of the existing and available ERT methodologies, which can be used to produce two-- and even three-dimensional slices of an aquifer's salinity as a function of linear location and depth to a distance of several hundred meters and over large expanses of the Salinas Valley Groundwater Basin. Brown-1

ERT has in recent years been used in two-dimensional applications, so as to show groundwater salinity as a function of depth over a particular area. Stanford University professor of geophysics Dr. Rosemary Knight has recently obtained data which show relative salinity as a function of depth in southern Monterey Bay between the CEMEX plant in northern Marina, to and beyond Marina's boundary with Seaside. This shows that even at the coastline, in the Marina area, there are substantial lenses of relatively fresh water, in both the 180-foot and 400-foot aquifers. This methodology utilizes dozens of metal electrodes implanted in the beach at specified distances from one another, and the measuring of multiple electrical resistances between such electrodes.

Though unstated in the DEIR, there is even a more sophisticated use of ERT that will produce a 3-dimensional grid of data points, showing relative salinity over not just a line, but a rectangular area (the "x" and "y" directions) and depth (th "z" direction), for which the Marina Coast Water District (MCWD) has contracted with Stanford University's Department of Earth Sciences. This method utilizes a helicopter-borne antenna array to accomplish the same things during the helicopter's overflight of multiple parallel paths, Brown-2

with the data from this approach to be used to obtain multiple two-dimensional imaging, with interpolation between such images giving an overall 3-dimensional aquifer picture that shows relative salinity as a function of very-specific and precise latitude, longitude, and depth. Dr. Knight, an expert in this field, is involved in this project as well. The multiple two-dimensional images will be compared with one another, and reasonably-small interpolations made between adjacent two-dimensional images, so as to result in a precise three-dimensional imaging, to several hundred meters in depth, over large parts of the Salinas groundwater basin, whose 180-foot and 400-foot aquifers contain water bearing capacities in quality from extremely brackish, all the way down to potable water containing no more than 500 mg of chloride per liter.

The many thousands of data points which will be obtained, as opposed to the few point data from sentinel wells, will be far superior for adequate groundwater modeling of the portion of the Salinas groundwater basin which potentially will be harmed by the pumping of seawater, in a finished plant, of millions of gallons per day. It is this type of data which, one obtained within the next few months, will result in a far superior groundwater model, ultimately to determine whether it really is true that the desalination plant will supposedly not cause or exacerbate already-existing sea water intrusion into any of Marina's three aquifers, the 180, 400, and 900-foot aquifers.
In summary, ERT 2-dimensional data, far superior to point data used in the current DEIR as limited point-data from sentinel wells, is not considered in the DEIR. The DEIR mentions ERT as a tool but speaks of it as though it is a new, experimental technique. It is not. Its use, at least in terms of electrical-resistance measurement along a linear path, to map groundwater salinity, is at least a decade old. See, e.g., Goldman, M., and U. Kafri, 2006, *Hydrogeological Applications in Coastal waters, in Applied Hydrogeophysics Proceedings of the NATO Advanced Research Workshop on Soils and Groundwater Contamination: Improved Risk Assessment*, ed. H. Vereecken, A. Binley, G. Cassiani, A. Revil, and K. Titov, pp. 233-254, Dordrecht, The Netherlands; Springer, 2006. Current published ERT data and conclusions should be incorporated into any groundwater modeling that purports to predict no harm to the aquifers near where the desalination-plant intake wells would be drawing millions of gallons per day.

Brown-2 cont.

The DEIR mentions ERT in the 2-dimensional context spoken of (though doesn't utilize such data, for reasons unstated), but utterly fails to mention the existence of the more recent helicopter-borne-antenna ERT methodology, to obtain 3-dimensional aquifer data, despite it having been used successfully, as shown in a paper published last year, in California's Central Valley. See Knight, R., Smith, R., Asch, T., Abraham, J., Canninia, J., Viezzoli, A., *Subsurface Mapping with Airborne Electromagnetics in the Central Valley of California*, Extended Abstract, Soc. of Exploration Geophysicists International Exposition and 86th Annual Meeting, Dallas, Texas, October 2016. The DEIR should utilize information from this methodology when it comes in, hopefully within several months.

Finally, the DEIR only states that the ERT along the Monterey Bay coastline is consistent with Cal-Am sentinel-well point data, and just 2-dimensional studies at that. And, on this point, there is no mention as to whether either the raw or analyzed ERT data could improve the prediction model, either as to the well-established 2-dimensional electrodal methodology, or the more recent 3-dimensional methodology mentioned above.

In essence, the DEIR's prediction of no increased salinity to the aquifers mentioned above, is based on limited sentinel-well point data, without consideration of even data obtained in two dimensions at the coastline, mush less 3-dimensional data that will likely be obtained soon.

Brown-3

Yours Truly,

/s/ *David W. Brown*

8.7.6 Charles Cech

California Public Utilities Commission
c/o Environmental Science Associates
550 Kearny Street, Suite 800
San Francisco, CA 94108
DEIR/DEIS, MONTEREY PENINSULA WATER SUPPLY PROJECT, PUBLIC COMMENT

ES.5.1 Description of the Proposed Project Page ES-5
The project area extends approximately 18 miles, from the town of Castroville in the north to the City of Carmel in the south (see Figure ES-1). The MPWSP would include a seawater intake system, which would consist of 10 subsurface slant wells1 (eight active and two on standby) extending offshore into the submerged lands of MBNMS, and a Source Water Pipeline. The slant wells would be constructed at the CEMEX sand mining site in the northern coastal area of the City of Marina and would extract 24.1 million gallons per day (mgd) of source water through the seafloor in MBNMS.

Public Comments

The test slant well was designated exclusively as a test device and as such CEQA requirements where circumvented. Now a footnote to ES.5.1 indicates that the test well will be converted to a production well without passing CEQA. Slant wells have never been used to draw ocean water for desalination anywhere in the world! Why should this slant well be allowed to operate in California without passing CEQA? Cech-1 Cech-2 Cech-3

Additionally the existing test well intake has two screens neither of which are located under the seafloor as state above. The screens are located in two aquifers that are well above the seafloor. These aquifers have been contaminated with seawater and extend under the farmland bordering the Monterey Bay. Some of the test slant well tracking data indicates a substantial increase in seawater intrusion of the 180-foot aquifer since the test slant well has been operational. Why is this happening? Cech-4 Cech-5

The water being pumped by the test slant well is not pure seawater it is contaminated ground water. Therefore the existing test slant well is not in compliance with the criteria called out by this DEIR. This fact should eliminate the test slant well as a potential production well. Why does this DEIR not address this issue? Cech-6

If the nine new slant wells being proposed will have intake filter packs and screens under the seabed they will not perform in the same way as the existing test slant well. This will render all of the data collected by the existing slant well useless and should require that the new sub-seabed slant well be installed and pass CEQA requirements. **How** can this DEIR propose that the test slant well be included as a production well when it does not meet the sub-seabed requirement? Cech-7

With the additional slant well intakes being placed under the seabed, the seawater being drawn will include additional minerals that will leach out of the seabed above Cech-8

the slant well intake. This would require much more elaborate filtering of the seawater prior to being desalinated. It may also require a different size and type of slant well intake filter pack and much larger pumps to achieve the 24.1 million gallons per day required. All of these issues will have a negative impact on the environment that has not been addressed in this DEIR. Does the DEIR plan on addressing this concern?

Cech-8 cont.

Groundwater Modeling, Impacts and Water Rights Page ES-13 Paragraph 1

CalAm's proposed use of subsurface slant wells to withdraw source water for the MPWSP Desalination Plant is the subject of two controversies: (1) whether CalAm has the legal right to extract groundwater from the Salinas Valley Groundwater Basin (SVGB); and (2) whether implementation of the MPWSP and operation of the subsurface slant wells would exacerbate seawater intrusion in the SVGB. The proposed subsurface slant wells at CEMEX would extend offshore and be screened in aquifer units of the SVGB that have long been intruded by seawater. Although the subsurface slant wells would draw seawater (i.e., source water for the MPWSP Desalination Plant) from beneath the ocean floor, a fraction of the source water would be drawn from inland portions of the SVGB.

Public Comments Paragraph 1 above

The statement regarding seawater intrusion is accurate, however it does not disclose the fact that there are projects in place that have dramatically slowed and is projected to halt seawater intrusion. These projects are designated the Castroville Seawater Intrusion Project (CSIP) which started delivering recycled water in 1998 and the Salinas Valley Reclamation Project (SVRP) a inflatable rubber dam that captures Salinas River water during rainy season for future use for agriculture. Why has the DEIR ES section overlooked the positive environmental impact these project have had on the Salinas River Basin. Why has this DEIR overlooked the negatively impact the test slant well has on these projects?

Cech-9

Cech-10

Groundwater Modeling, Impacts and Water Rights Page ES-13 Paragraph 2

In 2012, the CPUC asked the SWRCB to provide an opinion regarding whether CalAm has the legal right to extract source water for the MPWSP Desalination Plant from offshore aquifers of the SVGB. The SWRCB has indicated that for CalAm to appropriate groundwater from the SVGB, the MPWSP EIR/EIS must demonstrate that the proposed project will not harm or cause injury to other basin users (SWRCB, 2013) and made certain recommendations for further study.

Public Comments Paragraph 2 above

Monitoring well adjacent to the test slant well have experienced significant lowing of aquifer water levels when the teat slant well was operating. The HWG declared that the lower water level was due to irrigation, but offered no proof or data to support that assertion. Monitoring well 4M has experienced approximately 31% increase in

Cech-11

TDS when compares with the baseline of April 2, 2015. The HWG stated that this increase was due to stratification but provided no proof of this assumption. No one from Cal Am or the HWG has ever contacted adjacent property owners to check on the changes in their well water TDS or saline data. I suggest that if they take the time to determine the condition of the well water in the vicinity of the test slant well they will find that contamination has increase at a rate considerably higher than in the years prior to test slant well operation. Why is this overlook by this DEIR?

Cech-11 cont.

Groundwater Modeling, Impacts and Water Rights Page ES-13 Paragraph 3

The recommendations of the SWRCB have been implemented by a Hydrogeological Working Group (HWG) comprised of licensed hydrogeologists with pertinent experience in the Monterey Bay region. The HWG was a result of an August 2013 Settlement Agreement between CalAm and 16 parties whereby CalAm agreed their hydrologist and technical team would work with the Salinas Valley Water Coalition's and Monterey County Farm Bureau's assigned hydrogeologists, and other technical experts designated by CalAm. The HWG developed a work plan in order to reach agreement about the studies, well tests, field work, modeling, monitoring, and other data analyses that is needed to assess and characterize whether and to what extent the proposed operation of the MPWSP may adversely affect the SVGB and the water supply available to legal water users thereof. The resulting Hydrogeological study informed the analysis presented in Section 4.4, Groundwater Resources, as well as the corresponding analysis in Chapter 5, Alternatives. Refer to Section 2.6 in Chapter 2, Water Demand, Supplies, and Water Rights, for a discussion of water rights.

Public Comments Paragraph 3 above

An overriding factor to all of the data taken by the test slant well is that Dr. Dennis Williams was the Executive Director of the HWG and is also the holder of the slant well (when used for desalination) patent and his company Geoscience is the primary source of all of the data taken on the test slant well operation. Since he and his company will benefit financially from the successful operation of slant wells, why is this not considered another **major conflict of interest**?

Cech-12

Groundwater Modeling, Impacts and Water Rights Page ES-13 Paragraph 4

Furthermore, the groundwater model and results presented in the 2015 Draft EIR have been revised, to address questions about the accuracy and credibility of the groundwater modeling work that was the subject of potential conflict of interest comments. The CPUC made the groundwater data files available for public review, and the CPUC employed the Lawrence Berkeley National Laboratory to conduct an independent evaluation of that data; the results of that evaluation are provided in Appendix E1. The groundwater analysis from the 2015 Draft EIR has been updated by a new groundwater modeling consultant.

Public Comments Paragraph 4 above
Since Lawrence Berkeley National Laboratories, was required to essentially duplicate the original data analysis using the same software, there is a problem with this methodology. The problem is that if there is a fault with the modeling software, it will generate the same erroneous result. The National Lab was not required to evaluate the software or the reasonableness of the output. This was a major oversight in this evaluation. Why was an alternative modeling program not used to determine if the same results would be produced with different software?

Cech-13

Page 1-5
The secondary objectives of the MPWSP are to:
3. Improve the ability to convey water to the Monterey Peninsula cities by eliminating the **hydraulic lowpoint** in front of the Naval Postgraduate School, by improving the existing interconnections at satellite water systems and by providing additional pressure to move water over the Segunda Grade.

Public Coment:
There have been inquiries made to two major plumbing repair companies regarding the "hydraulic lowpoint" (sometimes named the hydraulic gradient and the hydraulic barrier). Both have indicated that they have worked on many homes and businesses in the vicinity of the Naval Post Graduate School and have never experienced this hydraulic phenomenon. Request of Cal Am to provide information regarding measurement techniques and data obtained to support the existence of this lowpoint have never been provided by Cal Am. Is there proof available that proves the existence of the hydraulic lowpoint?

Cech-14

4.1.3 Baseline Conditions Page 4.1-8 Paragraph 2
Since the CPUC issued its NOP in 2012, the Lead Agencies have developed or received new data on some of the resource areas, so they have updated the baseline data as appropriate. This document notes those updates in its discussions of the Setting/Affected Environment for the various resource areas and applies them in the pertinent analyses.

Public Comment
The following information was copied from a **Geoscience Technical Memorandum** dated April 20, 2015 and is provided as proof that the Monterey slant well was run for five continuous days prior to establishing the monitoring wells water levels and TDS baselines. It was reported in the Monterey Herald news paper that the slant well was pumping at the rate of 2200 GPM. This says that the test slant well pumped 15,840,000 gallons of water prior to establishing base lines..The result is that there is no way to compare subsequent data taken to a quiescent (no slant well ever run) baseline normally required as scientific evidence. Additionally, I believe that the Executive Director referred to in paragraphs 4, 5, and 6 below is Dr. Dennis

Cech-15
Cech-16
Cech-17

Williams, the president of Geosciences and the holder of the Slant well for Desalination patent. This would imply a conflict of interest. Cech-17 cont.

2.1 Special Condition No. 11 of CDP #A-3-MRA-14-0050

Special Condition 11 of the above referenced CDP entitled *Protection of Nearby Wells* and requires the following:

1. Prior to starting project-related pump tests, the permittee shall install monitoring devices in a minimum of four wells on the CEMEX site within 2,000 feet of the test well, and one or more offsite wells to record water and salinity levels within the wells.

Public Comment
Since these monitoring devices are installed to monitor the test slant well operation, why is the very large amount of data taken not usewd in this DEIR? Cech-18

2. Prior to commencement of long term pumping tests, the HWG shall establish baseline water and Total Dissolved Solids (TDS) levels in those monitoring wells and recommend these levels to the Executive Director of the California Coastal Commission.

Public Comment
Why is the baseline data taken prior to the five day pump rate test not used in this DEIR? Cech-19

3. During the project pumping tests, the Permittee (Cal-Am) shall, at least once per day, monitor water and TDS levels within those wells in person and/or with electronic logging devices.

Public Comment
Thousands of pages of date has been accumulated per this requirement, why has this data not been used to verify Dr. Williams modeling projections? Cech-20

4. The Permittee shall post data collected from all monitoring wells on a publicly-available internet site at least once per week and shall provide all monitoring data to the Executive Director upon request.

Public Comment
The permittee being did post this data on a weekly basis, however the data was all collected and published by Geosciences, who has a financial interest in the success of the test slant well. Why was a disinterested third party not used to collect and publish this vital data? Cech-21

5. If water levels drop more than one-and-one-half foot, or if TDS levels increase more than two thousand parts per million from pre-pump test conditions, the Permittee shall immediately stop the pumping test and inform the Executive Director. The Hydrogeology Working Group shall examine the data from Monitoring Well 4 if the test well is shut down due to either of these causes. The Hydrogeology Working Group shall determine whether the drop in water level or increase in TDS is from a cause or causes other than the test well, and will submit its determination to the Executive Director.

Public Comments

This in fact did happen but after analysis the criteria for shut down was altered by the CCC to allow the test well to continue operating. What was the justification for altering the shut down criteria? Cech-22

6. If the Executive Director agrees with the Hydrogeology Working Group that the cause of the drop in water level or increase in TDS was a source or sources other than the test well, then the Executive Director may allow testing to resume. If, however, the Executive Director determines that the drop in water level was caused at least in part by the test well, then the Permittee shall not re-start the pump test until receiving an amendment to this permit.

Public Comment

Since the Executive Director is Dr. Williams, the Slant Well patent holder, do you really think he will shut down his patented test slant well? Again, this must be considered, a conflict of interest. Cech-23

3.0 CEMEX TEST SLANT WELL AND MONITORING WELL CONSTRUCTION

3.1 Test Slant Well

The first Phase of Test Slant Well Investigation commenced with construction of a 724 ft Test Slant Well (TSW) at an angle of 19 degrees below horizontal at the CEMEX site. Construction began on December 27th, 2014 and was completed through the five-day pumping test on April 8, 2015. **The second phase of the Test Slant Well Investigation will include a long-term pumping test once baseline water and TDS levels have been established.**

Public Comment

How can the teat slant well data be accepted when quiescent baseline is not being used to compare ongoing operational data? Cech-24

Table 4.4-4 on page 4.4-22 Public Input

This table displays a very limited amount of data, and all of the data comes from Geoscience, the company that will benefit financially from positive analysis of the slant well. Cech-25

The test data contains no environmentally sensitive data regarding mercury, lead, or radiation measurements documented for the slant well water. Additionally the Central Cech-26 Cech-27

Coast Seawater Average TDS does not seem to agree with federal TDS measurements in the Monterey Bay Sanctuary. Why is this critical environmental information missing in this DEIR. Cech-27 cont.

3.2.3.6 Carmel Valley Pump Station

The Valley Greens pressure zone, in Carmel Valley south of the Segunda Reservoir, does not have sufficient hydraulic head to fill the existing Segunda Reservoir, which is located at the southern end of the existing Segunda Pipeline. The proposed Carmel Valley Pump Station, with a pumping capacity of 3 mgd (2,100 gpm), would provide the additional pressure needed to fill Segunda Reservoir. The pump station would be enclosed in a 500-square-foot, single-story building on a site located approximately 240 feet south of Carmel Valley Road near the intersection of Rancho San Carlos Road (see **Figure 3-10c**). A 50 kW (68 hp) portable diesel-fuel powered generator would be stored onsite for use in the event of a power outage. A separate 100-square-foot electrical control building would be constructed outside of the pump station building.

Public Comments

Since these facilities do not exist at present. Where are the environmental impact reports on these new buildings? Cech-28

What is the noise and air pollution impact of the 50 KW diesel generator? Cech-29

What is the traffic impact for accessing these facilities? Cech-30

How will these faculties impact the neighboring residents?

It has been disclosed by Mr. Svindland a Manager with Cal Am that Cal Am has been using the Segundo Pipeline to deliver Carmel River water to the city of Seaside on a daily basis. Has this use of the ASR pipeline passed CEQA? If not, why not? Cech-31

Comments should pertain to the accuracy and adequacy of the Draft EIR/EIS prepared for the MPWSP. All comments must be received by the CPUC no later than February 27, 2017. PLEASE PRINT LEGIBLY.

Comment:

Reports from "Just Water", "Water Plus" & other groups show that the slant well project in Marina is "stealing" Marina water, causing a seawater intrusion cone, and that technique hasn't worked anywhere in the US!

Response from Cal Am?

MEMORANDUM FOR: CALIFORNIA PUBLIC UTILITIES COMMISSION (CPUC) AND MONTEREY BAY NATIONAL MARINE SANCTUARY (MBNMS)

SUBJECT: PUBLIC COMMENT FOR DEIR/DEIS FOR THE MONTEREY PENINSULA WATER SUPPLY PROJECT – A 12-04-019

Please accept my comments and questions concerning the CalAm DEIR/DEIS MPWSP – A 12-04-019. Thank you for your work on the DEIR/DEIS as it was a major undertaking, and for taking your time to respond to my inputs. Please consider the NEPA as being included in references and questions to the CPUC. My public comment is meant in a constructive way, and should be construed as a search for truth and justice, and not in any way a criticism of those who prepared this extensive tome. The DEIR/DEIS chapters and sections cited are indicated for reference. My comments and questions are as follows:

Chapter 2: Water Demand, Supplies, and Water Rights:

1. The DEIR states (2.6 Water Rights, p. 2-31): "...if CalAm did not possess legal rights to use feedwater for the MPWSP desalination plant, then the desalination plant simply could not operate and the project would not go forward. That is why water rights factors in as a key project feasibility issue."

   If the MPWSP were to draw water solely from the ocean, then water rights concerns would not apply since ocean water usage does not require water rights (2,6,1, p. 32). In the case of the MPWSP, the current test slant well is drawing brackish and freshwater from its well, as will the other proposed slant wells. CalAm cannot measure with any certainty the quantity of seawater vs. freshwater that it is drawing from the well, and it has misled the public by confusing the definition of brackish water, which is a

Coppernoll-1

1

combination of seawater and freshwater, as a result of seawater intrusion. CalAm will be drawing 2100 gallons of SVGB water per minute from its proposed slant wells, and then depositing it back in the Monterey Bay, if it continues to do what it is currently doing. This water, that CalAm refers to as brackish, contains freshwater as well as ocean water, but with a seriously reduced percentage of salinity and different TDS than found in ocean water. The Salinas Valley Groundwater Basin (SVGB), classified as a high priority groundwater basin by the State of California and subject to groundwater sustainability designations and regulations (SB1168, AB1739, AB1319, State of California State Water Resources Control Board), is the Marina Coast Water District's (MCWD) sole water source; it has groundwater rights and it has been an established public water utility since 1961, and has enjoyed a many decades long golden track record of providing fresh, potable water at affordable prices to its customers, in its lawful jurisdiction and service area.

Coppernoll-1 cont.

MCWD has established water rights overlying the SVGB. These groundwater rights are superior rights accorded jurisdictions overlying groundwater basins, rights that supersede appropriative, prescriptive, or developed water rights. Additionally, MCWD can claim riparian water rights because it has relied on the Salinas Valley Groundwater Basin as its sole source of freshwater since its establishment in 1961, before the founding of the City of Marina in 1975. MCWD owns the water infrastructure network that services the Ord Communities. Even though CalAm owns/leases 46 acres in the CEMEX property area and vicinity, it does not supersede the MCWD's legal groundwater rights to the SVGB, which extends approximately 100 miles in area. The slant wells will draw from the entire SVGB because the aquifers extend in linear and vertical fashion across the entire regional basin network, with water flowing in the subsurface aquifers (180, 400 and 900 foot aquifers) from inland to sea, or vertically due to gravitational pull. The proposed project assumes, incorrectly, that sucking water from one well location does not affect the entire groundwater network system. CalAm's massive pumping, in comparison to MCWD's conservative, conservation oriented draws, is exacerbating seawater intrusion, a scientifically proven result of overpumping:

"Saltwater intrusion can occur in coastal groundwater basins, where overpumping of groundwater aquifers can cause seawater to be drawn into aquifers and contaminate the water supply.", p. 8., ("The Hidden Costs of Groundwater Overdraft", by Tara Moran, Janny Choy, and Carolina Sanchez, Chapter 4, "Understanding California's Groundwater", Stanford Woods Institute for the Environment and the Bill Lane Center for the American West. Also, see "The Steep Price of Overpumping for Many Ecosystems", same reference.

Coppernoll-2

In a related article, "Sustainable Groundwater Management Act (AB1739, SB1168, and SB1319)", in aquilogic, Inc., October 2014, 'The Problem with California Groundwater Management': "...excessive groundwater withdrawal can cause subsidence of the ground surface, which in turn decreases the soil permeability, aquifer storage capacity, and reduces the infiltration rates to recharge the aquifers. Additional problems related

2

to excessive groundwater withdrawal are failed wells, deteriorating water quality, and environmental damage. Therefore, GSP's are necessary to prevent the loss of productive aquifers and to ensure that reliable sources will be available in the future for drinking and irrigation purposes.", p,1.

Coppernoll-2 cont.

Can the CPUC support this ongoing harmful overpumping activity that causes environmental damage? This overpumping causes large cones of depression or subsidence, which, over time can lead to beach erosion that affects the entire Monterey Bay coastline, not just the CEMEX property area. This overpumping will permanently destroy the Salinas Valley Groundwater Basin as more and more seawater intrudes the aquifers, degrading water quality. This same irresponsible conduct will continue, even more so, with the other nine slant wells the CalAm proposed project plans to construct and install, which, as the DEIR asserts, will continue to pump from the Dune Sand Aquifer and180-Foot Aquifer.

Coppernoll-3

The MPWSP cannot be considered Feasible for the following reasons:

1. CalAm, the DEIR states, "would need an appropriative groundwater right to retrieve and export water from the basin" (2.6.1, p.32). The DEIR then continues on to assert that in order for CalAm to have the requisite appropriative rights to support the project, it will need the right to extraction of otherwise unusable Basin groundwater that will not harm lawful water users, and be able to guarantee that any fresh water extracted can be returned to the Basin without injury to existing legal water users. Only then would CalAm have rights to the portion of feedwater that comes from the Basin because the MPWSP product water that contains such Basin water would be "developed water." "Developed water is water that was not previously available to other legal users and that is added to the supply by the developer through artificial means as a new water source." (2.6.1, p. 32)

   Coppernoll-4

   How can the water that CalAm is currently drawing, and plans to draw, from the future proposed slant wells, be considered appropriative or developed? The SVGB is the sole water source for MCWD, thus for Marina and Ord Communities. This water, particularly the Perched Dune Sand Aquifer, through proper sustainable groundwater management plans and programs, has had freshwater restored through MCWD's good water conservation efforts, reversing seawater intrusion. There is a natural hydrogeological balance between ocean water and freshwater, through an equalized push pull system whereby freshwater aquifers, such as the Perched Dune Sand Aquifer, provide a wall against seawater intrusion into the aquifers, thus equalizing the balance between land and sea, a natural phenomenon. Overpumping causes downward pressures and subsidence that lower this natural barrier, allowing seawater intrusion. Sodium Chloride is the chemical character of ocean water, whereas the Dune Sand Aquifer Groundwater and the 180-Foot Aquifer Groundwater respectively reveal that the chemical character of groundwater in the related new wells is mainly calcium chloride and calcium

   Coppernoll-5

   Coppernoll-6

3

bicarbonate ("Technical Memorandum re North Marina Area Groundwater Data and Conditions", Curtis Hopkins, Principal Hydrogeologist, Hopkins Groundwater Consultants, Inc., to Keith Van Der Maaten, General Manager, Marina Coast Water District, May 26, 2015, Page 7).

Coppernoll-6 cont.

(Please see Exhibit A: Perched Dune Sand Aquifer (EKI Study) at Armstrong Ranch Project).

Return water is not legitimate water for CalAm to provide because the origination of the water used comes from the Basin, water that CalAm has no right to in the first place. All water within the Basin is usable to MCWD. The "brackish" water, whose definition CalAm misstates, consists of ocean and fresh water, but contains a much smaller fraction of salinity than ocean water and different TDS. CalAm fails to give the whole truth. CalAm has rights to purely ocean water, but CalAm has no rights to brackish or fresh water drawn from the SVGB. CalAm cannot create "return" water because CalAm has no water rights to legitimately extract groundwater at all, let alone later "return" it. On what basis does the CPUC legitimize this argument in the DEIR?

Coppernoll-7

If CalAm has no groundwater rights to extract the "brackish" water in the first place, how does it have a right to claim it as a right to create return water, or to developed water whose origination is groundwater? Does the CPUC comprehend the natural balancing of aquifer layers and subsurface structures that allow aquifers to be recharged and seawater intrusion to be reversed, resulting in freshwater restoration? Or that Brackish water, which is still groundwater, plays a significant role in this process? Does the CPUC recognize the fact that the CalAm MPWSP has no water rights within the SVGB, that MCWD does own SVGB water rights, or that the MPWSP is infeasible from the beginning? **Why did the DEIR omit any analysis of harm to the MCWD or even include it as if it were nonexistent in the equation?**

Seawater intruded water is still extracted from the groundwater basin and is still a more saline mixture than freshwater, but MCWD works with this challenge to restore the balance nature intended, and the affected aquifers have been, and continue to be restored to their natural equilibrium by the constant and consistent efforts on the part of MCWD, and water conservation efforts on the part of MCWD's customers. As stated, brackish water contains only a fraction of the salinity found in ocean water. Brackish water is usable and treatable groundwater. MCWD has treatment facilities in its sustainable groundwater management plans. Therefore, CalAm has no right to this water either. As attested to by Curtis Hopkins in his Technical Memorandum cited above, page 5, "Years of reduced pumping has resulted in beneficial groundwater conditions that are apparently slowing the movement of seawater and providing a freshwater source that is replenishing the aquifers. Notably, the fact that the Dune Sand Aquifer and 180-Foot Aquifer at Monitoring Well MW-7 are no longer contaminated by high concentrations of seawater can likely be explained by the changing hydrogeological conditions

Coppernoll-8

resulting from the efforts of MCWD (e.g., Annexation Agreement, etc.) and others to reduce pumping in the coastal area. As a result, recharge from rainfall into the Dune Sand Aquifer creates a mound of freshwater that flows toward the Salinas River and the ocean." Presently, CalAm is furiously pumping 2100 gallons per minute from the Dune Sand Aquifer, thus undoing all the good work the MCWD and others have done to restore freshwater to this aquifer. This overpumping is clearly causing harm to MCWD and its customers, and is destroying this critical aquifer in an already over drafted basin. How can CalAm claim the groundwater it extracts is unusable to legal users? If CalAm can use the water, then the legal owners can certainly use it. Where in the DEIR is there scientific proof that the CalAm extracted water is unusable to legal users? In fact, CalAm is intentionally and unlawfully wasting this water, making it unusable to anyone, especially its legal users.

Coppernoll-8 cont.

Coppernoll-9

Coppernoll-10

Does the CPUC acknowledge CalAm's unjustifiable illegal actions? Will the CPUC take action to protect the SVGB and its legal users? What is the fiduciary responsibility of the CPUC?

Coppernoll-11

Will the CPUC require more stringent baseline controls and scientific data be obtained before any approvals? Has the CPUC researched the Dana Point, California slant well experiment to find out why that slant well was not deemed viable, what its inherent technical, or other problems encountered were that halted its use? Has the CPUC established any scientific data to explain the level of efficiency dropping from 98% to 54% in the only other known slant well (Dana Point), as a point of comparison for the viability of the MPWSP, or why the CalAm test slant well is experiencing problems with clogged filters or how it will manage the toxic chemicals needed to clean the filters and wells? Will these chemicals enter the groundwater aquifers, causing further contamination? What scientific data or baseline controls have been established to justify these slant wells? So far, there are only assumptions based on faulty modeling and estimates, but no rock-solid science employed. Do the taxpayers and CalAm customers deserve a sounder basis on which to gamble this $300 million project, or does the CPUC determine it is just fine to move forward with an untested, unproven, and scientifically uncertain project? Where is the level of uncertainty for viability and feasibility been established or presented in the DEIR? All credible scientific analysis requires a determination of the level of uncertainty and peer reviewed, published, scientific scrutiny.

Coppernoll-12

Coppernoll-13

Coppernoll-14

Coppernoll-15

2. Has the CPUC visited the slant well sites to verify that the slant wells will be extracting ocean water from the subsurface of the ocean? Monitoring reveals the test slant well is extracting fresh water and salt water intruded water from the Dune Sand Aquifer and the 180-Foot aquifer, and not the ocean, which the DEIR confirms to be fact. In other words, there is a discrepancy between what the project design portrays and the actual slant well activity. The DEIR confirms that "The proposed slant wells would draw water from the Dune Sand Aquifer and the 180-FTE Aquifer", but the subsurface information CalAm asserts it has retrieved is not adequate because one test slant well cannot provide data for any other areas within the

Coppernoll-16

5

subsurface, and the data retrieved cannot provide data for the condition of the whole aquifer, or its aquitards, or any existing fissures. Only an Electrical Resistivity Tomography (ERT) field study can provide this appropriate scientific data. CalAm and the CEMEX property area had an opportunity to benefit from such a study that was conducted by Stanford professor, Dr. Rosemary Knight, at no cost to CalAm. CalAm chose to ignore this great opportunity to collect scientifically verifiable data on the entire subsurface area underlying its proposed slant wells to determine the true condition of aquifers and aquitards, the existence of fissures, and the extent of seawater intrusion. The ERT field research study revealed that there are fissures and seawater intrusion in the subsurface aquitards.

Coppernoll-16 cont.

There is a fault just south of the CalAm test slant well location. Has the CPUC DEIR evaluated the potential environmental damage seismic activity in the area of the test slant well and its proposed nine additional slant wells could sustain? Existing fissures indicate that future seismic activity is highly probable, and that more fissures could occur to further degrade aquitards and water quality. The attached ERT slides show there are fresh water layers and salt water intruded areas in the aquifers along the coast. It is unfortunate that CalAm neglected to take advantage of this unique ERT opportunity. As the Review and Comments on Draft EIR of the Monterey Peninsula Water Supply Project prepared by SWCA Environmental Consultants states, "The DEIR's evaluation of water rights relies heavily on the July 31, 2013, report prepared by the SWRCB (refer to Section 2.7 and Appendix B-2 of the DEIR). The report ultimately concluded that the determination of whether a legal means exists for Cal Am to extract water from the Salinas Valley Groundwater Basin (Basin) will depend on developing key hydrogeologic information to support a determination that the project would not cause injury to other users in the Basin." To date CalAm has failed to conduct such a study, even when one was available at no cost to CalAm. **Furthermore, CalAm will never have the water rights to export water from the SVGB to its Monterey Peninsula service area because state law precludes exporting groundwater from one jurisdiction and transporting it to another jurisdiction. (Please see Exhibit B: ERT of Monterey Bay)**

Coppernoll-17

Coppernoll-18

Coppernoll-19

Do you consider CalAm negligent for not obtaining this valuable data for this DEIR and the previous one? Is CalAm remiss for avoiding this scientific data retrieval process for its test slant well, and by extension, its other proposed wells? This important information would have had a serious impact not only on the test slant well, which CalAm plans to make permanent, as well as the other nine slant wells.

Coppernoll-20

3. The DEIR states that "The key principle of developed water is: if no lawful water user is injured, the effort of an individual to capture water that would otherwise be unused should be legally recognized." **This DEIR seems to be totally one-sided, not taking into consideration the needs and water supply demands of the MCWD jurisdiction. MCWD, a long established and community recognized lawful user, will be injured, and is being injured, by the actions of the MPWSP.** It is accepted

Coppernoll-21

Coppernoll-22

knowledge that the water in the SVGB is precious and scarce. All SVGB groundwater is deemed "usable" and productive for maintaining the natural hydrogeological balance.

How can the CPUC approve the MPWSP that purposely plans to export Marina's source water to another area, namely to CalAm's district service area, with total disregard for the harm the MPWSP is doing (exacerbating seawater intrusion through overpumping), and plans to repeat its past history of depleting precious water supplies? CalAm disregarded the law in the past, and plans to do so again. Its project plan specifically states its objective is to export the SVGB water outside the Basin to the CalAm service area, which is unlawful. (2.2) Further, CalAm announces in the DEIR its intention, via its slant wells, to calculatedly contaminate a potable groundwater supply in violation of multiple state regulations and water quality laws. Dumping illegally extracted groundwater into the Monterey Bay is wasting water. Through extensive overpumping of the SVGB's groundwater, CalAm is converting potable freshwater into contaminated brackish water, and eventually will convert the groundwater to mostly saltwater, or to use CalAm's terminology, brackish water. This is the strategy being used to justify its unlawful extraction of groundwater and its desalination plant. CalAm is not pumping ocean water as its feedwater. It is pumping SVGB groundwater and will deplete and destroy this invaluable asset. Why is the CPUC allowing this to occur? Why is the CPUC not collaborating with other agencies to ensure this unlawful activity is stopped? Or, how does the CPUC justify condoning this unlawful activity and ignoring in the DEIR the violation of the CEQA and state law requirement that CalAm must prove its actions will do NO HARM?

Coppernoll-22 cont.

Coppernoll-23

4. Monterey County Water Resources Agency Act stipulates that "no groundwater from the basin may be exported for any use outside the basin, except that use of water from the basin on any part of Fort Ord shall not be deemed such an export. If any export of water from the basin is attempted (MCWRA) may obtain from the superior court, and the court shall grant, injunctive relief prohibiting that export of groundwater." (2.6.3) (Since Fort Ord no longer exists, the latter portion of this Agency Act then, one can surmise, only applies directly to the SVGB and its lawful users). Continuing, the DEIR states that: "The proposed project will develop supplemental water supplies to serve CalAm's Monterey District area" (2.2.1) and CalAm must develop a replacement water supply to meet existing demand in the Monterey District service area. In addition, CalAm proposes to provide sufficient supply to meet demand associated with the development of existing legal lots of record, Pebble Beach water entitlements in the Del Monte Forest area, and tourism demand under improved economic conditions within its service area." (2.3)

Coppernoll-24

Where does the DEIR take into account the MCWD water supply demands and needs, and how the MPWSP will harm the MCWD's ability to protect and preserve its own water supply resources? Currently, the CalAm slant well is pumping massive amounts of water far in excess of what even the MCWD is pumping, dumping the freshwater back

Coppernoll-25

7

into the Monterey Bay, which violates state law that states that "all water use in California must be for beneficial purposes and by reasonable method of use." (AB3030) Wasting Marina's SVGB water is harmful to the 33,000 current Marina Coast Water District's customers. There is a limited supply of freshwater. CalAm has already demonstrated that it disregards the law (Carmel River, Seaside Groundwater Basin cases), and plans to continue doing so. How can the CPUC not recognize that CalAm has no legal groundwater rights, or any other rights, to the SVGB, especially since its objective, as stated, is to export the SVGB groundwater to its own service area, which is also illegal, as discussed above, and will deplete MCWD's water supply source? Can this MPWSP planned action to permanently degrade and delete the last freshwater frontier, the SVGB, in the immediate area of Marina be justified or approved?

Coppernoll-25 cont.

Coppernoll-26

How can the CPUC justify saddling the MCWD customers and Marina citizens with unsustainably high water rate increases to subsidize CalAm stockholders and incur the cost of this estimated $300 million MPWSP, or its stated unsustainable over use of the City of Marina's transportation network system since no agreements are in place to mitigate the ruining of roads that are already in a state of disrepair and marred with potholes, or avert costs to Marina taxpayers without compensation agreements in place? The DEIR does not quantify the cost, and dismisses the severe impact, of the thousands of round trips that will be made by the MPWSP trucks and vehicles over an extended period of time. Will the DEIR correct these omissions?

Coppernoll-27

Coppernoll-28

5. CalAm's MPWSP will harm the SVGB and injure the MCWD and its water customers because the project will pump massive amounts of brackish and fresh water from the SVGB aquifers, causing more and more seawater intrusion. It already has caused harm because it is undermining and undoing the water conservation and freshwater restoration accomplishments MCWD has thus far achieved. There is hardly enough groundwater supply to meet the needs and demands of the MCWD, or its future water demands for anticipated development, but with the continued freshwater restoration and conservation efforts MCWD is engaged in through its sustainable groundwater management plans and programs, there will be sufficient potable water for the MCWD jurisdiction and service areas. The SVGB water has been designated for use in Marina and the Ord Communities, Salinas and the agricultural industry's irrigation demands, but may not lawfully be exported to the CalAm service area, which is the express purpose of CalAm's project. How is the CPUC justifying this egregious injustice and harm to MCWD and Marina and Ord Communities, and the farmers?

   How can the CPUC not understand that this project will inflict irreparable harm on the MCWD by depleting its only source for fresh, potable water? MCWD has a vital need for its groundwater. The Perched Dune Sand aquifer is a critical source of freshwater supply. CalAm does not have any category of water rights to this groundwater asset that belongs to the MCWD. To allow another water district (CalAm) to invade the MCWD in order to procure its (MCWD) water only to

Coppernoll-29

8

transport that water outside the Basin to its own (CalAm) district's service area is an environmental, financial, and social injustice that cannot and should not be tolerated. **(Please see Exhibit A: Freshwater Perched Dune Sand Aquifer, Armstrong Ranch Project, EKI Study)**

Coppernoll-29 cont.

6. State water policy supports enhancement of beneficial uses of water and the prevention of wasting water. CalAm is violating this policy by pumping massive amounts of water (126,000 gallons of freshwater per hour), far in excess of the water being pumped by MCWD. CalAm is spouting that water back into the Bay, squandering MCWD's water supply source, as previously noted. (Article X, section 2, California Constitution and codified state policy). The unlawful, and environmentally unsound practices being employed by the MPWSP cannot be over stressed because they are directly related to the harm being done, and the cumulative irreparable damage that is taking place, thus connecting these legal, ethical, and environmental issues requires continued underscoring and exposure.

Coppernoll-30

Will the CPUC recognize that CalAm will repeat its past unlawful behavior to the detriment of MCWD and the other SVGB legal users? Can the CPUC legitimately make any other determination than "infeasible" for the MPWSP?

Coppernoll-31

7. For these reasons so far stated, and many more, **the MPWSP is not feasible.** MPWSP solutions for mitigation to avoid harm are pie-in-the sky proposals, are deceptive, and have no practical application in real time situations. The planned 21-mile water pipeline, that will disrupt life in Marina and elsewhere, is the pipeline CalAm intends to use to export MCWD's water to Cal'Am's service area, contrary to law, and to great harm to MCWD that depends on the Basin water for its service area. While it is a shame that CalAm mismanaged its own water supply sources, it is not the responsibility of MCWD or the City of Marina to jeopardize or destroy its own water supply source and harm its own customers and citizens in order to salvage the damage CalAm has chosen to inflict on its own service area customers. The law protects MCWD from such injury. The CPUC must do the same. The CPUC must do the morally and legally right thing, and in this case, the environmentally right thing, by declaring the MPWSP **infeasible.**

Coppernoll-32

The DEIR 2-40 claim that "...the project would appear consistent with the Agency Act and the Ordinance given that the project would return to the Basin any quantity of fresh water withdrawn from the Basin" is an absurd conclusion in that the "quantity of fresh water withdrawn from the Basin" could not legally be extracted from the Basin in the first place, or exported anywhere outside the Basin. MCWD has legal groundwater rights. CalAm is literally invading another water district's water source in order to illegally extract and export that water for its own water district's use without regard to the legal user's rights.

Coppernoll-33

Where does the DEIR provide validated scientific data proving the quantity of fresh water it is extracting? How can the proposed project determine the amount to return to the basin since it has no scientific exactitude to measure that quantity? The DEIR, 2.6.2, states that "In that the quantity of such fresh water component of the supply water is not currently known, the modeling and the EIR/EIS analysis assess a range of return water between 0 and 12 percent of the source water." Does this level of uncertainty cry out for scientific data to measure how much freshwater is being withdrawn? Is this not an affirmation that freshwater is, and will be, extracted from the basin and not subsurface ocean water? Please explain why the DEIR contradicts itself when the Appendix E-2 Geoscience diagrams show the slant wells to be in the 180-foot aquifer of the Salinas Valley Groundwater Basin on the one hand, then in 2.6.2, the DEIR asserts that "the project is not forecasted to draw any fresh water through the MPWSP source water supply wells over the life of the project", on the other hand. Is this not an obfuscation of the truth that the slant wells are extracting freshwater and are not in the ocean subsurface area as claimed? Confusing brackish water and freshwater demonstrates a lack of scientific knowledge pertaining to the subsurface area of the basin and how it functions vis-à-vis freshwater and freshwater that has been contaminated by seawater intrusion. The percentage of salinity in ocean water is far higher than salinity in brackish water, and the TDS is dissimilar. There is a big difference between the two, to include the cost of ocean water desalination and brackish water treatment. To extract purely ocean water requires no water rights. To extract brackish water does require water rights because brackish water is still groundwater whose quality has been degraded, usually through over drafting.

Coppernoll-34

Coppernoll-35

Coppernoll-36

As pointed out, doesn't the CPUC know that any return water is already, a priori, water that is unlawfully drawn from the groundwater basin, and is, therefore, an unacceptable solution?

8. Can the CPUC justify this regional environmental injustice? CalAm has already acted in such a manner as to lose the public trust. Can the CPUC expect City of Marina, or any other city, residents to trust CalAm or its proposed project? History tells us that the MPWSP and CalAm cannot be trusted to respect the law. DEIR 2-7 states that CalAm had "no valid basis of right" and was unlawfully diverting water (surface and subsurface flow) from Carmel River. The DEIR 2-7 continues to state that CalAm was in violation of Order 95-10 and Water Code Section 1052. CalAm was directed to "terminate all unlawful diversions from the river no later than December 31, 2016."

Coppernoll-37

In DEIR 2.2.4, the text, referring to the Seaside Groundwater Basin Adjudication, states that "By adjudicating the water rights for all users of the basin, the court intended to protect the basin from long-term damage associated with potential seawater intrusion, subsidence, and other adverse effects that commonly result from overpumping." On 2.2.4, p.2-8, the DEIR text continues to explain the Decision identified the "natural safe yield" throughout the basin in each of its subareas. The

10

Decision also found (and noted all parties agreed) that continued production in excess of the natural safe yield would result in seawater intrusion and deleterious effects on the basin." Additionally, the same DEIR text, p. 2-9, indicates that "...by the time the Laguna Secca Subarea will be allocated to other producers with overlying groundwater rights that are superior to CalAm's appropriative rights (Svindland, 2013a), CalAm has to replenish the Seaside Groundwater Basin over a 25-year 'repayment period'".

Coppernoll-37 cont.

Has the CPUC given adequate consideration to CalAm's history of violating the law, of requesting permission for more and more water rate hikes on its customers, or its history of disregarding the rights of other lawful water rights users? Not only should the MPWSP be deemed infeasible, but the CPUC should protect the CalAm rate payers from usurious water rate charges, charges that are intended to reward its shareholders, stockholders who for the most part do not even live on the Monterey Peninsula or pay taxes there. All in all, CalAm has damaged its reputation in the community, has lost the trust of its customers and many others, and should not be given another chance to repeat history. It has gotten away with unlawful behavior, in a sense, and manifestly intends to repeat history.

Coppernoll-38

Will the CPUC take into consideration, when deciding on the CalAm application to recover present and future costs for the proposed project, the Public Utilities Codes 451 and 454 that require that water service providers charge their customers "just and reasonable rates"?

Will the CPUC do the morally right thing for the Monterey Peninsula by denying CalAm its requested Certificate of Public Convenience and Necessity (CPCN) to build, own, and operate all elements of the MPWSP, and permission to recover present and future costs for the proposed project? Proposed Project approvals should not take place **BEFORE** any of the affected areas have given their permission or agreement, or had a chance to thoroughly assess the harm the proposed project will do. It is hoped the CPUC will deny DEIR and project approval, and refuse to issue the CPCN. That is the responsible action to take.

Coppernoll-39

9. The DEIR asserts, 2-30, that "Indeed, no government agency will formally grant water rights to CalAm for the proposed project." This DEIR seems to support the **infeasibility of the MPWSP**. It is important to note on 2-29 that the DEIR specifies that" It is the jurisdiction's responsibility to determine, subject to applicable plans, policies, laws, and regulations, whether or not to approve a new or intensified water use within its boundaries." If logic prevails, would this not mean that, as the responsible agency in the Marina area, with CalAm operating in the MCWD's jurisdiction, the MCWD would have a voice in this proposed project decision? If so, then can the CPUC explain how the DEIR statement on 2-30 can imply a unilateral decision in favor of CalAm: "This EIR/EIS assumes that water provided by the proposed project will be allocated to meet existing demand and that any water left over would be allocated in general proportion to

Coppernoll-40

Coppernoll-41

11

projected growth in the CalAm service area jurisdictions." Could the CPUC please explain or clarify this apparent contradiction?

Coppernoll-41 cont.

Chapter 4: Groundwater Extraction and Quality

Reasons the Proposed Project DEIR is Inadequate:

1. This DEIR is inadequate because it does not sufficiently consider the environmental impacts of the water pipelines extending to the CalAm service area, and the harm exporting SVGB groundwater to another service district will do to the MCWD service area, the quality of water based on scientific data, not inept science, and especially the severe adverse impact the proposed project will have on the integrity of the Perched Dune Sand Aquifer. **It is unconscionable that the CEQA and state law requirement to do NO Harm is currently being disregarded.**

Coppernoll-42

2. **DEIR Chapter 4 clearly states that "The proposed slant wells would draw water from the Dune Sand Aquifer and the 180-FTE Aquifer from about 30 feet below msl to 200 feet below mean sea level (GeoScience, 2016b) ...the Dune Sand Aquifer overlies the 180-FTE Aquifer with no aquitard between the units. The test slant well is screened across both units and has been sampled on a weekly basis when operational."** The CalAm pumping has increased seawater intrusion, much to the detriment of the Perched Dune Sand Aquifer that had its freshwater restored through MCWD's prudent water conservations and restorations plans and programs. This is a freshwater perched aquifer that CalAm had previously ignored in the last EIR, according to Curtis Hopkins, hydrogeologist, in a Technical Memorandum to MCWD, dated May 26, 2016.

Coppernoll-43

How can the slant well test be considered valid since only approximately half the total time required for the test will be considered operational time? There will be insufficient data to make any conclusive determinations concerning scientifically valid test results for safety and water quality. The well operations were halted due to construction defects and other related issues. Will the existence of the construction defects foreshadow additional more serious environmental impacts as a result of faulty or defective well and pipeline construction? Will the CPUC bank on untested, unproven technology that has no other successful slant well in the United States or the world, other than the failed Dana Point, California slant well, to use as a comparative analysis tool? Can the CPUC in good conscious take this risk? CalAm transmits the cost of its failures and unlawful conduct to its customers because it does not assume financial responsibility for its own poorly designed projects. In the Curtis Hopkins technical analysis (cited above), the faulty modeling used for the MPWSP is highlighted as providing erroneous data, and therefore should not be the source for decision making for the proposed project. Will the CPUC revisit this modeling, asking an independent third party to provide a more objective analysis?

Coppernoll-44

Coppernoll-45

12

Does the CPUC accept as valid the modeling proffered by the same individual who holds the patent to the slant well, or the same company, GeoScience, that reviews and evaluates the proposed project? Is a second round of conflict of interest at play?

Coppernoll-46

The Perched Dune Sand Aquifer is vital to the MCWD fresh water supply, which CalAm is damaging with its pumping, just as it harmed the Seaside Groundwater Basin and the Carmel River. **Based on CalAm statements and actions, it appears that CalAm's objective is to permanently reduce the quality of the SVGB aquifers and aquitards to render them completely seawater intruded, as a way to justify its proposed desalination project.** CalAm's Director of Engineering, Ian Crooks. is claiming publicly that the 180-FTE and 400-FTE aquifers are already permanently damaged due to seawater intrusion, and that "the (180-foot aquifer) was damaged and done a long time ago." (Monterey County Weekly, article "War of the Wells", 2-2-2017). Is this statement to be understood as the rationale for overpumping the Perched Dune Sand Aquifer? This is a misleading statement because, as Electrical Resistivity Tomography field tests have scientifically demonstrated, there are freshwater and seawater intruded layers in the subsurface structures, and an EKI study of the Perched Dune Sand Aquifer shows the salt water and fresh water areas in the subsurface of the aquifer. The Perched Dune Sand Aquifer is far from "damaged and done a long time ago", but if CalAm is allowed to continue pumping 2100 gallons per minute from this aquifer, as it plans to do for all future slant wells, then this Ian Crooks statement will become a reality, and the Marina Coast Water District's freshwater supply source will indeed be destroyed, which will be a disaster for Marina and the Ord Communities. **(See Exhibit B for examples of ERT field research study results, and Exhibit A for the EKI study of the Perched Dune Sand Aquifer, showing the saltwater intrusion and fresh water subsurface areas, and the balancing of water flow to create a natural barrier to seawater intrusion).**

Coppernoll-47

There is scientific proof that pumping causes sea water intrusion, as supported in scientific journals cited above. There is scientific data to prove MCWD has restored freshwater to SVGB aquifers through its restoration plans and water conservation programs. Information obtained from one well, it has been also scientifically proven, cannot provide adequate or accurate data for the Basin's extensive subsurface area, both linear and vertical. Only through ERT testing can accurate scientific data confirm the condition of the subsurface areas. Even if Ian Crooks' statement were true, this assumed aquifer condition would not give groundwater rights to CalAm, which it is desperately seeking at the expense of MCWD. CalAm in DEIR 4.4 also claims it has gathered sufficient information to make conclusions about the aquifer. This cannot be true because sentinel wells or test slant wells only provide, through monitoring mechanisms, information on the area directly below the well, but cannot possibly provide information pertaining to the entire groundwater basin. However, Electrical Resistivity Tomography (ERT) would have provided precise data on the extent of freshwater vs seawater intrusion, as well as data on the strata, fissures,

Coppernoll-48

and aquitards, but CalAm refused the ERT's request to include the CEMEX property in its field research study, which would have been free, accurate scientific data for CalAm. ERT is the only solid authentic method for obtaining sound scientific data on the aquifers and aquitards and their degree of health and structural condition.

Coppernoll-48 cont.

Why is the CPUC ignoring the Perched Dune Sand Aquifer being used by CalAm instead of ocean subsurface intake, as it has claimed it will do in its project design description? CalAm is not drawing in ocean subsurface water. It is depleting the SVGB freshwater Perched Dune Sand Aquifer, to great peril to the Basin and rightful groundwater users. Will the CPUC do anything to rectify this situation? It surely will be repeated in the other 9 slant wells once installed, if installed, because CalAm asserts in the DEIR that it will do exactly that.

Coppernoll-49

Will the CPUC heed all the inputs from the MCWD customers who are concerned about the degradation of its sole source of freshwater supply, the SVGB? Will it deny DEIR and project approval based on the project being infeasible? There is a moral imperative to do so. Can the CPUC accept the consequences of jeopardizing the critical water supply of one district to satisfy the needs of another water district whose stated purpose is to take the SVGB water and transport it to an outside the Basin district, risking grave, even irrevocable harm, to the injured party, MCWD and its customers, present and future?

Coppernoll-50

3. **In addition, this DEIR is inadequate because it fails to address several issues, and should not be certified or approved until those concerns have been addressed.**

Coppernoll-51

First, on a scientific level, the DEIR does not address the potential of seismic activity and how that activity would impact both the slant wells and the pipes and pipelines. A past Electric Resistivity Tomography (ERT) field research test demonstrated that there are fissures in the existing aquitards, but CalAm neglected to employ this important, and well known, scientific method for determining the condition of the subsurface structures in the SVGB aquifers and the aquitards, even though it recognized, in the DEIR, that ERT could be used as a tool to retrieve important data. The CalAm test slant well is located in an area that has a known existing fault just south of the slant well location. ERT could have revealed results of past seismic activity in that particular location or existing seismic damage to the aquifer and aquitard. Ignorance is not bliss, and finding out too late, after gambling a $300 million price tag for the proposed project, would be indeed tragic for all. Will this specific environmental impact risk be evaluated in this DEIR?

Coppernoll-52

Second, on another level, the DEIR is biased and inequitable in favor of CalAm, with a complete disregard for the impact on the Marina and Ord Communities' sole water supply source, a water source that CalAm is already harming, a water source that is vital to, and cherished by, the City of Marina and the Ord Communities that depend

Coppernoll-53

on this water source. That harm will be irreparable if the proposed project is allowed to proceed, and if the City of Marina, that has lead responsibility, is ignored or exploited by outside entities. To be adequate, the DEIR needs to address this side of the equation.

Coppernoll-53 cont.

Third, the City of Marina has responsibility for its certified Local Coastal Plan. The DEIR (1.5.4.3) states that the City of Marina would be receiving and approving an application for a Coastal Development Permit for the slant wells. However, approval is highly unlikely given the lack of mitigation for the significant irreparable harm to marine vegetation and ecosystems in the area of the proposed project.

Coppernoll-54

Should the City of Marina deny such permit, would CalAm be allowed to bypass the City of Marina and obtain a permit from the California Coastal Commission, which the DEIR states it will do? The City of Marina, as discussed above, has lead responsibility and should be the final step for approving or denying such permit. Under what circumstances would CalAm be able to circumvent the City of Marina and seek the Coastal Development Permit from the California Coastal Commission?

Coppernoll-55

4. The DEIR omits discussion on compensation for Marina residents and Ord Communities, and other affected areas, for the disruption its construction of the 21-mile pipeline and desalination plant heavy vehicle traffic on local roads and reduced recreational trail usage for the duration of the project construction will cause, plus the inconvenience incurred as a result of parking space displacement and commercial parking lot reduction to accommodate project vehicles and road blockages, and, most importantly, future high water rate increases that will be imposed on the MCWD customers too, if they are subsumed by CalAm, to pay for present and future costs of the MPWSP. Marina is basically a working-class city whose residents would most likely be at risk for losing their homes if water rates were to increase at the same pace and level as current CalAm customers' rates are.

Coppernoll-56

Coppernoll-57

Table 4.9-4 provides details on the number of heavy truck vehicles and passenger vehicles (workers) and the number of trips per day that will be used in the proposed project construction process, which is projected to occur over a 24 month period, with individual sections of the project taking varying lengths of time, with the construction running 24/7 per the 4.9 Traffic and Transportation requirements, impacts, and proposed mitigations which are based on the Traffic Control and Safety Assurance Plan, or Mitigation Measure 4.9-1 (Traffic Control and Safety Assurance Plan). It seems that this plan has not yet been presented. Will the CPUC require this plan to be developed for review before approving this DEIR/DEIS? Where in the DEIR is an implementation plan detailed for a Traffic Control and Safety Assurance Plan? The DEIR states that "However, with implementation of Mitigation Measure 4.9-1 (Traffic Control and Safety Assurance Plan) the impact would be reduced to a less-than-significant level. The mitigation measure includes provisions for reducing construction-related traffic and traffic congestion impacts on local streets." Yet in

Coppernoll-58

the same paragraph, the DEIR states that "**these traffic increases along lower-volume local and neighborhood (residential) streets in the Marina/Seaside area are considered to potentially result in substantial adverse effects." (DEIR 4.9-21).** Where is the mitigation measure found that will reduce these "adverse effects" to a less-than-significant level? And how will they be implemented? DEIR 4.9-18-21 discusses traffic details in terms of number of workers, trucks and trips, both round trip and one way trips. Where does the DEIR provide the details on the origination of the workers and trucks that are or will be commuting to and from the proposed project construction sites? Will adverse impacts on those roads be mitigated? It can be conjectured that many workers and trucks will originate in Salinas, a city that is also affected by any activity affecting the Salinas Valley Groundwater Basin. Blanco Road is a major connecting road between Salinas and Marina. Blanco Road is already riddled with pot holes, is a two-lane road that is already congested much of the time, and runs adjacent to agricultural fields. Will workers be commuting from Watsonville, or Castroville, or other locations? Will the CPUC address this insufficiency in the DEIR traffic and transportation impact analysis section? The Traffic Control and Safety Assurance Plan, not yet developed, will assume encroachment permit approvals from the City of Marina. Is this a reasonable assumption on the part of the CPUC, given that Marina's water supply concerns have been overlooked in this DEIR? And given that the significant overload on Marina's roadways has been diminished or dismissed as less-than-significant, despite no evidence or proof that this reduction of risk or harm is actual or that the harm can or will be mitigated? Reality says otherwise.

Coppernoll-58 cont.

Coppernoll-59

Coppernoll-60

On page 4.9-3 the DEIR states that Highway 1 and Del Monte Boulevard will have the greatest number of daily construction related truck trips. Will the CPUC delineate the precise impact this truck traffic will have on Del Monte Boulevard, a major thoroughfare through Marina's business and residential areas? Table 4.9-4, numbers are provided for workers, trucks, and trips. To give general numbers, based on this table, for which the construction spans a 24-month period, with individual sections of the proposed project lasting varying periods of time, we can estimate there will be 30,840 trips by workers, and 10, 320 trips by trucks per month. Will the CPUC require the DEIR to include a more detailed and accurate analysis of the actual impact on Marina's transportation network and what mitigation measures will be taken? Will a mitigation plan be provided that contains details instead of general statements without substance?

The DEIR is inadequate because it does not provide actual impact on Marina's streets and roads, or Highway 1 in terms of wear and tear and the cost to repair these traffic areas. Reservation Road is included in the use of Marina streets and roads, yet the adverse impact to this Marina roadway (reservation road), that is already in disrepair with a significant number of pot holes, is not adequately addressed. This substantial increase in heavy vehicle traffic will without doubt increase significantly the need for road repairs. Will the DEIR be required to provide precise details pertaining to the

adverse effects such heavy vehicle traffic will have on Marina's roadways? Already there is significant large size transport trucks coming daily through Marina, stressing its roads considerably, hence the increasing number of potholes that cause damage to local residents' cars and vans. To state, as the DEIR does, that a not yet published plan to mitigate damage is proof that the adverse impacts will be reduced to less-than-significant status is not acceptable or adequate. Can the CPUC please explain this gap in evidence that NO HARM will be done to Marina's residents? By stating that Charles Benson Road is the most heavily travelled does not prove that the other roads are not also heavily travelled since workers and trucks have to get to Charles Benson Road by some avenue of approach. Will the CPUC require the DEIR to provide proof that NO HARM will be done to Marina's transportation network system? DEIR Table 4.9-3, Summary of Impacts – Traffic and Transportation, p.4-9-18, **Impact 4.9-C, Cumulative Impacts related to traffic and transportation are rated SU, significant and unavoidable**. No indication of any attempt at mitigation is proposed. Will the CPUC require a pre-proposed project agreement process whereby Marina will be compensated for these significant cumulative impacts that cannot be mitigated? **Will the CPUC decide the proposed project is infeasible because its DEIR states it will DO HARM to Marina's transportation network system without mitigation or compensation**? An increase of 30,840 daily worker trips, coupled with 10,320 truck trips per month over an extended period of time could totally impair local residents' ability to get to work on time, or go anywhere, day or night, with the projected significant increase in traffic on the major roads, and some less major roads, in Marina. What will the CPUC undertake to address this challenge?

Coppernoll-60 cont.

It seems callous that the DEIR states in 4.9 that the proposed project will coordinate with Monterey Salinas Transit (MST) so the "transit provider can temporarily relocate bus routes or bus stops in work zones as deemed necessary". What selfish disregard for local residents whose only transportation to work is the MST! Will the CPUC require these Marina residents to take a taxi to the relocated bus route? What about seniors who take the MST to shopping or other destinations? No compensation can make up for this gross inconvenience. What will the CPUC do to rectify this injustice? This is another item overlooked in the DEIR assessment of adverse impacts, compounding the fact that the **proposed project is infeasible**.

Why were these important items not included in the DEIR?

Isn't CalAm requesting permission to recover present and future costs for the proposed project in its current project application? Just as its current customers are experiencing exceptionally high water rate increases to cover CalAm's past "expenses", won't MCWD customers and the City of Marina residents incur large water rate increases and transportation costs to restore roads, recreational trails, railroads, etc. to original condition?

Coppernoll-61

17

There have been no pre-project agreements to address these issues prior to project request for approval. Isn't the CPUC putting the proverbial cart before the horse? Coppernoll-61 cont.

5. A major insufficiency is the inherent conflict of interest that continues to exist because the slant well patent holder, Dennis Williams, is also an evaluator of the project, or is connected to both CPUC and CalAm, which precludes objective DEIR analysis and review. This should be deemed an irreconcilable impasse and render the project infeasible. Another conflict of interest, on top of the first one, associated with the failed regional desalination project, should raise ethical, as well as project credibility and viability, issues. Impartial, third party objective analysis is the hallmark of good scientific inquiry. Will the DEIR and CPUC demand this level of project review? Will the CPUC be transparent in disclosing such conflicts of interest? Doesn't the CPUC have a moral imperative to do so in the public interest and for the public good? Doesn't Marina have an inherent right to be considered in all aspects of the proposed project, and the impacts properly assessed, rather than being ignored as if Marina does not exist? Can the CPUC explain this injustice? Has the DEIR addressed potential environmental impacts that will affect Salinas, a major water rights user of the Salinas Valley Groundwater Basin? The entire basin subsurface area is affected by actions undertaken by overlying users, just as the whole human body is connected and affected by what happens to one part of the body.

Coppernoll-62

Coppernoll-63

Conclusion:

In concluding, and expressing appreciation for the CPUC and NEPA for having granted this opportunity to express our concerns, comments, and questions, please accept my sincere effort to encourage the CPUC and NEPA to seriously consider the regional water justice implications of the CalAm proposed project, and the **importance of providing a better solution that will be beneficial to everyone, not just one party.** This aspect, regional water justice, does have a very profound environmental impact. The SVGB is a regional water supply source. Regional water justice requires water projects that do NO HARM to any party.

To recap, this memorandum explains the reasons I oppose the MPWSP, request denial of certification, and denial of approval of the DEIR.

Please do not let greed, politics, or pressure influence this decision. **We all must do all we can to ensure fresh, potable water is affordable, accessible to ALL our citizens, not just a few.** Unfortunately, CalAm has a proven track record of unlawful behavior. It is well known that CalAm exhausted its other water sources through *unlawful water diversions and a disregard for governing law. There is no guarantee,* based on past history, that CalAm will respect all the parameters involved in this DEIR or the proposed project. Trust is a major component of any business relationship, so every effort should be made to restore trust and ensure justice is assured for all concerned.

Coppernoll-64

CalAm is again disregarding the law. By pumping water (2100 gallons per minute) from the fresh water Perched Dune Sand Aquifer and spurting it back into the Bay, CalAm is committing an unlawful act, over and over again, squandering Marina's only freshwater supply source, as mentioned earlier. CalAm is not pumping water from the subsurface of the ocean, as pointed out in the DEIR, or as claimed in the CalAm test slant well design depictions and statements. This is a major deception to cover up the actual source of its water not only for the test slant well, but for the other nine slant wells to be constructed. This is a falsehood that needs to be exposed in the interest of the public good. Coppernoll-65

One may surmise that this falsehood is promulgated to validate the unlawful taking of Marina's groundwater and to insinuate that CalAm does have water rights due to ocean water not requiring water rights, all the while its actions, by inducing more and more contaminated groundwater, it can later claim the aquifers are "damaged and done for"; therefore, it is justifiable to keep on stealing the water for use in its desalination plant. But, if the CPUC or the SWRCB condones such activity, will Marina, and others affected, be forced into costly litigation to protect their lawful, constitutional rights? Can the SWRCB continue to disregard the very constitution it is sworn to uphold? Coppernoll-66

CalAm's stated intention in the DEIR and proposed project is to transport the Perched Dune Sand Aquifer and 180-Foot Aquifer groundwater via a 21-mile pipeline over to CalAm's water district to meet the needs of its customers. Coppernoll-67

First, this is illegal. Law forbids transporting groundwater from one jurisdiction to another jurisdiction.

Second, this law intends to prevent the illegal extraction of SVGB groundwater from the Perched Dune Sand Aquifer and the 180-Foot Aquifer, via the proposed project's slant wells, and the exportation and discharge of this same groundwater into the Monterey Bay or Pacific Ocean. That compounded action constitutes an illegal exportation of groundwater, coupled with an illegal squandering of groundwater. The DEIR clearly asserts that the MPWSP's objective is to do exactly that. It is in fact currently doing that, and manifesting its intentions to do that, as its Monterey pipeline attests to. This is another crime to be committed if certification and/or DEIR approval is/are not denied. It cannot be over emphasized that CalAm's dumping of groundwater back into the Monterey Bay constitutes a prohibited waste of water, and is in direct violation of Article X, sec. 2 of the Constitution of California and the "Doctrine of Reasonable Use" (Peabody v. Vallejo (1935) 2Cal.2d 351-371. Coppernoll-68

Third, the astronomical cost will become another onerous burden on the CalAm rate payers, and eventually, on the City of Marina and the Ord Communities. CalAm must satisfy its stockholders' desire for higher and higher dividends. The injustice screams out at us. Water is a basic human right. Water must be affordable, accessible, and safe for drinking, cooking, and sanitary purposes. This is the declared position and Coppernoll-69

policy of the United Nations and the State of California. Water is not a for-profit commodity for investors. Unlike other consumer products, water is critical to survival. No one should take advantage of this.

Coppernoll-69 cont.

There is a higher purpose at play. That higher purpose is regional water justice. My most ardent plea is that the CPUC and the NEPA will have the courage and the moral integrity to do the right thing, not only to comply with the law, which includes environmental law, but to do what is fair and just for everyone. There are viable alternatives and available options, such as creating more water storage capacity, cleaning the Carmel River of debris and sediment from the Soberanes Fire, and capturing the now wasted farm runoff water that can be treated and used. That action would add approximately 6,500 afy to the water supply. These options, coupled with the significant reduction in water demand due to successful water conservation accomplishments would provide ample water supply. Implementing such options would not burden the CalAm ratepayers, or Marina and Ord Communities residents, with an additional $300 million price tag, as the proposed project would.

Coppernoll-70

We are trusting that the CPUC and the NEPA will do some deep soul searching and reflection, coupled with in-depth analysis of all the ramifications involved in this momentous decision. Our communities will not stand down because our survival is at stake. Marina and the Ord Communities view this proposed project as an existential threat to their collective well-being and their future. Our Marina Coast Water District is an ideal role model. As stated herein, it has a decades long, since 1961, golden track record of providing fresh, potable water at affordable rates to its customers, Marina and the Ord Communities. Instead of raising water rates as CalAm is doing, and punishing its customers for conserving water, Marina Coast Water District rewards water conservation efforts with incentives and provides customers with tools to prevent leakage and reduce water consumption. This public water purveyor has not performed any unlawful actions or done anything to harm or exhaust our water supply source. Quite the contrary. Marina Coast Water District has diligently worked to protect and preserve our water supply source. Through its sustainable groundwater management plans and programs, it has restored fresh water in our aquifers and reduced seawater intrusion. Yet, this DEIR is silent on the MCWD. There is no mention of the harm that is being done to Marina's sole water supply source, or the threat to MCWD's existence.

Coppernoll-71

Do not allow CalAm to split hairs over seawater or brackish water definitions. Our groundwater belongs to Marina and the Marina Coast Water District's service area. Brackish water is still our groundwater; brackish water treatment facilities are the purview of Marina Coast Water District. Those proclaiming support for the proposed project are myopic in vision, only considering their own perceived needs, but neglecting to consider other **viable options that will benefit all, and harm none.** The environmentally superior project would be a combination of options that are available and fully vetted, and to allow sage expert water management agencies and

Coppernoll-72

other stakeholders to explore those options, ones that have been evaluated to be the best solution by experts on the peninsula, ones that have a vested interest in supporting the best creative and just solution because they live and work there. The CalAm stockholders for the most part do not live here or pay taxes here, so they do not have a vested interest in doing what is best for the peninsula water consumers. Otherwise, at least give serious consideration to the other alternate desalination projects located in areas that do not harm Marina's sole water supply source. These projects may need modification to avoid harm to marine life and the hazard of brine discharge that suffocates ocean bottom marine life, but fortunately technologies are evolving quickly to address such challenges. For example, the People's desalination project, one of the alternative options that is of high value but not properly given full or fair review in the DEIR, would make an excellent choice because it already has required pipeline infrastructure with concomitant sustainable energy via a planned solar plant. It is far less costly and far more practical and environmentally sound. Ocean intake technology has become the gold standard worldwide for desalination plants. Why take a chance on slant well technology that has zero proven success over technology that is globally accepted as successful?

Coppernoll-72 cont.

We know upfront that the proposed project will bring irreparable harm to the Salinas Valley Groundwater Basin and to Marina and the Ord Communities. This MPWSP option should be eliminated from consideration, particularly since more valid and viable options are already planned in more geologically and environmentally acceptable locations, such as Moss Landing, which was cited by the California Coastal Commission as the best location for a desalination plant for the Monterey Bay area.

Coppernoll-73

Coppernoll-74

The MPWSP is truly infeasible, unlawful, unjust, and environmentally unsound. It has no credible science supporting its suppositions, estimates, and assumptions. The MPWSP cannot obtain legal groundwater rights because Marina Coast Water District, which has been operating as a highly credible and respected public water utility since 1961, does have established water rights and is operating within its lawful jurisdiction. CalAm cannot claim any category of groundwater rights to the SVGB, neither riparian, nor appropriative, nor developed, nor prescriptive. The project is, as hopefully demonstrated, infeasible, and should not be allowed to go forward.

Thank you so much for your consideration, for your efforts to include the public and for hosting public open houses and public hearings, for the tremendous work involved in this four volume DEIR/DEIS, and for your review of our inputs. The statements and assessments made herein are not to be construed in any way other than as constructive review of this DEIR as it currently exists. Observations are based on data, history, and a desire for transparency and justice. Repetition was necessary due to the need to correlate issues and emphasize underlying ideas or actions.

It is understandable that the proposed project is being propelled by a sense of emergency and urgency, but one must proceed with a creative vision for solutions

21

that do not do more harm than good. Everyone should work together in harmony for the benefit of all citizens, in the public interest, and for the protection of the environment. We can find a way for everyone involved to survive and thrive. That solution will be the best one.

We now await a wise decision.

Very Respectfully Submitted,

Margaret-Anne Coppernoll

Margaret-Anne Coppernoll, Ph.D.
Citizens for Just Water and Marina Resident
Marina, California 93933

mcopperma@aol.com

P.S. The time allotted to read and evaluate the four volume DEIR is insufficient for the public to adequately digest the thousands of pages involved. The sheer volume of material justifies recirculation of the DEIR, in all fairness to the public. It may make sense to delay the final comment period so the public can compare and evaluate all proposed desalination projects at the same time. This decision is of such paramount importance to the community that **recirculation** is the only way to ensure the public has adequate time to read and study the considerable amount of information, and to have access to technical data.

1. I am submitting to the record a violation of CPUC resolution ALJ-252 due to having access to sign up to speak at today's meeting, 2/16/17. Cortez-1

Rules for Public Comments at Commission Meetings

(Adopted June 24, 2010, Resolution ALJ-252)

You can sign up to speak at a Commission Meeting online.

The CPUC adopted Rules for Public Comment at Commission Meetings on June 24, 2010. The CPUC will follow these rules at all Commission Voting Meetings. The rules are as follows.

Rule 1. The deadline for individuals to sign up to speak is 10:00 a.m. (or the start of the meeting if not at 10:00) on the day of the meeting.

Rule 2. Individuals with a shared position are encouraged to select a spokesperson for their group.

Rule 3. Individuals who sign up by the deadline will have a maximum of three minutes to speak. The three minute speaking time may be changed by the Commission President, depending on the number of speakers. A speaker may not cede time to another speaker.

Rule 4. The order of speakers will generally be based on the order in which speakers sign up, but public officials may be taken out of order.

Rule 5. At the end of the Public Comment Session, the Commission President will ask if there are any additional individuals who wish to speak. Individuals who wish to speak but did not sign up by the deadline will be granted a maximum of one minute to make their comment.

Rule 6. The Commission President will declare when the Public Comment Session is closed. No speakers will be accommodated after the Public Comment Session is closed.

California Public Utilities Commission

The CPUC regulates privately owned electric, natural gas, telecommunications, water, railroad, rail transit, and passenger transportation companies. The CPUC serves the public interest by protecting consumers and ensuring the provision of safe, reliable utility service and infrastructure at just and reasonable rates with a commitment to environmental enhancement and a healthy California economy. We regulate utility services, stimulate innovation, and promote competitive markets, where possible. On this website you'll find information about the many initiatives underway at the CPUC.

CPUC Provides Valuable Support Programs

California LifeLine

Provides discounted home phone and cell phone services to eligible households

CARE / FERA

Lower your Energy Bills!

CASF

California Advanced Services Fund (CASF) promotes deployment of high-quality advanced communications services

DDTP

Provides assistive telecommunications equipment, speech generating devices and relay services

CTF

Provides discounted communications services to schools, community colleges, libraries, etc.

Overview of Support Programs

CPUC Regulates and Registers these Services to Protect the Public

Energy

The CPUC regulates investor-owned electric and natural gas utilities operating in California

Communications

The CPUC develops and implements policies for the telecommunications industry

Rail

The CPUC is the state agency that oversees rail safety; this includes freight, inter-city and commuter railroads, rail transit and rail crossings

Passenger & Moving

The CPUC also administers safety oversight and enforcement of moving companies and passenger carriers (limousines, shuttles, etc.)

Water

The CPUC investigates water and sewer system service quality issues, analyzes, and processes utility rate change requests

Public Participation

The Monterey Peninsula Water Supply Project aims to foster and maintain a partnership with local government agencies and elected officials and to provide regular oversight and input during the development of the project. The project sharing engineering, construction, permitting and public responsibilities throughout the Monterey Peninsula, planning decisions related to the project.

Governance Committee

Monterey Peninsula Water Supply Project Governance Committee is comprised of representatives of California American Water, the Monterey Peninsula Regional Water Authority, the Monterey Peninsula Water Management District and the County of Monterey, to ensure efficient and effective public input in the development and operation of the Monterey Peninsula Water Supply Project.

For the latest information on the Monterey Peninsula Water Supply Governance Committee, visit the Events section of the Monterey Peninsula Regional Water Authority page of the Governance Committee.

Bdelgado62@gmail.com

Dear Mz. Borak,

Thank you for considering these few comments.

1)Figure 4.4-9. Why isn't the active CEMEX well monitored? Without knowing why, I am concerned because it would seem to provide a worthwhile opportunity for monitoring water quality/quantity and without such monitoring it seems that the best available data is less comprehensive/useful for analyzing/addressing the proposed project's impacts to groundwater. Delgado1-1

2) In Section 4.20 (pg. 4.20-2) it is stated that "The proposed project's impacts considered together with **existing or foreseeable environmental burdens** experienced by nearby communities are analyzed throughout Chapter 4 in the Cumulative Effects subsection of each resource section."

However, Section 4.20 appears to exclude any mention of air emissions within or proximal to the City of Marina from the Cemex sand plant, the Monterey Regional Water Pollution Control Agency's facilities (including its wastewater treatment plant), the proposed advanced treatment plant for Pure Water Monterey, the Monterey Peninsula Regional Waste Management District's facilities (including its regional landfill and authorized composting operations), methane or other greenhouse gases from livestock ranching adjacent to Marina residential areas, or emissions from drift of pesticides, fertilizers, and other soil amendments from agricultural operations adjacent to or proximal to City of Marina residential areas. These cumulative impacts are important to the residents and visitors to the City of Marina for health and environmental justice reasons. There are currently frequent complaints from this City's residents of offensive odors apparently coming from north of the City and this is but one example of existing conditions from existing or planned future facilities affecting the City of Marina's air quality.

Action: Please a) describe current conditions of potentially nuisance or unhealthy odors and emissions proximate to the City of Marina, b) disclose the total emission of existing and planned facilities (such as those listed above), and c) include their individual totals, their cumulative total, and relevant numeric emission standards/metrics/thresholds in an additional table such as a new Table 4.20-7. Delgado1-2

3) No relevant numeric emission standards/metrics/thresholds are listed in section 4.20 including Table 4.20-6. Delgado1-3

Action: Please include an column or columns in Table 4.20-6 for relevant numeric standards/metrics/thresholds.

Delgado1-3 cont.

Thank you,

Bruce Delgado

Bruce Delgado
Letter 2

Dear Mz. Borak,

Please consider this additional comment/concern I have regarding the MPWSP DEIR.

I have heard the HWG includes 2 representatives paid by Cal Am (basically to represent Cal Am interests) and two representatives paid by the agricultural industry (basically to represent this industry's interests). My concern, if this is true, is that no one on the HWG could be expected to focus on the City of Marina's interests or that of MCWD. Given that Cal Am has a vested interest in the outcomes of the DEIR it seems a conflict of interest to have paid consultants of Cal Am providing advice/hydrogeological expertise, etc. to the CPUC regarding the DEIR issues.

In addition, I understand one of the Cal Am reps on the HWG holds one or more patents to slant well technology that may be employed in the MPWSP so of course there could be a conflict of interest on his part to both be advising the project and benefitting financially and otherwise were the outcome of the project proposal to be in his favor.

Could you please explain in the FEIR or revised DEIR who is on the HWG, who is paying the HWG members, and a detailed summary of the input they have had in the 2017 DEIR especially as that input may relate to GW monitoring, modeling, model calibration modifications, interpretation of test slant well project, and any other advice or input the HWG has provided to CPUC staff or others related to the MPWSP?

Also could you please explain how a conflict of interest has been avoided if it is the CPUC's opinion there is no conflict of interest?

Delgado2-1

thank you,
Bruce Delgado

SUBJECT: DRAFT EIR/EIS FOR THE MONTEREY PENINSULA WATER SUPPLY PROJECT/Review

Dear Staff:

Thank you for the opportunity to share with you some concerns and questions I have about the proposed project, and the quality and completeness of this DEIR relative to its claim of environmental preference, and its experimental nature.

1. 3.2.11, Pg 147, states, *"The seawater intake system would include 10 subsurface slant wells at the coast (8 active and 2 on standby…) that would draw seawater from beneath the ocean floor for use as source water for the MPWSP Desalination Plant."*

Please address the feasibility of the use of subsurface slant wells for this project, given the fact that they have not been used successfully anywhere in the world for desalination purposes.

A Google search of "slant well desalination" yields the following response:
"CA desalination slant wells prove promising…Near the Monterey Peninsula, where CAW's water supply project is …"—nothing has been proved to be workable or feasible, only claims. There are no responses showing the successful use of slant wells for desalination purposes anywhere in the world.

The test slant well that should have provided proof of concept for this project does not conform to the description of the project slant wells. It does not extend under the ocean floor and is not drawing pure seawater.

If the 10 project slant wells are planned to extend beyond the shore to collect seawater, why isn't there a test slant well that provides data showing this seawater collection system to be feasible and practical? If the slant wells will not extend beyond the shoreline to collect water, does CalAm have rights to the groundwater they will be drawing?

Please confirm that either actual seawater will be collected as stated above or that groundwater is being taken legally in order to avoid further destruction of the shoreline, and further expense, all for a non-feasible purpose.

Fisher-1

2. 4.5-52, Page 604, states: "*The vertical infiltration rate at the sea floor for the proposed MPWSP was estimated by assuming the entire 24.1 mgd (3,222,000 cubic feet/day) of seawater required to operate the MPWSP plant would be drawn through the sea floor located directly above the screened segment of the slant wells. The length of shoreline spanned by intake slant wells would be approximately 2,000 feet. If the sea floor area of water intake extended 500 feet offshore, the area of sea floor through which seawater would be taken into the wells would be approximately 1,000,000 square feet. Through this area of sea floor, a maximum of 3,222,000 cubic feet (24.1 million gallons x 0.1337 cubic feet per gallon) of water would be pumped each day. The vertical infiltration rate through the sea floor would have to be 3.222 feet/day or 0.0000373 ft/sec (approximately 0.011*

Fisher-2

mm/sec). This calculation is very similar to the 0.000051 ft/sec (approximately 0.016 mm/sec) peak vertical infiltration rates estimated by Williams (2010) for the South Orange Coastal Desalination Project. In comparison, an open ocean intake equipped with a wedgewire screen would draw water in at a rate of 0.5 ft/sec (152.4 mm/sec). For the purposes of this assessment, it is assumed that the infiltration flow rate of seawater through sea floor sediments and into the slant wells would be approximately 0.011 to 0.016 mm/sec."

As stated above, the capability of the proposed slant wells to take in a sufficient quantity of seawater for the proposed desal project is based on a series of assumptions and estimates derived from another proposed project in southern California, also designed by Williams of Geoscience Corp., the holder of the patent for the slant well design. The predicted rate of seawater collection is based completely on the assumptions that conditions here in Monterey Bay will be nearly the same as they are at Doheny Beach in Orange County. Where are the data from the already functioning Marina Beach test slant well, constructed at great cost to the local ratepayers, that prove the assumptions are correct? Where is the proper science to guide this experimental project?
No data are provided for this DEIR from the test slant well that has been operating only intermittently at the MPWSP since mid-April 2015, as stated in this DEIR.

Even the goals and objectives in the design for Williams' Doheny project call for the collection and analysis of test slant well data, collected over an extended period of time, to determine the performance of the well and the aquifer. Please see "The Final Summary Report—Doheny Ocean Desalination Project, Phase 3 Investigation, January 2014, p.46.

Fisher-2 cont.

Data from a different location on the California coast cannot be relied upon to provide accurate information for the Monterey Bay conditions. Please refer to: WaterReuse Assoc., 'Overviews of Desalination Plant Intake Alternatives', White Paper, June 2011, pp. 7-10, wherein it is stated "Subsurface geology typically limits capacity and performance (as compared to open ocean intakes…). It goes on to assert that ocean conditions and subsurface geology are not comparable in different areas of the coast, that location-specific data are required.

In a separate publication they go on to say, "In addition, the potential application of a subsurface intake is very site specific and highly dependent on the project size; the coastal aquifer geology (aquifer soils, depth, transmissivity, water quality, capacity, etc.); the intensity of the natural beach erosion in the vicinity of the intake site; and on many other environmental and socio-economic factors." WateReuse Association 'Desalination Plant Intakes", White Paper, Subsurface Intakes, p.10.

The Water Foundation further states: "Ongoing long-term studies of innovative subsurface intakes in Long Beach and Dana Point, California, are expected to provide comprehensive data that would allow completing a scientifically-based analysis of the viability and performance benefits of subsurface intakes for larger-size applications. The tested subsurface intake technologies are currently under evaluation and do not yet have established performance, reliability and environmental track records."

Given the highly experimental nature of using slant well technology for seawater intake, more relevant data are needed. Reliance on estimations and assumptions that are based on data from an area not at all comparable to the Monterey Bay is simply not good science.

Please provide test slant well data from the intended location of subsurface slant wells to ensure the feasibility of this experimental technology for obtaining adequate seawater.

Please identify the criteria the CPUC will use to determine if slant well intake is feasible in the current location given the lack of relevant data currently available.

Fisher-2 cont.

3. 5.4-43, Page 1507, states: "*Desalination Facility (Moss Landing Green Commercial Park)*
The desalination plant for Alternative 4 would be located at the Moss Landing Green Commercial Park, located on the southeast corner of Dolan Road and Highway 1. The approximately 200-acre site is zoned under the Monterey County General Plan for Heavy Industrial Coastal Dependent use. Of the total site, a 16.5-acre parcel is being proposed for developing the Alternative 4 desalination plant and would be fenced off from the rest of the property.
The desalination plant would include: (1) an equalization basin to receive and store the incoming source water; (2) an inlet pump station to convey source water from the equalization basin to a pretreatment system; (3) a pretreatment system; (4) a reverse osmosis system; (5) a post treatment system; (6) a return flow pipeline that would convey brine and wash water back to the disengaging basin; (7) chemical feed and storage facilities; and (8) facilities for residuals management. The desalination plant site would also contain a 5 million gallon treated water storage tank, as well as non-process administrative facilities."

This description does not include the planned 3.7 MW solar energy source to power the desalination plant, which is further described in the letter submitted by N. Selfridge, entitled, Section 4.1.8 Energy Conservation to which I refer the reader.

Please address this potential mitigation of energy usage and carbon emissions provided by Alternate 4 in the final EIR.

Fisher-3

This description of Alt.4 site omits the significance of an existing pipeline from the People's Project property that crosses under CA Hwy 1, under Moss Landing Harbor and the jetty opposite, that is already owned and available for both intake and outflow after certain improvements and alterations are made with minimal environmental consequences. The existence of this 36" pipeline eliminates the environmental damage that would result from digging or tunneling under a major California highway and harbor area in order to access seawater; it also obviates the need for certain permits, inasmuch as the pipeline has been transporting seawater for many years for the former Kaiser Refractory plant. Moss Landing was considered the ideal location on Monterey Bay for a desalination operation by the California Coastal Commission.* Given the time required for permitting, both speed and feasibility of this project should be greater than any other project in this area. The pipeline provides major environmental, feasibility and cost advantages over the proposed DeepWater Desal project, which currently has no seawater access, or any other proposal to draw seawater through a pipeline in that area.
* News article: "Moss Landing Desalination Plant favored, State Issues Recommendation for Peninsula's Water Source", D. Moran, Monterey Herald, P.1, Aug. 10, 2002

Fisher-4

Please address this omission that fails to demonstrate the significant mitigation of environmental impact or to demonstrate the greater feasibility of the People's Project.

Fisher-4 cont.

4, ES-11, Page 37, "*Alternative 2 (Open-Water Intake at Moss Landing), Alternative 3 (DeepWater Desal Project), and Alternative 4 (People's Project) would use screened, open water intakes, which would reduce or avoid several potential proposed project impacts on groundwater because of the absence of slant well pumping for source water, but would result in new significant impacts on marine resources. Significant and unavoidable impacts on marine habitat and biological resources would result from the in-water construction of new open water intakes. Operation of screened open-water intakes would result in impingement and entrainment of marine organisms, resulting in significant long-term direct and indirect effects on marine biological resources within MBNMS in Monterey Bay"*

Why is screened open-water intake considered to have "significant long-term direct and indirect effects on marine biological resources within MBNMS in Monterey Bay". As long ago as 2010 in a White Paper document by the WateReuse Association Desalination Committee a study of seawater intake at 19 power generation plants found that the daily fish impingement impact in a one year period amounted to no more than the amount caught by a pelican in a single day.* *

** https://watere use.org/wp-content/uploads/2015/10/IE_White_Paper.pdf

Since that publication, even greater improvements to open ocean intake screening have been developed, as stated in Item 5, below.

Fisher-5

Please address the designation of screened open water intake as "significant and unavoidable", given the improved mitigation methods currently available, further described below.

5. *App*. I1-1, Page1551, *"Consistent with the findings of an expert review panel convened by the SWRCB, Desalination Plant Entrainment Impacts and Mitigation (finalized October 9, 2013), and SWRCB's 2014 proposed Desalination Amendment to the California Ocean Plan (SWRCB, 2014b), this EIR assumes that all open-water intake options would be equipped with a passive, cylindrical wedgewire screen at the western terminus of the intake pipeline with slot openings sized to meet regulatory and/or permitting requirements[3] and would have a design velocity of 0.5 feet per second unless otherwise cited."*

Seawater intake screening is being improved. The data cited in this DEIR/EIS from 2013 are out of date for open ocean intake screening. Rotating and traveling screens with intake velocity of less than .3 ft/sec. to mitigate impingement and entrapment, are now available, eg. Invisihead by Elmosa Seawater Intake and Outfall Systems; "Water particles start to move toward the Intake Head from all directions with a velocity of about 0.0027 m/s (0.009 fps) max. 5 meters (15 ft) away from the Head entrance. It rises to 0.03 m/s (0.1 fps) max. one meter (3 ft) away. The final entrance velocity is 0.09 m/s **(0.3 fps)** max."

Please justify the designation of screened open water intake as "significant and unavoidable", given the improved mitigation methods currently available.

6. NOI Scoping recommendations for the proposed project:

"*A-16, Page 23, Alternatives*

•*The EIR should consider locational alternatives that would place all facilities outside of Western Snowy Plover habitat. [F_USFWS-06]*

•*The EIR should evaluate a full range of project alternatives. [L_Monterey-01]*

•*The descriptions of project alternatives in the EIR should be based on the most current information available. [L_MPWMD-03]*

•*The EIR should evaluate a locational alternative that would site the desalination plant at the former National Refractories site in Moss Landing. [G_AgLandTrust-17]*

•*The alternatives analysis should evaluate the commercial project alternatives (i.e., People's Moss Landing Desal, DeepWater Desal) but without mention of the commercial ventures. In addition, the EIR should evaluate a variety of design alternatives (i.e., facility locations, brine discharge facilities, pipeline alignments) that could be mixed and matched to address environmental impacts, project costs, and schedule considerations. [G_CalAm-03] "*

Fisher-6

Despite the above directives of the NOI Scoping review to include alternative projects that fulfill the above criteria, the People's Project, which clearly does do so, has been determined in this DEIR as not worthy of being carried forward as an alternative with the following statement on page 1466 of the DEIR:

"This desalination proposal has not been carried forward as an alternative to the MPWSP because the CPUC has no jurisdiction, the applicant has not yet engaged in any formal environmental review processes, project effects cannot be reasonably ascertained and the timing of its implementation remains uncertain."

The only accurate statement above concerns CPUC not having jurisdiction. People's Project has a completed EIR application in the preliminary review process. Information has been available, but apparently not requested. Inasmuch as the location of that project does not threaten the nesting Snowy Plover and already has much key infrastructure in place, as previously mentioned, and will be run on solar energy, its "environmental impacts and project costs" are therefore likely less than that of the proposed project. Additionally, the "timing of its implementation" is probably equal to or sooner than the proposed project. Nevertheless, it was not included as a reasonable alternative. The omission of this viable alternative project seems to be a self-serving maneuver.

Fisher-7

Furthermore, on Page 101 of the DEIR it is stated that "the only significant and unavoidable operational (long term) impact of the proposed project is to GHG", completely omitting the People's Project's planned use of solar power generation from the DEIR. Additionally, 5.5-333 of the DEIR, Alternative Impact Analysis—Energy Conservations states as follows:
For the same reasons described for Alternative 1, Alternative 4 would not have a considerable contribution to a significant cumulative impact associated with the unnecessary, wasteful, or inefficient use of energy, or with energy supply, either at a local or regional level, during

Fisher-8

Fisher-9

operation and maintenance. Overall, Alternative 4 would result in an increased impact conclusion compared to the proposed project, significant and unavoidable. Such a conclusion is totally incongruous with the facts. I refer the reader to the letter from Nancy Selfridge of February 8, 2017, which addresses Energy Conservation issues, wherein the description of the People's Project solar farm plan from Solar Vista is provided in her attachments.

Fisher-9 cont.

Can the above inaccuracies, omissions and inconsistencies pleased be reviewed and addressed? Given the preponderance of evidence, the People's Project should be included as a reasonable alternative to the proposed project. Then the DEIR should be amended with the missing information and re-circulated for further review.

Fisher-10

As a ratepayer on a fixed income, I thank you for your consideration.

General Comment

Dear NOAA:

I strongly oppose Cal Am's attempt to create a desalination plant at the Cemex Site. I am not a water expert, but I have seen countless companies like Cal Am who use the system to con community members out of our most precious resource-- water. I'm not opposed to desalination, but the proposed site will have some serious consequences on Marina's existing pre-historic aquifers, especially the 180 foot aquifer. Cal Am has not been forthcoming in their test well data by withholding important information about salt water intrusion. Professor Rosemary Knight of Stanford claims that Cal Am has not given important information about salt water intrusion for the stretch of land where they set up their test well. Gorman-1

As a citizen of Maria I know the water beneath us belongs to us. It's illegal for Cal Am to take away our water and their current desal plans are a serious threat to our vital water supply. We can not go back once our aquifers are polluted with salt water. Gorman-2

I urge you to demand full disclosure from Cal Am, and at a minimum, move very slowly until all environmental implications are known. Your purpose is to protect the small guy from corporations who long ago would have polluted our whole California Coast if given a chance. Don't let Cal Am, with its big sweeping arms, be the latest abuser of our precious coast. Like courageous administrators in California's past, please work with those of us in Marina to save what rightfully belongs to us. Gorman-3

Sincerely,

David Gorman

Re: Challenge to Purported Feasibility of the Monterey Peninsula Water Supply Project (MPWSP)

Dear Commissioners and Agency Officials:

I challenge the purported 'feasibility' of the Monterey Peninsula Water Supply Project (MPWSP) assumed by the draft Environmental Impact Report (DEIR). There have been NO successful, completed slant wells for subsurface ocean desalination anywhere in the U.S. or the world. There was only one attempted project at Dana Point, CA. Thus, there is a very high standard for assuming slant well technology for the MPWSP is 'feasible.' Before assuming the MPWSP is feasible, the draft Environmental Impact Report (DEIR) must address the following:

1. State agencies require a feasibility study of this new technology. With an untested and experimental design, the *highest standard* of scientific testing must be made before determining the MPWSP is 'feasible.' There is a more accurate method of mapping the saltwater intrusion in the Salinas Valley Groundwater Basin (called Electrical Resistivity Tomography-ERT) but this method is NOT used in the DEIR environmental review of impacts. Saltwater intrusion in the Salinas Valley is perhaps the most significant environmental issue in Monterey County. The DEIR must be put on hold until ERT imaging shows the potential impact of the MPWSP on Salinas Valley sea water intrusion; ERT technology is expected to become available this summer. Haines-1
2. Cal-Am has no water rights in the Salinas Groundwater Basin but they intend to pump another water district's groundwater. Feasibility is dependent on having requisite water rights. Legal determination of such rights is required before the MPWSP progresses further. Haines-2

Additionally, the DEIR must address the project's potentially significant traffic impacts. The linked 2014 article from the Orange County Register describes prohibitively high cost of water acquired through the still-experimental Dana Point slant well http://www.ocregister.com/articles/water-601981-district-project.html. The Monterey Peninsula has a sizeable low-income work-force that would be priced out of local housing should the cost of our water further increase; these workers would need to find housing outside this area. Thus, environmental impacts from increasing traffic into and out of the Peninsula caused by the increased cost of water resulting from slant well technology must be evaluated in the DEIR as a potentially significant environmental impact of the MPWSP. Haines-3

Sincerely,
Jane Haines

General Comment

As an active community member and local applied marine science graduate student, I'd like to submit input on the proposed CalAm plan to place a subsurface intake pipe in the Monterey Bay National Marine Sanctuary, in addition to the proposed request to use existing pipelines/outfalls for desalination infrastructure.

California has seen a nearly decade-long drought, and has no reason to expect this to be an anomaly as we move into the future. As an objective scientist, I recognize the need for effective management of our natural resources, and am open to the possibility that more drastic solutions eventually become a necessity in the face of growing environmental instability resulting from climate change.

That said, in 4 years of living in this community I have not seen CalAm make a legitimate effort to reduce local water consumption. I firmly believe they have no economic incentive to reduce water use of their customers - as their market share is not at risk in the face of unhappy water customers. Rather, they are financially incentivized to convince the community that water conservation is not a viable option - that we need this new "quick fix," despite the fact that they've had over 20 years to find an alternate solution to the problem. This is a charge that CalAm has FAILED to fulfill, simply because they serve to benefit financially from the alternative outcome. We as a community are therefore rewarding this complacency by allowing CalAm to move forward with this project despite the fact that they would have failed in a truly competitive market.

Herrmann-1

I'm primarily concerned with the false way in which the desalination option has been painted, and believe many of the external impacts have not been part of the impact assessment. The financial and environmental burden of these impacts will invariably rest on the shoulders of Monterey community members and taxpayers. An example of this would be the costly process of removing the San Clemente Dam - originally implemented as a solution to increased water needs for the local private tourism industry and as a fire safety measure - and while its installation was initially paid for by private industry, the nearly

Herrmann-2

$100 million cost of removal was paid by taxpayers. This doesn't even touch on the environmental impacts in the form of 95 years of salmon obstruction and hydrologic alteration - financial burdens we are yet to truly even experience.

Herrmann-2 cont.

CalAm has nothing to lose in this deal, and more than they deserve to gain. These major considerations have been overlooked.

1. Energy requirements: Energy demand to support a large desalination plant means the Monterey peninsula will need to expand its energy infrastructure. It is unfair for taxpayers to bear the weight of this expense. CalAm should include the impact of any increased energy infrastructure in their EIA/EIR, as this new infrastructure will be necessary to run the system and is therefore part of the same project.

Herrmann-3

2. Carbon emissions: Community members are unaware of the carbon footprint of a desalination solution. I believe it has been in CalAm's best interest to keep these external impacts as hidden as possible. Increased carbon emissions from energy consumption should be included in the EIA/EIR, as they are again part of the same project.

Herrmann-4

3. Quality of the water: Researchers that spend long tours at sea return with complaints of the vessel-board RO water. Many claim this super-filtered water leaches nutrients from your body. This may have adverse affects on the community - osteoporosis, for example, may become a long-term impact of exclusive RO water consumption over a lifetime, which would be an expensive and dangerous public health issue.

Herrmann-5

4. Brine is denser than seawater: many are concerned with brine's ability to affect benthic species. This is a concern, as multi-million-gallons of brine/day would run down the Monterey submarine canyon in the form of a stream, encountering a great area of habitat. This stream is also, however, likely to increase erosion within the canyon - which is a relatively unstudied process. This means that many of the associated risks are highly uncertain. This erosion may impact the proposed intake pipe or other subsurface infrastructure. These engineering considerations should be practically assessed for longevity, as repeated construction efforts in and around the Sanctuary resulting from premature failure will increase the impact above projected levels.

Herrmann-6

Herrmann-7

Overall, this project may be a local necessity. Broadly speaking, I would like to see CalAm being held to MUCH more rigorous standards than they have been. They have a lot to gain from this project, and therefore must be more accountable for their proposed actions. This is not an issue of "should they or shouldn't they," but instead an issue of "how hard should we make this for them." CalAm needs to take this project seriously with thorough pragmatism. So far, their effort has not been sufficient in this regard.

Herrmann-8

MEMORANDUM FOR:
CALIFORNIA PUBLIC UTILITIES COMMISSION (CPUC) AND
MONTEREY BAY NATIONAL MARINE SANCTUARY (MBNMS)

SUBJECT:
PUBLIC COMMENT FOR DEIR/DEIS FOR THE MONTEREY PENINSULA WATER SUPPLY PROJECT – A 12-04-019

These are my public comments and question upon review as follows:

Chapter 2: Water Demand, Supplies, and Water Rights:

The DEIR states (2.6 Water Rights, p. 2-31): *"…if CalAm did not possess legal rights to use feedwater for the MPWSP desalination plant, then the desalination plant simply could not operate and the project would not go forward. That is why water rights factors in as a key project feasibility issue."*

- Although the CPUC will not decide the water rights matter, it may approve the DEIR in a cart before the horse manner. If the DEIR is given approval to proceed by the CPUC, this will undoubtedly result in litigation and failure to develop a new water source as proposed by CalAm. If water rights are key to project feasibility, why has this DEIR has progressed so far without them?

Hofmann-1

The MPWSP cannot be considered *feasible* for the following reasons:

CalAm, the DEIR states, "*would need an appropriative groundwater right to retrieve and export water from the basin*" (2.6.1, p.32). CalAm would gain appropriative rights by creating "developed water." "*Developed water is water that was not previously available to other legal users and that is added to the supply by the developer through artificial means as a new water source."* (2.6.1, p. 32)

"*The key principle of developed water is: if no lawful water user is injured, the effort of an individual to capture water that would otherwise be unused should be legally recognized."*

Hofmann-2

1

- The goundwater that CalAm describes as “degraded” or "waste water" is very important to the city of Marina and its residents. It is currently available to its legal users. CalAm's preferred slant well location at the CEMEX plant would usurp the ability of the Marina Coast Water District to develop brackish groundwater treatment facilities as other small coastal communities with sea water intrusion have done. Brackish water becomes an important resource in a district's reliable water portfolio, and, a way to manage and control saltwater intrusion. Hofmann-2 cont.

- The use of purposely misleading words (such as “degraded” and “waste”) is part of a calculated water grab campaign by Cal Am to take possession of groundwater by appropriative rights and should not be supported by the CPUC. Such action would compromise Marina's future growth potential and is unjust. Hofmann-3

- CalAm must show that there will be no injury to the lawful water user. This DEIR has not proven “no harm” . Hofmann-4

ES.5.2 Summary of Potential Impacts and Mitigation Measures for Proposed Project (pg ES-6)

Alternative 2 (Open-Water Intake at Moss Landing), Alternative 3 (DeepWater Desal Project), and Alternative 4 (People’s Project) would use screened, open water intakes, which would reduce or avoid several potential proposed project impacts on groundwater because of the absence of slant well pumping for source water, but would result in new significant impacts on marine resources. Hofmann-5

- EIR establishes that there will be several impacts on groundwater using slant well technology – what are they? This point is avoided completely later in the DEIR.

ES.7.1 Key Impact Differences Between Alternatives (pg ES-12)

“For (Alternative 1 and 5b), operation of the slant wells at Potrero Road, Alternative 5b would lower groundwater levels in the Dune Sands/Perched-A aquifers in the Moss Landing area; operation of Alternative 1 would additionally lower groundwater levels in the 180- and 400-foot aquifers, thereby capturing groundwater that would have otherwise flowed into Elkhorn Slough. The direct and indirect permanent effects on marine and terrestrial biological resources at Elkhorn Slough from the lowering of groundwater levels would result in significant and unavoidable impacts.” Hofmann-6

- The Potrero Road alternative says there will be lowering groundwater levels to the 180 and 400-foot aquifers. The DEIR does not spell out adverse affects to groundwater at the proposed Cemex site in the 180 and 400-foot aquifers.

- What is that level of lowering predicted at the Cemex location? What are the *significant and unavoidable impacts?* Why are the effects different in the 2 proposed locations? Hofmann-7

ES.8 Areas of Controversy and Issues to be Resolved (pg ES-13)

CalAm’s proposed use of subsurface slant wells to withdraw source water for the MPWSP Desalination Plant is the subject of two controversies: (1) whether CalAm has the legal right to extract groundwater from the Salinas Valley Groundwater Basin (SVGB); and (2) whether implementation of the MPWSP and operation of the subsurface slant wells would exacerbate

seawater intrusion in the SVGB. The proposed subsurface slant wells at CEMEX would extend offshore and be screened in aquifer units of the SVGB that have long been intruded by seawater. Although the subsurface slant wells would draw seawater (i.e., source water for the MPWSP Desalination Plant) from beneath the ocean floor, a fraction of the source water would be drawn from inland portions of the SVGB.

- If the Slant Well proposal envisions pumping 24.1 million gallons per day (mgd) of source water – what is the fraction (amount in mgd) of fresh/brackish (not seawater) water that will be extracted from the Salinas Valley Water Basin at the CEMEX location? Hofmann-8

- If the desalination plant will be sized at delivering either 9.6 mgd or 6.4 mgd – how much is this amount captured groundwater? This could cause significant impact to fragile groundwater that the modeling does not adequately address. Hofmann-9

Required Decommissioning of Test Slant Well (pg 3-7) footnote 3

The DEIR/DEIS states "*The existing test slant well would be converted into a permanent well*".

- When the original test slant well was approved it was with the understanding that it was a temporary slant well that would be decommissioned. This was a concession of the original and the revised permitting and there was a one million dollar bond posted to ensure that this was carried out. Because of this agreement, the test well sidestepped CEQA requirements, such as an Environmental Impact Report.

- Why would this temporary test well be allowed to operate past its original agreed upon timeline? Is this a permit violation?

- Will there be an environmental review of the "conversion" required for this slant well?

- Is this a violation of the CEQA and NEPA processes?

Hofmann-10

4.1.3 Baseline Conditions (pg 4.1-8)

Although the Notice of Intent for the NEPA review contained within this document was issued in 2015, use of the 2012 baseline is appropriate and reasonable because (i) 2012 is a very recent point in time; (ii) the CPUC invested considerable resources amassing 2012 background/baseline data for the April 2015 Draft EIR; and (iii) environmental conditions in the study area have been relatively static such that 2012 conditions remain representative of meaningful baseline conditions.

- Livermore Berkeley analysis notes that data does not include data of the Salinas Valley Aquitard at the Cemex site. How is there a baseline for determining regional impact if this data is missing? Hofmann-11

- We have been in a drought for 4 years – new data might have been very revealing Hofmann-12

- Why is data from 2012, that is noted as incomplete (below), acceptable for basing long term impact in the region? This does not inspire confidence nor due diligence on the part of CalAm.

"As for our review of the foundation of the groundwater modeling, we find that there are shortcomings in the hydrostratigraphic model and simulation inputs that could potentially change the impact assessments. Chief among these was the absence of the Fort Ord-Salinas Valley Aquitard (FO-SVA), which hydraulically separates the Dune Sand and 180-foot equivalent (180- FTE) aquifers from greater than about 2 km east of the proposed extraction site." Appendix E1 Lawrence Berkeley National Laboratories peer review Conclusions Pg 2

- On Pg 4.4-3 the Geoscience 2016 graphic is peppered with question marks showing a lack of data regarding the actual extent and locations of the aquifer(s). How accurate is the modeling if based on incomplete data? Why is this acceptable for modeling probability of risk to our groundwater?

Hofmann-13

Sea Level Rise and Coastal Erosion (pg 4.2-22)

For example, a winter storm surge in early March 2016 exposed the buried MRWPCA ocean outfall pipe. Up to 15 feet of scour was observed around the exposed section of the outfall. The last time the outfall pipe was exposed was in 1997. The storm surge also broke the discharge pipe from the Test Slant Well to the outfall.

- What is the determined risk for storm events in the future? How would this affect the reliable operation of the slant wells?

Hofmann-14

- The outfall pipe/concrete pad is currently exposed and constitutes an eyesore.

Desalination plants should be designed to minimize visual impacts on coastal resources. pg 6-53 NOAA Desal Guidelines table

Hofmann-15

Corrosive or Expansive Soils (pg 4.2-23)

Additionally, sand mining in the region has increased sediment and sand loss and has contributed to disequilibrium, thus increasing the rate of coastal retreat in the southern Monterey Bay south of the Salinas River (Thornton et. al., 2006)

- What is the plan for continued erosion from the sand plant?

Hofmann-16

Seismic Groundshaking (pg 4.2-25)

As discussed above (Section 4.2.1.2), the WGCEP estimated that a major earthquake has a 72 percent chance of affecting the project vicinity in the next 30 years and would produce strong groundshaking throughout the region (WGCEP, 2015a, b).

- There is a high liquification area indicated on the chart 4.2-27 for the CEMEX site. What are the risks for this project in the event of a 7.0 earthquake event? No actual earthquake values are assigned to the charts.

Hofmann-17

Evaluation Criteria (pg 4.3-55)

Implementation of the proposed project (MPWSP), which would include 10 slant wells at CEMEX, would have a significant impact related to surface water hydrology and water quality if it would:

- *Violate any water quality standards or waste discharge requirements*
- *Otherwise substantially degrade water quality*

Here it relates to surface water in the DEIR, but the Anti-degradation policy reference on pg 4.3-35 includes ground waters.

"One significant difference between the State and Federal programs is that California's Basin Plan established standards for groundwater in addition to surface water." Pg 4.4-34 DEIR

- Why is "groundwater" not referenced here in regards to violation of water quality standards and degraded water quality?
- This Anti-degradation policy speaks to groundwater impacts as well as surface water

Hofmann-18

Dune Sand Deposits and the Dune Sand Aquifer (pg 4.4-8)

Based on the investigative work to correlate the hydrogeologic units of the Pressure Area, these Terrace Deposits along the coast appear to be at the same depth, and have similar geologic characteristics, as the inland Quaternary Alluvium of the 180-Foot Aquifer in the Salinas Valley (see Figure 4.4-3). Even though the Terrace Deposits are older than and lithologically different from the inland deposits of the 180-Foot Aquifer, the units are at the same depth interval, and groundwater likely flows from one unit to the next.

- Is this an assumption that the Cemex pump area is connected to the SVA aquitard? If they are connected, shouldn't there be more data to confirm affects of pumping to SVA water basin? Is this the Fort Ord-Salinas Valley Aquitard (FO-SVA*)* area Lawrence Berkeley National Laboratories peer review states lacked data?

Hofmann-19

Pg 4.4-11

Based on the recent groundwater testing data discussed in the Groundwater Quality subsection below, the quality of water in the 180-FTE Aquifer is directly influenced by seawater; this influence extends for miles inland, as discussed below in the Seawater Intrusion section. The lower portion of the proposed slant wells at the CEMEX site would have well screens installed across and would draw water from these deposits.

***180/400-Foot Aquitard** As shown on Figures 4.4-2 and 4.4-3, the 180- and 400-Foot Aquifers are separated by the 180/400-Foot Aquitard (Kennedy/Jenks, 2004). The unit is mostly 50 to 100 feet thick, is rarely as much as 200 to 250 feet thick, and may be absent in some areas. This aquitard is present beneath the CEMEX site at about 220 feet below the ground surface or about 200 feet below*

Hofmann-20

mean sea level,) and is 10 to 70 feet thick. The slant wells at the CEMEX site would not penetrate the 180/400-Foot Aquitard.

- Which is it – the slant wells will pull water from these deposits or will bypass? Are they different deposits? These are contradicting statements and the graphs show otherwise (fig 4.4-3).

Hofmann-20 cont.

Seawater Intrusion (pg 4.4-28)

… Over the past few years, Stanford environmental geophysics researcher Rosemary Knight has conducted a study to determine the viability of using electrical resistivity techniques to study seawater intrusion along the coast of the Monterey Bay. Professor Knight's initial survey was conducted along a 4-mile segment parallel to the beach between the cities of Seaside and Marina. The study found that the electrical resistivity readings positively correlated with measured TDS concentrations to a depth of 500 feet in four area groundwater wells.

- Missing here is the fact that Dr. Knight was unable to obtain permission to map the CEMEX property in her study.
- There is no ERT data for the CEMEX property and the groundwater below it.
- Why is Cal Am citing ERT data as if it relates to the CEMEX property!
- CalAm should employ its own ERT scan to study seawater intrusion instead of piggybacking this instance as if it is relevant to their project.
- Which four area ground water wells is this text referring to? Somewhere in Seaside? This is an unsupported supposition that data from area A is equal to Area B.

Hofmann-21

Regional and Local (pg 4.4-37)

The proposed project would not adversely affect groundwater management in the Basin, because it would be extracting groundwater that is not presently being used as a potable or an irrigation supply. Rather, when considering seawater intrusion and water surface elevations in the 400-Foot Aquifer, the proposed project may have a positive contribution to the sustainable management of groundwater. Regarding the former, groundwater modeling shows that the proposed project would retard the advance and limit the ultimate inland extent of seawater intrusion. With respect to the latter, by returning in-lieu desalinated water to the CCSD, the proposed project would provide recharge benefits to groundwater levels in the 400-Foot Aquifer. For these reasons, the proposed project would not conflict with the SGMA.

- Where is the data modeling that shows retardation of advancing seawater in to the Salinas Valley Basin? Appendix E2

Hofmann-22

- How will moving desalinated water taken from the Marina coast into the Castroville service district retard seawater intrusion at the Marina Coast location? Where is evidence?

Hofmann-23

- Conflict with SGMA if poor evidence is presented to support this claim that the project provides benefits to groundwater by retarding seawater intrusion. Again, how accurate is the modeling using ONE slant well with incomplete data? Hofmann-24

- Does the data show that the CEQA requirement (chapter 9.2) to do "No Harm" has been met adequately met? Hofmann-25

- What is the probability of certainty that the modeling informs predicted results? What is the probability of risk that the modeling shows an inaccurate assessment? Hofmann-26

MCWRA Act (1995) (Agency Act) pg 4.4-37

In accordance with the Agency Act, MCWRA is charged with preventing the waste or diminution of the water supply in its territory by, among other things, controlling groundwater extractions and prohibiting groundwater exportation from the SVGB (MCWRA, 1995). Specifically, section 9(v) of the Agency Act provides that MCWRA has the power:

To prevent the export of groundwater from the SVGB, except that use of water from the basin on any part of Fort Ord shall not be deemed such an export. Nothing in this act shall be deemed to prevent the development and use of the Seaside Groundwater Basin for use on any lands within or without that basin. If any person or entity attempts to export groundwater from the SVGB, the MCWRA may seek an injunction from the Monterey Superior Court to prohibit such export. The Agency Act further authorizes the MCWRA to commission groundwater studies to determine whether any portion underlying its territory is threatened with the loss of useable groundwater supply and to adopt an ordinance prohibiting further extraction of groundwater from an area and depth defined by the MCWRA.

As discussed more fully in Section 2.7, Water Rights, given the locations of the slant well screens beyond the jurisdictional boundaries of the County, it is not clear whether the Agency Act applies to the proposed project. However, as further discussed in that section, were the Agency Act to apply, it is preliminarily reasonable to conclude that the proposed project would be consistent. This is because the proposed project would return to the SVGB any incidentally extracted useable groundwater. The water available for export would be new supply, or developed water, not extracted from the SVGB.

- How does moving extracted water from Marina to Castroville conform to the intent of the MCWRA– this seems outside of the intent to keep groundwater at its local source.

- Where is the MCWRA on this subject? Has this agency issued any position on this project?

- The slant well screens may be beyond the jurisdictional boundaries, but the aquifer that is being drawn from is not. See Appendix E2 for draw down models. Do these cones of depression extend into the city limits? Does the draw down influence beyond the site boundary?

Hofmann-27

- Again, incidentally extracted groundwater from Marina and moving to Castroville – this seems outside of the intent to keep ground water at its source. Who decides that the incidental extracted groundwater uptake is new, or developed water? CalAm? MCWRA?

- If this is "useable ground water" by CalAm's admission, how can they have rights to it? Here again is the appropriative rights campaign to usurp water rights by calling it a "new supply".

Hofmann-27 cont.

MCWRA Ordinance (pg 4.4-38)

MCWRA Ordinance 3709 prohibits drilling into and pumping groundwater from the 180-Foot Aquifer within specific onshore areas, designated as Territories A and B (MCWRA, 1993). The proposed seawater intake system would be located at the westernmost edge of Territory B. Although the wells would be drilled within Territory B, the source water for the proposed project would be extracted from beneath the ocean floor, an area not located within the restrictive territories identified by Ordinance 3709.

- How much incidentally extracted ground water would be sucked up from the intake system? This could be considerable even if it is a fraction of the proposed 24.1 million gallons per day (mgd) of source water through the seafloor in MBNMS estimate.

- Why are there no numbers for the actual groundwater uptake from the slant wells?

Hofmann-28

Appendix E2 (pg 43)

… Rather, the flow path directions indicate that existing intrusion at these interface locations will slow proportionally to the relative lengths of the flow paths. Hence, slant well pumping retards the continued inland movement of the seawater interface in the southern portion of Model Layer 4.

"At the CEMEX site (24.1 MGD), the maximum distance from the well field to the 1-foot drawdown contour was about 15,000 feet under 2012 sea level, and about 20,000 feet in Model Layer 4." pg 43

- Does this move the project influence within city limits?

Hofmann-29

- How does slant well pumping retard seawater intrusion?

- Is this retard claim based on data modeling of only the one test well in Marina?

Hofmann-30

- Is any of the data to support this claim provided from actual operating desal slant wells?

Hofmann-31

- Data used in the modeling has already been tagged as incomplete by peer review yet this modeling is all we have to make a decision to put in 8-10 slant wells and extrapolate long term ground water impact.

Hofmann-32

THERE IS NO DATA FROM ANY OTHER OPERATING DESAL SLANT WELL CITED TO SUPPORT THIS CLAIM THA SLANT WELLS RETARD SEA WATER INTRUSION!

Hofmann-33

Significant and Unavoidable Environmental Effects (pg 6.3)

Several proposed facilities would occur in areas that may qualify as Primary and Secondary Habitat according to the City of Marina Local Coastal Land Use Plan (LCLUP). These facilities, which include the subsurface slant wells, and portions of the Source Water Pipeline, new Desalinated Water Pipeline, new Transmission Main, and the staging area at Beach Road, would be inconsistent with the City of Marina's LCLUP Policy 25 that prohibits development in Primary Habitat that is not protective of and dependent upon that habitat. The LCLUP states, "Primary habitat areas shall be protected and preserved against any significant disruption of habitat values and only uses dependent on those resources shall be allowed within those areas (City of Marina, 1982)." Implementation of mitigation measures would reduce impacts on special-status species habitat. However, given that project facilities proposed for such habitats are not resource-dependent, and because the LCLUP policy provides no exception to the requirements that development within such habitats be resource-dependent, potential conflicts with this policy would remain unresolved. The effect would be significant and unavoidable. Section 4.6, Terrestrial Biological Resources, for additional information.

- This plan is in conflict with the City Policy
- There are no exceptions in the City Policy for development.
- Why does this not spell out the "significant" impacts?
- If there are no exceptions and damages do occur – where are the mitigations?

Hofmann-34

Approach to Analysis (pg 6-12)

While Castroville is not in CalAm's service area, the analysis also considers the growth inducement potential of delivering Salinas Valley Groundwater Basin return water as desalinated supply, to the Castroville Community Services District (see Section 6.3.5.4).

- Why is Marina not included in this analysis? Clearly there will be an effect to growth if Marina has impacts from the slant wells causing harm to the water supply or CalAm's usurpment of rights to brackish water that Marina Coast might have developed as a brackish groundwater treatment water supply (desalter project) to serve the needs of Marina and Ord development.

Hofmann-35

Service Area Growth Trends 1990-2010 (pg 6-22)

Table 6.3-6 shows population and housing data from the U.S. census for the years 1990, 2000, and 2010. Except for Sand City, population in all of the cities in the service area declined between 1990 and 2000; population in the service area cities as a whole decreased by about 9 percent.

- So, all this projected water use demand is really going to Pebble Beach, Peninsula tourism, and undeveloped lots on record? Certainly not serving the declining residential population cited.

Hofmann-36

9

TABLE 6.3-9 SIGNIFICANT IMPACTS ASSOCIATED WITH PLANNED GROWTH IN THE PROJECT AREA (pg 6-40)

Significant and Unavoidable Impacts…

- *Degradation of visual character or quality of the area and surroundings*
- *Substantial new sources of light and glare*
- *Cumulative impacts on aesthetics, light and glare*
- *Effects on special status species*
- *Effects on riparian habitat and other sensitive natural communities…*
- *Increased demand for water supply and/ or water storage, treatment, and conveyance facilities and associated secondary effects*
- *Substantial depletion of groundwater supply*
- *Increased demand on groundwater in areas experiencing or susceptible to saltwater intrusion*
- *Cumulative impacts on groundwater quality*
- *Cumulative indirect impacts of water supply projects*
- *Demand for water resources that exceed available water supply*
- *Cumulative impacts on water supply…*

- Where are the details of the possible impacts? This is horribly uninformative and provides no foundation for informing regional decisions
- These are not spelled out in relation to the measurable impacts to Marina or the proposed Potrero Road location.

Hofmann-37

NOAA Desal Guidelines table (pg 6-48)

Where feasible and beneficial, subsurface intakes should be used. It must be ensured however, that they will not cause saltwater intrusion to aquifers, negatively impact coastal wetlands that may be connected to the same aquifer being used by the intake, and they must address the likelihood of increased coastal erosion in the future.

- Why is subsurface intake promoted as the preferred method when it has yet to be used reliably in any successful desal subsurface intake project to date?

Hofmann-38

- There is no long term data (over 10 years) for the effect of subsurface intake on coastal erosion.

Hofmann-39

10

- There is no long term data (over 10 years) for unique cost and repair issues for subsurface slant wells operating in coastal areas. Hofmann-40

- There are no desal slant wells providing water to customers. Why is this MPWP regional water solution adopting an untried, experimental and expensive technology to find a reliable water supply? Why has straight intake desal not been considered in more depth and dismissed so quickly? It is a proven, known technology and provides fresh water worldwide. Hofmann-41

- The DEIR must prove no harm on these issues and it does not give accurate assessment or long term risks. Hofmann-42

Conclusion: Deny approval of the DEIR

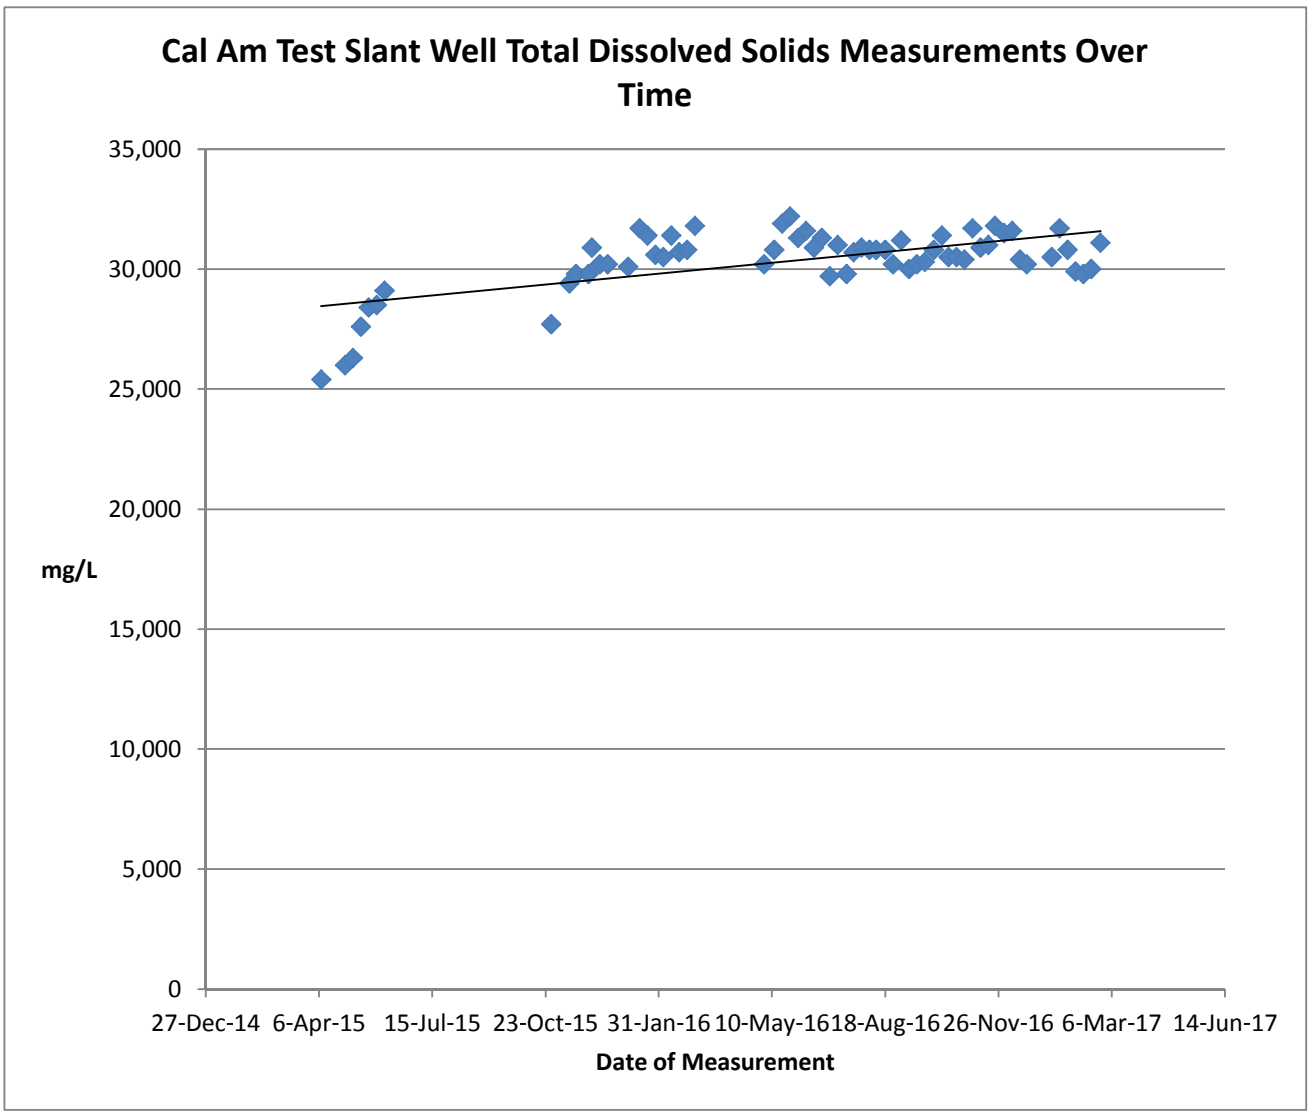
SUBJECT: Comments on the joint Draft Environmental Impact Report/Environmental Impact Statement (DEIR/DEIS) for the Monterey Peninsula Water Supply Project (MPWSP)

To Whom It May Concern:

1. The CALAM MONTEREY PENINSULA WATER SUPPLY PROJECT Draft Environmental Impact Report/Environmental Impact Statement (DEIR/DEIS) has stated that the test slant well on the CEMEX site is screened in substantial part in the 180/400 Sub-basin (as defined in Bulletin 118 of the State Department of Water Resources). (See page 3-15 of the DEIR/DEIS.)
2. The State Department of Water Resources has designated the 180/400 Sub-basin as a groundwater basin subject to critical conditions of overdraft. (See page 12 of the Interim Update 2016 to Bulletin 118.)
3. The DEIR/DEIS has proven that the operation of the test slant well on the CEMEX site has increased seawater intrusion in the 180/400 Sub-basin (as defined in Bulletin 118 of the State Department of Water Resources). The graph below shows the increases over time in the amount of total dissolved solids (TDS) in the water pumped from the test slant well. The TDS of water in the Monterey Bay varies from time to time but is generally in the vicinity of 34,000 mg/L.

Moore-1

1



This chart is generated from the data found in the Monterey Peninsula Water Supply Project Test Slant Well Long Term Pumping Test Monitoring Report No. 97 which is found on the website http://www.watersupplyproject.org/#!test-well/c1f1l, which, in turn, is briefly mentioned on page 4.4-42 of the CALAM MONTEREY PENINSULA WATER SUPPLY PROJECT Draft Environmental Impact Report/Environmental Impact Statement.

Moore-1 cont.

4. Further evidence that the test slant well has caused seawater intrusion into the 180/400 Sub-basin is provided by Figure 3 below, extracted from the GeoScience 2014b report in the appendices to the DEIR/DEIS.

Moore-2

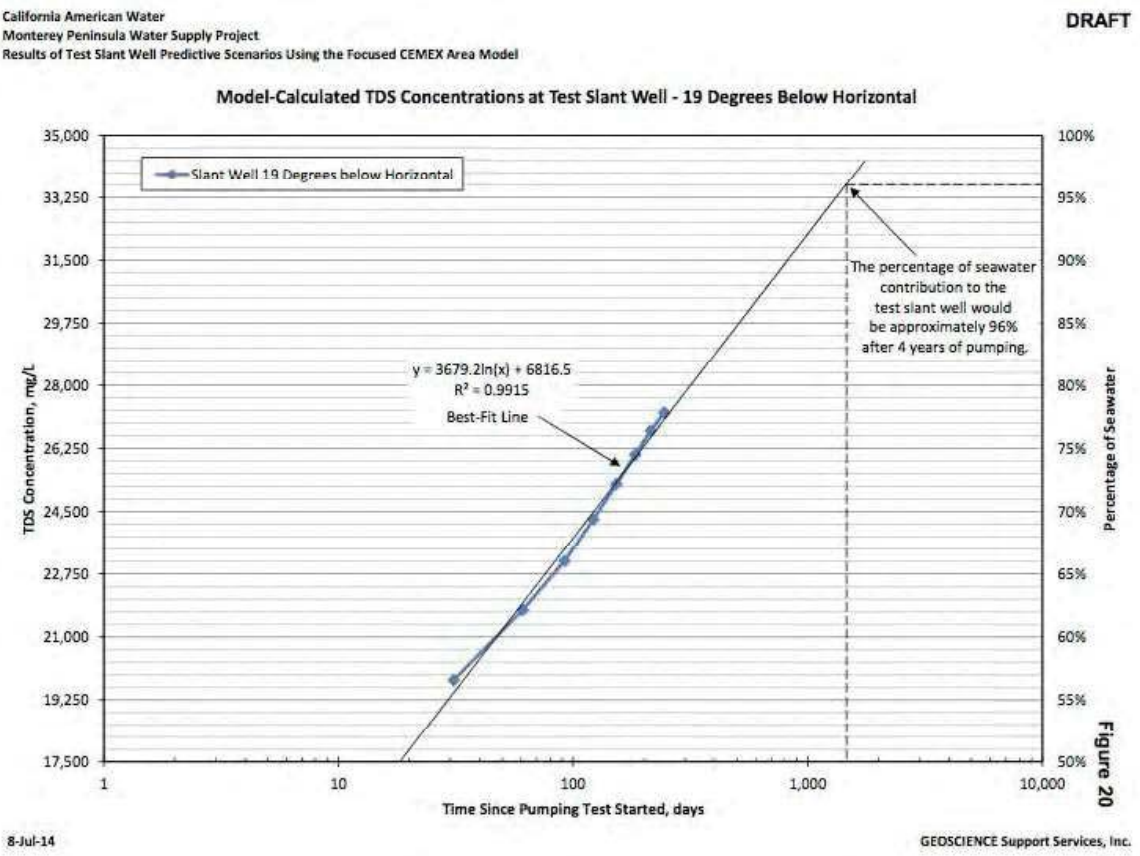


Figure 3 Time for Slant Well to Pull 96% Seawater (GeoScience 2014b).

5. The DEIR/DEIS has therefore proven that the operation of the test slant well has harmed the 180/400 Sub-basin by inducing more seawater intrusion into this sub-basin.
6. The DEIR/DEIR should have made this highly significant environmental impact (the increase in seawater intrusion caused by the pumping of the test slant well) far clearer, more prominent and in the main body of the DEIR/DEIS document rather than burying this information in the Appendices and a buried reference to a website.
7. The DEIR/DEIS states that, "Developed waters are available for use by the party who develops them, subject to the "no injury" standard discussed previously." Increasing seawater intrusion into a critically overdrafted sub-basin is a form of environmental injury.

Moore-2 cont.

Moore-3

Thank you for the opportunity to comment on the DEIR/DEIS. I look forward to reading your responses to the concerns I have raised.

Sincerely,

Thomas P. Moore

Thomas P. Moore

Please discard previous E-mail and accept this revised one .I request Deis/EIR//EIS should be rejected because injury caused to Marina lawful users. Data for model too little. Un scrambling water from two sources IS unscientific!

Quoted from the DEIS/eis/EIR etc,"The Report concludes that the withdrawal for creating developed water is appropriate so long as no injury is incurred by existing legal water users of the Basin. Setting up the test to discern whether Cal Am possesses water rights for the proposed project, the Report states: [I]n developing a new water source Cal-Am must establish no other legal user of water is injured in the process. Even if Cal-Am pumps water unsuitable to support beneficial uses, the water could not be considered developed water unless users who pump from areas that could be affected by Cal-Am's MPWSP are protected from harm. "

Olsen-1

Marina is using water from the 900 ft aquifer which the Army Core of engineers considers a temporary source. That water will run out. The water which Cal Am is proposed to use could be desalinated more cheaply than sea water and they would be permanently harmed if Cal Am uses it up. That water needs to be available to percolate down to the 900 ft aquifer.The water is usable even though not currently used. The intake needs to be far enough away so as to not take any water from under the land or the legitimate owners will be harmed! Cal Am plans to give water back to users they choose not the people they harmed which is not acceptable! When one test well was operating wells at some distance showed substantial depression. 9 wells would make the depression much greater. When I turn on the tap from Cal Am the water which comes out would include water stolen from Marina.

Olsen-2

Olsen-3

The people harmed must be a part of the DEIS/EIR/EIS and needs to be discussed even if that harm is in the future!

Reject all of the alternatives intakes which are located in Marina !

I request a determination as to how much data is enough to make an accurate model to be able to draw accurate conclusions from!

Olsen-4

Drawing water from both the land and from the sea is and trying to unscramble data is an unscientific way to go about this which should be grounds for rejecting the DEIS/EIS/EIR. Cal Am's process is like my 10 year old son putting every house hold chemical in a bottle of water then asking me to explain the reactions going on in the bottle! Keep it simple to be scientific!

8.7.18 Larry Parrish

Mary Jo Borak (CPUC), Karen Grimmer (MBNMS), and ESA
Feb. 23, 2017

Dear Ms. Borak & Ms. Grimmer and ESA:

Thank you for the opportunity to comment and submit some questions regarding the Monterey Peninsula Water Supply Project EIR/EIS. The draft EIR/EIS mentions erosion due to sea level rise and other factors, but it does not address coastal erosion due to excessive pumping and land subsidence. Here follows my comments and questions in that regard.

BEACH AND DUNE COASTAL EROSION FROM LAND SUBSIDENCE:

A. The test slant well:

Given that the test slant well (TSW) is not drawing it's intake water from below the sea floor, and; given that the TSW is drawing brackish water from the beach/dunes aquifers, (as much as 66%) and the remainder from the upper and lower portions of the 180' aquifer, and;
given that these aquifers are perched one on top of the other, and;
given that these aquifers are solely recharged from intermittent rainfall, and;
given that the cone of depression (COD) created from extensive and continual pumping from these aquifers is by and large beneath the land masses located inland of the mean high tide line, and;
given that the cone of depression is massively large,
therefore, I must conclude that there is definite potential for erosion of the land masses (i.e. the beaches and dunes) due to land subsidence caused by either aquifer-system compaction, hydrocompaction, or decomposition of organic soils located in and/or around the cone of depression zone. Since the pumping of the TSW (and ensuing production wells) will be continuous, there exists the potential for the aforementioned aquifers that lie above and/or around the well head pump(s) to actually be pumped into a state in which available source water could be drastically diminished or disappear altogether, particularly during dry (no rainfall) months and/or droughts. And once the source water is depleted sufficiently, subsidence will occur because "when long-term pumping lowers groundwater levels and raises stresses on the aquitards beyond the preconsolidation-stress thresholds, the aquitards compact and the land surface subsides permanently." (USGS) And once the land masses subside, the shoreline land masses become more vulnerable to increased wave action and erosion occurs (including wind erosion) and beaches disappear and/or the mean high tide line recedes inland.

Parrish-1

So, my questions are:

1. Have you taken comprehensive soil samples from throughout the entire cone of depression zone, including the aquitards within the zone? If not, why not? If so, where is the data?

Parrish-2

2. Are you now, or have you been monitoring and/or measuring land surface elevations in, above, or around the COD zone? If not , why not? Do you have baseline data with regard to these elevations? If not, why not? Please present the appropriate data.

Parrish-3

3. Have you conducted any data-based studies with regard to beach or dune erosion in or around the COD zone? If not, why not?

Parrish-4

4. Have you conducted any modeling (computer or otherwise) with regard to erosion or potential erosion in or around the COD? If not, why not? Please present the data.

Parrish-5

5. Have you considered that if/when beach or dune erosion occurs within the parameters of the COD zone that seawater intrusion into the nearby aquifers would likewise increase as a result? Have you presented any mitigations should seawater intrusion occur within these aquifers? If not, why not?

Parrish-6

B. Cumulative impacts:

Given that the intent is to deploy 8 -10 production wells along the Cemex property and perhaps elsewhere, I will ask the same questions asked previously above with regard to those additional cones of depression zones created by the production wells. In other words, what are the cumulative impacts from the entire group of production wells with regard to coastal erosion, which includes the beaches and dunes? You must also take into account the possible overlapping of some of the CODs which will exacerbate the negative effects of pumping from these aquifers and in the overlapping areas.

Also, since the Monterey Bay beach and dune areas on the Cemex property are all part of a much larger geological ecosystem and what happens in one area with respect to beach or dune erosion usually has adverse effects elsewhere along the Bay shoreline, I will ask you this question - What mitigations have you presented or offered in the event of beach loss or dune erosion due to the implementation of the MPWSP (desalination project) which includes the TSW and the proposed production wells?

Parrish-7

In conclusion, I must stress that my concerns are legitimate concerns and my questions are appropriate and should be answered and this issue of coastal erosion caused by land subsidence needs to be fully addressed. The EIR/EIS is therefore deficient and constitutes serious and unmitigated adverse environmental impacts and is not in compliance with CEQA requirements. Quite simply, the EIR/EIS needs to be revised and recirculated with these issues adequately addressed and attended to, otherwise the EIR/EIS will be subject to costly court challenges.

Parrish-8

Thank you for your consideration,

Respectfully yours,
Larry Parrish

General Comment

Although the DEIR provides detail on nearby faults in its' "Geology, Soils, and Seismicity" Section 4.2, it inadequately addresses the potential impacts of seismic activity of the Reliz (Blanco Section) and other nearby faults and does not present mitigation for any potential impacts. The Reliz (Blanco Section) underlies much of the project area and could cause rupture and/or displacement of the subsurface slant wells, source water pipeline, desalinated water pipeline, proposed brine discharge pipeline, transmission main and transfer pipelines. In the instance of rupture of the proposed brine discharge pipeline, large amounts of brine discharge would be released into a concentrated area and could be devastating to the biology of the immediate and adjacent areas of the Monterey Bay. Additionally, compromised pipelines could also have negative impacts to local agricultural lands. Pelot-1 Pelot-2

The DEIR does not adequately address the potential of subsidence due to all ten (10) wells pumping. Although the well design at this proposed site has been amended from that of Dana Point with the anticipated, but not yet known, outcome being there would be less subsidence at the top of the wells, subsidence will inevitably occur, albeit at what is assumed to be slower pace. Pelot-3

The DEIR does not present evidence that the impacts of subsidence, in conjunction with the seismic activity for the Reliz (Blanco Section) Fault Zone and other nearby fault systems that underlies much of the project area, have been modeled to evaluate the cumulative/combined impacts of seismic activity with that of subsidence. Pelot-4

General Comment

I am writing in regards to the Draft EIR for CalAm's proposed seawater desalination facility to be built on the shore of Monterey Bay. My comments are specific to analysis of brine for CalAm's desalination facility with a short comment on subsurface intakes.

Use of Wastewater for Brine Dilution:
I was happy to read a more thorough reanalysis (with a time component) in the sections involved with brine plume modeling compared to the earlier version of a similar DEIR from 2009. While the new analyses supports conclusions that brine from MRWPCA's offshore pipe will most likely comply with salinity requirements, Section 4.3 raises concerns that compliance may fail when pipe flow is low. Augmenting pipe flow with wastewater would solve that problem. However nowadays, most experts consider wastewater to be a valuable resource. Using it to dilute brine cannot be called a "beneficial use" under California water law

Reeb-1

Reeb-2

According to the DEIR, retrofitting MRCPCA's offshore pipe with high velocity jet diffusers (at a 60 angle) ensures salinity levels would comply with Ocean Plan regulations within the ZID. Unfortunately, Table ES-2 (Summary of Impacts and Mitigation Measures) does not list pipe retrofit as a mitigation measure. Monitoring is the action taken instead. Retrofitting the pipe now will save CalAm ratepayers money when flow augmentation with wastewater is not an option. Reeb-3

I believe third party environmental consultants best serve the public for monitoring environmental affects in and around the ZID, not private consultants paid by an industry operator. Seawater desalination in California is in its infancy. Marine scientists need publically available data to improve future brine outfall designs. Given the many marine institutes and research programs around the Bay, monitoring should involve researchers and students, which helps train our next generation of scientists too. Reeb-4

I am aware that approximately 6000 AFY of tertiary treated wastewater was currently discharged offshore last winter from MRWPCA. This volume is enough to replace much, if not all of CalAm's proposed plant capacity. Expanding GWR is a way to save ratepayers' money while turning an unwanted water source into a beneficial supply. Therefore, I question the need for seawater desalination at this time. It seems we do not have a water shortage after all. We have a break down of collaboration among communities that really must be overcome. Reeb-5 Reeb-6

California Market Squid and Brine Monitoring
The DEIR focuses on lethal salinity thresholds lethal to marine species and notes that Dorytheuthis opalescens can be reared in salinities up to 38 ppt in captivity (i.e. adequate food and no predators). Because salinity in the Bay never reaches 38 ppt, referencing Vidal and Boletzky's study on lab cultured market squid as proof eggs and paralarvae will be fine in the wild is misleading. Brine monitoring studies could include questions that address the unknown sublethal salinity impacts on survivorship. Reeb-7

Subsurface Intakes in Marina's Coastal Aquifer
Recently, Dr. Knight's lab (Stanford University) published a paper (Goebel et al. in press) showing clear evidence of freshwater flows interspersed among regions of elevated salinity in the Marina coastal region. Using electrical resistivity, 3D images of aquifers revealed complex patterns of seawater intrusion. These new images and findings are significant, given the way groundwater laws and water ownership is currently treated. It would be prudent to use this technology in the area of CalAm's proposed slant wells to ensure subsurface intakes do not harm the aquifer's productivity. Reeb-8

Having said that, I strongly believe subsurface intakes are essential for facilities located in Monterey Bay, where Red Tides" are commonplace. Algal blooms can clog/shut down seawater desalination facilities for days, weeks, or months making them unreliable (Caron et al. 2010; Richlen et al. 2010). Subsurface wells prevent this. Because there is no way to run "real-time" assays to test product water for soluble algal toxins leaking through old/poorly maintained filters, algal blooms become a critical issue for water providers should toxins enter the municipal supply. Reeb-9

Sincerely,

Carol Reeb

2-22-17

The Highway 68 pipeline crossing from Fairgrounds Road on the East over the overpass above Highway 68 to the West connecting onto Mark Thomas Drive, does not appear in this EIR/EIS or in the Pure Water Monterey EIS. Why? The cost estimates are also not included. Why? Highway 68 is designated as a Scenic Highway. How does Cal Am plan on getting a right of way to cross over this highway? There are also two "active" earthquake faults that run into the project: the Sylvan and the Navy. These faults are in a report issued by AMBAG. What do Cal Am's plans for these faults include?

Rotter-1
Rotter-2
Rotter-3
Rotter-4

A Department of Transportation letter to Cal Am dated October 23, 2015, stated that Cal Am had not completed any of the required items for its Encroachment Permit Applications 0514-6US-0229 Site No. 8-State Route 1, which was denied without prejudice. After the 45 day response time expired, the file was closed without prejudice. Why no response from Cal Am?

SUBJECT: DRAFT EIR\EIS COMMENTS FOR THE MONTEREY PENINSULA WATER SUPPLY PROJECT

Dear Staff:

Thank you for the opportunity to comment on a project which has far reaching implications to our community, and the residents of the City of Monterey. I have commented on three sections; Energy Conservation (Section 4.18), Determination of Environmentally Superior and Preferred Alternatives (Section 5.6.2) and Comparative Analysis of the Project Alternatives (Sections ES.6 to ES.8). I will submit each as a separate letter.

SECTION 4.18 ENERGY CONSERVATION

CEQA Sec. 21 100(b) "requires evaluation of the potential energy impacts of a proposed project. And consideration of mitigation measures that would avoid or reduce the wasteful, inefficient, and unnecessary consumption of energy associated with the project". Appendix F of the CEQA Guidelines provides three goals for energy conservation:

1. Decrease overall per capita energy consumption;
2. Decrease reliance on natural gas and oil; and
3. Increase reliance on renewable energy sources.

With regard to NEPA, the Council on Environmental Quality (CEQ) regulations 40 CFR 1502.16(e) requires "analysis of energy requirements and conservation potential of various alternatives and mitigation measures".

In the EIR documentation you state the requirements of the *Energy Policy Act of 2005*, State Regulations (4.18.2.2), including the *California Coastal Act*, the *State of California Integrated Energy Policy*, *Title 24 Building Energy Efficiency Standards (California Energy Code)* and the *California Green Building Standards Code (Cal Green).*

On pages 5.5-325, 5.5-32, 5.5-332 and 5.5-333 (see attached) the EIR\EIS document does a comparative analysis of the Energy Conservation and Usage criteria of each alternative. My comments are on the preferred project and Alternative 4, People's Moss Landing Water

Desalination Project. The conclusion drawn by the author of the EIR\EIS regarding Energy Conservation for Alternative 4 is as follows: "Overall, Alternative 4 would result in an *increased impact conclusion* compared to the proposed project, significant and unavoidable".

In the Executive Summary, and again, in the body of the text of the EIR\EIS the author describes the rigorous analysis employed in the preparation of the document and the use of the best data available to reach its conclusions.

ALTERNATIVE 4 ENERGY CONSERVATION MEASURES:

In July of 2016, the Peoples Project entered into detailed discussion with a solar contractor, (see attached) for the construction of a 3.7 MgW to 5.0 MgW solar energy farm designed to reduce the reliance of the project on fossil fuels. To date, the project design is approaching completion, the PG&E interface study has been performed and multiple milestones have been achieved. The solar project has been discussed in public meetings and is in the minutes of several public agencies. In addition, a state of the art brine containment system is also being designed for the Project, thereby significantly reducing the return water impacts to the environment.

The solar project will need a dedicated 18-20 acres of an approximate 200 acre business park and the owner has designated 2 separate parcels to achieve the goal. Permits from the County of Monterey have been applied for and the process is proceeding.

QUESTIONS FOR THE EIR\EIS CONSULTANT:

1. In preparation for this comment to the EIR\EIS some research was done into who, if anyone, associated with the Peoples Project had been contacted by ESA, Cal Am, the PUC or anyone associated with the project regarding the Energy Conservation section. The Moss Landing Harbor District was not contacted, counsel for said Agency, which is the lead agency for the Project was not contacted, counsel for the Peoples Project was not contacted, the solar contractor was not contacted, no consultant or employee of the Peoples Project was contacted and the owner of the property was not contacted. No one was contacted!!!

Selfridge1-1

QUESTION: How is it possible, in the context of a thorough review of project alternatives, that the only Project attempting to comply with the multiple State and Federal laws discussed above was not consulted regarding components of their Project?

QUESTION: The EIR\EIS for the Peoples Project has been presented to the lead Agency for review and Aspen Consulting is performing this work. The joint document will be available for review shortly, so I understand the consultant for the proposed project does not have access to it. How did the consultant arrive at the conclusion that Alternative 4 would result in an *increased impact conclusion* compared to the proposed project? Selfridge1-2

QUESTION: Referencing Table 5.6-1, Alternatives Impact Study, Page 5.6-18, there are 3 impacts analyzed. In each case, alternative 4 is given the same rating as the proposed project, and yet in each case, the rating is adjusted to being more significant for Alternative 4. Please explain the rationale? Selfridge1-3

QUESTION: Impact 4.18-2, "**Use large amounts of fuel and energy in an unnecessary, wasteful or inefficient manner during operations".** Might this lower rating for Alternative 4 been modified if the consultant was aware of the construction of a solar array to service the Moss Landing Green Business Park? Should the consultant have performed a necessary level of due diligence to even be aware of said solar energy park? Selfridge1-4

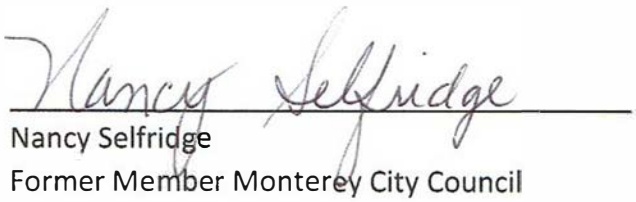
QUESTION: Impact 4.18-3, "**Constrain local or regional energy supplies, require additional capacity, or effect peak and base periods of electrical demand during operations." T**he Moss Landing Green Business Park will be self-sufficient, or possibly, an actual contributor of energy to the grid. Please explain how the existence of the solar array farm on the property might affect the answer to this rating question? Selfridge1-5

Each and every one of my questions, criticisms and observations incorporated herein constitute significant unmitigated adverse impacts as defined by CEQA and NEPA, and these significant deficiencies in the draft EIR\EIS cause the EIR\EIS to be defective and not in compliance with the mandates of CEQA or NEPA. Further, the significant adverse impacts and deficiencies, which have largely been intentionally ignored by the preparers of the EIR\EIS, cause the document to need to be significantly revised and recirculated so as to avoid damaging both the environmental and natural resources of Monterey County and the individual rights of innocent land owners who have not received the statutorily (CEQA) mandated mailed notices inasmuch as their groundwater resources are now being proposed to be stolen by Cal Am. Selfridge1-6

Failure to make these necessary and legally required revisions, and to identify and mitigate these significant adverse impacts will cause this EIR\EIS to be defective and subject to successful challenge in Court.

Please see attached data for your reference.

Sincerely,



Nancy Selfridge

SUBJECT: DRAFT EIR\EIS COMMENTS FOR THE MONTEREY PENINSULA WATER SUPPLY PROJECT

Dear Staff:

Thank you for the opportunity to comment on a project which has far reaching implications to our community, and the residents of the City of Monterey. I have commented on three sections; Energy Conservation (Section 4.18), Determination of Environmentally Superior and Preferred Alternatives (Section 5.6.2) and Comparative Analysis of the Project Alternatives (Sections ES.6 to ES.8). I will submit each as a separate letter.

SECTION 5.6.2 DETERMINATION OF THE ENVIRONMENTALLY SUPERIOR AND PREFERRED ALTERNATIVE:

CEQA and NEPA both require extensive comparison of a variety of factors in comparing the proposed project and identifiable alternatives. In fact, in referencing Table ES-1, Alternative Impact Summary there are 115 comparative analytics. These are assigned grades (ie: LS, Less than Significant, SU, Significant and unavoidable, etc). These weighted grades are then used as a component in the consultant selecting the environmentally superior and preferred alternative. I will compare the preferred alternative to Alternative 4, the Peoples Project.

On page 5.6-5 the consultant specifically notes (see attached) the following impacts are unique to Alternative 4 (Peoples Project):

1. Construction of the desalination plant could impact (currently unsurveyed) historical resources, resulting in a significant and unavoidable impact;
2. Operation and siting of the intake pumping facilities on top of the existing caisson at the existing shoreline could result in the long-term direct effects on coastal erosion and scour processes that could expose adjacent properties to coastal flooding and a change in sediment transport, resulting in potentially significant impacts;
3. Operation and siting of the desalination plant facilities within a 100 year flood one could cause long-term direct effects related to redirection of flood flows, resulting in a significant and unavoidable impact.

Following are questions regarding the Alternatives Impact Summary:

QUESTION: Impact 4.2.1 *Substantial soil erosion or loss of topsoil during construction*. Where is the analysis of the topsoil that may exist at the Moss Landing Business Park in the appendix or body of the report? Selfridge2-1

QUESTION: Impact 4.2.10 *Accelerate and\or exacerbate natural rates of coastal erosion, scour, or dune retreat, resulting in damage to adjoining properties or a substantial change in the natural coastal environment*. The Peoples Project is being built on an existing location that has been in business operation for over 80 years and has the necessary infrastructure in place to intake seawater (it currently does so now) and has existing outfall. The preferred project will contemplate 10 wells being drilling on the coastline, Alternative 4 uses preexisting infrastructure. Where in the EIR\EIS is the support data to study the comparative impacts of the two projects on coastal erosion? Selfridge2-2

QUESTION: Impact 4.2.11 *Degrades the physical structure of any geologic resource or alters any oceanographic process, such as sediment transport, that is measurably different from pre-existing conditions.* The preferred alternative receives a grade of NI, No Impact, whereas Alternative 4 receives a SU, Significant and Unavoidable. The preferred alternative drills 10 wells, pumps, delivery systems, etc on pristine beach in a Marine Sanctuary and Alternative 4 uses existing infrastructure already buried in the ground. Where in the EIR\EIS is the supporting study and science to support this logic? Selfridge2-3

QUESTION: Impact 4.3.1 *Degradation of water quality associated with increased soil erosion and inadvertent releases of hazardous chemicals during general construction activities.* The preferred alternative receives a grade of LS, Less than Significant and Alternative 4 a grade of SU, Significant but Unavoidable. The preferred alternative is being constructed in various locations, all within the Coastal Zone on virgin ground, some of it contiguous to the coastline. Alternative 4 is being built in an existing business park which is almost all concrete in the 16.5 acre building site. Where is the study in the EIR\EIS that supports the conclusions drawn in the Summary? Selfridge2-4

QUESTION: Impact 4.3-9 Impedance *or redirection of flood flows due to the siting of project facilities in a 100 year flood hazard area.* The preferred alternative receives a grade of LS, Less than Significant and Alternative 4 receives a grade of SU, Significant and Unavoidable. According to the Monterey County Water Resource Agency web site the ENTIRE coastal region of the Monterey Peninsula, Moss Landing and Santa Cruz are in a 100 year flood hazard area. Alternative 4 is protected by rock jetty's, large sand bars and a harbor. The Moss Landing Business Park is built at least 20 feet above sea level. Selfridge2-5

Conversely, the preferred alternative is contemplating building 10 well sites at approximate sea level, per the EIR\EIS, all within the 100 year flood hazard zone. The transmission lines will all be built with in the 100 year flood hazard zone, both of these tasks in sand. Please provide the scientific study that shows the preferred alternative well sites and transmission pipelines at less than a significant risk. Please provide the scientific analysis that supports the conclusion that the risk to Alternative 4 is many magnitudes greater than to the preferred alternative. How is it possible that Alternative 4 is subject to grave risk, in a 100 year flood one, at an elevation of 20+ feet, with a concrete berm, when the preferred project components are built in sand at sea level and are deemed to have little, if any, risk?

Selfridge2-5 cont.

QUESTION: Impact 4.3-10 *Exposure of people or structures to a significant risk or loss, injury or death from flooding due to a tsunami.* The preferred project receives a grade of LS, less than significant, whereas Alternative 4 is deemed Significant and Unavoidable. I raise the same objection as the previous section. The consultant is comparing projects that both lie in the same National Marine Sanctuary, on the same coastline within the same Bay. Is the EIR\EIS suggesting the tsunami would be targeted only at Moss Landing? Please provide the scientific study that shows the evidence that Moss Landing is at a significantly higher risk for such an event than any other area of the Bay. Please provide context to the issue by providing the historical data to show the impacts and location of a tsunami in the Monterey Bay. Has there ever been a measurable tsunami in the last 100 years of records in the Monterey Bay?

Selfridge2-6

QUESTION: Impact 4.3-11 *Impact of people or structures to a significant loss, injury, or death from flooding due to sea level rise.* The preferred project receives a grade of LS, less than significant while Alternative 4 receives a grade of SU, significant and unavoidable. Being redundant, the preferred project is at sea level and Alternative 4 is not. What scientific data was used by the consultant to arrive at this conclusion? How is it possible to draw this conclusion when the EIR\EIS discusses possible sea level rises in its modeling work and does not list a major concern for any significant issue over the next 20 years?

Selfridge2-7

QUESTION: Impact 4.15-1 *Cause a substantial adverse change in the significance of a historical resource as defined in Section 15064.5 of the CEQA Guidelines or historic properties pursuant to 36 CFR 800.5.* The preferred project received a grade, undoubtedly appropriately of NI, No impact. The Alternative 4 received a grade of SU, significant and unavoidable.

I asked the owner and consultants of the project, as well as the Moss Landing Harbor District if they has ever been consulted by the EIR\EIS consultant for this document, regarding this issue. No one was ever contacted. The owner has already paid for a historical resource study on the property, as required by the aforementioned laws. The conclusion in the study; no significant historical issues, with the exception of one strip of the property which is in no way jeopardized by the project during operation or construction. How is it possible that during a complete and exhaustive analysis of competing projects as required by CEQA and NEPA this

Selfridge2-8

report was not known to the consultant? Why was this information never requested by the consultant in the preparation of the EIR\EIS document?

Selfridge2-8 cont.

QUESTION: Impact 4.15-2 *Cause a substantial adverse change during construction in the significance of an archaeological resource pursuant to Section 15064.5 of the CEQA Guidelines or historic properties pursuant to 36 CFR 800.5.* The preferred project received a LSM grade, less than significant, mitigations available, Alternative 4 received the same grade but more severe mitigation measures required. Refer to the prior question, same facts apply. If the consultant had simply asked any members of the Alternative 4 team, from the lead agency to employees, they would have discovered the historical and archaeological studies had been done with no significant impacts.

Selfridge2-9

SUMMARY: The consultant (ESA) uses the grid analysis for Alternatives Impact Study to grade 115 separate impacts and determine the best possible outcome. The consultant could have accomplished a far more fair and valuable comparison, as required by CEQA and NEPA if he had simply consulted with the members of Alternative 4, and perhaps a very different conclusion may have been reached. These analyses need to be redone and recirculated.

Selfridge2-10

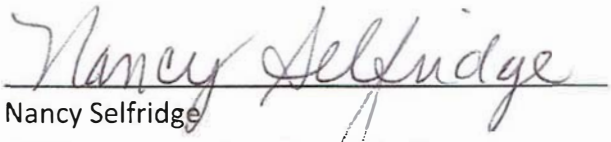
Each and every one of my questions, criticisms and observations incorporated herein constitute significant unmitigated adverse impacts as defined by CEQA and NEPA, and these significant deficiencies in the draft EIR\EIS cause the EIR\EIS to be defective and not in compliance with the mandates of CEQA or NEPA. Further, the significant adverse impacts and deficiencies, which have largely been intentionally ignored by the preparers of the EIR\EIS, cause the EIR\EIS to need to be significantly revised and recirculated so as to avoid damaging both the environmental and natural resources of Monterey County and the individual property rights of innocent land owners who have not received the statutorily (CEQA) mandated mailed notice inasmuch as their groundwater resources are now being proposed to be stolen by Cal Am.

Selfridge2-11

Failure to make these necessary and legally required revisions, and to identify and mitigate these significant adverse impacts will cause this EIR\EIS to be defective and subject to successful challenge in Court.

Please see attached data for your reference.

Sincerely,



Nancy Selfridge

SUBJECT: DRAFT EIR\EIS COMMENTS FOR THE MONTEREY PENINSULA WATER SUPPLY PROJECT

Dear Staff:

Thank you for the opportunity to comment on a project which has far reaching implications to our community, and the residents of the City of Monterey. I have commented on three sections; Energy Conservation (Section 4.18), Determination of Environmentally Superior and Preferred Alternatives (Section 5.6.2) and Comparative Analysis of the Project Alternatives (Sections ES.6 to ES.8). I will submit each as a separate letter.

SECTION ES.6 to ES.8 COMPARATIVE ANALYSIS OF THE PROJECT ALTERNATIVES:

Pursuant to Section 15123(b) (1) of the California State CEQA Guidelines and NEPA regulations (40 CFR 1502.12), and EIR\EIS shall identify areas of controversy known to the lead agency including issues raised by agencies and the public and the issues to be resolved (including the choice among alternatives and whether or how to mitigate significant effects).

Section ES-8 Groundwater Modeling, Impacts and Water Rights: (See page ES-13) *Cal Am's proposed use of subsurface slant wells to withdraw source water for the MPWSP Desalination Plant is the subject of two controversies; (1) whether Cal Am has the legal right to extract groundwater from the Salinas Valley Groundwater Basin (SVGB); and (2) whether implementation of the MPWSP and operation of the subsurface slant wells would exacerbate seawater intrusion in the SVGB.*

FACT: Per Section 2.6, Water Rights, page 2-30 (*Indeed, no government agency will formally grant water rights to Cal Am for the proposed project*), page 2-31 (*Cal Am has no prescriptive groundwater rights in the Basin*) and (*Naturally, however, if Cal Am does not have the right to the supply water for the proposed project, the proposed project could not proceed and would thus prove unfeasible*). The consultant admits that Cal Am has no water rights and this is obviously a contentious issue.

Selfridge3-1

QUESTION: Would it have not been prudent for Cal Am and the PUC to resolve the water rights issue prior to spending millions of dollars of ratepayer money on test wells? What cost contingency has been built into the process if, as expected, the issue is determined by Courts and Cal Am has been deemed to have seriously damaged a State protected basin and stolen other people's water?

Selfridge3-1 cont.

FACT: Page ES-13 of the EIR\EIS states: "the proposed subsurface slant wells at CEMEX would extend offshore and be screened in aquifer units of the SVGB that have long been intruded by seawater. Although the subsurface slant wells would draw seawater (i.e., source water for the MPWSP Desalination Plant) from beneath the ocean floor, a fraction of the source water would be drawn from inland portions of the SVGB)".

QUESTION: The test slant well, per the consultants own data, does not extend under the sea floor, but rather, under the beach high mean tide line. How does the empirical data derived from the test well correspond to subsurface wells hundreds of feet deeper in the SVGB aquifer? Please explain and provide the hydrologic data and basis for this conclusion, discussed in the EIR\EIS.

Selfridge3-2

FACT: For the last 25 years, the ratepayers in Zone 2B (12,000 acres of irrigation land commonly referred to as the Castroville Seawater Intrusion Project (CSIP)) and all Salinas Valley Groundwater Basin members (Zone 2C) have paid assessments to the County of Monterey through the Resource Agency to protect the 12,000 acres from basin degradation and sea water intrusion advancement. Farmers in the area have willingly given up their pumping rights in the aquifer to protect against further seawater intrusion. Further, the Coastal Commission, the County of Monterey and the State of California are legislatively mandated to preserve and protect the SVGB, specifically the North County area.

QUESTION: How does voluntarily complying with a County Ordinance equate to abandoning the water in the aquifer making it "found water"? Further, how do the protective bodies of government not only allow this type of devastation to occur in a protected zone, but actually condone and actively participate by ignoring its own ordinance and legislative mandate?

Selfridge3-3

FACT: Per the Monterey County Water Resource Agency website the 25 years of drastically reduced pumping in the 12,000 acres has seen a steady rise in water tables, a slight increase in fresh water component and an almost complete cessation of seawater intrusion into this area. Taxpayers have paid millions of dollars to the County to protect them and carry out the provisions of the CSIP.

QUESTION: Please provide the baseline statistics for the contiguous area around the CEMEX site from 1992 to 2015, (prior to the test slant well) and compare to the condition of the same area today? Please explain how pumping approximately 2,000 gallons per minute, in an area

Selfridge3-4

previously left primarily un-pumped through County Ordinance, has not been impacted by such high pumping rates.

Selfridge3-4 cont.

FACT: Section 2.6.1 State Water Resources Control Board Report page 2-32 (see attached). *"Developed water is water that was not previously available to other legal users and that is added to the supply by the developer through artificial means as a new water source."* As previously stated, the water in the perched 1800 and upper dunes sand aquifers was not abandoned or unavailable to the overlying land owners, it was voluntarily not pumped, as the landowners had, and are, continuing to pay to protect the Zone 2B basin.

QUESTION: How does the consultant justify classifying the water in the aquifers under CEMEX as "not previously available to other water users" when the landowners legally agreed to use CSIP water that they were paying for? How do the legislatively mandated bodies ignore the legal mandate created by the passage of laws designed to protect an impaired water basin? How does the consultant and the PUC ignore these laws that have been on the books for many years? Please present the study documents used by the consultant for this section of the EIR\EIS for public review?

Selfridge3-5

FACT: Section 2.6.1 State Water Resources Control Board Report page 2-33 "State water policy favors enhancement of beneficial uses of water. Specifically, Article X, section 2 of the California Constitution requires "**that the water resources of the State be put to beneficial use to the fullest extent to which they are capable, and that waste or unreasonable use or unreasonable method of use of water be prevented**".

QUESTION: The test slant well, when operational, has been pumping approximately 2,000 gallons per minute, or, 2,880,000 gallons per 24 hour day. This equates to over 8 acre feet per day. Much of this water was fresh water, agreed by various government bodies to not be available. The test slant well, by design draws the water into its test pump and immediately diverts it back out into the ocean. This is known within the industry as "pump and dump". How does the consultant and the PUC justify an obvious violation of State law by not adhering to the beneficial use concepts of State law? Please provide the analysis and study documents prepared in conjunction with this EIR\EIS to justify said process.

Selfridge3-6

FACT: Much of the water being "pumped and dumped" is coming from contiguous land owners, all of whom possess prescriptive water rights to said water. One of those land owners is the Agland Trust, who purchased the land for agricultural perpetuity 30+ years ago. The land was purchased with a grant from the United States government, specifically the Department of Agriculture. One of the tenets of the purchase was that the land stay permanently agriculture and that all assets of the property, **including its water**, be used only for the said purpose. The potential penalty, per the documents, if violating any of the provisions was reversion of the

property back to the Federal Government. (Please see the attached purchase documents with the reversion language therein)

QUESTION: Much of the water "pumped and dumped", by the Cal Am test slant well belongs to the Agland Trust. Did the consultant communicate with the owners of the Agland Trust property prior to the start of pumping to determine the existence of any such restrictions? Did the consultant communicate with the United States Department of Agriculture prior to the start of the test slant well to determine if use of their potential asset was agreeable to them? Has the consultant considered the potential negative conversion impacts to the Agland Trust in the event the Federal government exercises its rights under the initial contract? Please provide the documentation that must surely exist, that shows the inappropriate theft of Federal property by Cal Am was preapproved by the United State government.

Selfridge3-6 cont.

Each and every one of my questions, criticisms and observations incorporated herein constitute significant unmitigated adverse impacts as defined by CEQA, and these deficiencies in the draft EIR\EIS cause the EIR\EIS to be defective and not in compliance with the mandates of CEQA and NEPA. Further, the significant adverse impacts and deficiencies, which have largely been ignored by the preparers of the EIR\EIS, cause the document to need to be significantly revised and recirculated so as to avoid damaging both the environmental and natural resources of Monterey County and the individual property rights of innocent land owners who have not received the statutory (CEQA) mandated mailed notice inasmuch as their groundwater resources are now being proposed to be stolen by Cal Am.

Selfridge3-7

Failure to make these necessary and legally required revisions, and to identify and mitigate these significant adverse impacts will cause this EIR\EIS to be defective and subject to successful challenge in Court.

Please see attached data for your reference.

Sincerely,

Nancy Selfridge

8.7.23 Jan Shriner

These comments are sent to the CPUC by me as a resident of Marina. I am also a Director of the Board of Marina Coast Water District and these comments are not authorized by the Board but submitted as an individual resident of Marina.

March 28, 2017

The first of the slant wells was called a "test" well and proposal received scant environmental written review as if it would be removed when test was complete. The definition of the completion was vague but a target date of February 2018 is specified on page 155 in project description section 3.2. Shriner-1

Annual erosion rate of 2014 in the coastline of Cemex nearly doubled from 220,000 to 380,000 cubic yards in 2016 according to analysis by Ed Thornton and reported in the Monterey Herald. State Parks uses a 7 feet per year estimate in planning. On page 374 of Appendix C-2 of the Draft EIR it states the erosion data was
provided by California American Water Company (Cal Am). Shriner-2

The projected loss due to erosion for Potrero Road is 120 feet and the Cemex location of 300 feet for 2060. Based on this projection, the calculated erosion rates of 2.5 feet per year at Potrero and 6.4 feet per year at Cemex between 2014 and 2060. In the public workshop in Seaside on February 15, 2017, no one would tell me what erosion rate was used in the study for the draft EIR. Shriner-3

The "test" well is now proposed to be left in its location but the other proposed 9 slant wells to be located 800’ inland of shoreline at an angle of 14 degrees off horizontal rather than 19 degrees as is the "test." The test is to remain about 400' seaward of the new wells. The panorama photo, attached, shows the test well (blue pipe in right side of photo, next to vertical yellow posts) to be within 300’ inland of the intertidal at an elevation of about 15 feet. The current situation is flatter and closer than the DEIR states, suggesting that the test slant well needs to be removed before 2018 during a season when Snowy Plover nests will not be impacted by the removal activity. Shriner-4

The Figures 4.2 7 and 8 are compressed to exaggerate the angles and mislead the public. The well head is within 30 feet in elevation from the intertidal zone. The vertical and horizontal axes in the figures are shown to be in feet but the scale being an order of magnitude different is misleading. Shriner-5

Page 4.2-70 at the top of the page explains "The coastal retreat study determined that under a conservative predicted erosion rate and considering the additional scour caused by a 100-year storm event in that time horizon, the proposed slant wells would remain buried in the dunes and would not become exposed on the beach until sometime after 2060."

"According to the evaluation criteria for coastal erosion (see Section 4.2.4, Evaluation Criteria above), the proposed project would cause a significant impact if it accelerated and/or exacerbated natural rates of coastal erosion, scour, or dune retreat resulting in substantial adverse change in the coastal environment. The proposed slant wells would not be exposed during the operational life of the slant production wells (anticipated to be 20 to 25 years) and would not contribute to Shriner-6

further coastal erosion or changes in the beach environment. Therefore, the proposed location of the proposed slant wells would not represent a potential erosion hazard and would not contribute to a significant impact of the proposed project."

"Given the test slant well's forward location on the beach at the estimated 2060 future 100-year storm coastal erosion profile and lower profile envelope, it is possible that the well casings and concrete well head vault might become exposed on the beach sometime during the operational life of the project. If exposed, the subsurface slant well could contribute to accelerated and/or exacerbated natural rates of coastal erosion, scour, and dune retreat that could alter the natural coastal environment."

The following two statements are alarming due to the impact on a local business. CEMEX sand mining is a questionable business practice but so is the questionable or illegal business of over-pumping the Carmel River. It appears that the Cal Am would like CEMEX to eliminate sand mining in favor of two alternatives for a project area. Due to cumulative impacts by sand mine and test slant well, the alternates off Cemex properties more feasible. Page 147 states: "the subsurface slant wells would be located in the City of Marina, about 2 miles south of the Salinas River, in the retired mining area of the CEMEX sand mining facility (see Figure 3-3a)." Page 374 states ..."interventions may change shore recession." There are no real cumulative impact evaluations because Cal Am is trying to eliminate the existing business or pretend it will no longer exist instead of revealing the cumulative impacts.

Shriner-6 cont.

I have looked at Figure 5.1 for the modeling of the sea level rise for 2073. The problem is that the difference in scale makes this figure difficult to compare with the schematics of Figure 3-13 but it appears the sea level rise is expected to impact the Cemex site more severely than the Potrero Road site. The Figure 5.1 of Appendix E-2, page 377 needs to be revised to the same scale as Figure 3-13 for the final EIR to clarify the projected coastal contour at the site. Add a section modeling sediment transport and projected impacts to function of screens and pumps with anticipated seafloor modification, to determine if intakes be exposed or develop greater depth in sand than initial engineering.

When the possibility exists of losing 300 feet of coastline that is reportedly 30 feet above the Mean High Water (MHW) then at the same time create a model of the new corresponding bottom contour and depth in the sand of the intake pipes. If the test well is to remain in place, modeling is needed for the eventual exposure of the test slant well cumulative impacts to coastal erosion in the project site in comparison to the alternatives without a test well. Expand on cumulative impacts terrestrial section for best and worst case scenarios. Expand on terrestrial impacts section for mitigation of 300 feet for half mile of loss to dunes habitat.

Cumulative impacts to the location should describe the additional impacts with the sediment ponds and MRWPCA outfall as well as the proposed MCWD desalination project. Cumulative impacts need to include projected reconstruction of multiple sets of slant wells over the anticipated operational life of the desalination project. The projections require far more construction and reconstruction impacts than currently described and mitigated by this analysis.

Cumulative impacts of the components of the project should not include The Monterey Downs as MPWSP is designed only as replacement water for The Carmel River and MCWD would have been the water purveyor for Monterey Downs. The inclusion of Monterey Downs is now moot as it is currently retired due to inadequate support. Shriner-7

The Draft EIR has not made the modeling assumptions and graphic representations clear. On February 15, members of the public were invited to ask questions of the "experts." The implication for the public was that reasonable and detailed answers would be made in response to the questions. I found the experts to be quite defensive and the most valuable answers were about which section numbers and appendices numbers would narrow my search. Hovering at the tables was the Project Manager of the proponent who was actually quite condescending in regards to the question "what is the erosion rate used in the modeling?" His behavior was unnecessarily hostile for the public process and made me concerned that the CPUC experts were being monitored and intimidated by the employees of Cal Am. Shriner-8

I suppose the pumping history of Fort Ord and reduction of rate is not relevant if the appearance of a localized pressure head of the freshwater is fantasy as CPUC scientists told me at the Oldemeyer workshop of February 15. Otherwise, I believe the history is relevant to the groundwater management of the Dune Sands and 180 Equivalent aquifers. I have not been offered any reasons yet for why the CPUC scientists can't verify the evidence of the recovery efforts and reduced total dissolved solids in the preliminary well pumping data. Shriner-9

Please extend the public comment time for a more thorough investigation into the assumptions, cumulative impacts, and modeling. Shriner-10

The alternatives have not yet been given adequate review. Shriner-11

The scientists of the San Francisco office of the CPUC have not been adequately open to the peer reviewed science of other experts. Shriner-12

California Public Utilities Commission
Mary Jo Borak
Energy Division CEQA Unit 505 Van Ness Ave

The public was informed the desalination (desal) project would save the Carmel River. The California American Water (CalAm) Water Supply Project draft environmental impact report and environmental impact statement say nothing about how this project will impact the Carmel River and ESA listed fish and frogs. There will be two new ASR wells ASR 5 and ASR 6. Will these be used to store more water from the Carmel River? What are the effects on the Carmel River? Cal Am diversion wells are deep wells and it takes time for surface water to percolate to the deep zones. How long is surface flow reduced until the deep deficit is restored? Thomas-1 Thomas-2 Thomas-3

There is a plan for a new Carmel Valley Pumping Station. How much water and when will it be pumped from the river. Thomas-4

I have heard that Cal Am will take its water from desal and ASR in the summer and take Carmel River in the winter. Is this the case? Thomas-5

How will the new project improve the spring, summer, and fall flow on the Carmel River? Thomas-6

There are two 3 million gallon tanks 33 ft. diameter x 130 ft. tall as described in the EIR. What is the water source for these tanks? It appears to be related to the Carmel Valley pumping station. Thomas-7

There is no explanation of how and when project water will be used. Thomas-8

There is no discussion on how the project will affect the Carmel River environment Section 7.1.1, mentions the ESA but does not discuss the “take” of steelhead and their environment. It also mentions in 7.1.2 the Mag-Stevens Fish Conservation Essential Habitat but does not explain what, if anything, the project will do; help or destroy essential habitat. Thomas-9

Cal Am: Monterey Peninsula water supply Project (Cont)

There is a mention of 700 AFY to be added and left in the Seaside groundwater basin. This "Payback" would amount to 17.500 AF over 25 years. Is any or all of this water coming from the Carmel River what are the environmental effects of this? What is the lag time for percolation into the deep extraction well on the Carmel River? The Carmel River has been flowing now for over 4 months. The flow at Robles Del Rio gage is

Thomas-10

1000 cubic ft. per second (CFS), the lower Carmel River gage) is 722 CFS. There are 3 major tributaries between these two gages. The lower gage should read much higher flow than the upper gage. The 3-400 CFS is water still percolating into the ground from the overdraft. It takes time for the surface flow to make up for pumping deep wells. If Cal Am pumps "excess flow" during the winter it may well reduce essential surface flow in spring and summer. ASR water should only be extracted from the surface flow, not deep wells.

Thomas-11

The public has been told that desal ASR and recycled water will reduce the use of Carmel river water in the summer. The EIR does not say how much and when. In the spring maximum surface flow is very important. This is when the fish and the frogs hatch and spread out on the river. Edge habitat is extremely important for the young of the year.

Thomas-12

Why is there an interconnect for Ryan Ranch – Bishop? Are they allowed Carmel water, are they paying for this project?

What about Main System – Hidden Hills interconnect improvements. Are they paying project expenses, are they allowed to use Carmel river water?

Thomas-13

An EIR is about environmental impacts on a project. The environmental impacts on the Carmel River and its ESA listed Fish and Frogs are not addressed.

Thomas-14

8.7.1 Responses to Comments from Michael Baer

Baer-1 A lead agency is required to recirculate an EIR when significant new information is added after the release of the draft, but prior to certification. CEQA Guidelines Section 15088.5 provides guidance on what might constitute significant new information and notes that recirculation is not required where the new information merely clarifies or amplifies, or makes insignificant modifications in an adequate EIR. Nothing in this comment letter or the associated responses triggers a need for recirculation per CEQA Guidelines Section 15088.5. Master Response 9, Electrical Resistivity Tomography (ERT), provides supplemental information and further clarification on ERT and its use as a method to help characterize water quality and seawater intrusion along the coast of Monterey Bay. Master Response 11, CalAm Test Slant Well, Section 8.2.11.8, provides a discussion of the evolving slant well technology. Not only has source water intake technology evolved over the past several years, but so have the regulations governing intake systems. EIR/EIS Section 5.3.1 presents regulatory considerations that govern desalination plant intake systems and Section 5.3.1.1 specifically states that, "The [State Water Resources Control Board] SWRCB prefers subsurface intakes, but allows surface water intakes where subsurface intakes are not feasible or economically viable (SWRCB, 2016)." Section 5.4 describes and Section 5.5 evaluates several alternatives (Alternatives 2, 3, and 4) with open water intake systems. Please see responses to comments that follow.

Baer-2 Consistent with CEQA Guidelines Section 15147, the information contained in the EIR/EIS included summarized technical data, maps, plot plans, diagrams, and similar relevant information sufficient to permit full assessment of significant environmental impacts by reviewing agencies and members of the public. Placement of highly technical and specialized analysis and data in the body of an EIR was avoided through inclusion of supporting information and analyses as appendices to the main body of the EIR/EIS. Additional clarifying language has been added throughout the EIR/EIS, and via responses to comments, to help break down some of the more difficult concepts. While these clarifying descriptions are intended to further assist the public in understanding technical concepts, they do not change the conclusions of the EIR/EIS.

Baer-3 The Draft EIR/EIS explains in Section 1.3 that the MPWSP is needed to reduce and eventually terminate surface water diversions from the Carmel River in excess of CalAm's legal right, and to comply with the Seaside Groundwater Basin adjudication which substantially reduced the amount of groundwater available to CalAm. Details of SWRCB Order 95-10 and the associated Cease and Desist Order on the Carmel River are presented in Draft EIR/EIS Section 2.2.3. Details about the Seaside Groundwater Basin Adjudication are presented in Draft EIR/EIS Section 2.2.4.

Baer-4 See Master Response 3, Water Rights, Section 8.2.3.2.

Baer-5 The data from the test slant well is collected by staff from Geoscience (CalAm's contractor), and not by the Hydrogeologic Working Group (HWG). Data from the test

slant well is presented to the HWG members for their peer review, interpretation and reporting. The EIR/EIS did not evaluate the impacts of the test slant well and made no conclusions about the impact of the test slant well on the surrounding groundwater. The EIR/EIS evaluated potential impacts associated with the proposed conversion of the test slant well to a production well, including analysis of the potential impacts on groundwater supplies and/or recharge from operation of all project wells (converted and new production wells), in Impact 4.4-3. Such impacts were determined to be less than significant.

Baer-6 Regarding the parties to the August 2013 Settlement Agreement that established the HWG, see Section 8.2.5.1 of Master Response 5, The Role of the Hydrogeologic Working Group and its Relationship to the EIR/EIS. As noted in the comment, CalAm, along with the other parties, "agreed their hydrologist and technical team would work with the Salinas Valley Water Coalition's and Monterey County Farm Bureau's assigned hydrogeologists." Thus, this group of hydrogeologists is considered to represent the diverse interests of the 16 parties to the Settlement Agreement, who agreed to this representation. Neither CPUC nor MBNMS convened the HWG or determined its membership.

Baer-7 Regarding the role of Dr. Dennis Williams and potential conflicts of interest, see Master Response 5, Section 8.2.5.6.

Baer-8 The conflict of interest was discussed in the Draft EIR/EIS Executive Summary Section ES.8 on page ES-14, and again in Section 1.4.3. More detail is provided in Master Response 5, Section 8.2.5.6.

Baer-9 As noted in the Draft EIR/EIS Section 1.4.3, in July 2015, the CPUC terminated its relationship with Geoscience and "the CPUC Energy Division extended the public comment period on the [April 2015 MPWSP] Draft EIR … to address a possible conflict of interest associated with one of the CPUC's environmental subconsultants, Geoscience." See responses to comments PWN2-2 in Section 8.6.17, Baer-5, Baer-6, and Master Response 5, Section 8.2.5.6.

Baer-10 See response to comment Baer-6 and Master Response 5, Section 8.2.5.3.

Baer-11 See Master Response 5, Section 8.2.5.6. Note that the Lead Agencies have no authority over the HWG membership.

Baer-12 The reference to Section 4.4.3.2 has been revised to read 4.4.4. Section 4.4.4, titled "Approach to Analysis" as was noted in the footnote on Draft EIR/EIS page 4.4-4, does discuss the HWG.

Baer-13 The HWG did not contribute directly to the preparation of the Draft EIR/EIS. They were a resource to the Lead Agencies as explained in Master Response 5, Sections 8.2.5.4 and 8.2.5.5.

Baer-14 See Section 8.2.11.2 of Master Response 11, CalAm Test Slant Well.

Baer-15 The comment is not correct. The appeal was filed because pursuant to the California Coastal Act Section 30603(a)(5), the CCC may hear an appeal of a local agency denial of a permit for a major public works project. See Master Response 11, Section 8.2.11.2.

Baer-16 The comment incorrectly states that the decommissioning of the test slant well "was a contingency of avoiding the EIR process." See Master Response 11, Section 8.2.11.7.

Baer-17 See Master Response 11, Section 8.2.11.4, regarding baseline levels and compliance with Special Condition 11. The Executive Director of the CCC (Charles F. Lester) informed CalAm that the water level decrease appeared to be caused in part by the pump test and acknowledged that based on the data, several influences other than pumping of the test slant well were responsible for the decrease. See also Master Response 11, Section 8.2.11.5, regarding the influence of regional pumping.

Baer-18 Inflows to and outflows from the Salinas Valley Groundwater Basin are discussed in Draft EIR Section 4.4 on page 4.4-19, and in Table 4.4-3. One of the sources listed for the table is MCWRA, 2015, which is the 2014 Groundwater Extraction Report for Monterey County. The HWG established seasonal and regional trends in a July 23, 2015 letter to Charles Lester (HWG, 2015).

Baer-19 The publicly available HWG-prepared Monthly Test Slant Well Monitoring Reports (https://www.watersupplyproject.org/test-well) include rainfall events as blue bars on each of the groundwater elevation and salinity plots. As explained in Master Response 5, Section 8.2.5.4, the HWG prepared the Hydrogeologic Investigation Workplan and the Hydrogeologic Investigation Technical Report; the latter is included in the Final EIR/EIS as Appendix E3. Section 2.1.7.4 of Appendix E3 presents test slant well electrical conductivity results and explains the relationship between precipitation events and how they impact groundwater and TDS levels in the test slant well and monitoring wells.

Baer-20 See Master Response 11 Section 8.2.11.4, which discusses the April 15, 2015 report titled *Baseline Water and Total Dissolved Solids Levels* prepared by the HWG.

Baer-21 See responses to comments Baer-18 through Baer-20.

Baer-22 This comment misrepresents the text from page 11 in Section 5.3.2 of HWG Monthly Report 15. The text in HWG Monthly Report 15 states, "Figure 3-3 shows conductivity in MW-4M is slightly increasing continuously with time, for the monitoring period from April 22, 2015 to January 31, 2017. The consistent slight rise in TDS shows no change with TSW [test slant well] pumping and is strongly indicative of a regional trend in TDS concentration. ...The regional very slight increase in conductivity may be indicative of continued slow progress of seawater intrusion due to the continued landward groundwater gradient in the aquifer penetrated by MW-4M." See responses to comments Baer-18 through Baer-20 and also Baer-24.

Baer-23 The historic seawater intrusion maps of the 180-Foot and 400-Foot Aquifers cited in the comment (Draft EIR/EIS Figures 4.4-10 and 4.4-11) are prepared annually by MCWRA (see EIR/EIS Sections 2.6.3 and 4.4.2.3). MCWRA defines the leading edge of inland seawater intrusion as groundwater containing TDS at 500mg/L or more. Regarding baseline conditions, see responses to comments Baer-18 through Baer-20.

Baer-24 The Lead Agencies do not prepare the HWG Monthly Reports, and are not responsible for how terms are defined. However, the phrase "regional slightly increasing trend" is not used anywhere in HWG Monthly Report 15, Section 5.3.2; see response to comment Baer- 22. The HWG Monthly Report 15 does state that ". . . conductivity in MW-4M is slightly increasing **continuously with time** [emphasis added], for the monitoring period from April 22, 2015 to January 31, 2017." While Table 2 does in fact show an increase of 29 percent over 21 months, that represents a slight increase (continuously with time) of about 1.4 percent per month.

Baer-25 The Lead Agencies acknowledge receipt of comments submitted to the CCC on or about February 2015. The Lead Agencies do not direct the HWG, nor can they compel the CCC to respond to the commenter's questions directed to Tom Luster. Further, the Lead Agencies do not possess the information to respond to these questions directly, nor would such responses be within the scope of this EIR/EIS.

Baer-26 Source water ocean intake technology has evolved over the past several years, as noted in response to comment Baer-1. See Master Response 11, Section 8.2.11.8 for a discussion of slant well technology. As described therein, the loss of well efficiency at the Doheny Test Slant Well (aka Dana Point) was expected due to the inability to fully develop the well during construction. The report cited by the comment is referenced in the EIR/EIS Section 4.4 as Geoscience, 2012.

Baer-27 This comment is not correct; see Master Response 11, Section 8.2.11.8 and response to comment Baer-26.

Baer-28 See Master Response 11 regarding the long-term pump test results and use of test slant well data in the Draft EIR/EIS. The comment references "slant well performance expectations." The Draft EIR/EIS did rely on observed, reported data from the test slant well monthly reports as described in Master Response 11 Section 8.2.11.6. "Expectations" or projections of future test slant well results not yet reported as of publication of the Draft EIR/EIS would have been speculative; however, because the reported results informed the revised groundwater model, the Draft EIR/EIS did incorporate modeled projections of MPWSP pumping results that were based in part on test well data. See, e.g., Draft EIR/EIS pages 2-34 ("Test slant well pumping and monitoring data was used to refine the aquifer properties represented in the revised version of the groundwater model…") and 4.4-42 ("The results have been used to refine the groundwater models and inform the analysis of the proposed project.")

Baer-29 Reporting of the test slant well performance was a condition of the CDP and those publicly available reports were filed with the CCC in compliance with Special Condition 11. The table does not include the interruptions from 2015 because those events are described in the text that precedes the table. See also Master Response 11, Section 8.2.11.5. Test slant well performance has been a topic in the CPUC proceeding and will be taken into consideration during the decision-making process (see EIR/EIS Section 1.5.4.1). In addition, test slant well data is discussed further in Master Response 11, which is part of the Final EIR/EIS. See also response to comment Baer-19 and Final EIR/EIS Appendix E3, Section 3.4, wherein the HWG summarizes the results of the 2.5-year slant well pumping test.

Baer-30 Power interruptions accounted for 19 days of test slant well outages over the two-year (730-day) period between April 2015 and April 2017. EIR/EIS Section 3.2.5 describes the proposed project electrical power facilities and states that "new underground and aboveground power lines would be installed at the CEMEX active mining area" as well as new electrical control cabinets for more reliable electric service to avoid these types of power outages (see Draft EIR/EIS page 3-44). As described in Section 3.2.2.2, "CalAm would install a 750-kilowatt (kW) (1,000 hp) emergency diesel fuel-powered generator and a 2,000-gallon, double-walled, aboveground diesel storage tank next to the [RO] process building. The generator would provide backup power for critical desalination plant facilities (e.g., lights, electrical controls, and high-service pumps to empty the clearwells) during power outages." (see Draft EIR/EIS page 3-26). In the event of an extended outage, CalAm would rely on its other supply sources including the Carmel River, Seaside Basin groundwater, the Sand City Desalination Plant, and Carmel River and desalinated water that have been stored in ASR. See also Section 3.4.1, Table 3-7, which discusses recovery operations of the desalination plant following a shut-down.

Baer-31 As stated in EIR/EIS Section 4.3.5.4, Impact 4.3-6, because slant well maintenance activities would be considered a "land disturbance activity" the Construction General Permit would apply and require the contractor to prepare a SWPPP that includes specific measures to manage pollutants generated during maintenance activities. Pollutants could include those generated from equipment fueling and storage, inadvertent releases of toxic chemicals (i.e., solvents or oxidizers), if used, and discharges of cleaning effluent. Sediment is also a concern as it could contain well cleaning chemicals, but, it also could be released to the waters of the Monterey Bay, locally increasing the sediment load and degrading the visual quality of the water. The Construction General Permit does not permit sediment to be released into surface water bodies.

Baer-32 See response to comment Baer-31. Environmentally inert refers to substances that are not reactive with soil, water, and air. Properly used, environmentally inert cleaning agents have been successful in cleaning well screens. The test slant well has been cleaned using standard well cleaning procedures with no issues.

Baer-33 As the slant well design for groundwater wells is adapted from the technology that has been employed in the oil industry for many years, products and procedures to maintain these large extraction wells have long been established and successful. The well cleaning procedures are described in Master Response 11, Section 8.2.11.9.

Hydrogeologic Working Group (HWG), 2015. Letter to Charles Lester, California Coastal Commission, July 23.

8.7.2 Responses to Comments from David Beech – Letters 1 through 6

8.7.2.1 Responses to Comments from David Beech – Letter 1

Beech1-1 See Master Response 11, CalAm Test Slant Well, Sections 8.2.11.2 and 8.2.11.3. Regarding Special Conditions 6 and 17 of the CDP, which address decommissioning of the test slant well and posting a bond to ensure that it is carried out, see response to comment MCWD-80 in Section 8.5.2.

Beech1-2 See Master Response 11, Section 8.2.11.7.

Beech1-3 See Master Response 11, Section 8.2.11.2.

Beech1-4 See Master Response 11, Section 8.2.11.2.

Beech1-5 The operation of the test slant well pursuant to its existing permits is outside the scope of this EIR/EIS; therefore, this comment does not address the Draft EIR/EIS. The Lead Agencies do not manage the test slant well and thus do not have data in response to the commenter's question.

Beech1-6 See response to comment Cech-11 in Section 8.7.6, and Master Response 11, Section 8.2.11.5.

Beech1-7 See Master Response 11, Section 8.2.11.7.

Beech1-8 As explained in the EIR/EIS in Section 3.1, the test slant well is now permitted to operate until February 2019 and it is not part of the Proposed Project being evaluated in this EIR/EIS. If the MPWSP with subsurface slant wells at CEMEX is not approved and implemented, the test well would be removed. The CPUC, as the CEQA Lead Agency for the MPWSP EIR/EIS, does not have jurisdiction over the test slant well, nor the terms and conditions of the CDP issued by the CCC. See Master Response 11.

Beech1-9 This comment does not address the adequacy or accuracy of the Draft EIR/EIS.

Beech1-10 The Lead Agencies acknowledge receipt of the commenter's letter to Mr. Traylor at the CCC Enforcement Office. The Lead Agencies do not have jurisdiction over the CCC or the terms and conditions of the CDP issued by the CCC. See also Master Response 11.

Beech1-11 See Master Response 11, Sections 8.2.11.2, 8.2.11.3 and 8.2.11.7.

8.7.2.2 Responses to Comments from David Beech – Letter 2

Beech2-1 As noted in EIR/EIR Appendix I1, "Subsurface intakes . . . collect source water through the ocean bottom and coastal aquifer sediments." Footnote 4 in Draft EIR/EIS Section 1.3.2.1 states, ". . . The proposed slant wells would draw ocean water through the seafloor sediments, which would pre-filter the seawater for use at the desalination plant." See Master Response 2, Source Water Components and Definitions, Master Response 11, Section 8.2.11.5, as well as response to comments PWN2-52 in Section 8.6.17, and Coppernoll-36 in Section 8.7.8.

Beech2-2 See Master Response 8, Project Source Water and Seawater Intrusion. Also see response to comment Cech-4 in Section 8.7.6, regarding the position of the slant well screens.

Beech2-3 The EIR/EIS indicates that proposed slant wells would extract primarily seawater and a smaller volume of brackish inland groundwater, and evaluates the impacts of this proposed source water intake. See Master Response 8.

Beech2-4 The performance and reliability of vertical wells are well known. They would penetrate the same aquifer units as the proposed slant wells and would be located the same distance inland from Mean High Water because of the effects of coastal erosion. As explained in EIR/EIS Appendix I1, at least 24 vertical wells would be needed over a linear distance of at least one mile to provide the 24.1 mgd of source water required for the MPWSP; alternative subsurface intakes would result in a smaller construction and operational footprint than vertical wells. Therefore, vertical wells were considered infeasible for the MPWSP, both from a construction and operation perspective and in terms of economic, legal (permitting), and environmental factors.

Beech2-5 See Master Response 11, Section 8.2.11.8, which addresses comments about the evolving slant well technology.

As explained in EIR/EIS Appendix I1, to be screened in the Dune Sands and 180-FTE Aquifers, a vertical well at the CEMEX location would have to be drilled to about 200 feet deep to avoid penetrating the Salinas Valley Aquitard; the well screens could not be any longer than the 200 feet, minus any allowance for the non-screened portions of the well casing. Vertical wells have a yield of between 0.1 and 1.5 mgd. The proposed slant wells, on the other hand, would be screened for approximately 400 to 800 feet and like the test slant well, would pump approximately 2,000 gpm, or about 3 mgd. Therefore, vertical wells do not have the same output as slant wells.

Beech2-6 See response to comment Beech2-5.

Beech2-7 EIR/EIS Table 3-2 presents the lengths of permanent slant wells seaward of mean high water (MHW) line. Mean High Water was mapped because it delineates

MBNMS jurisdiction; Mean Low Water has not been mapped. The term "offshore" is used in the table to identify lengths within MBNMS.

Beech2-8 See Master Response 11, Section 8.2.11.9.

Beech2-9 Assumptions are explained in the footnotes to EIR/EIS Table 3-2, and are further explained in EIR/EIS Appendix C2, Analysis of Historic and Future Coastal Erosion with Sea Level Rise.

Beech2-10 Draft EIR/EIS Figure 3-3a on page 3-13 is true-to-scale and shows the wells within the City of Marina, as well as extending beyond MWH 2020, which puts them within MBNMS jurisdiction.

Beech2-11 The well screens will be at depths corresponding to the Dune Sand and the 180-FTE Aquifers. Ocean water and a small percentage of seawater-intruded groundwater that originated in the Salinas Valley Groundwater Basin would be drawn through these aquifer units as source water. See also Master Response 8.

Beech2-12 See Master Response 11, Sections 8.2.11.9 and 8.2.11.5.

Beech2-13 The proposed project includes a permanent connection to the outfall, which will eliminate outages from storm events, and new electrical control boxes for more reliable electric service to avoid these types of power outages. See also Master Response 11.

Beech2-14 See Master Response 11, Section 8.2.11.9.

Beech2-15 Only minor design changes would be allowed without a further discretionary approval process and any such process could trigger additional NEPA or CEQA review. CEQA Guidelines Sections 15162 through 15164 describe the circumstances under which further CEQA review is required after an EIR has been certified, and the extent of such review. Similarly, NEPA at 40 CFR 1502.9(c) describes the responsibility of agencies to prepare supplements to environmental impact statements if substantial changes in the proposed action are made that are relevant to environmental concerns. In the event that CalAm proposes changes to the project after completion of the CEQA and NEPA evaluation processes, the Lead Agencies will fulfill their responsibilities pursuant to these requirements.

Beech2-16 The EIR/EIS analyzes the effects of the totality of the proposed project's production wells (as described in EIR/EIS Section 3.2.1.1) throughout the EIR/EIS, and not as a cumulative scenario. The 2016 version of the North Marina Groundwater Model ($NMGWM^{2016}$) was used to simulate the impacts of the proposed project pumping. See EIR/EIS Section 4.4.4.2 and Appendix E2 regarding the groundwater model and methodology.

Beech2-17 The existing Begonia Iron Removal Plant (BIRP), with a throttling valve at Valley Greens, currently provides the pressure for the water to reach the Segunda Reservoir. If the MPWSP were operating and the lower Carmel River wells were not, there would only be a minimal maintenance flow going through the BIRP. At this low flow, the Carmel Valley Pump Station would be necessary to boost water up to Segunda Reservoir.

Beech2-18 The MPWMD, as the Lead Agency for the Monterey Pipeline CEQA review, determined that an Addendum was the appropriate CEQA document to prepare. The Lead Agencies for the MPWSP EIR/EIS do not have jurisdiction over the MPWMD. This comment does not address the adequacy or accuracy of the MPWSP Draft EIR/EIS.

Beech2-19 Master Response 2 addresses the topic of water rights. This comment does not address the adequacy or accuracy of the Draft EIR/EIS. The Lead Agencies do not take a position in this EIR/EIS regarding cost recovery.

8.7.2.3 Responses to Comments from David Beech – Letter 3

Beech3-1 The 2011 RBF report was prepared for CalAm, it was a preliminary review of potential alternatives to the Coastal Water Project (and the Regional Project) at that time, and it was not used in the EIR/EIS. The 2011 RBF report concludes that "the next step is to complete an assessment of the permitting and schedule impact for each alternative. This will be presented in a subsequent technical memorandum at which point a final recommendation as to the most attractive alternate or alternates can be determined." The Lead Agencies have not seen the final recommendation but it appears as though CalAm considered the RBF recommendation in its preparation of the project description included in its application for the MPWSP that was submitted to the CPUC on April 23, 2012.

The evaluation of alternatives in Chapter 5 of the EIR/EIS includes a reasonable range of alternatives to the proposed MPWSP that meets the requirements of both CEQA and NEPA. One of the documents considered in the alternatives analysis was the January 9, 2013 memo prepared by RBF titled *Memorandum: Contingency Planning for the MPWSP (Update of November, 1, 2012 TM)* and cited in the Draft EIR/EIS as RBF, 2013 (see Draft EIR/EIS page 5.3-5).

The RBF-conceived Alternative 9 was based on the assumption that water rights could be obtained to divert significant amounts of water from either the Carmel River or the Salinas River in the winter months, for storage in the Seaside Groundwater Basin for extraction in the summer months. The alternative was described by RBF as including (but not being limited to) a separate intake and pumping station located at the existing Salinas River Diversion Facility Inflatable Dam, 4,000 feet of new 48-inch diameter pipeline to convey raw water to a new surface water treatment plant, and 16 new ASR wells in the Seaside Basin to inject and extract a long term average

of approximately 6,850 afy in the Seaside Groundwater Basin. EIR/EIS Section 5.2.3 discusses that it was previously determined the purchase of water rights from the Salinas River was fatally flawed and infeasible (see EIR/EIS Table 5.2-1 and also response to comment Beech3-3).

Beech3-2 Master Response 15, Alternative Desalination Projects – Status, Information Sources, and Cumulative Scenarios, describes the status of the DeepWater Desal Project and People's Project, as well as the communication among the Lead Agencies and proponents of these projects.

Beech3-3 The availability of winter runoff would not meet the peak month demands of CalAm's customers without significant storage. See response to comment Beech3-1. In 2010, the State Water Resources Control Board (SWRCB) issued a Notice of Proposed Revocation of Water Right Permit #11043,[1] asserting that the Monterey County Water Resources Agency (MCWRA) had "failed to commence, prosecute with due diligence and complete the work necessary to appropriate water under Permit #11043" (SWRCB, 2010). In 2013, the SWRCB approved a Settlement Agreement[2] that amended Water Right Permit #11043, reducing the face amount of the permit and setting forth required Salinas River bypass flows. In addition, the Settlement Agreement outlined a series of 12 milestones that MCWRA is required to meet in order to demonstrate progress towards implementing Phase II of the Salinas Valley Water Project (SVWP): a timely petition for extension of time was submitted to the SWRCB and a Notice of Preparation for the Salinas Valley Water Project Phase II Draft EIR was issued by July 1, 2014. However, a Draft EIR was not released by July 1, 2015; a draft financing plan was not issued by July 1, 2016; and a Final EIR was not certified by July 1, 2017. Therefore, several milestones within the Settlement Agreement have not been met and the future availability of water under Permit #11043 is extremely uncertain.

Beech3-4 The water provided under Permit #11043 would be for irrigation and municipal purposes within portions of Zone 2 of the MCWRA and would be an important part of the SVWP Phase II solution to seawater intrusion. However, since the SWQCB issued a Notice of Proposed Revocation of Water Right Permit #11043 in 2010, and since several annual milestones within the Settlement Agreement that amended Water Right #11043 have not been met, the future availability of water under Permit #11043 in Zone 2 is extremely uncertain (see response to comment Beech3-3). Therefore, since the SWRCB has proposed to revoke the permit, and MCWRA has failed to meet all but the first of 12 milestone cited in the Notice of Proposed Revocation of Water Right Permit #11043, the prognosis for refinements by the SWRCB to allow the water to be used outside of MCWRA's Zone 2 in the CalAm service area is extremely uncertain and not reasonably foreseeable or attainable.

1 Available online at http://www.co.monterey.ca.us/home/showdocument?id=19020
2 Available online at http://www.co.monterey.ca.us/home/showdocument?id=24248

Beech3-5 See responses to comments Beech3-3 and Beech3-4.

Beech3-6 The Interlake Tunnel project was considered and discussed in EIR/EIS Section 5.2.5.

Beech3-7 Source waters for Pure Water Monterey GWR will include stormwater, wastewater, food industry process water as well as impaired surface waters of the State. The SWRCB, not the Salinas Valley farmers, will determine the place of use of water from Permit #11043.

Beech3-8 If Salinas River surface water could be made available to CalAm (see responses to comments Beech3-3 and Beech 3-4), it would be less expensive to treat than seawater. The RBF 2011 report presumed, however, that Salinas River water would: 1) be of suitable quality that it would be possible to meet drinking water standards with membrane filtration treatment, and; 2) that regulatory or public concerns over water quality issues do not prevent Salinas River water from being stored in the Seaside Groundwater Basin. Both of these issues are currently uncertain (RBF, 2011). The delivery pipeline might be sharable, and the CA Department of Public Health, Division of Drinking Water, would need to make that determination.

Beech3-9 The Pure Water Monterey GWR Final EIR evaluated source water quantities in excess of the needs of that project in the event one or more sources may not be available. The availability of water under Permit #11043 for an expansion of GWR is extremely uncertain. See responses to comments Beech3-3 and Beech3-4.

Beech3-10 See responses to comments Beech3-3, Beech3-4, Beech3-8 and Beech3-9.

Beech3-11 The comment does not address the adequacy or accuracy of the Draft EIR/EIS.

Beech3-12 See responses to comments Beech3-1, Beech3-3, Beech3-4, Beech3-7, Beech3-8 and Beech3-9.

Beech3-13 "Plan C" as described in the comment is not much different than Alternative 5a or 5b (reduced-size desalination plant plus ASR and GWR), but for the unlikely addition of Salinas River ASR. See responses to comments Beech3-1, Beech3-3, Beech3-4, and Beech3-9.

Beech3-14 Both the DeepWater Desal Project and the People's Project are considered as alternatives to the proposed project, as defined in Chapter 5 of the EIR/EIS. This allows decision-makers to judge the options against each other, and to consider which option best meets the project objectives and minimizes environmental impacts. Master Response 15 describes the status of these projects, as well as the communication among the Lead Agencies and proponents of these projects. There is no specific requirement under either CEQA or NEPA to coordinate reviews of projects that share one or more project objectives. These projects are at different stages of development and have different lead agencies. For example, the CPUC is the CEQA Lead Agency

for the proposed project, but the Moss Landing Harbor District is the CEQA Lead Agency for the People's Project, and the State Lands Commission is the CEQA Lead Agency for the DeepWater Desal Project. CEQA and NEPA do contain requirements on timely preparation of CEQA and NEPA documents for a proposed project such that a lead agency could not readily delay analysis of a project because a competing project lagged behind in review. Furthermore, a basic objective of the MPWSP is to comply with state orders directing CalAm to secure a replacement water supply for certain water being taken from the Carmel River. The need to comply with such state legal requirements dictates against delaying a decision on the best option to select for CalAm to meet its customers' water needs.

Beech3-15 As described in EIR/EIS Section 1.5.2, the comment period for the MPWSP Draft EIR/EIS commenced on January 13, 2017, the date of publication. Draft EIR comment periods under CEQA are governed by CEQA Guidelines Section 15105. Draft EIS comment periods under NEPA are governed by NEPA implementing procedures at 40 CFR 1506.10(c). Proposals for other projects by other proponents do not affect the comment periods relevant to the MPWSP. See also response to Beech3-14, and Coppernoll-75 in Section 8.7.8.

Beech3-16 See responses to comments Beech3-14 and Beech3-15 and Master Response 15 regarding the status of environmental review of the DeepWater Desal Project and People's Project.

Beech3-17 No comments received on the Draft EIR/EIS have raised issues that would require recirculation of the Draft EIR/EIS.The Final EIR/EIS does not alter the significance conclusions reached in the Draft EIR/EIS or identify new and feasible alternatives or mitigation mesures to address significant effects, which alternatives or mitigation measures will not be incorporated into the project.

Beech3-18 See responses to comments Beech3-7 through Beech3-10.

Beech3-19 The Lead Agencies will take all comments into consideration in the decision-making process. See also EIR/EIS Section 1.5.4 and Master Response 15.

8.7.2.4 Responses to Comments from David Beech – Letter 4

Beech4-1 The representation of the test well in the EIR/EIS is not inconsistent with the CCC staff report that is provided as a link in the comment. The project purpose in the staff report is presented correctly by the commenter ("If the data collected from this proposed test well demonstrates that **this** well design and location would provide the necessary amount of water . . ."), and as a result of operating the test slant well, CalAm indeed revised this well configuration (design) at this location, as described in EIR/EIS Section 1.4.4. Furthermore, revising the representation of the test slant well's stated project purpose in the EIR/EIS would not change or alter any of the analysis or

conclusions of potential impacts associated with the conversion of the existing test slant well to a permanent production well. No change has been made to the text.

Beech4-2 The slant wells described in the EIR/EIS, Section 3.2.1.1 were used in the groundwater modeling scenarios presented in EIR/EIS Section 4.4 and in Appendix E2. See also Master Response 11, Section 8.2.11.9.

See Master Response 11, Sections 8.2.11.2 and 8.2.11.3, for a discussion of the CEQA/NEPA review of the test slant well. Footnote 2 has been revised accordingly in the Final EIR/EIS.

Beech4-3 As noted in response to comment Beech4-2, the footnote has been revised in the Final EIR/EIS. See Master Response 11, Section 8.2.11.2.

Beech4-4 The HWG was not established by the CPUC. See Master Response 5, The Role of the Hydrogeologic Working Group and its Relationship to the EIR/EIS, Sections 8.2.5.2, 8.2.5.3, and 8.2.5.6.

Beech4-5 The pump test was suspended in June 2015, in compliance with the CDP Special Condition 11. See Master Response 11, Section 8.2.11.5 for a discussion of the long-term pump test and the provisions of Special Condition 11 that required suspension of the test in response to specific monitoried conditions. The HWG provided the CCC with two analyses of groundwater elevations and TDS trends in the compliance monitoring wells, and demonstrated the influence of regional pumping. Also note that the water level in the monitoring wells continued to drop even when the test slant well was not operating. The CPUC does not have authority to review the monitoring well data, nor does it have authority over the HWG. The CPUC therefore, cannot compel that group to respond to the questions posed by the commenter to the CCC.

Beech4-6 This comment addresses the test slant well permits and is not a comment on the adequacy or accuracy of the MPWSP Draft EIR/EIS. As stated in the CCC staff report referenced by Beech4-1, “Cal-Am would use the test slant well to conduct a pumping and testing program over an approximately 24-month period . . .” The commenter is correct -- the CDP for the test slant well did not preclude voluntary interruption of testing.

The issue of ratepayer liability is outside the scope of the CEQA and NEPA; see response to comment PWN2-22 in Section 8.6.17.

Beech4-7 Regarding the feasibility of slant well technology, see Master Response 11, Section 8.2.11.8. Regarding ratepayer liability, see response to comment Beech4-6.

Beech4-8 See response to comment Beech4-6.

Beech4-9 An EIR/EIS does not recommend approval or disapproval of a proposed project. The basic purposes of CEQA, described in the CEQA Guidelines at Section 15000, are to:

(1) Inform governmental decision makers and the public about the potential, significant environmental effects of proposed activities.

(2) Identify the ways that environmental damage can be avoided or significantly reduced.

(3) Prevent significant, avoidable damage to the environment by requiring changes in projects through the use of alternatives or mitigation measures when the governmental agency finds the changes to be feasible.

(4) Disclose to the public the reasons why a governmental agency approved the project in the manner the agency chose if significant environmental effects are involved.

The purposes of NEPA are very similar. An EIR/EIS objectively evaluates the environmental effects of the proposed project and feasible alternatives to the project so that the decision-makers can take that information into account.

Beech4-10 The receipt of the January 17, 2016 letter to Dr. Charles Lester is acknowledged.

Beech4-11 The commenter is correct; the test slant well CDP Special Condition 11 was modified by the CCC to include taking regional trends into account when considering the test slant well's contribution to changes in water levels. Because, for example, water levels in some of the monitoring wells continued to drop while the test well was not pumping. But the commenter is not correct that each [monthly] report sets a new baseline; the CEQA/NEPA use of the baseline is not violated. See Master Response 11, Section 8.2.11.5, specifically Figure 8.2.11-1.

Beech4-12 This comment does not address the EIR/EIS. The Lead Agencies are not responsible for publishing the test slant well data. See EIR/EIS Appendix E2, Section 4.2, for how the test well data was used to calibrate the groundwater model.

Beech4-13 See response to comment Beech4-12.

8.7.2.5 Responses to Comments from David Beech – Letter 5

Beech5-1 The use of the EIR/EIS in decision making, specifically the CPUC and MBNMS processes, is explained in EIR/EIS Section 1.5.4. CPUC and MBNMS must complete the CEQA and NEPA processes, respectively, before taking action to consider approving the proposed project or an alternative.

Beech5-2 See responses to comments Beech3-1, Beech3-3, Beech3-4, Beech3-7, Beech3-8, Beech3-9, Beech3-10, and Beech5-1. The Lead Agencies will require publication of the Final EIR/EIS before any decisions are proposed by either Lead Agency.

Beech5-3 The Lead Agencies will require publication of the Final EIR/EIS before any decisions are proposed by either Lead Agency.

Beech5-4 Termination of a project would obviate the requirement to continue CEQA or NEPA work to evaluate the project. Here, the Lead Agencies will require publication of the Final EIR/EIS before any decisions are proposed by either Lead Agency.

Beech5-5 EIR/EIS Chapter 5 includes a suite of alternatives, and the decision-makers could select any one of them, or some combination of alternatives. See also response to comment Beech5-1 and Master Response 15.

Beech5-6 Nothing in the comments received on the EIR/EIS changes the conclusion of the environmentally superior alternative identified in EIR/EIS Section 5.6. See response to comment Beech5-2.

8.7.2.6 Responses to Comments from David Beech – Letter 6

Beech6-1 The comment does not address the adequacy or content of the environmental analysis in the Draft EIR/EIS.

State Water Resources Control Board (SWRCB), 2010. Notice of Proposed Revocation of Water Right Permit #11043t. Available online at http://www.waterboards.ca.gov/waterrights/water_issues/programs/hearings/mcwra/010610mcwraproprevo.pdf

8.7.3 Responses to Comments from Kathy Biala

8.7.3.1 Responses to Comments from Kathy Biala – Letter 1

Biala1-1 Regarding the issue of seawater versus groundwater extraction, water rights, and harm, see Master Response 3, Water Rights, Section 8.2.3.5. Regarding all comments in this letter that quote the EIR/EIS as "CalAm's statement," please note that this EIR/EIS was prepared by the CPUC as the CEQA Lead Agency, and MBNMS as the NEPA Lead Agency and by independent consultants on behalf of these agencies, and not by CalAm, the project applicant. See Master Response 1, EIR/EIS Authorship.

Biala1-2 See Master Response 3, Water Rights, Section 8.2.3.2.

Biala1-3 The concept of "harm" as used in EIR/EIS Section 2.6 is specific to water rights; see Master Response 3, Water Rights, Section 8.2.3.5. Impacts on groundwater levels and groundwater quality are addressed as required by CEQA and NEPA in EIR/EIS Section 4.4. Groundwater drawdown in the Salinas Valley Groundwater Basin (SVGB), as calculated by the North Marina Groundwater Model v. 2016 ($NMGWM^{2016}$), is not dependent on relative volumes of freshwater originating in the Basin (the "Basin water" referred to in the quoted text) and seawater that are expected to be drawn into the supply wells. Accordingly, Master Response 12, The North Marina Groundwater Model (v. 2016), explains that $NMGWM^{2016}$ was employed to calculate the water level decline (drawdown) in response to proposed project pumping. Regarding the method of estimating the ocean water percentage (OWP) in project source water, see Master Response 4, Agency Act and Return Water, Section 8.2.4.3 and EIR/EIS Appendix E3.

Biala1-4 See Master Response 3, Water Rights, Section 8.2.3.3, as well as Master Response 11, CalAm Test Slant Well, Section 8.2.11.8, regarding the Dana Point slant well at Doheny State Beach.

Biala1-5 The Lead Agencies' assertion (not CalAm's, see Master Response 1, EIR/EIS Authorship), that the water that would be extracted by the slant wells would be brackish, is because the sampled water drawn from the monitoring wells within the capture zone indicate the water is brackish. See Master Response 8, Project Source Water and Seawater Intrusion, Section 8.2.8.2, and responses to comments MCWD-Hopkins Groundwater Consultant (HGC) in EIR/EIS Section 8.5.2.2. Note also that the HGC January 2016 memo cited in the comment refers to the modeling effort associated with the April 2015 Draft EIR, known as $NMGWM^{2015}$; that version of the model was updated for the January 2017 Draft EIR/EIS; see Master Response 12, The North Marina Groundwater Model (v. 2016).

Biala1-6 See Master Response 4, Agency Act and Return Water, Section 8.2.4.3, and EIR/EIS Appendix E3 for information regarding the calculation of the OWP; and Master Response 8, Project Source Water and Seawater Intrusion, for further information on

the groundwater quality of the slant well capture zone. When the Draft EIR/EIS was prepared, the estimate of the OWP in the source water was not finalized, but based on monitoring work at the test slant well, it appeared that the actual OWP necessary to gauge return water amounts would range between 0 and 12 percent. For example, the test slant well at CEMEX was extracting water that was reported to be in the range of 29,400 mg/L (see Table 3 in Geoscience, 2016a), or 12 percent of ocean water salinity (33,500 mg/L), suggesting 12 percent was a reasonable upper limit. EIR/EIS Section 2.6.2 has been revised to acknowledge, as discussed in Section 4.4, Groundwater Resources, that as a result of the data generated from the test slant well long-term pump test, the HWG estimates that the long term amount of fresh water within the source water (stabilizing over the first several years of project operation) would be between 1 and 4 percent. The water in the capture zone of the slant wells is currently brackish to saline, so it was reasonable to expect the feedwater would contain about 88 to 100 percent seawater. As discussed in EIR/EIS Impact 4.4-3, the groundwater modelers used these return water percentages to capture minimum, maximum, and mid-range estimates of return water volumes for purposes of projecting groundwater response.

Biala1-7 See Master Response 2, Source Water Components and Definitions, and Master Response 3Water Rights.

Biala1-8 See Master Response 4, The Agency Act and Return Water, and Master Response 3, Water Rights. The EIR/EIS does not assert that return water would benefit MCWD. Impacts on groundwater resources, both local and "regional" (to the extent that project impacts would extend beyond the slant well capture zone) are fully analyzed in EIR/EIS Section 4.4 and determined to be less than significant.

Biala1-9 See responses to comments MCWD-HGC in Section 8.5.2.2.

Biala1-10 See Master Response 2, Source Water Components and Definitions, and Master Response 3, Water Rights.

Biala1-11 CalAm monitoring well MW-7S, -7M and 7D all show signs of groundwater quality impacts by seawater intrusion. These wells range in Total Dissolved Solids (TDS) from 1,200 milligrams per liter (mg/L) in the shallow well to 26,700 mg/L in the deep well. Curtis Hopkins, in his January 2017 memo to MCWD, states that groundwater in monitoring wells MW-7S and MW-7M has a calcium chloride signature indicative of recharge from an overlying layer and not seawater. However, as explained in the responses to comments MCWD-HGC in Section 8.5.2.2, this is a mischaracterization of the data since a calcium chloride character suggests a cation exchange between sodium and calcium and is an indicator of incipient seawater intrusion.

The water quality data does not verify that the well is no longer "contaminated by seawater" and there is no historical record of data confirming the assertion that any or

all of the MW-7 wells are "no longer contaminated by high concentrations of seawater." While it has been demonstrated that "responsible curtailing of pumping results in decreases in seawater contamination," current efforts in the Marina Area to reduce pumping in the 180-Foot Aquifer and 400-Foot Aquifer would likely have a diminutive positive effect on decreasing seawater intrusion since the inland hydraulic gradient has been established for years and seawater continues to intrude inland. As discussed in Master Response 8, Project Source Water and Seawater Intrusion, the proposed pumping under the MPWSP would occur in a coastal-adjacent capture zone that receives recharge from the ocean, thereby capturing seawater that would otherwise migrate inland. As discussed in Impact 4.4-4, groundwater modeling and particle tracking shows that the MPWSP would not exacerbate seawater intrusion and would be expected to retard future inland migration of the seawater intrusion front.

Biala1-12 The EIR/EIS does not state that drawing fresh water in the future in any way determines CalAm's water rights; it does state that if the water in the underlying groundwater basin were to become fresher in the future, steps may need to be taken to ensure that no harm ensues to existing legal users of groundwater. See also Master Response 3, Water Rights.

Biala1-13 The hydrogeologic understanding that pumping 24.1 million gallons per day (mgd) of groundwater from a capture zone along the coast would retard future inland migration of seawater intrusion is not a theory but an expected outcome based on an understanding of the regional hydrogeology and the output of a groundwater model. The scientific evidence is contained in the results of an independent, validated physically-based groundwater flow model that has been calibrated using data from numerous soil borings and wells. The EIR/EIS Impact 4.4-4 and Appendix E2 explain how the groundwater model was used to project how groundwater would respond to the proposed pumping. See Master Response 12, The North Marina Groundwater Model (v. 2016), Sections 8.2.12.2 and 8.2.12.3, for more information on model construction and calibration. Also, see Master Response 8, Project Source Water and Seawater Intrusion, Sections 8.2.8.1 and 8.2.8.4, which provide additional information on the capture zone and cone of depression that form in response to the proposed MPWSP pumping.

Biala1-14 The comment is noted and will be considered by decision-makers. But the comment is incorrect in that a 9.6 mgd and a 6.4 mgd desalination plant would extract 27,000 afy (24.1 mgd) and 17,360 afy (15.5 mgd) respectively, as source water. If CalAm's return water obligation was 6 percent (the mid-point evaluated in the EIR/EIS), CalAm would be required to return 1,620 afy or 1,042 afy, depending on the size of the desalination facility. See also Master Response 3, Water Rights, Section 8.2.3.6 and Master Response 4, Agency Act and Return Water, Section 8.2.4.3.

Biala1-15 See Master Response 2, Source Water Components and Definitions, and Master Response 3, Water Rights.

Biala1-16 The EIR/EIS clearly and repeatedly describes that the slant wells would draw water from the Dune Sand and 180-Foot Aquifers; see for example, EIR/EIS Table 3-1, "The slant wells would draw water from groundwater aquifers that extend beneath the ocean floor (the Dune Sands Aquifer and the 180-Foot-Equivalent Aquifer of the Salinas Valley Groundwater Basin) for use as source water for the MPWSP Desalination Plant." See Section 4.4, Groundwater Resources, for an analysis of project impacts on groundwater resources. Also see Master Response 3, Water Rights.

Biala1-17 Impacts on groundwater resources, both local and "regional" (to the extent that project impacts would extend beyond the slant well capture zone) are fully analyzed in Section 4.4. See also Master Response 3, Water Rights, and Master Response 9, Electrical Resistivity Tomography (ERT) and Airborne Electromagnetics (AEM).

Biala1-18 See response to comment Biala1-3. The text cited in the comment is from EIR/EIS Section 2.6, Water Rights, and the scientific data to support those claims are presented in EIR/EIS Section 4.4, Groundwater Resources, which is supported by Appendices B2, C1, C2, C3, E2 and E3.

Biala1-19 As stated in the EIR/EIS text quoted in the comment, "Given that the well pumps and the screens are set *at least tens of feet* below the existing groundwater level," (emphasis added), a drawdown of less than 5 feet would not affect these wells. See EIR/EIS Section 4.4, Groundwater Resources, concerning the expected project effects on local groundwater levels and wells. See Master Response 11, CalAm Test Slant Well, for information on the history and status of test well activities and results. The condition imposed on test slant well operations by the California Coastal Commission with respect to a water decline resulting from the test well (which is discussed in detail in Master Response 11) was not necessarily correlated to the water rights question of whether existing legal water users would be harmed by the project, nor was that condition of approval informed by the analysis (including groundwater modeling of project effects) contained in the EIR/EIS. Also, see Master Response 3, Water Rights.

Biala1-20 Conclusions in the EIR/EIS are supported by scientific study and evidence cited in the EIR/EIS and included in the administrative record; see responses to comments Biala1-13 and Biala1-18. See also Master Response 3, Water Rights.

Biala1-21 ERT/AEM provides a static image representing a point in time and does not, as the comment states, "provide a detailed record of changes in the aquifers." See Master Response 9, Electrical Resistivity Tomography (ERT) and Airborne Electromagnetics (AEM), Section 8.2.9.3.

Biala1-22 See Master Response 3, Water Rights. In particular, see Section 8.2.3.2.

Biala1-23 See Master Response 11, CalAm Slant Test Well, concerning the status of data available from the test slant well. Test well data received to date have been used by the Lead Agencies to assess project feasibility and impacts on groundwater resources, and the Lead Agencies will consider this data during the decision-making process. See also EIR/EIS Section 1.5 and Appendix E3.

Biala1-24 See Master Response 12, The North Marina Groundwater Model (v. 2016), Section 8.2.12.1, which indicates that the $NMGWM^{2016}$ is a *more accurate representation* of the hydrostratigraphic framework of the Fort Ord area than the $NMGWM^{2015}$ and Salinas Valley Integrated Ground and Surface Water Model (SVIGSM). The nine recently installed monitoring wells were used to aid with this improved layer delineation and re-calibration; however, they were not the only points used in the model development and calibration. Model layering was defined using: available cross section data points from many sources; conductivity values were initially estimated from the SVIGSM and then modified based on pumping test results and calibration to water levels, and; measured water levels from multiple wells used in the SVIGSM as well as the nearby monitoring wells were used to access the model calibration. See also Master Response 9, Electrical Resistivity Tomography (ERT) and Airborne Electromagnetics (AEM), Section 8.2.9.2.

Biala1-25 The model was employed to answer questions about the effects of slant well pumping on groundwater levels; see EIR/EIS Appendix E2, Section 1. The purpose for the model was not to test a hypothesis; an explicit hypothesis was not stated prior to model development. Its purpose was to "solve the groundwater changes due solely to the proposed project," which is not a hypothesis statement. It is however, a reasonable attempt at a statement of the method used for answering questions about the effects of slant well pumping. EIR/EIS Section 4.4.4.2, Groundwater Modeling, states "Modeling scenarios were developed to project the drawdown from groundwater pumping at the CEMEX site and the alternative location at Potrero Road, and to assess the uncertainty in drawdown to model assumptions and input" (see Draft EIR/EIS page 4.4-50). Factors mentioned "such as seasonal climate and agricultural pumping trends" were considered and reviewed. However, the objective was to isolate the effects of slant-well pumping. Thus, the superposition model was developed. As indicated in Master Response 12, The North Marina Groundwater Model (v. 2016), Section 8.2.12.3, superposition is employed to isolate the expected change in groundwater levels and fluxes due solely to the slant wells. It is not necessary to study the impacts of agricultural pumping on the Basin because they do not inform the effects of slant well pumping using superposition. Therefore, it was not necessary to calibrate the revised model to the seasonal agricultural impacts on the basin. The uncertainty of the parameter values used in the model are discussed in EIR/EIS Section 4.4.4.2 and Appendix E2, Section 6.

Biala1-26 The percentage of seawater contribution to the test slant well was projected to be approximately 96 percent *after four years of pumping* (emphasis added); see Figure 3

from Geoscience 2014b, as cited in EIR/EIS Appendix G2, and in response to comment Moore-2 in EIR/EIS Section 8.7.16.

As described in Master Response 4, The Agency Act and Return Water, Section 8.2.4.3, the return water volume (i.e., 100 percent minus the Ocean Water Percentage or OWP) was expected to be more than 0 percent but less than 12 percent, based on preliminary groundwater model runs and calculations. Therefore, to account for the variable return water volumes, the NMGWM^{2016} was run with pumping scenarios that included representative return water volumes of 0, 3, 6, and 12 percent of the total source water volume. As further explained in Master Response 4 and EIR/EIS Appendix E3, the models used to estimate return water percentage confirmed that this range of assumptions was reasonable. Note that the analytical equation and numerical modeling methodology used to estimate the OWP from slant well pumping is different from the use of the NMGWM^{2016} to estimate changes in groundwater levels. See the discussion titled "Return Water Considerations" in EIR/EIS Section 4.4.4 for discussion.

Biala1-27 This comment is addressing a product of the HWG (Monthly Report #14), and not the EIR/EIS. The NMGWM^{2016} was not intended to be used to predict the results of test slant well pumping and was not used to assess the salinity of the test well water pumped. See EIR/EIS Appendix E2, Section 4.2, Test Slant Well Pumping, for an example where real-world monitoring data is utilized to compare measured drawdown with the drawdown calculated with the superposition model. See also Master Response 12, The North Marina Groundwater Model (v. 2016). The NMGWM^{2016} is a valid model because: 1) it synthesizes the current hydrologic conditions in the area; 2) it is based on a solution of accepted mathematical equations that describe flow in porous media; and 3) the rigorous evaluation of uncertainty and its performance described in the EIR/EIS Appendix E2, Section 6, ensures that model errors are only a small part of the overall model response and the model meets the requirements for a well calibrated model. Also, as discussed in Appendix E2 Section 4.1, the NMGWM^{2016} simulates the measured historical water level elevations from nearby wells within acceptable modeling criteria.

Biala1-28 The modeling has not been limited to a small area of the Salinas Valley Groundwater Basin. The NMGWM^{2016} is based on the telescopic mesh refinement approach, where a relatively coarse model grid is utilized to represent the regional groundwater system defined by the physical limits of the aquifer, and a second smaller model having a relatively fine grid is utilized to represent a subregion of the aquifer. See Master Response 12, The North Marina Groundwater Model (v. 2016), for more information regarding the approach to groundwater modeling. The CPUC does not manage the HWG or its membership; see Master Response 5, The Role of the Hydrogeologic Working Group and its Relationship to the EIR/EIS.

Biala1-29 The text cited in the comment is from the Test Slant Well Long Term Pumping Monthly Monitoring Reports that are prepared by the Hydrogeologic Working Group

for the California Coastal Commission in compliance with CalAm's Coastal Development Permit Special Condition 11, and is not from the Draft EIR/EIS. The NMGWM^{2016} was not employed to project the rate of salinity rise due to future test slant well pumping, nor was it calibrated using test slant well pump data. Data obtained during the pump test was used to validate the model. Therefore, any interruptions are part of the historical data set considered as part of that validation. See also EIR/EIS Appendix E3.

Biala1-30 See EIR/EIS Section 2.3, CalAm Service Area Demand, Section 4.4, Groundwater Resources, and Section 4.20, Socioeconomics and Environmental Justice. Consistent with NEPA and CEQA, the EIR/EIS analyzes the project as it was proposed by CalAm, the applicant. Likewise, the project objectives within the EIR/EIS (see Section 1.3) reflect the purposes for which CalAm proposed the project; to develop water supplies for the CalAm Monterey District service area. As discussed in EIR/EIS Section 2.3, CalAm Service Area Demand, CalAm must develop a replacement water supply to meet existing demand in its Monterey District service area, based on State Water Board Orders 95-10 and 2016-0016, and the Seaside Groundwater Basin adjudication. See also response to comment Hofmann-35. The Lead Agencies are not required to analyze the water supply and demand needs of jurisdictions outside the service area of the proposed project's applicant; however, EIR/EIS Section 4.4, Groundwater Resources, analyzes the physical impacts of the proposed project on the quality and quantity of water in the regional aquifers that could be affected by the project, thus providing data as to whether and how the water needs of other water users could be affected. See Master Response 3, Water Rights, specifically Section 8.2.3.7. EIR/EIS Section 4.20 analyzes the distributional patterns of minority and low-income populations in the region and characterizes the impacts of the proposed project on these communities, consistent with NEPA and CEQA. Water demand and the potential effects of the project on regional and local groundwater resources are fully evaluated in the EIR/EIS; no supplement is needed regarding these issues.

Biala1-31 The Lawrence Berkeley National Laboratory (LBNL) was scoped, as described in the comment, to address questions about the accuracy and credibility of the groundwater modeling work that was the subject of the potential conflict of interest comments, and the CPUC employed the LBNL to conduct an independent evaluation of that data. The text in EIR/EIS Appendix E1 – *near the shoreline* – is qualifying the phrase, "extraction of saline groundwater from beneath the sea floor *near the shoreline*." The wells are indeed, *near the shoreline*.

EIR/EIS Appendix E2 explains that the Salinas Valley Groundwater and Surface Water Model (SVIGSM) represents the entire Salinas Valley Groundwater Basin; whereas, the NMGWM represents a 149 square mile subset of the over 650 square mile SVIGSM area; see response to comment Biala1-28. Master Response 12, The North Marina Groundwater Model (v. 2016), Section 8.2.12.1, explains that the NMGWM^{2016} is based on the telescopic mesh refinement approach, where a relatively coarse model

grid is utilized to represent the regional groundwater system defined by the physical limits of the aquifer, and a second smaller model having a relatively fine grid is utilized to represent a sub-region of the aquifer. Continuity between the two models is maintained by extrapolating and specifying the simulated water levels from SVIGSM, at the NMGWM^{2016} boundaries. See Master Response 12, Section 8.2.12.2 for information regarding the scope of the LBNL peer review of the NMGWM, as well as EIR/EIS Appendix E1. Also, see Master Response 9, Electrical Resistivity Tomography (ERT) and Airborne Electromagnetics (AEM), Section 8.2.9.2 and 8.2.9.3 for information on the use and application of ERT/AEM data for the EIR/EIS groundwater analysis. Refer to Impacts 4.4-3 and 4.4-4 for a discussion of the impacts of the project on regional groundwater resources. See also Master Response 8, Project Source Water and Seawater Intrusion, Section 8.2.8.4 for additional clarity regarding the effects of slant well pumping on the SVGB.

The CPUC decision-making process is explained in EIR/EIS Section 1.5.4. Pursuant to CEQA Guidelines Section 15090, as CEQA Lead Agency, the CPUC must certify that the Final EIR/EIS complies with CEQA and reflects the CPUC's independent judgment and analysis prior to approving the MPWSP or an alternative. If the CPUC certifies the Final EIR/EIS, it will then decide whether or not to grant the Certificate of Public Convenience and Necessity (CPCN) for the MPWSP, as proposed or modified. In addition to environmental impacts addressed during the CEQA process, the CPCN process will consider any other issues that have been established in the record of the proceeding.

Biala1-32 See Master Response 12, The North Marina Groundwater Model (v. 2016), Section 8.2.12.2. See also Master Response 9, Electrical Resistivity Tomography (ERT) and Airborne Electromagnetics (AEM), Section 8.2.9.2 and 8.2.9.3 for information on the use and application of ERT for the EIR/EIS groundwater analysis.

The NMGWM^{2016} has been demonstrated to produce reliable results in light of the quantified uncertainty. Substantial effort has been expended to quantify model uncertainty and incorporate the uncertainty into estimated drawdown due to slant well pumping. ERT data (Pidlisecky et.al., 2016) and Dr. Knight's preliminary AEM report (Gottstchalk and Knight, 2017) were carefully reviewed by the EIR/EIS preparers. It was determined that ERT data will not necessarily produce greater certainty for a three-dimensional model because of the uncertainty in the ERT methodology. As discussed in Master Response 9, Electrical Resistivity Tomography (ERT) and Airborne Electromagnetics (AEM), ERT requires correlation and ground truthing with known data that describe the geologic, groundwater, and water chemistry. Additional limitations include the spacing of arrays required and avoiding potential sources of "noise" (or interference), such as pipelines or buried utility cables. Additionally, it is important to note that information regarding subsurface geology, groundwater flow and occurrence, and groundwater chemistry used in the EIR/EIS were obtained from known scientific sources and included some of the same sources that Dr. Knight's team used to verify the ERT survey findings. Given the uncertainty inherent in ERT, it would not be

appropriate to add a supplemental section comparing ERT data to modeling, but Master Response 9 provides supplemental information on ERT technology and data. See also EIR/EIS Appendix E3, Section 3.1.8.

Biala1-33 The shortcomings noted in the comment (i.e., exclusion of the Fort Ord Aquitard) were addressed as part of the updates to the $NMGWM^{2015}$ – i.e., the $NMGWM^{2016}$. HydroFocus included 14 wells located south of the Salinas River from various depths in the $NMGWM^{2016}$ to assess the calibration; see Appendix E2 Section 3.1 and Figure 3.1. For both the A-Aquifer and FO-SVA in this area, reported hydraulic conductivity measurements from Fort Ord documents were used, and the model was then calibrated to the new wells added south of the Salinas River. As stated in Master Response 12, The North Marina Groundwater Model (v. 2016), the inclusion of these geologic features are consistent with, but were implemented independently of the Lawrence Berkeley National Laboratory (LBNL) recommendations. The LBNL recommendations are based on their review of the previous model version ($NMGWM^{2015}$), and not the $NMGWM^{2016}$. The LBNL review and recommendations are provided in EIR/EIS Appendix E1; updates to the $NGMWM^{2015}$ are documented in Appendix E2.

Model-calculated water levels from the historical model run (1979-2011) were compared to measured water levels throughout the basin. Additionally, although outside the model time period, 2015 water level data measured from monitoring wells were also compared against model-calculated water levels.

Biala1-34 As part of the FO-SVA addition in the $NMGWM^{2016}$, a transition clay layer was also added based on available cross section data and presence of clay in monitoring well boring logs (see EIR/EIS Appendix E2, Section 3.3). Similarly, hydraulic conductivity of this transition zone was adjusted based on water level data collected from nearby monitoring wells. This clay layer was not found directly beneath the CEMEX site, and therefore, the 180-Foot Aquifer is considered unconfined at that location. Moving eastward into to model domain, the 180-Foot Aquifer becomes confined. See EIR/EIS Figure 4.4-3.

Biala1-35 See responses to comments MCWD-HGC in Section 8.5.2.2.

Biala1-36 See response to comment Biala1-1; the Lead Agencies, and not CalAm, are the authors of this EIR/EIS. The above responses describe the Lead Agencies' consideration of available information, and the analyses contained herein reflect the independent judgment of the Lead Agencies. See also responses to comments MCWD-HGC in EIR/EIS Section 8.5.2.2.

Biala1-37 The EIR/EIS relies on groundwater modeling completed in 2017 by HydroFocus using the $NMGWM^{2016}$ which is documented in EIR/EIS Appendix E2. See response to comment Biala1-33.

Biala1-38 See response to comment Biala1-32. See also Master Response 12, The North Marina Groundwater Model (v. 2016), Section 8.2.12.2 for information regarding the scope of the LBNL peer review of NMGWM[2016], and Master Response 9, Electrical Resistivity Tomography (ERT) and Airborne Electromagnetics (AEM), Sections 8.2.9.2 and 8.2.9.3 for information on the use and application of ERT/AEM data for the EIR/EIS groundwater analysis. The NMGWM[2016] adequately incorporates the area necessary to assess the impacts of the proposed project on groundwater resource and a new model is not needed to incorporate ERT/AEM data, since the ERT/AEM data has a higher degree of uncertainty than the NMGWM[2016].

Biala1-39 See Master Response 3, Water Rights.

Biala1-40 See Master Response 9, Electrical Resistivity Tomography (ERT) and Airborne Electromagnetics (AEM), Section 8.2.9.2 and 8.2.9.3 for additional clarity on the usefulness and applicability of ERT/AEM. Also, see responses to comments Biala1-32 and Biala1-38. Groundwater monitoring wells are necessary to ground-truth and correlate ERT/AEM data, and without a monitoring well network that can collect ongoing data, the uncertainty of ERT/AEM data would increase and not be representative of actual conditions. ERT/AEM is a not a substitute for traditional data acquisition through groundwater monitoring wells.

CalAm's commitment to implementing Applicant Proposed Measure 4.4-3, Groundwater Monitoring and Avoidance of Well Damage, does not signify that, as the comment states, "there are some inadequacies of data in their proposal." As explained in EIR/EIS Section 4.4.5.2, CalAm recognizes the long-term nature of the proposed project and the need to provide continued verification that the project would not contribute to lower groundwater levels in nearby wells within the SVGB. CalAm proposes to expand the existing regional groundwater monitoring program to include the area where groundwater elevations are anticipated to decrease by one foot or more in the Dune Sand Aquifer, the 180-FTE Aquifer and the 400-Foot Aquifer. Expanding a monitoring network is a prudent common practice for verifying groundwater response projected by a groundwater model in large groundwater pumping programs.

The NMGWM[2016] is based on the telescopic mesh refinement approach, where a relatively coarse model grid is utilized to represent the regional groundwater system defined by the physical limits of the aquifer, and a second smaller model having a relatively fine grid is utilized to represent a subregion of the aquifer. The regional aquifer network is therefore, considered as part of modeling slant well pumping. The modeling was employed to calculate the area where the difference between pumping and non-pumping water levels (the drawdown) are greater than or equal to 1 foot.

Biala1-41 Source water for the MPWSP would be extracted at the coast from a capture zone in the Dune Sand and 180-Foot Aquifers. This zone is recharged by seawater that infiltrates through the Terrace Deposits at the coast, and not from areas further

inland. See Master Response 8, Project Source Water and Seawater Intrusion, Section 8.2.8.1 for the extent of the capture zone.

The project would return desalinated water to the CCSD as in-lieu pumping. The results from the NMGWM^{2016} provide the evidence supporting the conclusion that the MPWSP would increase groundwater levels through in-lieu groundwater pumping. The NMGWM^{2016} was the key analytical tool used to project aquifer response and assess groundwater level impacts associated with the proposed project. See Master Response 4, The Agency Act and Return Water, Section 8.2.4.1 regarding returning water to an area different from where it was pumped. Providing desalinated surface water (new water) would replace the groundwater that is presently used, thereby lowering demands for groundwater and reducing overdraft, which ultimately would improve groundwater levels. As discussed in EIR/EIS Section 4.4.5.2 (Impact 4.4-3) and shown on Figures 4.4-15 and 4.4-16, the water returned to the basin would increase groundwater levels in the 400-Foot Aquifer beneath the CCSD, but not in the 400-Foot Aquifer to the south in the Marina area. However, note also that the slant wells would not draw groundwater from the 400-Foot Aquifer beneath the City of Marina.

Biala1-42 See Master Response 8, Project Source Water and Seawater Intrusion, Section 8.2.8.1. The MPWSP slant wells would extract a mixture of brackish groundwater and seawater from an area close to the coast and the effects of the capture zone would not extend inland. The particle tracking analysis completed under the NMGWM^{2016} shows that slant well pumping would intercept seawater that is currently moving inland and contributing to seawater intrusion. By capturing the seawater source of recharge, slant well pumping would provide a degree of protection against seawater intrusion.

Biala1-43 See Master Response 4, The Agency Act and Return Water, Sections 8.2.4.2 and 8.2.4.3. Given the location of the capture zone, the quantities of return water would likely not increase because as the ocean recharges the capture zone, the salinity within the capture zone would likely stabilize; see EIR/EIS Appendix E3. The NMGWM^{2016} addresses changes in the return water volumes by calculating the area where the difference between pumping and non-pumping water levels (the drawdown) are greater than or equal to one-foot under a range of return water volume scenarios ranging from 0 to 12 percent return water, under the 24.1 mgd and 15.5 mgd pumping rates. These percentages equate to return water volumes ranging from 0 acre feet per year (afy) to 3,242 afy.

Biala1-44 See EIR/EIS Appendix E3, Master Responses 3, Water Rights, and Master Response 4, Agency Act and Return Water. See also Master Response 1 regarding authorship of this EIR/EIS.

Biala1-45 The Lead Agencies have considered available information on slant wells, including the information referenced in the comment. EIR/EIS Section 4.4 references Geoscience, 2012, which is the aquifer pumping test analysis and evaluation of the

test slant well at Doheny State Beach, in Dana Point, California. See also Master Response 11, CalAm Test Slant Well, Section 8.2.11.8, which discusses the Dana Point Test Slant Well, the Huntington Beach Subsurface Intake Feasibility Report and the Santa Barbara Subsurface Desalination Intake Feasibility Study; see also the References in Section 8.2.11.10.

Biala1-46 See Master Response 3, Water Rights.

CalAm is a public utility under the CPUC's jurisdiction, and has applied to the CPUC for a Certificate of Public Convenience and Necessity (see EIR/EIS Section 1.2.1). CalAm also requested from MBNMS, authorization and permits to construct, operate, maintain, and decommission subsurface intake facilities under the Sanctuary and to allow brine discharges through an existing ocean outfall facility within the Sanctuary (see EIR/EIS Section 1.3.2). This EIR/EIS evaluates the project that was applied for by the applicant, as well as alternatives to the proposed project, and assumes the applicant will comport with applicable laws and regulations. The Lead Agencies are responsible for enforcing the implementation of the measures adopted in the MMRP. See also response to comment MCWD-115; the CPUC Energy Division will contract with an independent third-party construction monitoring provider to ensure that a neutral third party will oversee the Applicant's implementation of all mitigation measures. Further, any monitoring reports that are submitted to the CPUC and/or MBNMS will be public records and will be accessible to the public upon request. Questions regarding CalAm's history are outside the scope of CEQA/NEPA.

Biala1-47 EIR/EIS Section 2.2 presents background on CalAm's existing supplies, and Section 2.2.4 speaks specifically to the adjudication of the Seaside Groundwater Basin. The court intended to "protect the basin from long-term damage associated with potential seawater intrusion, subsidence, and other adverse effects that commonly result from overpumping" by adjudicating the water rights for all users of the basin. As described in EIR/EIS Section 2.2.4, the adjudication was initiated because CalAm sued a number of parties who held or potentially held water rights in the Seaside Basin, and asked the court to adjudicate those rights.

As described in EIR/EIS Section 4.4.1.3, the Salinas Valley Groundwater Basin (SVGB) is in overdraft because outflow, including pumping, exceeds inflows. To avoid court intervention, several projects have been implemented in the SVGB to promote recharge and halt seawater intrusion; specifically, the Castroville Seawater Intrusion Project and the Salinas Valley Water Project. The EIR/EIS makes no determinations on what obligations take precedence over others. The EIR/EIS evaluated the potential impacts of the CalAm proposed project, and considered how the proposed project would interact with other proposed projects, in the evaluation of cumulative effects. See EIR/EIS Section 4.1.7.

Biala1-48 EIR/EIS Section 4.4.1 presents the setting/affected environment for groundwater resources. Seawater intrusion in the SVGB and the SGB are described in this section

and the situations are different; the SVGB is experiencing seawater intrusion and the SGB is at risk of seawater intrusion. The word "ameliorate" or "ameliorating" is not used anywhere in the EIR/EIS.

As stated in EIR/EIS Section 2.2.4, CalAm's eventual allocation from the Coastal subarea of the SGB would be 1,474 afy (compared to their 2016 operating yield of 2,254 afy, see EIR/EIS Table 2-1). As a result of the adjudication, the court also required that production from the SGB in excess of natural safe yield be replenished. CalAm and the SGB Watermaster agreed to a replenishment schedule of 25 years at a replenishment rate of 700 afy by either in-lieu or artificial replenishment. CalAm has committed to only extracting 774 afy of their 1,474 afy allocation from the SGB for 25 years.

Biala1-49 EIR/EIS Section 5.5 fully examines the effects of numerous project alternatives on groundwater resources. EIR/EIS Section 5.5.4 evaluates alternatives to the MPWSP that include open water intakes and that do not include subsurface intakes; the EIR/EIS concludes that the operation of these alternatives would have no impact on local groundwater levels in the SVGB, a reduced potential for impact compared to the proposed project. See EIR/EIS Sections 5.5.4.5 for that conclusion about Alternative 2 (Open Water Intake at Potrero Road), Section 5.5.4.6 for Alternative 3 (DeepWater Desal) and Section 5.5.4.7 for Alternative 4 (People's Project). See also response to comment Marina-144 (EIR/EIS Section 8.5.1). Note however, that Section 4.4, Groundwater Resources, finds that the proposed project would not degrade the quality of surface water or groundwater. The policies cited in the comment speak to ensuring that high quality water is maintained, but do not mandate that existing brackish water be improved to a higher quality. See also Master Response 3, Water Rights.

Biala1-50 Appendix J2 is appended to the EIR/EIS in support of the analysis in EIR/EIS Section 6.3, Growth Inducing Impacts, which addresses the potential indirect growth inducing impact of the water supply that would be provided by the proposed project. Growth induced by the project water supply would occur in areas that would receive it – the CalAm's service area – which would not include the City of Marina. The impacts of project construction and operation, such as impacts on air quality, groundwater and traffic, are evaluated in Chapter 4 of the EIR/EIS and the impacts of project alternatives are evaluated in Chapter 5, Section 5.5.

Biala1-51 The localized and regional impacts of the MPWSP on hydrology and groundwater are evaluated in EIR/EIS Sections 4.3 and 4.4, respectively. Appendix J2 summarizes the impacts of growth in the area that would be served by project water supply since the provision of water supplies to this area could result in growth-inducing effects. Other areas such as the City of Marina are not included in the growth-inducement evaluation because the project would not serve these areas and therefore would not contribute to growth in these areas, as noted in response to comment Biala1-50, and response to comment Hoffman-35.

Biala1-52 This comment is addressing the EIR/EIS Section 1.4.4, Introduction. EIR/EIS Section 5.5.4 presents the potential impacts of the proposed project, the No Action and all "action" alternatives, on groundwater resources with the same rigor. The scientific data are presented in EIR/EIS Section 5.5, which is supported by Appendices B2, C1, C2, C3, E2 and E3. Master Response 3, addresses water rights; Master Responses 4, 5, and 12 address The Agency Act and Return Water, The Hydrogeologic Working Group, and The North Marina Groundwater Model (v. 2016), respectively. The same version of the NMGWM^{2016} was used to evaluate all alternatives (see EIR/EIS Appendix E2) and modeling of the reduced-size project (Alternative 5a) does not change the conclusions reached in the modeling analysis. The modeling analysis shows a lesser extent of drawdown under the reduced slant well scenario. A summary and comparison of impacts of alternatives is presented in EIR/EIS Section 5.6.1; see Table 5.6-1.

Biala1-53 As noted in EIR/EIS Section 1.1, CalAm's application also includes an option that would meet all of the project objectives by combining a reduced capacity desalination plant (6.4 mgd) with a water purchase agreement for 3,500 acre-feet per year (afy) of product water from another source, the Pure Water Monterey Groundwater Replenishment (GWR) Project. As stated in EIR/EIS Section 1.1, this capacity option is reflected in Alternative 5a. While both of these options were proposed by CalAm (in an "either/or" fashion) and thus represent the project proposed by the applicant, the larger desalination plant was selected to be analyzed as the "Proposed Project" in Chapter 4 of the EIR/EIS since it is larger and thus was expected to have greater impacts than the smaller capacity option, which is fully examined as an alternative in Chapter 5. The reduced size alternatives evaluated by the Lead Agencies in the EIR/EIS (Alternatives 5a and 5b) would meet the same need for water as the proposed project, not a reduced need for water, since 3,500 afy of GWR supplies would be included in the overall supply for Alternatives 5a and 5b; see EIR/EIS Section 5.5.6. See also Master Response 13, Demand (Project Need) and Growth, and EIR/EIS Appendix L for more information on water demand and growth under various supply scenarios.

Biala1-54 See Chapter 5, Alternatives Screening and Analysis for detailed descriptions (Section 5.4) and analysis of impacts (Section 5.5) of all alternatives. See Chapter 4, Environmental Setting (Affected Environment), Impacts, and Mitigation Measures for the analysis of the proposed project. See Master Response 3, for more information on water rights.

Biala1-55 See Master Response 11, CalAm Test Slant Well. The process and timeline for decommissioning of the test slant well are governed by the permits for that well, and are not pertinent to the EIR/EIS analysis of the environmental effects of the proposed MPWSP.

Biala1-56 CalAm cannot bypass the City of Marina's CDP process. However, an applicant or any person who participates in the local permitting process for a project, or who

otherwise communicates their concerns to the local government, may file an appeal to the California Coastal Commission. In addition, any two Coastal Commissioners may also appeal projects to the Commission. (CCC, 2007)

8.7.3.2 Responses to Comments from Kathy Biala – Letter 2

Biala2-1 As described in EIR/EIS Section 3.3.2.1, Subsurface Slant Wells, slant well construction would take approximately 15 months to complete, not 2 years. The 9-acre construction area would have a temporary impact on western snowy plover habitat because the site would be returned to pre-construction conditions. With implementation of the mitigation measures described in Impact 4.6-1, these impacts would be reduced to a level that is less than significant. As described in Impact 4.6-6, maintenance activities would be conducted every 5 years and this is considered a permanent loss of habitat. Permanent impacts would be reduced to less than significant with implementation of Mitigation Measure 4.6-1d (as revised; see Final EIR/EIS Section 4.6). Existing snowy plover use of areas within and at the proposed northernmost slant well cluster in the CEMEX mining area (described in EIR/EIS Section 4.6.1.8), which has been subject to disturbance associated with mining activities, suggests that temporary construction disturbance would not result in irreversible impacts on snowy plover use of this area following restoration.

Biala2-2 See responses to comments CURE-Owens-9 and CURE-Owens-10 regarding the use of western snowy plover data for the impact analysis. The approach to analysis of impacts on all special-status species, including western snowy plover, was described in EIR/EIS Section 4.6.4.

Biala2-3 See response to comment Biala2-2. The western snowy plover is protected under the Federal Endangered Species Act (federally listed as threatened) and is considered a California species of special concern by CDFW. Impacts on this species are analyzed pursuant to the Federal Endangered Species Act and in accordance with its special status under both federal and state laws, and mitigated accordingly. Additionally, MBNMS is undertaking the required consultation with USFWS under the Federal Endangered Species Act; see EIR/EIS Section 7.1. The City of Marina resolution referenced by the commenter does not obligate the Lead Agencies to require that CalAm provide compensation to the City of Marina for potential impacts on western snowy plover.

Biala2-4 Mitigation Measure 4.6-1d describes the required protocols for identifying and avoiding nests for any work that cannot be completed during the non-nesting season, and requires that any additional avoidance and minimization measures required by USFWS as a result of consultation under the Federal Endangered Species Act be incorporated and implemented as part of this measure. The duties of the Lead Biologist and the related monitoring and reporting requirements are described in Mitigation Measure 4.6-1a. CalAm would be required to comply with these measures as would be documented in an adopted Mitigation Monitoring and Reporting

Program (MMRP). The full text of these measures, as revised, is provided in Final EIR/EIS Section 4.6.

Biala2-5 The required qualifications of the Lead Biologist are described in detail in Mitigation Measure 4.6-1a. The Lead Biologist would be responsible for implementing the Lead Agencies' adopted biological resource-related mitigation measures to the extent described in adopted measures, including 4.6-1a, and would report to the Lead Agencies as described in Mitigation Measure 4.6-1a.

Biala2-6 See Mitigation Measure 4.6-1d which restricts construction time periods to the western snowy plover non-breeding season, unless otherwise approved by USFWS and with the incorporation of specific avoidance and minimization measures. Master Response 3 addresses concerns related to water rights.

Biala2-7 Per Mitigation Measure 4.6-1d, pre-construction nesting surveys shall be conducted by a "qualified western snowy plover biologist" "within 24 hours of initiation of construction activities." See subpart 3 of revised Mitigation Measure 4.6-1d for the required actions to be implemented if a nest is located in the project area. This measure was developed based on knowledge of western snowy plover biology, a review of similar measures that have been required by USFWS and other CEQA and NEPA lead agencies, and experience developing and implementing similar measures.

Biala2-8 Consistent with CEQA, the EIR/EIS analyzes impacts from the proposed project compared to the baseline conditions, which include existing sand mining operations. The purpose of subpart 4 of Mitigation Measure 4.6-1d is to minimize visual impacts from construction activities on nesting western snowy plover. See Impact 4.8-2 in EIR/EIS Section 4.8, Land Use and Recreation, which explains that there is no existing public access to the slant well construction site.

Biala2-9 See responses to comments Biala2-4 and Biala2-5.

Biala2-10 See response to comment Biala2-7 above and Subparts 3b and 3c of Mitigation Measure 4.6-1d. Further, as described in Mitigation Measure 4.6-1a, "The Lead Biologist shall be onsite, or shall appoint qualified biologists and/or qualified biological monitors to be onsite, during all fencing and ground disturbance activities." This is the most frequent monitoring that can be conducted. Additionally, Mitigation Measure 4.6-1d specifies that a biologist will also conduct periodic monitoring during construction to determine if there are any new western snowy plover nest starts.

Biala2-11 Reporting requirements are described in Mitigation Measure 4.6-1a. As is the case for CPUC-approved projects, the public is allowed access to records and reports used to track the monitoring program. Monitoring records and reports will be made available for public inspection by the CPUC on request. The CPUC and CalAm will develop a filing and tracking system. Public access to records will be addressed in the MMRP.

Biala2-12 Point Blue raised several concerns on the 2015 Draft EIR in their June 2015 comment letter and those concerns were addressed in the Draft EIR/EIS. Indeed, Point Blue acknowledges that these issues were addressed in their comment letter on the Draft EIR/EIS. See responses to comments Point Blue-1 through Point Blue-6 for response to Point Blue's comments on the Draft EIR/EIS. See also response to comment CURE-Owens-9 and revised Mitigation Measure 4.6-1d in Final EIR/EIS Section 4.6, Terrestrial Biological Resources.

Biala2-13 See the responses to Biala2-4, Biala2-5, and Biala2-10.

Biala2-14 As described on Draft EIR/EIS page 4.6-237, the brine storage basin is a component of the proposed MPWSP Desalination Plant that would be located on Charles Benson Road. Construction and operation of this facility would not occur in or around western snowy plover habitat. Mitigation Measure 4.6-6 would reduce potential operational impacts from the brine storage basin on migratory waterfowl to less than significant. The proposed project would not result in similar potential operational impacts on western snowy plover, so a similar measure is not described for western snowy plover.

Potential impacts on western snowy plover, and mitigation measures to reduce impacts to less than significant, are described in the subsurface slant well section in Impact 4.6-1 and Impact 4.6-6 and in the Source Water Pipeline section in Impact 4.6-1. As described in Mitigation Measure 4.6-1a, full-time biological monitoring will be required during all fencing and ground disturbance activities.

Biala2-15 In response to this comment, Mitigation Measure 4.6-6 has been revised to clarify that it is the Lead Biologist's responsibility to determine what adaptive management measures, if any, are needed to remedy problems detected during monitoring.

Biala2-16 Mitigation Measure 4.6-6 would be implemented to reduce impacts on migratory waterfowl from operation of the brine storage basin, and is unrelated to construction impacts. Construction impacts on nesting western snowy plover and special-status birds are described in Impact 4.6-1.

Biala2-17 As explained in CEQA Guidelines section 15040, CEQA is intended to be used in conjunction with discretionary powers granted to public agencies by other laws. The CPUC and other jurisdictional agencies are responsible for enforcing the procedures adopted for monitoring based on the enforcement authorities provided by laws governing those agencies. CalAm would be responsible for successfully implementing all of the measures in the MMRP, including compliance with the provisions of Mitigation Measure 4.6-6, if adopted. The MMRP will outline a dispute resolution process in the event that a dispute concerning the implementation of adopted measures arises. However, at this time, the Lead Agencies are not aware of, nor does the commenter provide evidence, that CalAm has violated the terms of mitigation measures or other such requirements in the past. Therefore, there is no reasonable basis

to assume that CalAm may attempt to "undermine the ability of the Lead Biologist to act ethically and swiftly" or tamper with potential evidence of bird impacts related to operation of the brine storage basin. Further, as explained in Impact 4.6-6, it is unlikely that many birds would become sick or die at the brine storage basin; Mitigation Measure 4.6-6 is recommended to ensure that this expectation is borne out or that adaptive management techniques are implemented if needed. No revision to Mitigation Measure 4.6-6 has been made in response to this comment.

Biala2-18 Per subpart 1 of Mitigation Measure 4.6-1c, the project work area shall be delineated with stakes and flagging prior to construction and construction-related disturbance outside of these boundaries shall be prohibited without approval of the Lead Biologist. This measure does not rely on fencing installed by other agencies.

8.7.3.3 Responses to Comments from Kathy Biala – Letter 3

Biala3-1 Table 1 in EIR/EIS Appendix C2 presents the erosion rate data sources that were included when the consultants to the Lead Agencies established historic shoreline change trends that were used in the development of dune erosion profiles; Dr. Thornton's work is the first entry in that table. The methodology for projecting future vertical and horizontal erosion profiles is described in EIR/EIS Section 4.2.4.5 and in Section 3 of Appendix C2; the analysis considered localized erosion (rip currents), long term erosion (including Dr. Thornton's data), and sea level rise (see EIR/EIS Appendix C1) to develop the erosion profiles. EIR/EIS Figures 4.2-7 and 4.2-8 present the erosion profiles and envelopes for the test slant well and the production wells, respectively. As shown in Figure 4.2-7, coastal erosion could expose the test slant well in a 100-year storm event by the year 2060, and Mitigation Measure 4.2-10 requires implementation of a Slant Well Abandonment Plan that would address this potential exposure. With implementation of Mitigation Measure 4.2-10, the impacts of the anticipated future presence of the test slant well on the beach would be reduced to a less than significant level. All of the other proposed wells would be located further inland of the 2060, 100-year flood event envelope as shown on Figure 4.2-8. Impacts on the 180-FTE Aquifer from project operation are described in Section 4.4.5.2 and were determined to be less than significant; therefore, the EIR/EIS identified no significant impact that would necessitate moving these proposed wells closer to the shoreline.

As explained in EIR/EIS Appendix E3, while placement of production well screens closer to or under the ocean may achieve the maximum Ocean Water Percentage (OWP) in the first few months and a very slight increase in the medium-term OWP, a difference of a few hundred feet in screen placement relative to the ocean boundary would have minimal overall effect on OWP because of the volume of seawater at the recharge boundary. If CalAm needs to replace a slant well, they will be required to apply for a Coastal Development Permit to do so, and they may also be required to apply for an MBNMS authorization or permit. Under NEPA, replacement of a slant well would not necessitate a supplement to the EIS unless the lead agency makes

substantial changes in the proposed action that are relevant to environmental concerns, or if there are substantial new circumstances or information relevant to environmental concerns and bearing on the proposed project or its impacts (40 CFR 1502.9). Likewise, under CEQA, a supplemental EIR would only be necessary if substantial changes are proposed in the project or substantial changes occur with respect to the circumstances under which the project is being undertaken which will require major revisions in the environmental impact report; or if new information, which was not known and could not have been known at the time the environmental impact report was certified as complete, becomes available. (CEQA Guidelines Section 21166). Since the slant wells would draw mostly seawater through the aquifers (see Master Response 8, Project Source Water and Seawater Intrusion), dune recession would not affect project operations. See also responses to comments MCWD-78 and MCWD-79.

8.7.4 Responses to Comments from William Bourcier

Bourcier-1 Responses to the commenter's specific comments on the Trussell Technologies' Memorandum (Draft EIR/EIS Appendix G2) are provided in responses to comments Bourcier-2 through Bourcier-13 and demonstrate why the Trussell estimates are lower and more representative of the actual off gassing process expected from the operation of the MPWSP slant wells at CEMEX.

Bourcier-2 The commenter's agreement with the assumption in the Trussell analysis that the CO_2 in the permeate (product water) stream would be released to the atmosphere upon exiting from the reverse osmosis (RO) process is acknowledged. However, as explained in response to comment Bourcier-3, the permeate is treated after the RO process and prior to distribution; therefore, off gassing of CO_2 is prevented. It should also be noted that off-gassing is a slow process, and any water that is exposed to the atmosphere will take time to equilibrate and release CO_2. However, since the release of brine will be a dynamic, ongoing process, so will be the release of CO_2 following the initial equilibration.

Bourcier-3 The first part of the comment regarding treatment is correct; the Trussell report (Draft EIR/EIS Appendix G2) at page 3 states, "The water in the finished water tanks would travel through each treatment process prior to equilibration with the atmosphere. During post-treatment, the pH of the desalinated water would be adjusted to ensure that carbon dioxide would not be released from the desalinated water as it contacts the atmosphere."

Typical seawater RO permeate, or product water, regardless of whether the source water was obtained with screened open water intakes or subsurface intakes, is treated for corrosion control prior to distribution due to the aggressiveness of the RO permeate. The same chemicals in approximately the same amounts would be used to treat RO permeate regardless of the intake method. Corrosion control involves the addition of chemicals to adjust pH, alkalinity, and calcium hardness. To control corrosion from the RO permeate, the MPWSP plant would use CO_2 to adjust alkalinity, lime to adjust calcium hardness, and sodium hydroxide to adjust pH as described in Draft EIR/EIS Section 3.2.2.3, Post-treatment System. For information on the estimated amounts of specific chemicals that would be used to adjust pH at the proposed MPWSP plant, refer to Draft EIR/EIS Table 3-3, Desalination Chemicals and Annual Usage. The comment suggests that caustic would be used in the treatment process, but as shown in Table 3-3 and described further in response to comment Bourcier-4, caustic would not be used for this project and its use was not assumed in the Trussell analysis.

Bourcier-4 As shown in Draft EIR/EIS Table 3-3, lime is the chemical that would be most widely used to treat permeate during the proposed desalination process, not caustic. And the CO_2 carbon footprint that would be released during the production of lime used to treat the RO permeate is not included in the Trussell analysis. The

production of lime involves a series of steps including the quarrying, crushing, sizing, and transportation of raw materials. However, quantifying GHG emissions from producing lime requires specific information that is unavailable at this time and attempting to quantify such emissions would be overly speculative.

GHG life cycle emissions are also emitted from the fuel combustion process used to heat the kiln for the calcination process, calcining the raw materials to produce lime, and (if required) hydrating the lime to calcium hydroxide. Calcination is the process by which limestone, which is mostly calcium carbonate ($CaCO_3$) is heated in a kiln to produce quick lime (CaO). CO_2 is a byproduct of this reaction and is usually emitted to the atmosphere. The GHG Protocol Initiative has developed a model based on methods and default values contained in Intergovernmental Panel on Climate Change (IPCC) Guidelines for National Greenhouse Gas Inventories (The GHG Protocol Initiative, 2007). This model could be used to make a general estimate of life cycle GHG emissions that would be associated with the production of lime that would be used for operations of the proposed project. However, because manufacturing plant-specific information and values, such as the process type, proportion of hydrated lime, water content of hydrated lime, CaO content of lime, fraction of calcination achieved from carbonate, type of fuel(s) to heat the kiln for the calcination process, etc., are not known or available at this time, the estimation would have to rely completely on default values, which would make quantification overly speculative.

In addition, CEQA guidance does not require production-related life cycle analyses of GHG emissions for materials since the term "life cycle" is not well defined and is too speculative, which is why the California Office of Planning and Research (OPR) removed the term from the CEQA guidelines within its 2010 amendments.

Therefore, the EIR/EIS does not address the lifecycle emissions associated with the lime or any other chemical or fuel, or construction materials such as concrete and steel. Therefore, neither the CO_2 that would be released from the permeate (if post-treatment as proposed were not to occur), nor the lifecycle emissions from the production of lime is included in the Trussell conclusions or the GHG emissions of the project as a whole.

Bourcier-5 The comment indicates that the water quality of the "15 wells sampled to date in the Marina area" would result in a higher CO_2 release than the test slant well water quality used in the Trussell analysis, and the Lead Agencies agree. However, the Trussell analysis treats the water from the currently-operating test slant well as "worst-case" because it would result in higher CO_2 levels than seawater from Monterey Bay, which would eventually displace the intruded seawater once the full scale project is operational.

The commenter provided estimates of CO_2 releases from 15 wells and the one where fluid composition data was used for the Trussell analysis. The 15 wells

discussed by the commenter are exploratory boreholes that are not indicative of source water quality to the desalination plant, as explained below.

The water quality data collected from these 15 boreholes was used by the hydrogeologists to:

- characterize the aquifer units for the conceptual groundwater model;
- characterize the water contained in the aquifer units (to determine if it is seawater, groundwater, or seawater intruded groundwater); and
- determine if the Salinas Valley Aquitard (a blue clay layer) exists between the aquifer units at this location.

The water quality from these exploratory boreholes is not representative of the source water quality for the desalination plant. The desalination plant would employ slant wells that are expected to pull approximately 93 percent seawater from the Monterey Bay and 7 percent groundwater that originated from the surrounding area. The exploratory borehole water quality samples used in the commenter's analysis are static, and not from an active, operating slant well, and therefore, have a different water quality composition than the test slant well water quality composition used in the Trussell analysis. Because the test slant well is a full-scale well that has been producing water intermittently since April 2015 for the purpose of collecting water quality data for the MPWSP, it is more appropriate to use the test slant well water quality data than to use the static water quality data from the 4-inch vertical exploratory boreholes designed to characterize the composition of the aquifer.

The test slant well is being operated to gain a better understanding of the water quality that would be fed to the full-scale desalination plant. When the test slant well began operation in April 2015, there was old, intruded seawater present in the aquifer. Water quality sampling at the test slant well suggests that even after two years of intermittent production, the well is drawing a great deal of old intruded seawater; and this water, which has been in the aquifer for many years, has a lower pH and higher silica concentration than Monterey Bay seawater. Once the proposed full-scale production slant wells begin to operate at a steady rate, they are expected to displace the old, intruded seawater in the aquifer. The slant wells would draw mostly Monterey Bay seawater with a small fraction of water that originated from inland. Thus, the quality of the water currently being produced by the slant well and the quality of fresh Monterey Bay seawater set bounds on the future quality of the water to be withdrawn by the full-scale slant wells once they are in operation. Calculations show that if the desalination plant operated on the water being withdrawn by the test slant well after two years of intermittent production (with higher amounts of old, intruded seawater), it would release more CO_2 than would be released when the desalination plant begins to operate on fresher Monterey Bay seawater. As a result, the Trussell analysis treats the water from the test slant well as "worst-case" and the Monterey Bay seawater as the "best case."

Bourcier-6 See response to comment Bourcier-13 regarding validating the method for estimating GHG releases from an actual feed source. The similarities of the commenter's methods to estimate CO_2 off gassing with the methods identified in the Trussell analysis and the commenter's suggestion that the two methods are accurate and verified are noted.

Bourcier-7 The Trussell analysis did not conclude that carbon dioxide releases from subsurface intakes is likely to take place in significant tonnages. The Trussell analysis concludes the current test slant well water quality represents the "worst-case" scenario for off gassing, since it has a lower pH and higher alkalinity than seawater, and that fresh Monterey Bay seawater would be the "best case" scenario because ultimately, there should be minimal change in pH and alkalinity as the water travels through the ground, to the slant well, and into the desalination plant. This analysis shows that the projected range of released carbon dioxide would be 95 to 735 metric tons per year. The commenter indicates that the Trussell analysis and the Bourcier analysis identified similar levels of CO_2 off gassing, which verifies the method of calculation for both parties. This is correct, although the commenter estimated that 822 to 14,577 metric tons of carbon dioxide would be released if the exploratory boreholes cited in the DEIR were the source water for the MPWSP. As noted in response to comment Bourcier-5, the exploratory borehole data are not indicative of the source water quality for the proposed project.

Bourcier-8 See response to comment Bourcier-3.

Bourcier-9 See response to comment Bourcier-5.

Bourcier-10 See responses to comments Bourcier-3 and Bourcier-4. The purpose of the Trussell analysis was to evaluate the GHG releases anticipated from the source water used for the MPWSP. There is no need to revise the Trussell analysis as requested.

Bourcier-11 See responses to comments Bourcier-3 and Bourcier-4.

Bourcier-12 See response to comment Bourcier-5.

Bourcier-13 The Lead Agencies asked CalAm to collect water samples from its existing test slant well to measure the CH_4 content.

Three water samples were collected from the test slant well on March 2, 2017, and were analyzed for methane on March 6 and 7, 2017. The results ranged from 0.54 to 0.58 micrograms per liter (MBAS, 2017a and 2017b). Two additional water samples were collected from the test slant well along with travel blanks on March 9, 2017 and March 15, 2017. These samples were analyzed on March 16, 2017 and March 24, 2017, respectively. In the two additional water samples from the test slant wells, methane concentrations were 0.55 and 0.68 micrograms per liter, respectively (MBAS, 2017c and 2017d); however, on the second occasion,

travel blanks were also taken and analyzed and these contained methane concentrations of 1.9 and 2.5 micrograms per liter, respectively.

A travel blank is purified water from the analytical lab which is transported in a sealed bottle to the site where it is used to fill an empty sample bottle in the field at the same location and in the same manner as the target sample. Travel blanks are used as a quality control measure to assure that methane is not introduced into the sample while it is being handled at the field site. In this case, the travel blanks have concentrations of methane that do not appear to be significantly different from the target samples taken from the test slant well itself, indicating that methane was likely introduced during the sampling. From this analysis, there is no evidence that the water from the test slant well contains methane.

While the travel blanks suggest there is no evidence of methane in the test slant well water, for the purposes of this discussion, the amount of methane that would be released by the project was estimated using the results of the sampling events. It is assumed that methane in the full source water flow would be released to the atmosphere. Using the full source water flow of the desalination plant (i.e., 24.1 million gallons per day (mgd)), a maximum CH_4 concentration of 0.68 as discussed above, and a global warming potential for CH_4 that is 25 times that of CO_2 (CARB, 2016), it is estimated that up to 0.70 metric tons CO_2 equivalent (CO_2e) CH_4 per year would be released. This is substantially less than the 735 metric tons CO_2 estimated to be released from the discharged brine and does not change the significance of the conclusion.

8.7.5 Responses to Comments from David Brown

Brown-1 The conclusion that the MPWSP would not harm the aquifers underlying Marina (discussed further in Master Response 3, Water Rights) is based on an analysis that incorporated data obtained from a validated, physically based groundwater flow model, groundwater quality data obtained from the installation and testing of several clustered groundwater wells, and data obtained from the test slant well. See Section 4.4.4 for a description of the key elements that contributed to the analysis on groundwater. For additional information on the 2016 version of the North Marina Groundwater Model, see Master Response 12, Section 8.2.12.3, and Master Response 8, Project Source Water and Seawater Intrusion, Section 8.2.8.4.

Brown-2 See Master Response 9, Electrical Resistivity Tomography (ERT) Airborne Electromagnetics (AEM).

Brown-3 The Draft EIR/EIS did not predict salinity would not increase in the aquifers. Impact 4.4-4 in EIR/EIS Section 4.4.5.2, acknowledges that project pumping would result in changes in the local groundwater quality around the slant wells and within the capture zone, measured as an increase in total dissolved solids (TDS), a measure of salinity; however, this localized increase in salinity within the capture zone would not interrupt or eliminate the available potable groundwater for other users in the basin (Draft EIR/EIS page 4.4-76). See also: Master Response 3, Water Rights, Section 8.2.3.7; Master Response 8, Project Source Water and Seawater Intrusion, Section 8.2.8.2 and Section 8.2.8.4, and; Master Response 9, Section 8.2.9.3.

8.7.6 Responses to Comments from Charles Cech

Cech-1 See Master Response 11, CalAm Test Slant Well, Section 8.2.11.2.

Cech-2 The conversion of the test slant well to a permanent well is part of the proposed project and is evaluated in the EIR/EIS. See Master Response 11, Section 8.2.11.7.

Cech-3 See Master Response 11, Section 8.2.11.8.

Cech-4 The screens of the test slant well are not located above the seafloor. EIR/EIS Figure 4.2-3 is a cross section of the geology that includes the location of the test slant well. This cross section indicates that the seafloor is composed of a thin layer of Deltaic Deposits overlying Older Dune Sand and Terrace Deposits (this unit is also known as the 180-Foot Equivalent Aquifer). The screens of the test slant well are indeed located in the Dune Sand and 180-FTE Aquifer units. See also Figure 7b in EIR/EIS Appendix C3.

Cech-5 As noted in Master Response 11, Section 8.2.11.5, the Dune Sands Aquifer and the 180-FTE Aquifer have been intruded by seawater for decades, and the monitoring wells show distinct seasonal trends in salinity, reflecting the effects of increased regional pumping in the summer months during irrigation season, and reduced regional pumping in the winter months, especially following rain events. The test slant well tracking data indicate an increase in salinity at and near the test slant well and not an increase in seawater intrusion in the 180-Foot Aquifer. See also Master Response 8, Project Source Water and Seawater Intrusion, Sections 8.2.8.1 and 8.2.8.2.

Cech-6 The water being pumped by the test slant well is not pure seawater; this fact is acknowledged in the Draft EIR/EIS, for example on page 4.4-60, which explains that the project "would extract primarily seawater and a smaller volume of brackish inland groundwater from a localized area with only minor localized groundwater drawdown." Further, as stated in the EIR/EIS in Impact 4.4-3, "The groundwater in the 180-Foot Aquifer that is underlying the area influenced by the MPWSP pumping, up to about 4 miles inland, has been intruded with seawater for decades, and far exceeds the State Drinking Water Standard of 500 mg/L of total dissolved solids (TDS)." The comment does not provide enough specificity regarding which criteria the test slant well is out of compliance with to allow the Lead Agencies to provide further substantive response.

Cech-7 As noted in Master Response 11, Section 8.2.11.8, a 5-inch artificial filter pack was installed around the screens of the test slant well. No evidence is available to indicate or suggest that the nine new wells will not perform in the same way as the test slant well. The proposed nine new wells (and the test slant well) are described in EIR/EIS Section 3.2.1.1. See response to comment Cech-4 regarding the location of the test slant well screens in relation to the seafloor.

Cech-8 See response to comment Cech-4 regarding the location of the test slant well screens in relation to the seafloor. The EIR/EIS describes the pre-treatment, reverse osmosis

treatment, and post-treatment components of the proposed project in Chapter 3, Sections 3.2.2.1 through 3.2.2.3, respectively. As described therein, these systems would provide treatment of intake water to address, at minimum, iron, manganese, pathogens, suspended solids, salts and other minerals, alkalinity, calcium hardness, and pH.

Cech-9 The Draft EIR/EIS describes these "Groundwater Enhancement Programs in the SVGB" in Section 4.4.1.3 at page 4.4-19.

Cech-10 See Master Response 11, Sections 8.2.11.2 and 8.2.11.3 regarding the impacts of the test slant well. The EIR/EIS evaluates the potential impacts the whole of the proposed MPWSP would have on groundwater quality, including conversion of the test slant well to a permanent well (see Master Response 11, Section 8.2.11.7). EIR/EIS Section 4.4.6 evaluates the cumulative impacts of the MPWSP in relationship to the groundwater enhancement programs mentioned in comment Cech-9.

Cech-11 Monitoring wells have experienced both a lowering and rising of groundwater levels whether the test slant well was operating or not. See Master Response 11, Section 8.2.11.5 for a summary of the HWG's conclusions regarding groundwater levels and TDS concentrations in MW-4S and MW-4M, which indicate that there have been no impacts resulting from test slant well pumping. As noted in EIR/EIS Table 4.4-10, the only wells that are screened in the Dune Sands and 180-FTE Aquifers are owned by the Monterey Peninsula Landfill; three are used for dust control and the fourth is inactive. The monitoring wells installed by CalAm in the Dune Sand and 180-FTE Aquifers offer the most comprehensive data set of water quality in the area of influence.

Cech-12 Dr. Dennis Williams is not the Executive Director of the HWG. As explained in Master Response 5, The Role of Hydrogeologic Working Group and its Relationship to the EIR/EIS, Section 8.2.5.2, the HWG does not have an executive director or any other leader; Dennis Williams represents CalAm as a member of the HWG. As explained in Master Response 5, Section 8.2.5.5, CalAm entered into an agreement with Dr. Williams granting a royalty-free license for the technology, resolving a potential financial conflict of interest.

Cech-13 As explained in Master Response 5, Section 8.2.5.5, several parties, including Lawrence Berkeley National Laboratories (LBNL), received the groundwater data files from the April 2015 Draft EIR. However, LBNL was not provided with the groundwater modeling software. In order to run the data files, LBNL (and HydroFocus and any other user of the data files) needed to independently download or otherwise obtain the application software MODFLOW, a three-dimensional finite-difference groundwater flow model, which is published by the U.S. Geological Survey. MODFLOW is an industry standard model that simulates steady and non-steady flow in an irregularly shaped flow system in which aquifer layers can be confined, unconfined, or a combination of confined and unconfined.

Cech-14 The hydraulic lowpoint is an issue that was resolved with the CPUC's September 2016 Phase 2 GWR decision that included approval of the Monterey Pipeline. The EIR/EIS does not evaluate the Monterey Pipeline as part of the proposed project (rather, it is considered a project relevant to the cumulative impact analysis). Accordingly, comments regarding the hydraulic lowpoint are no longer pertinent to the proposed project.

Cech-15 See Master Response 11, Section 8.2.11.4. As confirmed in the *Baseline Water and Total Dissolved Solids Levels* report, prior to initiating this five-day test, groundwater level measurements and groundwater quality samples were collected from the test slant well and all monitoring wells.

Cech-16 See Master Response 11, Section 8.2.11.4, regarding establishing baseline conditions prior to pumping, as well as response to comment Cech-15.

Cech-17 The passages quoted in the comment letter and referenced in this comment are from the test slant well CDP, and all references to the "Executive Director" in these quoted passages refer to the Executive Director of the CCC. Dennis Williams is not currently, and has never been, the Executive Director of the CCC. See also response to comment Cech-12.

Cech-18 As explained in Master Response 11, Section 8.2.11.6, the available data were indeed used to assess the reliability of the North Marina Groundwater Model used in the EIR/EIS (referred to as $NMGWM^{2016}$).

Cech-19 The baseline water levels and salinity collected prior to the 5-day pump test indicate trends, not a static condition. The *Baseline Water and Total Dissolved Solids Levels* report (see response to comment Cech-15 and Master Response 11, Section 8.2.11.4) as well as the monitoring data collected while the test slant well was not pumping (during the 144-day shutdown), were used by the HWG to establish regional trends. The data were used in the EIR/EIS to help calibrate the $NMGWM^{2016}$, as described in Master Response 12, The North Marina Groundwater Model (v. 2016), Section 8.2.12.3. See also response to comment Cech-18.

Cech-20 See Master Response 11, Section 8.2.11.6 and Master Response 5, Section 8.2.5.5. Dr. Williams did not perform modeling for the Draft EIR/EIS. HydroFocus performed the groundwater modeling used in the EIR/EIS and they used the test slant well data to update the calibration of the $NMGWM^{2016}$ as described in Master Response 12, Section 8.2.12.3.

Cech-21 The CCC set the terms of Special Condition 11 in the CDP, requiring the permittee (i.e., CalAm) to collect and post the data. See response to comment Cech-12 and Master Response 5, Section 8.2.5.5 regarding potential conflicts of interest.

Cech-22 See Master Response 11, Section 8.2.11.5. The shut down criteria were altered to better incorporate local and regional trends.

Cech-23 See response to comment Cech-12 and Cech-17.

Cech-24 See response to comment Cech-15 and Master Response 11, Section 8.2.11.4.

Cech-25 The Draft EIR/EIS text states (on page 4.4-22) that the data shown in Table 4.4-4 summarizes water quality results from a single sampling event. See also Master Response 11, Section 8.2.11.6 for a discussion of the test slant well data, and Master Response 5, Section 8.2.5.5 for a discussion of the conflict of interest.

Cech-26 Ocean water quality data are shown in Draft EIR/EIS Table 4.3-5 (page 4.3-32), water quality of the brine discharge based on test slant well water quality data is shown in EIR/EIS Appendix D3 Table 4, and a summary of test slant well laboratory water quality results are provided by CalAm in every Test Slant Well Monthly Monitoring Report (see Master Response 11, Section 8.2.11.5 for detailed references to these reports).

Cech-27 Ocean water quality in Monterey Bay (e.g., temperature and salinity) varies by season, as explained in EIR/EIS Section 4.3.1.3 as well as in EIR/EIS Appendix D1 Table 1. The comment does not provide enough specificity regarding federal TDS measurements in MBNMS and potential differences between such measurements and the Central Coast Seawater Average TDS measurement (reported in Table 4.4-4 on Draft EIR/EIS page 4.4-22) to provide a substantive response. See also response to comment PWN2-52.

Cech-28 As a component of the MPWSP, the Carmel Valley Pump Station (including the electrical control building) is described in EIR/EIS Section 3.2.3.6. The potential construction and operational impacts of the Carmel Valley Pump Station are addressed in all topical sections of Chapter 4 and these are summarized in EIR/EIS Table ES-2.

Cech-29 The direct and indirect noise impacts of the Carmel Valley Pump Station are addressed in EIR/EIS Section 4.12.6; the direct and indirect air quality impacts are addressed in Section 4.10.5; and the direct and indirect traffic impacts are addressed in Section 4.9.5.

Cech-30 See response to comment Cech-28.

Cech-31 The operation of existing pipelines or other facilities not related to the proposed project is outside the scope of the analysis of the proposed project in this EIR/EIS. Therefore, this is not a substantive comment on the Draft EIR/EIS.

8.7.7 Responses to Comments from Bob Coble

Coble-1 See Master Response 3, Water Rights.

Coble-2 See Master Response 11, CalAm Test Slant Well, Section 8.2.11.5, for a discussion of the results of the test slant well long-term pump test. See also Master Response 8, Project Source Water and Seawater Intrusion, for a discussion of the modeled cone of depression projected to be caused by project pumping, and its relationship to ongoing seawater intrusion.

Coble-3 See Master Response 11, Section 8.2.11.7, for a discussion of the evolving slant well technology.

8.7.8 Responses to Comments from Margaret-Anne Coppernoll

Coppernoll-1 The comments regarding water rights are addressed by Master Response 3, Water Rights. The comments regarding basins are addressed in Master Response 6, Sustainable Groundwater Management Act. The comments regarding the method for calculating return water are addressed in Master Response 4, The Agency Act and Return Water.

Coppernoll-2 Draft EIR/EIS Section 4.4.4.1 describes an extensive subsurface investigation that included drilling exploratory boreholes to identify and correlate the subsurface geologic units, to collect groundwater quality data, and to build clusters of monitoring wells. The details of the subsurface exploration are presented in Appendix C3 and were used to develop a conceptual hydrogeologic model of the project area that ultimately became the North Marina Groundwater Model (NMGWM). In addition, see Appendix E2 where vertical and horizontal parameter zones are described in Section 3.3 and are presented in Figures 3.3a and 3.3b. The NMGWM was used to predict, not assume, the effects on groundwater from proposed project pumping. Clarification on the NMGWM is provided in Master Response 12, The North Marina Groundwater Model (v. 2016). Additionally, Master Response 11, CalAm Test Slant Well, provides a discussion on how the test slant well is not exacerbating seawater intrusion.

As noted in Draft EIR/EIS Section 4.4.1.3 on page 4.4-19, the estimated 555,000 afy of groundwater pumping and evapotranspiration in the Salinas Valley exceeds the 504,000 afy of inflow, resulting in basin overdraft. Draft EIR/EIS Section 4.2.5 at page 4.2-66 explains that as a result of this overdraft, saltwater has replaced the freshwater in those areas, thereby preventing subsidence (Monterey County, 2010). Section 8.2.6.3 of Master Response 6, Sustainable Groundwater Management Act, describes why project pumping would not cause subsidence.

Coppernoll-3 The impact on seawater intrusion is discussed in the Draft EIR/EIS on page 4.4-77, and concludes that "the proposed project would facilitate the reduction of seawater intrusion in the long term, and the impacts of the proposed project are considered less than significant." In addition, Master Response 4, The Agency Act and Return Water discusses how fresh groundwater (the fresh water component of brackish groundwater) pumped by the slant wells, if any, would be returned to the Salinas Valley Groundwater Basin resulting in a net zero impact relative to groundwater pumped from the basin.

Coppernoll-4 See Master Response 3, Water Rights, Master Response 6, Sustainable Groundwater Management Act, and Master Response 4, The Agency Act and Return Water.

Coppernoll-5 The groundwater referred to in this comment originates in a perched groundwater-bearing zone located inland of the proposed slant wells. Groundwater flows to the edge of this zone and "waterfalls" into the underlying Dune Sand or 180-Foot Aquifer formations. The edge of the perched layer occurs 1.5 miles inland from the capture zone of the proposed slant wells. There is no evidence that the groundwater in the perched zone is reversing seawater intrusion or providing "protection" against seawater intrusion. This is evident in the fact that there is documented seawater intrusion further inland, which has been occurring for decades. The projected capture zone for the proposed slant wells is located at the coast and the effects of that capture zone would not encroach on the inland perched groundwater bearing zones. Refer also to Master Response 8, Project Source Water and Seawater Intrusion, Section 8.2.8.4.

Coppernoll-6 See Master Response 2, Source Water Components and Definitions, for clarification of the chemical character of source water components. As listed in Table 4.4-4, while sodium and chloride are major components of ocean water, the chemical character is actually composed of numerous cations (positively charged ions) and anions (negatively charged ions), only some of which are listed in the table. While the chemical character of groundwater located further inland may be mainly calcium chloride and calcium bicarbonate, groundwater in the area around the slant wells has been intruded by seawater for decades and shows a predominant seawater chemistry, as discussed on Draft EIR/EIS pages 4.4-28 through 4.4-31, and shown on Figure 4.4-10. The Total Dissolved Solids (TDS) concentrations, a measure of all of the dissolved ions, including sodium and chloride, are shown on Figure 4.4-3. As shown on Figure 4.4-3, many of the groundwater samples collected from the Dune Sand Aquifer, 180-Foot Equivalent Aquifer, and 400-Foot Aquifer have elevated TDS concentrations clearly strongly influenced by seawater intrusion and the sodium and chloride ions that dominate seawater chemistry.

Coppernoll-7 See Master Response 3, Water Rights, and Master Response 4, The Agency Act and Return Water. In addition, Impacts 4.4-3 and 4.4-4 discuss how the impact on water supply and well users within the affected area would be less than significant. Applicant Proposed Measure 4.4-3 would be implemented by CalAm, but is not necessary to reduce a significant impact to a less-than-significant level.

Coppernoll-8 This comment is mostly about water rights, which are addressed in Master Response 3, Water Rights and Master Response 4, The Agency Act and Return Water. The commenter notes that various actions throughout the Salinas Valley Groundwater Basin have slowed seawater intrusion and that brackish water can be treated and put to beneficial use, both of which are true. See response to comment Coppernoll-5 regarding claims about MCWD's water quality restoration efforts. The example provided in the comment of the observed conditions in CalAm's monitoring well MW-7 is a mischaracterization of the water quality data. Water quality data in monitoring well MW-7 clearly displays chemistry consistent with

seawater intrusion. The deep well in the MW-7 cluster shows total dissolved concentration at 26,700 mg/L, which is indicative of seawater intrusion. The mid-range well in the MW-7 cluster shows a concentration of 3,832 mg/L, which is an elevated TDS concentration indicative of incipient seawater intrusion. See also Master Response 2: Source Water Components and Definitions, and response to comment Biala1-11 in Section 8.7.3.

Coppernoll-9 See Section 8.2.11.5 of Master Response 11, CalAm Test Slant Well for discussion of how the test slant well has not been observed to cause harm to the seawater-intruded Dune Sands Aquifer.

Coppernoll-10 See Master Response 3, Water Rights, specifically Sections 8.2.3.5 and 8.2.3.6. See also Master Response 4, The Agency Act and Return Water, Section 8.2.4.1.

Coppernoll-11 EIR/EIS Section 1.2 explains that the CPUC is the CEQA Lead Agency, and is a constitutionally established state agency charged with regulating investor-owned utilities in the transportation, energy, communications, and water industries. CalAm is a public utility under the CPUC's jurisdiction, and has applied to the CPUC for a Certificate of Public Convenience and Necessity under Public Utilities Code Section 1001 to build, own, and operate all elements of the MPWSP, and also for permission to recover present and future costs for the proposed project by short-term rate increases. As the federal lead agency, MBNMS has joined in the preparation of this EIR/EIS for purposes of NEPA compliance and consideration of authorizations for CalAm's proposed project. The authority for MBNMS actions is outlined in EIR/EIS Section 1.3.2.

In addition, see Master Response 3, Water Rights, Sections 8.2.3.5 and 8.2.3.6, and Master Response 4, The Agency Act and Return Water, Section 8.2.4.1.

Coppernoll-12 As discussed in Impact 4.4-3 and Master Response 4, The Agency Act and Return Water, CalAm would work with MCWRA to expand the existing program to monitor the response of the aquifers in nearby wells to the operation of the slant wells, and to measure the actual percentage of seawater in the source water.

Coppernoll-13 The operation of the Dana Point test well is discussed in Section 8.2.11.7 of Master Response 11, CalAm Test Slant Well.

Coppernoll-14 There is no evidence that the test slant well is experiencing problems with clogged filters. Maintenance procedures for the proposed wells are described in EIR/EIS Section 3.4.1, which notes that if chemical cleaning products are needed for well maintenance, only environmentally inert products would be used. In addition, the test slant well has undergone successful and uneventful routine maintenance cleaning events. See also Master Response 11, CalAm Test Slant Well.

Coppernoll-15 See Master Response 12, The North Marina Groundwater Model (v. 2016), regarding the NMGWM. The test well has been operating since April 2015, and the data collected from the test well has been made publically available. See also Master Response 11, CalAm Test Slant Well.

Coppernoll-16 Lead agency staff has visited the test slant well. Sampling of the test slant well water reveals the salinity of the pumped water has varied over time, ranging from 25,400 mg/L of TDS at start-up in April 2015 (76 percent ocean water salinity) to 31,800 mg/L in November 2016 (95 percent ocean water salinity). This comment is further addressed in Master Response 11, CalAm Test Slant Well.

The Dune Sand Aquifer and the 180-Foot Equivalent Aquifer are both predominantly recharged by the ocean during pumping, and this phenomenon is explained in EIR/EIS Section 4.4.5.2. Stratigraphic data from the boreholes that CalAm drilled were used to develop the conceptual groundwater model, and the data from the monitoring well have been used to calibrate the $NMGWM^{2016}$; the modeling was used to predict the effects of the full scale project as described in EIR/EIS Section 4.4.4.2. See Master Response 12, The North Marina Groundwater Model (v. 2016), Master Response 8, Project Source Water and Seawater Intrusion, and Master Response 9, Electrical Resistivity Tomography (ERT) and Airborne Electromagnetics (AEM).

Coppernoll-17 EIR/EIS Section 4.2.1.2 describes the seismicity and faults in the project area. The Reliz-Rinconada Fault Zone is the nearest known potentially active fault (no known Holocene movement) and is located a little over 1 mile to the south of the slant wells. Impacts from seismicity and faults are analyzed in Impacts 4.2-2, 4.2-3, and 4.2-4.

Coppernoll-18 See Master Response 9 regarding ERT, specifically Section 8.2.9.3.

Coppernoll-19 See Master Response 3, Water Rights, Section 8.2.3.6, and Master Response 4, The Agency Act and Return Water, Section 8.2.4.1.

Coppernoll-20 See Master Response 9, Electrical Resistivity Tomography (ERT) and Airborne Electromagnetics (AEM), specifically Section 8.2.9.3.

Coppernoll-21 See Master Response 3, Water Rights, Sections 8.2.3.5 and 8.2.3.7 and Master Response 4, The Agency Act and Return Water.

Coppernoll-22 Much of this comment is addressed in Master Response 3, Water Rights and Master Response 4, The Agency Act and Return Water. In addition, Impacts 4.4-3 and 4.4-4 explain how the MPWSP would not worsen seawater intrusion and actually would, in fact, incrementally reduce seawater intrusion.

Coppernoll-23 Comments about the concept of “harm” as defined in the State Water Resources Control Board report are addressed in Master Response 3, Water Rights. There is

no requirement under CEQA that the project do "no harm;" rather, that concept is related to the water rights discussion. Nonetheless, the Draft EIR/EIS addressed this concept in Chapter 2 and Section 4.4, Groundwater Resources; see, for example, Impact 4.4-3 and Applicant-Proposed Measure 4.4-3.

Coppernoll-24 Much of this comment is addressed in Master Response 3, Water Rights and Master Response 4, The Agency Act and Return Water. In addition, Impacts 4.4-3 and 4.4-4 explain how the MPWSP would not adversely impact the water supply within the current jurisdiction of the MCWD.

Chapter 4, Environmental Setting (Affected Environment), Impacts, and Mitigation Measures, evaluates the impacts of project construction and operation, including impacts on surface water hydrology and water quality (Section 4.3), groundwater resources (Section 4.4), and public services and utilities (Section 4.13).

Coppernoll-25 The test slant well was pumping 2,100 gallons per minute (about 3 mgd, or annualized to 3,300 afy) in April 2015. In comparison, MCWD pumped 4,200 afy in 2015 (MCWD, 2016). Furthermore, the test slant well has not been pumping fresh water; but rather brackish to saline (water with the TDS of seawater) water ranging from 25,400 mg/L[1] of TDS at start-up (76 percent ocean water salinity) to 31,800 mg/L in November 2016 (95 percent ocean water salinity). Regardless, the CPUC does not manage the operation of the test slant well and is not responsible for determining water rights related to the test slant well, nor application of the reasonable use doctrine to its operation. See Master Response 11, CalAm Test Slant Well, Sections 8.2.11.1 and 8.2.11.4. See also Master Response 3, Water Rights, Section 8.2.3.7.

Coppernoll-26 See Master Response 3, Water Rights and Master Response 4, The Agency Act and Return Water.

Coppernoll-27 The issue of ratepayer liability is outside the scope of CEQA and NEPA requirements; however, as described in Draft EIR/EIS Section 1.5.4.1, the CPUC decision to grant or deny a Certificate of Public Convenience and Necessity for the project (i.e., project approval) would follow a process after certification of the EIR during which the Commission will consider any other issues that have been established in the record of the proceeding, including but not limited to economic issues, social impacts, specific routing and alignments, and the need for the project. Therefore, comments regarding ratepayer liability are relevant to and will be considered as part of that proceeding.

The CPUC has no regulatory authority over MCWD because MCWD is a municipal utility and not investor-owned. Therefore, the MCWD Board of Directors, not the CPUC, establishes what MCWD customers pay for water.

[1] Seawater generally has a TDS of 33,500 mg/L

Coppernoll-28 The Draft EIR/EIS (Impact 4.9-6, page 4.9-31) identifies increased wear-and-tear on designated haul routes used by project construction vehicles as a potentially significant impact. Mitigation Measure 4.9-6 (page 4.9-32) stipulates that prior to commencing project construction, CalAm and the affected jurisdiction(s) shall enter into an agreement to repair roads damaged by project-related construction vehicles. The measure also requires that those roads shall be repaired to a structural condition equal to that which existed prior to construction activities. The EIR/EIS did not quantify the cost of implementing this mitigation measure because such cost analyses are outside the scope of the CEQA and NEPA analysis, and not necessary to identify the significance of the impact or identify appropriate mitigation measures. However, to clarify CalAm's financial responsibility for implementation of Mitigation Measure 4.9-6, the text of this measure is modified to include the following as the last sentence:

> <u>CalAm shall be responsible for paying for all repairs needed to fix the damage caused by project-related construction vehicles.</u>

Coppernoll-29 The response to comment Coppernoll-3 addresses the issue of seawater intrusion. The cumulative impact analysis in the EIR/EIS considers MCWD's reasonably foreseeable projects (see EIR/EIS Section 4.1.7). Regarding water rights, see Master Response 3. See also Master Response 4, The Agency Act and Return Water and response to comment MCWD-Hopkins and MCWD-EKI.

EIR/EIS Table 4.4-10 describes the City of Marina's municipal wells: "Wells 10, 11, and 12 are over 2 miles to the southeast, and are screened in the 900-Foot Aquifer (MCWD, 2005). The Ord Community Wells 29, 30, and 31 are located 5 plus miles to the southeast and are screened in the lower 180-Foot and the 400-Foot Aquifers." See also Master Response 3 regarding water rights and Master Response 4 regarding the Agency Act and return water.

Coppernoll-30 See response to comment Coppernoll-25.

Coppernoll-31 EIR/EIS Section 1.5.4 describes the lead agencies' decision-making processes.

Coppernoll-32 Regarding project feasibility, water rights, and harm, see Master Response 3, Water Rights. As discussed in Section 2.6, the proposed project does not intend to export water from the SVGB. Although the comment does not specify which mitigation measures "to avoid harm" are considered inadequate, the Lead Agencies note that as explained in EIR/EIS Section 2.6 and Master Response 3, in the context of water rights in which this EIR/EIS uses the term "harm," no mitigation for significant impacts under CEQA and NEPA is required, because no significant impacts would occur. Rather, CalAm has proposed Applicant-Proposed Measure 4.4-3, Groundwater Monitoring and Avoidance of Well Damage, to ensure that if the project causes groundwater levels to damage local active wells, those active wells would be repaired or replaced. This measure would be implemented in coordination with the Monterey County Water

Resources Agency (MCWRA), and would be incorporated into the Mitigation Monitoring and Reporting Program (MMRP) that will be adopted by CPUC if the project is approved, providing a monitoring and reporting mechanism to ensure that the measure is implemented as proposed.

Additionally, the proposed project does not include a "21-mile pipeline," but as summarized in Table 3-1 in EIR/EIS Chapter 3, Description of the Proposed Project, includes approximately 21 total miles of pipelines. The potential impacts of these pipelines are analyzed throughout EIR/EIS Chapter 4, and mitigation proposed as appropriate to reduce significant impacts.

Coppernoll-33 See Master Response 3, Water Rights and Master Response 4, The Agency Act and Return Water.

Coppernoll-34 See Master Response 3, Water Rights, Section 8.2.3.6. See also Master Response 4, The Agency Act and Return Water, Sections 8.2.4.2 and 8.2.4.3.

Coppernoll-35 Figure 4.2-3 is a cross-section of the local geology and shows the test slant well penetrating the Dune Sands Aquifer and the 180-Foot Equivalent Aquifer. (Appendix E2 was prepared by HydroFocus and does not include a Geoscience diagram showing the slant wells in the 180-Foot Equivalent Aquifer.)

Section 2.6 explains that the entirety of the geographical area of the Basin that would be affected by the project contains brackish water. Therefore, the slant wells would be extracting brackish water, not fresh water. As the pumping continues, the predominant source of water replacing the extracted water is expected to be from the ocean. Master Response 2, Source Water Components and Definitions, provides further discussion of source water components. See also Master Response 4 regarding return water.

Coppernoll-36 See responses to comments Coppernoll-16 and Coppernoll-25. The water being extracted by the test slant well is not fresh water; it is much closer to ocean water salinity (33,500 mg/l) than to fresh water; see Master Response 11, CalAm Test Slant Well. The definition of the term "brackish water" is defined in Master Response 2. Water rights are discussed in Master Response 3.

Coppernoll-37 The lead agencies acknowledge that CalAm's water supplies have been constrained by legal decisions affecting the Carmel River (see Section 2.2.3) and the Seaside Groundwater Basin (see Section 2.2.4).

Coppernoll-38 See response to comment Coppernoll-27.

Coppernoll-39 See response to comment Coppernoll-27, as well as Sections 1.5.4.2 and 1.5.4.3 for a discussion of other agencies' consideration of the EIR/EIS and proposed project. In addition, Table 3-8 discusses the anticipated permits and approvals that may be required by federal, state, and local agencies.

Coppernoll-40 Section 2.6 discusses water rights, and the sentence on Draft EIR/EIS page 2-30 following the sentence cited in the comment explains that in California, "groundwater . . . is regulated through common law (court cases) rather than through the issuance of permits by government bodies." Section 2.6 concluded on Draft EIR/EIS page 2-39 with the statement that CalAm would likely possess water rights for the project; this conclusion has not been revised in the Final EIR/EIS. See Master Response 3 regarding water rights for additional details.

Section 2.5.4, including Draft EIR/EIS page 2-29 as cited in the comment, describes the assumptions about the allocation of MPWSP water supplies to jurisdictions within the boundaries of the MPWMD; the MPWMD is the jurisdiction to which the quoted sentence refers. MCWD provides water to Central Marina and the Ord Community and does not provide service within the boundaries of the MPWMD. MCWD is a party to the CPUC proceeding but does not have any authority to carry out or approve the MPWSP and therefore, does not meet the CEQA Guidelines Section 21069 definition of a Responsible Agency. The City of Marina is a Responsible Agency as described in Section 1.5.4.3 and their permit authority is described in Table 3-8 (see Draft EIR/EIS page 3-65).

Coppernoll-41 The discussion at the bottom of Draft EIR/EIS page 2-29 explains that one of the key functions of the MPWMD is to allocate water supplies within its boundaries, and Draft EIR/EIS page 2-30 concludes with the assumption that water provided by the proposed project would be allocated by the MPWMD (not by the CPUC). Because the MPWMD has not yet determined the allocation of supply that would be provided by the project, the discussion in Section 2.5.4 simply discloses the assumptions, for the purpose of the EIR/EIS analysis, of how the water would generally be distributed. The discussion in Section 2.5.4 does not contradict the discussion of water rights presented in Section 2.6, Water Rights. As stated there (on Draft EIR/EIS page 2-30), the issue of water rights is addressed in the EIR/EIS as one of project feasibility. Assuming the project is feasible and approved, it would provide water supply to the CalAm service area. See also response to comments MPWMD-21 and Coppernoll-40.

Coppernoll-42 The impacts of the proposed pipelines are discussed in every topical section of Chapter 4. The impacts on the SVGB are described in Section 4.4.5.

Coppernoll-43 See response to comment Coppernoll-5. The "Perched Dune Sand Aquifer" referred to in this comment has not been affected by CalAm pumping at the test slant well.

Coppernoll-44 See Master Response 11, CalAm Test Slant Well, Sections 8.2.11.5 and 8.2.11.8.

Coppernoll-45 See Appendix E-1, which reports on the peer review of the North Marina Groundwater Model ($NMGWM^{2016}$) by Lawrence Berkeley National Laboratory

(LBNL) and Master Response 12, which responds to comments on the construction, assumptions and operation of the NMGWM[2016]. See also response to comment Coppernoll-43.

Coppernoll-46 The groundwater modeling used in the Draft EIR/EIS was conducted by HydroFocus, not by Geoscience; see Master Response 12 regarding the NMGWM[2016]. Also see Master Response 5, The Role of the Hydrogeologic Working Group and its Relationship to the EIR/EIS, Section 8.2.5.5 for a discussion of the alleged conflict of interest.

Coppernoll-47 See response to comments Coppernoll-29 and Coppernoll-43. Project objectives are presented in EIR/EIS Section 1.3.1. The local and regional hydrogeology is presented in Section 4.4.1.2; the Dunes Sands Aquifer is described on page 4.4-6 and the 180-Foot Aquifer is described on page 4.4-8. The 180-Foot and 400-Foot aquifers referred to in the comment are not equivalent to the Dune Sands Aquifer; regardless, the EIR/EIS did not rely on the quoted statement or other statements from CalAm to determine potential groundwater impacts. See Master Response 9 for a discussion of the relevance of ERT data.

Coppernoll-48 See Master Response 9, which discusses how the ERT survey results are consistent with the characterization of the Basin in Section 4.4. As the property owner, CEMEX refused to grant access for the ERT study; neither CalAm nor the CPUC had authority to grant access.

Coppernoll-49 See response to comment Coppernoll-47 and Section 8.2.8.1 of Master Response 8, Project Source Water and Seawater Intrusion.

Coppernoll-50 The CPUC decision-making process is described in EIR/EIS Section 1.5.4.1. All input will be considered by the lead agencies.

Coppernoll-51 Seismic activity is addressed in Section 4.2.5; specifically, in Impacts 4.2-2, 4.2-3, and 4.2-4. See also response to comment Coppernoll-17.

Coppernoll-52 See Master Response 9, Electrical Resistivity Tomography (ERT) and Airborne Electromagnetics (AEM), which discusses how the ERT survey results are consistent with the characterization of the SVGB in Section 4.4.

Coppernoll-53 See response to comment Coppernoll-29.

Coppernoll-54 See response to comment Coppernoll-40. The comment does not specify what "significant irreparable harm to marine vegetation and ecosystems" lacks mitigation; see Sections 4.5.5 and 4.6.5 for a discussion of direct and indirect impacts on marine biological resources and terrestrial biological resources, respectively.

Coppernoll-55 Appeals may be filed with the California Coastal Commission (CCC), pursuant to Coastal Act Section 30603(a)(5), for any development that constitutes a major public works facility.

Coppernoll-56 See response to comment Coppernoll-28 regarding the discussion of increased wear-and-tear and subsequent repair of the designated haul routes used by project-related construction vehicles. The project's temporary effects on recreational trail usage (during periods of pipeline installation within or adjacent to the Monterey Peninsula Recreational Trail, not for the duration of the project construction) are discussed under Impact 4.9-5 in Section 4.9. Of note, as part of the Traffic Control and Safety Assurance Plan (Mitigation Measure 4.9-1), CalAm and its contractors would be required to schedule construction activities to minimize impacts during heavy recreational use periods (e.g., weekends and holidays). The project's effects caused by temporary displacement of parking spaces are discussed under Impact 4.9-7. As described, roadways that could be affected by project construction have less-than-substantial demand for the available on-street parking spaces, and/or alternative parking spaces are present nearby, and the impacts associated with temporary displacement of on-street parking would be less than significant. Of note, Mitigation Measure 4.9-7, which applies to staging areas in publicly-used parking lots, would require that the construction contractors coordinate with the affected entities to design the staging areas to avoid or minimize parking impacts in those lots.

Coppernoll-57 See response to comment Coppernoll-27.

Coppernoll-58 As stated on page 4.9-24 of the Draft EIR/EIS, the Traffic Control and Safety Assurance Plan (Plan) shall be developed on the basis of detailed design plans for the approved project. Such detailed plans are not yet available, and consideration of approval of the Draft EIR/EIS is not dependent on a detailed Plan. The Draft EIR/EIS presents the required major elements of and performance standards to be included in the Plan, but clearly states that the Plan shall not necessarily be limited to the elements listed on page 4.9-24 to 4.9-26. This is standard practice for EIRs/EISs.

The comment quotes two statements from the Draft EIR/EIS, but presents them in reverse order from how they appear within the cited paragraph on Draft EIR/EIS page 4.9-21. The reference to potentially substantial adverse effects on local and residential streets is followed by, not preceded by (as implied by the comment), the statement that implementation of Mitigation measure 4.9-1 would reduce that same impact to a less-than-significant level.

Coppernoll-59 The trip distribution (origins and destinations) of project-generated construction traffic is addressed as part of the discussion of "Combined Construction-Related Traffic Increases" in different areas within the project area (i.e., North Marina Area [Draft EIR/EIS page 4.9-19], Marina/Seaside Area [Draft EIR/EIS

page 4.9-21], and Monterey Area [Draft EIR/EIS page 4.9-22]). As stated at the start of each area's discussion, the estimated number of project trips on the area's access roads was based on assumptions developed by a professional traffic engineer regarding the origins and destinations of those trips. By way of example, project construction-related trips to and from the North Marina Area are reasonably expected to be split as follows: about 50 percent on Highway 1 north of Reservation Road (trip origins/destinations in the Highway 1 and Highway 101 corridors; about 25 percent on Highway 1 south of Reservation Road (trip origins/destinations in the Highway 1 corridor; and 25 percent on Reservation Road (trip origins/destinations in the Highway 1 corridor southeast of the project area).

Coppernoll-60 See response to comment Coppernoll-59 regarding project trip distribution. Project trips would disperse among an increasingly wide network of roads as one gets farther away from the project area, decreasing the number and effects of added traffic on roads removed from the corridors near-in to the project construction sites. For example, trips from Salinas to the various construction sites could travel on (could be dispersed among) Highway 183, Blanco Road, Nashua Road, Davis Road, or Highway 68.

See response to comment Coppernoll-58 regarding the timing of development of the required Traffic Control and Safety Assurance Plan.

The Draft EIR/EIS analysis of impacts from project construction trips (trucks and workers) on area roadways was conducted using an approach and methodology consistent with standard practice for such analyses. The basis for the commenter's estimate of truck and worker trips per month is unknown, but trips per month is not a measure germane to traffic analyses. Traffic operating conditions are judged on a daily and hourly basis, with conditions during the peak morning and evening commute hours having the greatest potential for significant impacts. It is this latter point that typically leads (and in this case, does lead) to the need for a mitigation measure (see the 4th bullet of Mitigation Measure 4.9-1, page 4.9-24 of the Draft EIR/EIS) to "schedule truck trips outside of peak morning and evening commute hours to minimize adverse impacts on traffic flow (i.e., if agencies with jurisdiction over the affected roads identify highly congested roadway segments during their review of the encroachment permit applications)."

See response to comment Coppernoll-28 regarding increased wear-and-tear on and subsequent repair of the designated haul routes used by project-related construction vehicles.

The statement about the project's use of Charles Benson Road cited by the commenter pertains to vehicle trips associated with operations of the MPWSP Desalination Plant. The Plant-generated vehicle trips on any other roads would be lower than that on Charles Benson Road (i.e., immediately reduced by a split

between Del Monte Boulevard either north or south of Charles Benson Road, and then further reduced as trips disperse onto different roads farther removed).

Regarding cumulative impacts during project construction (Draft EIR/EIS pages 4.9-36 to 4.9-38), the cumulative analysis discusses Mitigation Measures 4.9-1, 4.9-6, and 4.9-7, each of which would lessen the project contribution to cumulative construction-related traffic and transportation impacts. On top of that, the EIR/EIS identifies Mitigation Measure 4.9-C (Construction Traffic Coordination Plan), which is designed to further reduce the project's incremental contribution to the potential cumulative impact. The significant and unavoidable cumulative impact determination is based on the fact that there is no guarantee that local agencies would participate in the coordination efforts.

Regarding impacts on public transportation during project construction, there are no full road closures anticipated, so while individual bus stops could need to be temporarily relocated, relocation of bus routes would not be needed. The last bullet of Mitigation Measure 4.9-1 (page 4.9-26) is revised as follows:

- Coordinate with Monterey-Salinas Transit so the transit provider can temporarily relocate ~~bus routes or~~ bus stops in work zones as deemed necessary.

Coppernoll-61 See responses to comment Coppernoll-27 and -28.

Coppernoll-62 Dennis Williams is not under contract to the CEQA/NEPA Team and did not participate in the preparation of the Draft EIR/EIS; see Section 8.2.5.5 of Master Response 5, The Role of the Hydrogeologic Working Group and its Relationship to the EIR/EIS, for a detailed discussion of the alleged conflict of interest. Potential impacts on water supply are analyzed in Section 4.4, Groundwater Resources. See also Section 8.5.1 for comments from and responses to the City of Marina.

Coppernoll-63 The operational impacts of the proposed project on groundwater resources are addressed in Section 4.4.5.2 and do not extend to Salinas. See Figure 4.4.13.

Coppernoll-64 Potential impacts on the SVGB are addressed in Section 4.4.5, and environmental justice is addressed in Section 4.20. Legal constraints on CalAm's water supplies are acknowledged in Sections 2.2.3 and 2.2.4.

Coppernoll-65 See response to comment Coppernoll-25. Regarding the source water components and location, see Master Response 2. See also Master Response 8, Project Source Water and Seawater Intrusion.

Coppernoll-66 See Master Response 3 regarding water rights and Master Response 8 regarding source water and seawater intrusion. The Lead Agencies have no jurisdiction over SWRCB actions.

Coppernoll-67 See Master Response 1, EIR/EIS Authorship, regarding EIR/EIS authorship. The project objectives are presented in Section 1.3.1. The water produced by the MPWSP and delivered to CalAm customers would be "developed water" (see Draft EIR/EIS page 2-32).

Coppernoll-68 See Master Response 3, Water Rights, master Response 8, Project Source Water and Seawater Intrusion, and Master Response 11, CalAm Test Slant Well.

Coppernoll-69 See response to comment Coppernoll-27.

Coppernoll-70 The ASR component of the proposed project would create more storage capacity; therefore, this suggestion already is proposed. It is not clear from the comment how removing debris from the Carmel River would provide additional supply, nor would such an action respond to the SWRCB orders to reduce diversions from the Carmel River. The farm runoff that is available for capture and reuse is one of the sources of water for advanced treatment by Pure Water Monterey GWR, a project considered in the cumulative scenario that is part of the basis for considering a reduced-size desalination plant under Alternatives 5a and 5b; thus, this potential source of water already is accounted for in alternatives to the proposed project. However, the GWR project would provide 3,500 afy as described in EIR/EIS Table 5.4-1 and in Section 5.4.7.1, not 6,500 afy.

Coppernoll-71 Impacts on MCWD wells are discussed in response to comment Coppernoll-29.

Coppernoll-72 See Master Response 1, EIR/EIS Authorship, regarding EIR/EIS authorship, Master Response 2 regarding source water definitions, and Master Response 3 regarding water rights. The other desalination projects being proposed in the Moss Landing area are described in Sections 5.4.3 (DeepWater Desal) and 5.4.4 (People's Project) and they are evaluated as alternatives to the MPWSP in Section 5.5. See also Master Response 15, Alternative Desalination Projects – Status, Information Sources, and Cumulative Scenario, for a discussion on the status of the Moss Landing desalination proposals.

Coppernoll-73 Regarding harm to existing water users, see Section 8.2.3.5 of Master Response 3.

Coppernoll-74 See Master Response 15, Alternative Desalination Projects – Status, Information Sources, and Cumulative Scenario, for a discussion of the status of the Moss Landing desalination proposals. As noted in response to comment Coppernoll-72, several Moss Landing alternatives were analyzed in the EIR/EIS in Chapter 5. No reference is provided for the CCC statement described in the comment.

Coppernoll-75 As described in Section 1.4.3, the MPWSP Draft EIR was issued in April 2015 for a 60-day review period that was extended until September 30, 2015. Following that 5-month review period, the CPUC announced that the April 2015 Draft EIR would be modified and recirculated as a joint EIR/EIS in coordination

with MBNMS. CEQA Guidelines Section 15105 states, "the public review period for a draft EIR shall not be less than 30 days nor should it be longer than 60 days except under unusual circumstances." The Draft EIR/EIS was released on January 13, 2017, for a 45-day review period that was then extended by 30 days, for a total review period of 75 days. CEQA Guidelines Section 15088.5, which provides guidance on circumstances requiring recirculation of a Draft EIR, does not include the length of the public review period as a potential reason for recirculation.

Marina Coast Water District (MCWD), 2016. Draft 2015 Urban Water Management Plan, May. [http://www.mcwd.org/docs/agenda_minutes/2016-06-06_board/Item%2011-A%20-%20MCWD%20Draft%202015%20UWMP%20v20160520.pdf]

8.7.9 Responses to Comments from Herbert Cortez

Cortez-1 The comment on CPUC Resolution ALJ-252, Rules for Public Comments at Commission Meetings, was submitted at the MPWSP Public Hearing on Thursday, February 16, 2017, in Carmel, CA. The public hearing was announced in the January 13, 2017 Notice of Availability of the MPWSP Draft EIR/EIS as a chance to interact with technical staff and preparers of the Draft EIR/EIS, and as an opportunity for the public to provide oral and/or written comments. The Public Hearing on the Draft EIR/EIS was not a CPUC Commission Meeting; therefore, rules described in CPUC Resolution ALJ-252 did not apply to the Public Hearing.

8.7.10 Responses to Comments from Bruce Delgado

8.7.10.1 Responses to Comments from Bruce Delgado – Letter 1

Delgado1-1 As explained in EIR/EIS Table 4.4-10, the CEMEX South Well is located about 1,600 feet southeast of the insertion point of the proposed slant wells. The well screen is set between 400 and 506 feet below ground surface and is separated from the intake portion of the slant wells by the 180/400-Foot Aquitard. The CEMEX North Well collapsed and is unusable. The monitoring well clusters installed by CalAm have known depths and provide more accurate data.

Delgado1-2 See response to comment Marina-135 in Section 8.5.1, which addresses comments regarding the cumulative analysis and analysis of environmental justice effects of air quality impacts in Section 4.20, Socioeconomics and Environmental Justice. Further, as described in Impacts 4.10-3 and 4.10-5, project construction and operation would not create objectionable odors that would affect a substantial number of people, and cumulative impacts related to odors are addressed in Impact 4.10-C. Because no odor-related impacts affecting people are anticipated, they are not discussed further in the environmental justice analysis in Section 4.20.

Delgado1-3 The last row in EIR/EIS Table 4.20-6 displays the Monterey Bay Unified Air Pollution Control District (MBUAPCD) Significance Thresholds for ROG, NO_x, CO, PM_{10} and $PM_{2.5}$. See also Section 4.10.5.1, which discusses construction-related air quality impacts; specifically, see Table 4.10-5 and Table 4.10-6. See also Section 4.10.5.2 (Operational and Facility Siting Impacts); specifically see Table 4.10-7.

8.7.10.2 Responses to Comments from Bruce Delgado – Letter 2

Delgado2-1 Master Response 5, The Role of the Hydrogeologic Working Group and its Relationship to the EIR/EIS, addresses this comment. Sections 8.2.5.1 through 8.2.5.3 describe the establishment of the Hydrogeologic Working Group (HWG) and its membership as defined by a 2013 settlement agreement. Section 8.2.5.5 describes the relationship of the HWG to this EIR/EIS. Section 8.2.5.6 describes the potential conflicts of interest raised in comments. Regarding authorship of this EIR/EIS, see also Master Response 1.

8.7.11 Responses to Comments from Myrleen Fisher

Fisher-1 See Master Response 11, CalAm Test Slant Well, regarding the test slant well and the feasibility of slant well technology, and Master Response 3 regarding water rights. See also Master Response 2, Source Water Components and Definitions, for a discussion of the location and composition of the source water.

Fisher-2 The calculation of the infiltration rate at the seafloor in the EIR/EIS was performed by the EIR/EIS consultants for this project, at this location, and was compared to conditions at Doheny State Beach. EIR/EIS Section 4.5.5.2 presents the independent calculation of the infiltration rate at the seafloor at CEMEX that was then compared to, but not derived from, the work by Dr. Williams at Dana Point. See Master Response 11 regarding the test slant well, which has provided the site-specific data requested in the comment. The issue of slant well feasibility is addressed in response to comment PWN2-8 in Section 8.6.17.

Fisher-3 See Master Response 15, Alternative Desalination Projects – Status, Information Sources, and Cumulative Scenarios, Section 8.2.15.2, regarding the status of and information about the People's Project (Alternative 4) with respect to solar energy. Responses to comments from Nancy Selfridge are provided in Final EIR/EIS Section 8.7.22.

Fisher-4 The information provided by the People's Project applicant showed the alignments of the intake and discharge pipelines that were presented in Chapter 5, Alternatives Screening and Analysis. The description of Alternative 4 (People's Project) in EIR/EIS Section 5.4.6.1 specifically identifies the existing caisson for the proposed open water intake system, and the existing 51-inch-diamter concrete pipe that originates at the Moss Landing Green Commercial Park and crosses under the marina and marina parking lot island, under the commercial harbor and under the island, that extends 800 feet from shore. As described in Section 5.4.6.1, both the intake and discharge pipelines would need to be extended offshore. Section 5.5.5 provides detailed descriptions and analysis of impacts of all alternatives; Section 5.5.5.6 addresses the DeepWater Desal Project and Section 5.5.5.7 addresses the People's Project. As explained in EIR/EIS Section 5.5.5.7, the new offshore intake and discharge pipelines proposed as part of the People's Project would be laid on the seafloor with concrete collars and protected with approximately 100,000 cubic yards of riprap armoring, and this construction effort would still result in the need for permits. EIR/EIS Table 5.6-1 presents the impact conclusion against baseline/existing conditions for each impact statement, for every topical area evaluated, for the proposed project and for all alternatives, and further provides a relative impact severity for each alternative (increased, decreased or same) compared to the proposed project. Regarding the suggestion of the "greater feasibility of the People's Project," analysis of alternatives under CEQA and NEPA compares the environmental impacts of *feasible alternatives*. The EIR/EIS does not attempt to characterize the relative

feasibility of alternatives because the proposed project and all alternatives (1 through 5a/5b) are considered feasible as described in Chapter 5.

Fisher-5 The executive summary text on Draft EIR/EIS Page ES-11 that discusses impacts resulting from open water Alternatives 2, 3 and 4, is a summary of the detailed analysis that is presented in EIR/EIS Sections 5.5.5.5, 5.5.5.6, and 5.5.5.7, respectively. The conclusion of a significant and unavoidable impact on marine organisms resulting from the screened open water intakes considered under Alternatives 2, 3, and 4 is not based on the impingement of adult fish. As indicated for Alternative 2 in Section 5.5.5.5 (see Draft EIR/EIS page 5.5-117), "Direct impingement of larger fish and invertebrate organisms is not expected due to the wedgewire screens and the low flow rate." For Alternative 2, the significant and unavoidable impact conclusion for marine biological resources is based on the uncertainty of the efficacy of proposed mitigation to reduce entrainment of plankton, larval invertebrates, and larval fish. As shown in Table 4.5-8, the swimming speeds of plankton, invertebrates, and larval fish evaluated range from 0.2 millimeters per second (mm/sec) to 600 mm/sec. An open ocean intake that would draw water in at a rate of 0.5 ft/sec (152.4 mm/sec) or even the 0.3 ft/sec (91.4 mm/sec) suggested in the comment would have the potential to entrain most of the plankton and invertebrates listed in Table 4.5-8. Such an entrainment effect is the basis for the calculation of Area of Production Foregone in Section 5.5.5.5. Note that in Mitigation Measure ALT-2-Marine-2, item 1 requires that *in addition to* the required operational standard of limiting through-screen velocity at the intake to not exceed 0.5 ft/sec, CalAm would be required to implement the best available technology feasible to minimize intake and mortality of all forms of marine life in the context of design and operation of an open ocean intake. Thus, if Alternative 2 were implemented and CalAm could feasibly install intakes with through-screen velocity of 0.3 ft/sec, the mitigation measure would require them to do so; however, the significance conclusion would not change.

Similarly, the analyses for Alternatives 3 and 4 (Sections 5.5.5.6 and 5.5.5.7, respectively) conclude that impacts may remain significant and unavoidable for the same reasons specified for Alternative 2, and would result in greater Areas of Production Foregone than Alternative 2 as a result of their greater proposed intake volumes. However, the impact conclusion was not determined based on the order of magnitude of the impact; it was based on the fact that "residual impacts may remain due to the uncertainty of the efficacy of the mitigation."

Fisher-6 The comment appears to refer to the April 2015 Draft EIR, in which the quoted statement appears on page 7-13 (page 1466 of the CD version of the Draft EIR). The quoted statement does not appear in the January 2017 Draft EIR/EIS. The People's Project was described and analyzed in detail as Alternative 4 in Chapter 5, Alternatives Screening and Analysis.

Fisher-7 See response to comment Fisher-6 and Master Response 15 regarding the status of the People's Project and MPWSP Lead Agency efforts to obtain information about that project from the applicant.

Fisher-8 The comment appears to refer to the April 2015 Draft EIR, in which the quoted statement appears on page ES-79 (page 101 of the CD version of the Draft EIR). The quoted statement does not appear in the January 2017 Draft EIR/EIS. Any proposal made by the People's Project applicant to use solar power would not affect the significance conclusions relevant to the proposed MPWSP. See Master Response 15, Section 8.2.15.2, regarding the potential for the People's Project to use solar power. Further, see response to comment USEPA-4, in Section 8.3.5, for revised Mitigation Measure 4.11-1, regarding the proposed project's greenhouse gas emissions; based on revisions to this measure, the proposed project's greenhouse gas impacts have been reduced to less than significant with mitigation in Final EIR/EIS Section 4.11.

Fisher-9 See response to comment Selfridge1-2, in Section 8.7.22, which describes the EIR/EIS text revision made at the specified location in the alternatives analysis.

Fisher-10 See responses to comments Fisher-5, Fisher-6, Fisher-7, Fisher-8, and Fisher-9. The People's Project was described and analyzed in detail as Alternative 4 in EIR/EIS Chapter 5, Alternatives Screening and Analysis. The Final EIR/EIS has not been altered in such a way as to identify new or substantially more severe significant environmental impacts compared to the Draft EIR/EIS, nor has the Final EIR/EIS identified new, feasible mitigation measures or project alternatives to reduce significant impacts that the project proponent refuses to incorporate into the project. The comments on the Draft EIR/EIS have not raised issues or presented data so as to cause the Lead Agencies to conclude that the Draft EIR/EIS was fundamentally flawed. For these reasons, the EIR/EIS need not be recirculated for further public review.

8.7.12 Responses to Comments from David Gorman

Gorman-1 Lead agencies consider all comments on the Draft EIR/EIS when making decisions about the proposed project. See Master Response 8, Source Water and Seawater Intrusion, Section 8.2.8.1, which explains that the MPWSP would extract seawater and brackish water from a coastal capture zone, the effects of which would not negatively impact the water quality (including salinity) of the inland portions of the 180-Foot Aquifer. See also Master Response 9, Electrical Resistivity Tomography (ERT) and Airborne Electromagnetics (AEM), for a discussion of the use of ERT in the analysis of groundwater quality and seawater intrusion impacts in the EIR/EIS.

Gorman-2 See Master Response 3, Water Rights.

Gorman-3 Refer to Section 1.1, Introduction, which explains that, as required by CEQA and NEPA, the EIR/EIS analyzes and discloses potentially significant environmental consequences of the proposed project, pursuant to CEQA and NEPA. With regards to water rights, see Master Response 3.

8.7.13 Responses to Comments from Jane Haines

Haines-1 Master Response 11, CalAm Test Slant Well, explains that the test slant well was installed and operated in order to test the feasibility of slant well technology at the CEMEX site, and describes the results of that testing. See also Master Response 9, Electrical Resistivity Tomography (ERT) and Airborne Electromagnetics (AEM).

Haines-2 See Master Response 3, Water Rights.

Haines-3 See Master Response 11, Section 8.2.11.8 regarding the Dana Point test slant well. The information in the OC Register article cited in the comment is not relevant to this project or EIR/EIS. See EIR/EIS Section 4.20, Socioeconomics and Environmental Justice, which addresses the potential impacts of rate increases on low-income ratepayers and low-income ratepayer assistance programs (Draft EIR/EIS pages 4.20-17 and 4.20-18).

8.7.14 Responses to Comments from Clifton Herrmann

Herrmann-1 As described in Section 2.2, Background, State Water Resources Control Board (SWRCB) Order 95-10 directed CalAm to implement conservation measures to offset 20 percent of demand while it pursued an alternative water supply, and Order 2009-0060 directed CalAm to reduce diversions from the Carmel River by an additional 5 percent, starting in October 2009, with additional annual reductions starting in October 2011. Table K-1 in Appendix K summarizes key CalAm and Monterey Peninsula Water Management District (MPWMD) conservation programs and estimated water savings for those that are quantifiable, for years 2010 through 2015. As stated on page K-4, these programs have contributed to the Monterey Peninsula having among the lowest residential per capita water use rates in the state. The potential reductions in demand from continued implementation of these programs is described in EIR/EIS Section 5.4.2.3. The only identified additional feasible conservation measures are those included in the MPWMD's 2016 Monterey Peninsula Water Conservation and Rationing Plan, which as explained in Section 5.4.2.3 would be triggered by severely supply-constrained conditions that could occur as a result of the No Project Alternative, and are not considered to be reasonable or feasible elective conservation measures.

Herrmann-2 San Clemente Dam, from its construction in 1921 to its deconstruction in 2015, is described in EIR/EIS Section 2.2.2.1. The issue of ratepayer liability is outside the scope of CEQA and NEPA requirements; however, as described in EIR/EIS Section 1.5.4.1, the CPUC decision to grant or deny a Certificate of Public Convenience and Necessity for the project (i.e., project approval) would follow a process after certification of the EIR during which the Commission will consider any other issues that have been established in the record of the proceeding, including but not limited to economic issues, social impacts, specific routing and alignments, and the need for the project. Therefore, comments regarding ratepayer liability are relevant to and will be considered as part of that proceeding.

Herrmann-3 Power demands of the proposed project are described in EIR/EIS Section 3.4.5 and impacts of the proposed project related to energy use and conservation are presented in Section 4.18. The electrical power facilities required for the proposed project are described in EIR/EIS Section 3.2.5 and evaluated by resource area in Chapter 4. As described on Draft EIR/EIS page 4.18-17, PG&E has indicated that it has adequate capacity and infrastructure to support the proposed project; therefore, no expansion of energy infrastructure would be necessary, other than that described in Section 3.2.5 for the proposed project.

Herrmann-4 EIR/EIS Section 4.11 specifically addresses issues related to greenhouse gas (GHG) emissions (including carbon dioxide) resulting from implementation of the proposed project. The section presents an overview of climate change, describes the various GHGs that have been identified as a source of climate change, and

analyzes the potential GHG impacts associated with implementation of the proposed project.

Herrmann-5 The SWRCB Division of Drinking Water regulates public water systems and requires permits for water treatment facilities to ensure public health and safety. CalAm must secure a Permit to Operate a Public Water System, consistent with California Public Health and Safety Code Section 116525, before operating the project (see Draft EIR/EIS Table 3-8). The California Public Health and Safety Code regulates contaminants in drinking water, and does not require the presence of minerals or other materials in drinking water (such as those that reverse osmosis treatment may remove). Furthermore, as shown in Table 2-4 in Section 2.4, desalinated water from the MPWSP would make up only 44 to 66 percent of total supply in CalAm's Monterey District.

Herrmann-6 In preparing the Draft EIR/EIS, the brine plume was modeled under various flow scenarios which are described in Draft EIR/EIS Section 4.3.5.2 (Table 4.3-10) for the proposed project, and in Section 5.5.3 for the alternatives; see also Appendix D1. As explained therein, dilution model results indicate the brine discharge would meet the Ocean Plan objective of less than 2 parts per thousand above ambient salinity at the point of regulation. How the plume would move across the seafloor is described on Draft EIR/EIS page 4.3-82. The plume would not run down the canyon as a dense stream.

Herrmann-7 EIR/EIS Section 4.2 addresses potential impacts of the proposed project on geology, soils, and seismicity and considers whether or not the brine discharge would cause erosion on the seafloor. Table 4.2-8 on Draft EIR/EIS page 4.2-71 compares ambient ocean currents at depth with the estimated current velocities of the jet plume, and concludes the impact would be less than significant.

Herrmann-8 The comment has been noted and the Lead Agencies will consider all comments in their decisions on the project. The need for the project is presented in Draft EIR/EIS Section 1.3.

8.7.15 Responses to Comments from Juli Hofmann

Hofmann-1 See Master Response 3, Water Rights, Section 8.2.3.2.

Hofmann-2 See Master Response 3, Water Rights, Sections 8.2.3.5 and 8.2.3.7.

Hofmann-3 The discussion in the EIR/EIS on water rights (Section 2.6) relies upon the July 2013 SWRCB Final Report (EIR/EIS Appendix B2) concerning the facts that could establish CalAm's water rights for the project and that Report uses the words noted in the comment. See also Master Response 3, Water Rights, Sections 8.2.3.3 and 8.2.3.5.

Hofmann-4 See Master Response 3, Water Rights, Sections 8.2.3.5 through 8.2.3.7.

Hofmann-5 The text cited in the comment is from the EIR/EIS Executive Summary, Section ES.7.1, Key Differences Between Alternatives. EIR/EIS Executive Summary Section ES.5.2 presents a summary of potential impacts and mitigation measures for the proposed project and explains that, "significant impacts may occur relative to: geology and soils; surface water hydrology and water quality; groundwater resources . . . [a]ll impacts would be reduced to less than-significant levels. . .". See also EIR/EIS Table ES-1.

EIR/EIS Section 4.4.5 addresses the direct and indirect effects of the proposed project on groundwater resources; see Table 4.4-9. Section 4.4.5.1 presents the construction-related impacts and Section 4.4.5.2 presents the operational-related impacts. Alternatives 2, 3, and 4 would use screened open water intakes and the impacts of these alternatives on groundwater resources and marine biological resources, and a comparison to the proposed project's impacts on the same resources, are addressed in EIR/EIS Section 5.5.

Hofmann-6 EIR/EIS Section 4.4, Groundwater Resources, presents a complete description of the background, current baseline conditions, groundwater modeling, and the analysis of proposed project impacts on groundwater levels and quality, including impacts on the Dune Sand, 180-Foot, 400-Foot and Deep aquifers; see EIR/EIS Figures 4.4-14, 4.4-15 and 4.4-16, and response to comment Hofmann-5. As stated therein, the proposed project would have less-than-significant impacts on groundwater levels and quality. See also Appendix E2 for the groundwater modeling analysis.

Hofmann-7 See response to comment Hofmann-6. The significant and unavoidable impacts on terrestrial or marine biological resources that the comment refers to would occur only under Alternatives 1 and 5b, which would locate the slant wells at Potrero Road. There would be no such significant and unavoidable impact on terrestrial or marine biological resources resulting from lowering of groundwater levels under the proposed project (or Alternative 5a), which would locate the slant wells at the

CEMEX site and would not affect Elkhorn Slough (but would affect flows in the Salinas River and Tembladero Slough, that would have a less than significant impact on steelhead; see EIR/EIS Section 4.6.5.2, Impact 4.6-6). There would be no significant and unavoidable impacts of the proposed project (or Alternative 5a) related to a changes in groundwater levels, but there would be a significant and unavoidable impact at CEMEX related to compliance with the City of Marina's Local Coastal Land Use Plan; see EIR/EIS Table 4.6-5, Impact 4.6-4.

EIR/EIS Section 5.5.4 presents a description of the groundwater basin conditions for each alternative and the analyses of alternatives' impacts on groundwater resources. The effects are different in the two proposed locations because the stratigraphy is different. As explained in EIR/EIS Section 5.5.4.1, and as shown in Figure 4.4-2, the Dune Sands Aquifer transitions into a similar shallow aquifer underlying the Moss Landing Area to the north, referred to as the Perched-A Aquifer. The Perched-A Aquifer differs from the Dune Sand Aquifer in that it is underlain by a defined layer of less permeable, fine-grained sediments (clay) known as the Salinas Valley Aquitard. The Salinas Valley Aquitard is not present at the CEMEX site.

Hofmann-8 See Master Response 4, Agency Act and Return Water, Sections 8.2.4.2 and 8.2.4.3.

Hofmann-9 See Master Response 4, Agency Act and Return Water, Sections 8.2.4.2 and 8.2.4.3 for information on ocean water percentage of feedwater and Master Response 12, The North Marina Groundwater Model (v. 2016) for information regarding the reliability and use of the $NMGWM^{2016}$. A range of return water scenarios from 0 to 12 percent was tested in the groundwater modeling as explained in EIR/EIS Section 4.4.4.2.

Hofmann-10 See Master Response 11, CalAm's Test Slant Well, Section 8.2.11.2 for a discussion of the CEQA and NEPA reviews completed for the test slant well. Master Response 11, Section 8.2.11.7 discusses the conversion of the test slant well to a permanent well. In order for the test slant well to operate past its original agreed upon timeline, CalAm would need to apply to the Coastal Commission for an extension of the Coastal Development Permit. There is no violation of CEQA or NEPA since the review of the proposed conversion is addressed throughout this EIR/EIS; see EIR/EIS Section 3.2.1.1.

Hofmann-11 The data are not missing; the Salinas Valley Aquitard (SVA) is not present at the CEMEX site. As explained in EIR/EIS Section 4.4.1.2, the SVA is a blue or yellow sandy clay formation up to 100 to 150 feet thick that lies mostly north of and generally parallel to the northwest-flowing Salinas River. The SVA thins and becomes discontinuous away from the centerline and at the Pacific Ocean, and was not observed in the exploratory borings at the CEMEX site.

Lawrence Berkeley National Laboratories (LBNL) performed a peer review of the version of the North Marina Groundwater Model (NMGWM) that was utilized for the April 2015 Draft EIR; that model is referred to as $NMGWM^{2015}$. LBNL noted in EIR/EIS Appendix E1, "the absence of the Fort Ord-Salinas Valley Aquitard (FO-SVA), which hydraulically separates the Dune Sand and 180-foot equivalent (180-FTE) aquifers from greater than about 2 km east of the proposed extraction site." As explained in EIR/EIS Appendix E2, Section 3, Table 3.1, HydroFocus added the FO-SVA and transition zone to the NMGWM, and adjusted the horizontal and vertical conductivity values based on reported aquifer tests and modeling studies to improve comparisons between measured and model-calculated water levels. The modeling conducted for this EIR/EIS included all the revisions recommended by LBNL and that model is referred to as $NMGWM^{2016}$. See EIR/EIS Appendix E2, and Master Response 12, The North Marina Groundwater Model (v. 2016).

Hofmann-12 The discussion of baseline conditions in EIR/EIS Section 4.1.3 acknowledges that since the CPUC issued its NOP in 2012, the Lead Agencies have developed or received new data on some of the resource areas, so the baseline data have been updated as appropriate. This document notes those updates in its discussions of the Setting/Affected Environment for the various resource areas and applies them in the pertinent analyses. For instance, in Section 4.6, Terrestrial Biological Resources, updates to survey information for biological resources are described in Section 4.6.1.2, Information Sources and Survey Methodology. As another example, the conceptual model of the Salinas Valley Groundwater Basin was improved with the borehole data obtained when the monitoring wells were drilled in 2015 and 2016, and the groundwater model was revised using data from those monitoring wells that were generated during the test slant well pump test.

However, a drought would not have an effect on the groundwater modeling and would not affect the results. As explained in EIR/EIS Section 4.4.4.2, Groundwater Modeling, using the method of superposition solves only for the groundwater changes that would be due solely to the proposed project pumping. These changes would be independent of the effects from the other stresses on the basin such as drought, seasonal climate and agricultural pumping trends, other pumping wells, injection wells, land use, or contributions from rivers. See Master Response 12, The North Marina Groundwater Model (v. 2016), for additional information on superposition.

Hofmann-13 The LBNL text quoted from EIR/EIS Appendix E1 does not indicate that data from 2012 were "incomplete." See response to comment Hofmann-11; the modeling conducted for this EIR/EIS included all the revisions recommended by LBNL. See also Master Response 1, EIR/EIS Authorship; CalAm did not prepare the model.

The question marks placed on EIR/EIS Figure 4.4-13, Project Area Hydrogeologic Cross Section, indicate where the geologic contact must be considered approximate between well borings. This is standard convention for developing cross sections in geology when the stratigraphic data is available from only a select number of well borings over a given distance. The depth and location of geologic contacts that extend a considerable distance between well borings and localized, discontinuous features (e.g., lenses of clay) that can end or pinch out between wells are typically indicated by question marks and dashed lines. This does not necessarily mean lithologic data necessary to represent a geologic unit is non-existent; rather, it means that the available lithologic data (from well borings) must be interpreted and in some cases, extrapolated at locations where actual soil samples or down-hole geophysical data are not available.

The NMGWM^{2016} was constructed using hydrogeologic data from several sources (i.e., monitoring well logs, existing production well logs, geophysical data) that, when combined, yield a reasonably accurate portrayal of the depth and location of aquifers and aquitards in the project area. The approximations of geologic contacts represented on Figure 4.4-3 do not affect the overall accuracy of the groundwater model and its capability to project the regional groundwater response from the MPWSP slant well pumping.

Hofmann-14 As explained in EIR/EIS Section 4.2.4.5, the rate of coastal retreat was modeled through the year 2100 to identify the anticipated time by which coastal retreat would reach, and potentially expose the slant wells. This analysis included consideration of storm events and their effect on coastal erosion. Impact 4.2-10 describes the anticipated effect of coastal erosion with respect to exposing slant well infrastructure. Mitigation Measure 4.2-10 requires monitoring of the actual rate of coastal retreat and implementation of well abandonment procedures prior to well exposure. In addition, as shown on EIR/EIS Figure 3-5a, the brine discharge pipeline from the desalination plant would connect to the outfall pipeline at the Monterey Regional Water Pollution Control Agency (MRWPCA) Regional Wastewater Treatment Plant, located about 2 miles inland and well outside of the extent of coastal retreat anticipated to occur over the project lifetime.

Hofmann-15 The outfall pipeline and concrete pad beneath the beach structure are existing facilities that are owned and operated by the MRWPCA; the MPWSP would not change these structures. See response to comment MRWPCA-4 in Section 8.5.9 regarding the separate and independent project to address the previously exposed beach structures.

Hofmann-16 The operations of the CEMEX sand mining facility are not related to the MPWSP and are therefore, not the subject of this EIR/EIS. See Master Response 14,

CEMEX Settlement Agreement, which addresses the relationship between the settlement agreement and the MPWSP.

Hofmann-17 EIR/EIS Figure 4.2-5 indicates that the areas where the well heads of the slant wells would be constructed on the CEMEX site would be in an area of moderate liquefaction potential. The potential impacts from seismically induced liquefaction are analyzed in Impact 4.2-4. The risks from liquefaction are high in sandy areas with shallow groundwater. The well heads are set back from the beach behind the sand dunes, where the depth to groundwater would be deeper (approximately 30 feet below ground surface), thus reducing the risk. In addition, as discussed in EIR/EIS Section 4.2.3, Approach to Analysis, the proposed project components would undergo a final geotechnical investigation and CalAm would implement all geotechnical recommendations in design and construction of the project to resist damage from seismic shaking.

Hofmann-18 EIR/EIS Section 4.3 addresses surface water hydrology and water quality, while Section 4.4 addresses groundwater quality; Impacts 4.4-2 and 4.4-4 address the project's potential to degrade groundwater quality. California's anti-degradation policy (Resolution 68-18), as it applies to groundwater quality, is described in EIR/EIS Section 4.4.2.2.

Hofmann-19 The Terrace Deposits at the CEMEX site are not connected to the Salinas Valley Aquitard (SVA). As explained in response to comment Hofmann-11, the SVA does not extend beneath the CEMEX site. The EIR/EIS text cited in the comment is in reference to the similarities between the sediments of the inland 180-Foot Aquifer and the near-coast Terrace Deposits. The EIR/EIS text goes on to state that because of the similar physical characteristics between the coastal Terrace Deposits and 180-Foot Aquifer, the Terrace Deposits underlying the CEMEX site are referred to as the 180-Foot Equivalent Aquifer or in shorthand, 180-FTE Aquifer. See EIR/EIS Section 4.4.1.2 for the complete explanation of the 180-FTE Aquifer. The SVA and the Fort Ord Aquitard (FO-SVA) are two distinct units.

The peer review by LBNL was conducted on the NMGWM[2015], which both LBNL and HydroFocus determined to be deficient in the simulation of the Fort Ord area and the Dune Sand aquifer. As part of the HydroFocus NMGWM[2016] review and revision, available geologic reports from the area were reviewed. HydroFocus determined the need to include the A-Aquifer and the FO-SVA independent of the LBNL review. See Master Response 12 for more information.

Hofmann-20 See EIR/EIS Section 4.4.1.1, Terminology and Concepts. As shown in EIR/EIS Figure 4.4-3 and described in Section 4.4.1.2, the slant wells would draw water from the Dune Sand Aquifer and the 180-FTE Aquifer. The slant wells would not extend vertically, beyond the bottom of the 180-FTE Aquifer, and would not therefore, extend into the 180/400 Foot Aquitard. It should be noted that Draft

EIR/EIS Figure 4.4-3 incorrectly labels the "180/400-Foot Aquitard" as the "180/400-Foot Aquifer." This has been corrected in Final EIR/EIS Figure 4.4-3.

Hofmann-21 See Master Response 9, Electrical Resistivity Tomography (ERT) and Airborne Electromagnetics (AEM).

Hofmann-22 A discussion of the impact analysis and modeling data regarding MPWSP effects on seawater intrusion is provided in Impact 4.4-4. See also response to comment MCWD-187, and Master Response 8, Source Water and Seawater Intrusion, Section 8.2.8.4.

Hofmann-23 The EIR/EIS does not conclude that the return water would retard seawater intrusion. Impact 4.4-3 concludes that return water would improve groundwater conditions in the 400-Foot Aquifer underlying the CSIP, CCSD, and adjacent areas as water levels increase. See Impact 4.4-4, and Section 5.4 of Appendix E2 which discuss the project's effect on seawater intrusion.

Hofmann-24 There are several required steps and many sources of key input data necessary to construct, calibrate, and run the NMGWM^{2016} so that an accurate projection of project effects can be obtained. The modeling did not use a single well and it is not clear from the comment what is meant by the data being incomplete. EIR/EIS Appendix E2 provides a description of the efforts made to develop a reliable modeling tool and Master Response 12, The North Marina Groundwater Model (v. 2016), Section 8.2.12.3 further clarifies the use of the NMGWM^{2016}.

Hofmann-25 See Master Response 3, Water Rights, Section 8.2.3.5.

Hofmann-26 See Master Response 12, The North Marina Groundwater Model (v. 2016), Sections 8.2.12.2 and 8.2.12.4.

Hofmann-27 See Master Response 4, The Agency Act and Return Water. See also Master Response 3 regarding water rights.

Hofmann-28 See Master Response 4, Section 8.2.4.3, for a description of the how the ocean water percentage (OWP) of the feedwater was calculated and applied. See also Master Response 2, Source Water Components Defined.

Hofmann-29 Under most scenarios, the projected cone of depression from the MPWSP pumping extends into the city limits of Marina, as shown in EIR/EIS Figures 4.4-14, 4.4-15, and 4.4-16. See Master Response 8, Source Water and Seawater Intrusion, for a description of the difference between the cone of depression and the capture zone.

Hofmann-30 Slant well pumping would retard seawater intrusion because the slant wells would intercept seawater that would otherwise migrate inland; see Impact 4.4-4, Figure 4.4-17, and response to comment MCWD-187. See also EIR/EIS

Appendix E2, Section 5.4 and Figure 5.7, and Master Response 8, Project Source Water and Seawater Intrusion.

The modeling did not use a single well; see response to comment Hofmann-24.

Hofmann-31 As described in Master Response 12, The North Marina Groundwater Model (v. 2016), Section 8.2.12.4, monitoring well data collected during test slant well pumping at CEMEX was available and utilized to adjust aquifer parameter zones and parameter values in the $NMGWM^{2016}$ model layers (see also EIR/EIS Appendix E-2, Section 3.2, Aquifer Parameter Zones). As described in EIR/EIS Section 4.4.4.2 and Appendix E-2, as well as Master Response 8, Section 8.2.1.1, the $NMGWM^{2016}$ used forward particle tracking to simulate the movement of the seawater intrusion front as a result of proposed project slant well pumping.

Hofmann-32 See response to comment Hofmann-19.

Hofmann-33 See response to comment Hofmann-31.

Hofmann-34 The EIR/EIS presents the proposed project's inconsistency with the City of Marina's LCLUP in Impact 4.6-4 and concludes this would be a significant and unavoidable impact. Mitigation recommended for significant impacts on terrestrial biological resources in Impacts 4.6-1 through 4.6-3 would apply to this impact as well; see Impact 4.6-4 discussion for applicable mitigation measures. See also response to comment MCWD-150 in Section 8.5.2.

Hofmann-35 EIR/EIS Section 6.3.5.4 considers the potential growth-inducing impact (i.e., the potential to remove an obstacle to growth) of delivering Salinas Valley Groundwater Basin (SVGB) return water to Castroville. Section 6.3 as a whole evaluates the growth-inducing impact of water supply provided by the project. The area that would receive project water primarily consists of CalAm's service area; however, the potential for SVGB return water and associated infrastructure to induce growth in the Castroville area was also considered. Because the City of Marina is outside the CalAm service area and would not receive water supply or SVGB return water, project water supply would not remove an obstacle to growth in Marina. The impacts of project construction and operation, including impacts on groundwater supplies, are evaluated in Chapter 4 of the EIR/EIS. See also Master Response 3, Water Rights, Section 8.2.3.7, Effect on Marina Coast Water District.

Hofmann-36 See Master Response 13, Demand (Project Need) and Growth.

Hofmann-37 As explained in EIR/EIS Section 6.3.6.1, the impacts of growth within the service area jurisdictions have been analyzed in the jurisdictions' general plan CEQA documents; these are the impacts of growth that would be supported, to some degree, by the proposed project, as described in EIR/EIS Section 6.3.

As stated in the response to comment Hofmann-35, the growth-inducing impacts of project water supply would occur in the area served by project water. Both Marina and the Potrero Road area are outside CalAm's service area.

Hofmann-38 Subsurface intakes are preferred, not promoted. EIR/EIS Section 5.3.1 presents regulatory considerations in the development and screening of alternatives; Section 5.3.1.2 presents the MBNMS Guidelines for Desalination Plants. These non-regulatory guidelines are meant to ensure that future desalination plants in the sanctuary are properly sited and designed, and are operated in a manner that results in minimal impacts on the marine environment. To that end, the Guidelines emphasize that the feasibility of using subsurface intakes as an alternative to open water intakes should be investigated. Where feasible and beneficial, subsurface intakes should be used. Where subsurface intakes are not feasible, open-ocean intakes should be sited with existing pipelines of acceptable structural integrity. If new pipelines are necessary, sub-seafloor placement should be evaluated to minimize disturbances to biological resources and to recreational and commercial activities. Questions about the contents of NOAA's Desalination Guidelines, which were prepared by MBNMS staff in collaboration with staff from the California Coastal Commission, the Central Coast Regional Water Quality Control Board, and NOAA's National Marine Fisheries Service in 2010, are outside the scope of this EIR/EIS.

Hofmann-39 The comment is correct; but pipes (like the existing MRWPCA outfall) have been in the ground along the coast for decades, and until they are exposed, they do not cause, contribute to, or exacerbate coastal erosion. The analysis of potential impacts of the proposed project from, and on coastal erosion is addressed in Impact 4.2-10, and is supported by substantial evidence (including facts, reasonable assumptions predicated upon facts, and expert opinion supported by facts) that is presented in EIR/EIS Section 4.2 and in the Coastal Retreat Study cited in Section 4.2.4.5. See also response to comment Hofmann-14.

Hofmann-40 See response to comment Hofman-39. It is unclear what is meant by "repair issues," however, Impact 4.2-10 addresses the potential need to abandon slant wells before coastal retreat migrates the beach inland, and exposes the subsurface slant wells. Issues related to project operational costs are outside of the scope of this EIR/EIS.

Hofmann-41 See Master Response 11, CalAm Test Slant Well, Section 8.2.11.8, regarding the use of subsurface slant wells as a "new technology." No intake option, nor any other component of the proposed project or an alternative, has yet been adopted. See response to comment MCWD-170 regarding the EIR/EIS approach to alternatives. Alternatives 2, 3, and 4 would each use screened open water intakes (referred to in the comment as "straight intake desal"), and are analyzed in detail in EIR/EIS Section 5.5.

Hofmann-42 The term “harm,” as used in this EIR/EIS, is specific to water rights and is addressed in Master Response 3. Comments regarding the adequacy and accuracy of the EIR/EIS analysis have been addressed above, where the comment provided enough specificity to allow a substantive response.

8.7.16 Responses to Comments from Thomas Moore

Moore-1 The information presented in the comment does not substantiate the claim that the Draft EIR/EIS has "proven that the operation of the test slant well on the CEMEX site has increased seawater intrusion" in the aquifers in which it is screened. See Master Response 11, CalAm Test Slant Well, Section 8.2.11.5, which describes the seasonal salinity trends observed during the long-term pump test using the monitoring wells. See also Master Response 8, Project Source Water and Seawater Intrusion, Sections 8.2.8.1 and 8.2.8.2. The proposed MPWSP slant wells would draw feedwater from a capture zone, which is located at the coast in an area heavily intruded with brackish groundwater. It is expected that the concentrations of total dissolved solids (TDS, a measure of salinity) within the capture zone would increase over time with pumping because seawater would recharge the capture zone, replacing the ambient brackish water that was initially in the coastal Terrace Deposits. However, as shown in Master Response 8, Section 8.2.18.1, the capture zone of the slant wells does not extend inland and would not exacerbate existing seawater intrusion in areas of the basin outside of the capture zone.

Moore-2 Figure 3 from Geoscience 2014b, as cited in EIR/EIS Appendix G2, presents modeled results of the anticipated salinity at the test slant well over time and therefore in the capture zone; it does not illustrate observed results of the test slant well, nor does it provide evidence of increased seawater intrusion. The graph shows how many days are expected to elapse, from the start of pumping, before the test slant well would capture 96 percent seawater. It is not accurate to consider this evidence of seawater intrusion in the 180 and 400-Foot Aquifers. In addition, the test well was not operating until 2015, after the release of the referenced Geoscience 2014 report. As stated in response to comment Moore-1, as the highly brackish, ambient groundwater would be extracted by the slant wells, seawater would recharge the capture zone and the percentage of seawater would increase. The slant wells would capture seawater that would otherwise flow inland, thereby reducing the potential for seawater intrusion inland of the capture zone. See Master Response 8, Section 8.2.8.1 for a description of the hydrogeologic characteristics of the feedwater capture zone. No significant impact on groundwater quality has been observed as a result of test slant well operation.

Moore-3 See Master Response 3, Water Rights, Section 8.2.3.5.

8.7.17 Responses to Comments from Hebard Olsen

Olsen-1 The proposed slant wells would extract brackish groundwater and seawater from the Dune Sands Aquifer and the 180-Foot Aquifer in a capture zone at the coast and the proposed slant well pumping would not influence groundwater in the deep aquifers. See Master Response 7, The Deeper Aquifers of the Salinas Valley Groundwater Basin and Master Response 8, Project Source Water and Seawater Intrusion.

Olsen-2 See Master Response 4, The Agency Act and Return Water, for information on compliance with the Agency Act and the details concerning return water.

Olsen-3 The data collected during the operation of the test slant well (see Master Response 11, CalAm Test Slant Well), indicated that groundwater levels increased and decreased as a result of regional pumping, regardless of whether the test slant well was pumping or not, particularly at Monitoring Well-4, the compliance point for Special Condition 11 of the Coastal Development Permit. See Impact 4.4-3 and Master Response 8, for an analysis of the groundwater impacts from groundwater pumping proposed under the MPWSP. See Master Response 3, Water Rights, for additional details regarding the potential for the MPWSP to cause harm to other users in the basin.

Olsen-4 The discussion of environmental impacts relied on in an EIR/EIS must reasonably set forth sufficient information to foster informed public participation and to enable the decision makers to consider the environmental factors necessary to make a reasoned decision. The reliability of the groundwater model for simulating drawdown from slant well pumping was assessed using test slant well pumping data; there is generally good agreement between the 2016 version of the North Marina Groundwater Model ($NMGWM^{2016}$)-calculated and the measured groundwater levels. See EIR/EIS Appendix E2, Section 4.2, and Master Response 12, The North Marina Groundwater Model (v. 2016).

Olsen-5 The science behind the groundwater modeling conducted for the EIR/EIS is described in EIR/EIS Section 4.4.4.2. Groundwater models are computer simulations that represent water flow in the environment using mathematical equations to simplify complex conditions. The “model” is a mathematical model, meaning that groundwater flow is simulated by solving a governing mathematical equation that represents the physical processes that occur in a groundwater system. See Master Response 12, which provides detailed information about the groundwater modeling approach, methods, and software used.

8.7.18 Responses to Comments from Larry Parrish

Parrish-1 The proposed project would extract groundwater from a localized coastal-adjacent capture zone, which has been verified by water quality testing to contain groundwater with an elevated concentration of TDS and chloride from decades of legacy seawater intrusion. EIR/EIS Section 4.4.1.2 explains that water quality of the Dune Sand Aquifer is directly influenced and controlled by seawater, and the quality of water in the 180-FTE Aquifer is directly influenced by seawater; this influence extends for miles inland. Seasonal rainfall recharges the Dune Sand Aquifer but the larger volume of water comes from the ocean due to the immediate proximity and hydraulic connection.

The slant wells would initially extract this ambient brackish water from the ground and, over time, the feed water supplied by (removed from) the capture zone would be replaced by seawater. As stated in Impact 4.4-3 and as discussed in Master Response 8, Project Source Water and Seawater Intrusion, the predominant majority of the water pumped by the slant wells would be from the ocean. While EIR/EIS Section 4.4.5.2 considered the source water could range from 88 percent to 100 percent ocean water, Master Response 4, The Agency Act and Return Water, Section 8.2.4.3 explains that the ocean water percentage would rise to about 90 percent within 90 days and would reach 95 percent within five years since as explained above, the Dune Sand Aquifer and the 180-FTE Aquifer are both recharged by seawater that has historically and is continuing to intrude the aquifers.

EIR/EIS Impact 4.2-8 addresses the potential for the proposed project to expose people or structures to substantial adverse effects related to land subsidence. The analysis of potential subsidence determined that no impact would occur. Subsidence of the land surface would not occur around the slant wells because of the predominantly granular nature of the subsurface materials and because the close proximity to the ocean would provide an essentially limitless source of water to refill the pores between grains. As explained above, since the predominant majority of the source water would be from the ocean, an essentially infinite source, it would continually refill the capture zone and subsidence would not occur anywhere in the cone of depression as a result of the MPWSP. For these reasons, land masses would not subside, and shoreline land masses would not become more vulnerable to increased wave action and erosion as a result of the proposed project.

Parrish-2 As discussed in Section 4.2.4.4, numerous soil samples were collected from soil borings and monitoring wells installed within the area of the cone of depression. The data is available in EIR/EIS Appendix C3.

Parrish-3 As explained in Impact 4.2-8 and in response to comment Parrish-1, subsidence would not occur as a result of the MPWSP. While land surface elevation monitoring has not been conducted specifically for the EIR/EIS, the Coastal Retreat Study (see EIR/EIS Section 4.2.4.5) used high-resolution coastal elevation data sets from the

CA Coastal Mapping Program for the topography at CEMEX. The 2010 data was collected using LiDAR, a state-of-the-art remote sensing technology in conjunction with high resolution aerial photography; see EIR/EIS Appendix C2, Table 3.

Parrish-4 EIR/EIS Section 4.2.4.5 presents the Coastal Retreat Study, with supporting studies presented in Appendices C1 and C2; historic beach erosion was one of the considerations in the analysis. As described in response to comment Parrish-1, no subsidence would occur and therefore, subsidence-induced coastal erosion would also not occur. The potential for the proposed project to accelerate and/or exacerbate natural rates of coastal erosion, scour, or dune retreat is analyzed in Impact 4.2-10, which concludes the impact would be less than significant with mitigation. Mitigation Measure 4.2-9 would require CalAm to monitor the rate of coastal retreat and require CalAm to remove the slant well prior to exposure on the beach to avoid the potential impact from occurring at all.

Parrish-5 See response to comment Parrish-4.

Parrish-6 Since the EIR/EIS concluded that the proposed project would not accelerate and/or exacerbate natural rates of coastal erosion, scour, or dune retreat (see response to comment Parrish-4), no additional beach and dune erosion would result that could cause seawater intrusion into the underlying aquifers. Section 4.4.5.2 and Impacts 4.4-3 and 4.4-4 considered sea level rise in assessing the impacts of the proposed slant well pumping and the potential for the project to contribute to seawater intrusion, and concluded the impact would be less than significant; therefore, no mitigation is required. Master Response 8 provides a supplemental discussion on the hydrogeologic characteristics of the capture zone and cone of depression.

Parrish-7 EIR/EIS Section 4.1.7 explains that cumulative impacts in an EIR/EIS refer to two or more individual affects that, when taken together, are "considerable," or that compound or increase other environmental impacts. In the CEQA and NEPA analyses, cumulative impacts refer to the combined effects of two or more separate projects (that otherwise may not be considered in combination). In the case of the MPWSP, the project-level analysis in the EIR/EIS addressed the collective "whole of the action," which includes the conversion of the test slant well to a production well as well as all the other new production wells. As part of the same project, this group of production wells is analyzed as a whole within the project-level analysis. As explained in EIR/EIS Section 4.4.5.2, the pumping of the production wells would create only one capture zone for the whole of the project; see Figure E-8 and Figure 5.6 in EIR/EIS Appendix E2. See also Master Response 8. Responses to comments Parrish-1 through Parrish-6 address the impacts of the whole of the MPWSP action.

The EIR/EIS concluded that the proposed project would not accelerate and/or exacerbate natural rates of coastal erosion, scour, or dune retreat (see response to comment Parrish-4) and therefore, would not contribute to a cumulative impact. Due to the potential exposure of the test well as a result of ongoing coastal retreat,

Mitigation Measure 4.2-9 would require CalAm to monitor the rate of coastal retreat and require CalAm to remove the slant well prior to exposure on the beach to avoid the potential impact from occurring at all.

Parrish-8 See responses to comments Parrish-1 through Parrish-7. A lead agency is required to recirculate an EIR when significant new information is added after the release of the draft, but prior to certification. Nothing in these comments or the associated responses has raised issues or presented data so as to cause the Lead Agencies to conclude that the Draft EIR/EIS is fundamentally flawed and in need of revision and recirculation, per CEQA Guidelines Section 15088.5.

8.7.19 Responses to Comments from Paula Pelot

Pelot-1 As explained in Table 4.2-3 in Section 4.2, Geology, Soils, and Seismicity, the Reliz-Rinconada fault zone, which includes the Blanco section, is not mapped as active by the State of California because these faults do not display evidence of recent displacement (the last 11,000 years). This fault underlies only the new Transmission Main, as stated in Table 4.2-3; no other project components would be affected. As explained in Impact 4.2-2, while it is possible that an older age Quaternary fault (i.e., displacement between 1.6 million years ago to 11,000 years ago or older) could reactivate and generate an earthquake and rupture at the surface, the potential for such an occurrence to expose people or structures to substantial adverse effects related to fault rupture is low because the fault is concealed beneath sediments and the project component is a pipeline transmitting drinking water. In the unlikely event that the Reliz Fault did generate an earthquake and cause surface rupture, the rupture area would be localized, resulting in a minor offset associated with low-level groundshaking. Damage could include localized pipeline leaks that would be immediately repaired.

Pelot-2 As listed in Table 4.2-3 and shown on Figure 4.2-4, there are no known active faults that pass beneath the Brine Discharge Pipeline; therefore, as concluded in Impact 4.2-2, the Brine Discharge Pipeline would not be vulnerable to fault rupture and no impact from fault rupture would occur.

Pelot-3 As explained in Impact 4.2-8, subsidence would not occur as a result of the MPWSP because the materials at and above the slant wells are predominantly composed of sand and gravel. Geologic units composed of sands and gravels are less prone to subsidence because the granular structure is better able to support the overlying weight of soil. In addition, because the subsurface slant wells would draw water from the Dune Sand and 180-Foot-Equivalent Aquifers, seawater would replace the water pumped from the slant wells, as discussed in Section 4.4, Groundwater Resources, keeping the pore spaces between the grains filled with water, further supporting the granular structure.

Pelot-4 This comment was addressed above in the responses to comments Pelot-1, Pelot-2, and Pelot-3. As discussed on Draft EIR/EIS pages 4.2-16 to 4.2-21 in Section 4.2.1.2, Seismicity and Faults, the Working Group on California Earthquake Probabilities has modeled the faults in the project area for the potential for seismic activity and the results of their modeling was included for the various faults in the area.

8.7.20 Responses to Comments from Carol Reeb

Reeb-1 As described in detail in EIR/EIS Sections 4.3.5 and 5.5.3, salinity levels would not exceed 2 parts per thousand (ppt) above ambient salinity at the edge of the Brine Mixing Zone (BMZ; measured as 100 meters or 328 feet from the diffuser), the regulatory compliance point for salinity discharges from desalination plants that is prescribed in the California Ocean Plan. For all discharge scenarios assessed, including scenarios with no and low wastewater flows, operational discharges are projected to be below the 2 ppt salinity standard at a maximum distance of 54 feet from the diffuser, well within the BMZ. These findings are supported with the assessment of additional discharge flow scenarios that were analyzed subsequent to the publication of the Draft EIR/EIS to provide higher resolution dilution analyses to support NPDES permitting for the Pure Water Monterey Groundwater Replenishment (GWR) Project by the Monterey Regional Water Pollution Control Agency (see response to comment MRWPCA-9 in Section 8.5.9). Consistent with Ocean Plan requirements, and reflected in the detailed and comprehensive dilution modeling performed to assess salinity impacts (see EIR/EIS Appendix D1), the proposed project would include commingling brine with MRWPCA wastewater, when it's available, as well as the use of an existing multiport diffuser for brine disposal.

Reeb-2 As noted in Mitigation Measure 4.3-5, flow augmentation with water that has densities closer to freshwater could be a potential component of mitigation to increase the dilution of the brine, if necessary. Since the availability of wastewater for dilution is limited by season (very limited in the irrigation season, see response to comment Reeb-5) and since the MRWPCA anticipates using some of the wastewater as source water for the Pure Water Monterey GWR Project, the availability of wastewater cannot be relied upon for dilution.

Reeb-3 Retrofitting the diffuser port angle is included as a corrective action in Mitigation Measure 4.3-5 in order to meet water quality objectives established in the NPDES permit for constituents other than salinity; see response to comment Reeb-1. EIR/EIS Table ES-2 (Draft EIR/EIS p. ES-32) summarizes the impact conclusions and associated mitigation measures for the proposed project. Impacts 4.3-4 and 4.3-5 assess water quality impacts related to operational discharges and, based on these analyses, two mitigation measures are required, as summarized in Table ES-2 and discussed in detail in EIR/EIS Section 4.3. Mitigation Measure 4.3-4 involves operational discharge monitoring, analysis, and compliance reporting to ensure operational discharges do not exceed water quality or biological resource regulatory standards, as defined in an NPDES permit. Mitigation Measure 4.3-4 establishes that if the monitoring indicates deleterious effects on receiving water quality or marine biological resources from MPWSP operational discharges do occur, corrective actions detailed in Mitigation Measure 4.3-5 must be implemented. Mitigation Measure 4.3-5 provides for the implementation of additional design features (e.g. treatment with Granular Activated Carbon), engineering solutions (e.g. inclined jets), and/or operational measures (e.g.

flow augmentation) to reduce the concentration of water quality constituents in the operational discharges such that they conform with regulatory standards and NPDES permit requirements. Included in Mitigation Measure 4.3-5 is the protocol for retrofitting the outfall diffuser with inclined jets as a corrective action to increase dilution and mixing (see also response to comment MRWPCA-20 in Section 8.5.9). Retrofitting the outfall diffuser with inclined jets prior to implementation of the project may be premature, since a physical solution, and therefore, the associated temporary impacts to the marine environment, may not be necessary to reduce the concentration of water quality constituents in the operational discharges. The need for such a reduction would be determined based on the monitoring and assessments required under Mitigation Measures 4.3-4 and 4.3-5. See response to comment Reeb-2 for additional discussion of wastewater availability.

Reeb-4 The identification of monitoring roles and responsibilities will be defined in the mitigation monitoring and reporting program (MMRP). An MMRP must be prepared and adopted at the time a lead agency makes findings in preparation for approving a project (CEQA §21081.6; CEQA Guidelines §§15091(d) and 15097; see response to comment Marina-1 in Section 8.5.1 for additional details). Each lead and responsible agency has the discretion to define its own approach for monitoring and/or reporting and the release of any associated monitoring data will be at the discretion of the lead and responsible agencies. Data associated with permit monitoring and compliance, such as NPDES discharges permits, are available publicly (see response to comment USARMY-12 in Section 8.3.2). Decisions related to who shall conduct mitigation monitoring (e.g., agency staff, consultants, researchers, etc.) have not yet been made. However, the lead agencies would typically contract with third-party independent consultants to undertake monitoring of the MMRP.

Reeb-5 The MRWPCA discharges secondary (not tertiary) treated wastewater into Monterey Bay in the winter months. During the irrigation season, almost all of the available wastewater is tertiary treated and delivered to agricultural users within the area served by the Castroville Seawater Intrusion Project and the ocean discharge is negligible. The Pure Water Monterey GWR Project is an indirect potable reuse project that proposes to treat a variety of source waters to produce 3,500 afy of potable water that would be injected or percolated into the Seaside Groundwater Basin for later extraction and use by CalAm. The GWR Project would include improvements that would enable more of the municipal wastewater to be recycled than is possible today; thus, less municipal wastewater would be discharged through the ocean outfall in the future. Furthermore, the MRWPCA has observed that municipal wastewater flows to the Regional Treatment Plant have been decreasing for the past several years due to aggressive water conservation efforts by MRWPCA member agencies, and flows are projected to continue to decrease over the next decade. If winter wastewater that is currently discharged into Monterey Bay were to be treated for potable use, the water would need to be stored and retained in the Seaside Groundwater Basin to ensure a treatment "polishing" in compliance with SWRCB Division of Drinking Water requirements (i.e., response retention time) prior to extraction and use by CalAm. To the point, however, a

portion of the winter wastewater flows that are currently discharged into Monterey Bay is proposed to be made available for treatment, storage, and use by CalAm, in lieu of desalinated water as part of the already-approved GWR project (see Alternatives 5a and 5b in EIR/EIS Sections 5.4.7 and 5.4.8). Therefore, 6,000 afy of winter wastewater flows will not be available in the future to solve the water supply shortage on the Monterey Peninsula because of the declining wastewater flows as a result of conservation and the GWR project. See also response to comment Reeb-6.

Reeb-6 EIR/EIS Section 5.2.6 discusses the Pure Water Monterey GWR Project as an alternative to the MPWSP, and concludes it would not produce enough water to meet the basic project objective of the MPWSP. The MRWPCA certified the GWR Final EIR and approved the GWR Project in October 2015; the GWR Project is described in EIR/EIS Section 4.1, and is one of the projects included in the cumulative scenarios. EIR/EIS Section 5.4 describes Alternative 5a, which would meet all of the MPWSP objectives by combining a reduced-capacity desalination plant (6.4 mgd) with a water purchase agreement for 3,500 acre-feet per year (afy) of product water from the Pure Water Monterey GWR Project; Alternative 5a is evaluated in EIR/EIS Section 5.5. Although implementation and/or expansion of the GWR project could possibly result in the need for an even smaller than 6.4 mgd desalination facility (or none at all), there is currently no formal proposal to do so. Until such time as an expanded GWR project is proposed by MRWPCA, and unless environmental documentation is prepared and the CEQA process completed, the alternative is not reasonably foreseeable and is considered speculative at this time. See also Master Response 13, Demand (Project Need) and Growth, concerning demand and supply assumptions. The Lead Agencies will consider all evidence in the record concerning demand and supply prior to acting upon the project, and may conclude that a smaller desalination plant (or some other alternative) would indeed satisfy the basic objectives of the project.

Also note that Alternative 5a was developed by CalAm in cooperation with the MRWPCA. The Monterey Peninsula Regional Water Authority, composed of the mayors representing the Peninsula cities, and no less than 25 other parties continue to actively participate in the ongoing proceeding before the CPUC. In addition, the MBNMS Desalination Guideline that "Desalination plant proponents should pursue collaborations with other water suppliers and agencies currently considering water supply options in the area to evaluate the potential for an integrated regional water supply project," is listed on page 6-47 of the Draft EIR/EIS, and has been determined to be addressed by the scope of the overall EIR/EIS analysis.

Reeb-7 Impact 4.5-4 assesses the potential impacts of elevated salinity from operational discharges on marine biological resources. The analysis presents evidence that operational discharges from the MPWSP would not increase salinity levels in a manner that violates Ocean Plan water quality objectives or waste discharge requirements that are protective of marine organisms, or otherwise degrades the quality of receiving waters in Monterey Bay and MBNMS, and concludes that impacts on Sanctuary marine biological resources would be less than significant. The Ocean Plan establishes an

allowable salinity increase of less than 2 ppt above ambient conditions at the BMZ boundary; this is comparable to other international regulatory guidelines (see EIR/EIS Table 4.5-11). This incremental salinity increase limit, however, is a conservative threshold for marine organisms, as none of the studies reviewed as part of the impact assessment (see below) found adverse effects on survival, growth, or behavior at salinities as low as the Ocean Plan objective.

The impact conclusion for market squid is not based on the referenced study by Vidal and Boletzky (2014) that recommends a salinity range of 34 to 38 ppt for successful laboratory culture of the market squid, nor on a salinity threshold of 38 ppt. Impact 4.5-4 presents, in part, the results of a comprehensive literature review related to the salinity tolerances of relevant marine organisms (see EIR/EIS Table 4.5-9). A study of salinity effects based on approved marine organism toxicity test protocols (Phillips et al., 2012) reported median effect concentrations (EC50) ranging from 36.8 ppt to 61.9 ppt on various physiological processes (see EIR/EIS Table 4.5-10). Impact 4.5-4 assessed salinity levels both within the zone of initial dilution (ZID; i.e., 3 to 11.9 meters or 10 to 39 feet from the diffuser) and the BMZ, as well as at the edge of these zones for potential impacts on marine biological resources. In assessing a conservative worst-case scenario, the highest anticipated ambient salinity of 33.89 ppt is expected to occur during the upwelling oceanic season. This peak ambient salinity would also coincide with the proposed project's maximum concentrated brine discharge stream, when the brine would not be combined with treated wastewater effluent from the MRWPCA regional wastewater treatment plant, resulting in the maximum salinity at the edge of the ZID of any discharge scenario analyzed. As discussed in detail in Section 4.5.5, except for the limited area immediately adjacent to the discharge ports above the ocean floor, the predicted salinity increase at the edge of the ZID due to the MPWSP would be less than 2 ppt above ambient. Under this brine-only discharge scenario, the maximum increase in salinity at the edge of the ZID would be 1.6 ppt above ambient (see Scenario 2 in EIR/EIS Table 4.5-12). The assessed maximum anticipated salinity at the edge of the ZID and BMZ due to the brine discharge therefore, would be 35.45 and 35.19 ppt respectively, and would not exceed the lowest mean effective salinity reported by Phillips et al. (i.e., 36.8 ppt). Mitigation Measure 4.3-4 involves operational discharge monitoring, analysis and compliance reporting to ensure operational discharges do not exceed water quality or biological resource regulatory standards and includes provisions for monitoring benthic community health, aquatic life toxicity, and hypoxia, throughout the water column within the ZID. Sublethal salinity impacts will be determined through the monitoring of aquatic life toxicity.

Reeb-8 See Master Response 9, Electrical Resistivity Tomography (ERT) and Airborne Electromagnetics (AEM), Sections 8.2.9.1 and 8.2.9.3.

Reeb-9 The fact that subsurface intakes are not affected by algal blooms is noted in a footnote in EIR/EIS Section 3.4.1.

8.7.21 Responses to Comments from Dick Rotter

Rotter-1 The pipeline segment referenced in the comment is referred to as the "new Monterey Pipeline." As explained in EIR/EIS Executive Summary Section ES.8, Areas of Controversy and Issues to be Resolved, the new Monterey Pipeline was evaluated as an alternative route in the April 2015 Draft EIR, and in the October 2015 Pure Water Monterey Groundwater Replenishment (GWR) Project Final EIR, which was certified in January 2016, prior to publication of the MPWSP Draft EIR/EIS. Since the CPUC approved the new Monterey Pipeline and ASR Pump Station in September 2016, along with the Water Purchase Agreement for the GWR Project, the new Monterey Pipeline is not a component of the MPWSP. As an approved project with utility independent from the proposed MPWSP, the new Monterey Pipeline and ASR Pump Station are evaluated as cumulative projects in this EIR/EIS since they are no longer a part of the proposed project. See also EIR/EIS Section 1.4.4 (Items 3 and 4), Project 60 on the last page of Table 4.1-2 in Section 4.1.7.2, and Section 5.2.6.

Rotter-2 CEQA and NEPA do not require an EIR or EIS to evaluate costs. CEQA Guidelines Section 21082.2(a) explains that lead agencies shall determine whether a project may have a significant effect on the environment based on substantial evidence. But CEQA Guidelines Section 21082.2(c) further explains that economic impacts which do not contribute to, or are caused by physical impacts on the environment, are not substantial evidence. Furthermore, as noted in response to comment Rotter-1, this pipeline is no longer part of the proposed project.

Rotter-3 See response to comment Rotter-1. No component of the proposed project would cross Highway 68.

Rotter-4 EIR/EIS Section 4.2.1.2 addresses seismicity and faults. Table 4.2-3 lists the Monterey Bay - Tularcitos Fault Zone, which includes the Navy Fault, as a late Quaternary fault zone with evidence of Holocene activity (Potentially Active) that crosses beneath the proposed Main System–Hidden Hills Interconnection Improvements (see Figure 4.2-4). The Sylvan Thrust Fault is a branch off of the Monterey Bay - Tularcitos Fault Zone that does not cross any of the project components, and therefore, is not discussed in the EIR/EIS.

Other mapped faults intersect the proposed new Transmission Main and the Ryan Ranch-Bishop Interconnection Improvements. As discussed in Impact 4.2-2, (see Draft EIR/EIS pages 4.2-56 through 4.2-58), past studies have identified that certain segments of these faults do exhibit Holocene-age displacement leading to the conclusion that certain segments could be considered active. Impact 4.2-2 explains that damage to the new Transmission Main and the Ryan Ranch-Bishop Interconnection Improvements pipelines could include localized pipeline leaks that would be immediately repaired. This impact is considered less than significant for these facilities. For all other components of the proposed project, no impact would result because mapped faults do not occur at or near to the locations of the other components.

Rotter-5 The October 2015 letter from Caltrans to CalAm was relevant to permits associated with the new Monterey Pipeline. See response to commnent Rotter-1.

EIR/EIS Table 3-8, Anticipated Permits and Approvals, lists the California Department of Transportation Encroachment Permit (Cal. Streets and Highway Code §660 et seq.) for encroachments in, under, or over any portion of a State highway right-of-way, including Highway 1, as a permit that would likely be required to build, operate, and maintain the proposed project. While the Lead Agencies anticipate that CalAm would begin the process of securing such permits if the project or an alternative is approved, preparing the permit applications is the responsibility of CalAm and is related to, but separate from this EIR/EIS process.

8.7.22 Responses to Comments from Nancy Selfridge– Letters 1 through 3

8.7.22.1 Responses to Comments from Nancy Selfridge – Letter 1

Selfridge1-1 See Master Response 15, which explains the extent of contact between the People's Project applicant and Lead Agencies during preparation of the Draft EIR/EIS.

Selfridge1-2 See Master Response 15, regarding the status of other proposed desalination projects. Given the status of the People's Project application to MBNMS, it is unclear if or when a joint document may be prepared.

In response to this comment, the EIR/EIS preparers reviewed the conclusion that Alternative 4 would have a significant and unavoidable contribution to significant cumulative impacts related to energy consumption and found that this conclusion statement was inadvertently included, despite the preceding text explaining that Alternative 4 would *not* have a considerable contribution to this cumulative impact. Text in the last paragraph of Section 5.5.18.7 has been revised as follows:

> For the same reasons described for Alternative 1, Alternative 4 would not have a considerable contribution to a significant cumulative impact associated with the unnecessary, wasteful, or inefficient use of energy, or with energy supply, either at a local or regional level, during operation and maintenance. Overall, Alternative 4 would result in ~~an ***increased impact conclusion*** compared to the proposed project, significant and unavoidable~~ the ***same impact conclusion*** as the proposed project, less than significant with mitigation.

The comparison of alternatives in Executive Summary Section ES.7 (Draft EIR/EIS page ES-12), the summary of impacts in Table ES-1 (Draft EIR/EIS page ES-28), and the discussion of the Environmentally Superior Alternative/ Preferred Alternative in Section 5.6 (Draft EIR/EIS page 5.6-5) and Table 5.6-1 (Draft EIR/EIS page 5.6-18) treated this impact as less than significant with mitigation. Therefore, the above revision does not affect the consideration of Alternative 4 compared to the proposed project and other alternatives.

Selfridge1-3 As described in Draft EIR/EIS Section 5.5.18.7 on page 5.5-332 (which also was attached to the comment letter), construction of Alternative 4 would require the use of construction equipment that would cause an increase in gasoline and diesel fuel use compared to the proposed project. Similarly, as described on the same page, long-term operations of the People's Project would produce approximately 25 percent more product water that would require an approximately 25 percent increase in energy demand compared to the proposed project. Therefore, although the significance conclusion is the same as the proposed project for these

impacts (less than significant with mitigation for Impact 4.18-1 during construction, less than significant for Impacts 4.18-2 and 4.18-3 for operation), the magnitude of each impact is increased as a result of the associated increase in energy consumption.

Selfridge1-4 See Master Response 15, Section 5.2.15.2, for a discussion of the use of solar panels for Alternative 4. The two pages attached to the comment letter that appear to pertain to a potential solar project at the People's Project site do not provide sufficient information to justify revising the approach used in the EIR/EIS.

Selfridge1-5 See Master Response 15, Section 8.2.15.2 regarding the consideration of solar panels for Alternative 4 in this EIR/EIS.

Selfridge1-6 The comment letter describes no "significant unmitigated adverse impacts" that are not identified in the Draft EIR/EIS. Regarding alleged deficiencies, Master Response 15, Section 8.2.15.2 explains the assumptions around project components and available studies for the People's Project. Revisions in response to this comment letter are minor and do not require recirculation of the Draft EIR/EIS.

Regarding notification requirements under CEQA, see response to comment ALT1-5 in Section 8.6.1, which explains that the CPUC exceeded CEQA notification requirements, including mailing Notices of Availability of the Draft EIR/EIS.

8.7.22.2 Responses to Comments from Nancy Selfridge– Letter 2

Selfridge2-1 The People's Project Desalination Facility would be located at the former National Refractories Facility at the Moss Landing Commercial Park at Dolan Road and Highway 1. The 16.5-acre parcel would be located within the approximately 200-acre parcel that is currently developed, and as discussed in Section 5.5.2.1, the ground consists of an intermediate mix of fill material and underlying native sandy loam soil. Therefore, no loss of topsoil would result at this site during construction. Section 5.5.2.7 has been revised to reflect this information.

Selfridge2-2 Draft EIR/EIS Section 5.5.2.2 presents a summary of the direct and indirect effects of the proposed project on geology, soils and seismicity that are fully described in Section 4.2.5. Impact 4.2-10 is presented in its entirety for the proposed project on page 4.2-68 and is summarized on page 5.5-9: "The anticipated future presence of this slant well on the beach due to coastal retreat could result in a significant impact. Mitigation Measure 4.2-9 (Slant Well Abandonment Plan) would reduce the impact to a less-than-significant level by requiring CalAm to monitor coastal retreat rates and initiate well decommissioning if coastal retreat threatens the slant wells."

Section 5.5.2.7 presents the direct and indirect effects of Project Alternative 4, The People's Project, on geology, soils and seismicity. Page 5.5-23 explains how the existing caisson is already being subjected to coastal erosion, and the continued use of the caisson on the beach could result in accelerated erosion, could alter the existing landforms along the coast and could expose adjacent properties to coastal flooding. The application of shoreline protective measures that would be necessary to protect the existing caisson could result in accelerated erosion, could alter the existing landforms along the coast, and could expose adjacent properties to coastal flooding, and that while mitigation may be proposed to reduce such impacts, the details of any proposed mitigation are unknown and therefore, their efficacy cannot be determined at this time.

See also Appendix C1, Coastal Water Elevations and Sea Level Rise Scenarios, and Appendix C2, Analysis of Historic and Future Coastal Erosion with Sea Level Rise.

Selfridge2-3 Impact 4.2-11 responds to a significance criterion that is specific to geologic resources and oceanographic processes. Draft EIR/EIS explains on page 4.2-54, that this evaluation criterion is not relevant to the proposed project because the proposed project would not affect onshore or offshore geologic resources and would not alter oceanographic processes. As noted in EIR/EIS Section 3.2.1.1 on page 3-7, the subsurface slant wells would be located in the retired mining area of the CEMEX sand mining facility and not within a "pristine beach."

Alternative 4 (the People's Project) is described in EIR/EIS Section 5.4.6 and the use of existing infrastructure is acknowledged, including the existing caisson and the existing 51-inch diameter discharge pipeline. But as noted on page 5.4-40 of the Draft EIR/EIS, the previous intake pipeline was removed and does not currently exist. Therefore, the existing caisson structure would be rehabilitated to include a new 40-inch diameter intake pipe that would extend approximately 1,400 feet out from the existing caisson into MBNMS. The near shore portion of the pipe (the first 300 feet) would be drilled under the seafloor and the remaining 1,100 feet would be laid on the seafloor and covered with riprap armoring.

Due to the age and condition of the existing 51-inch diameter outfall pipeline (see Draft EIR/EIS page 5.4-40), a new 36-inch-diameter pipeline would be slip-lined within the existing pipeline and extended approximately 700 feet on the seafloor to a water depth of approximately 120 feet at the edge of the submarine canyon.

As noted in EIR/EIS Section 5.5.2.7, because the open-water intake and brine disposal structures in Monterey Bay would be anchored on the slopes of the Monterey Submarine Canyon in MBNMS, the potential for future slope instability and underwater landslide would be increased compared to the proposed project. Also, placement of an open water intake and brine disposal

system on the seabed of MBNMS could affect seabed substrate and alter oceanographic processes such as sediment transport in the vicinity of Monterey Submarine Canyon.

Selfridge2-4 Draft EIR/EIS Section 5.5.3.2 presents a summary of the direct and indirect effects of the proposed project on surface water hydrology and water quality that are fully described in Section 4.3.5. Impact 4.3-1 is presented in its entirety for the proposed project on page 4.3-58 and is summarized on page 5.5-31 of the Draft EIR/EIS: "Soil disturbing activities could result in soil erosion and the migration of soil and sediment in stormwater runoff to downgradient water bodies and storm drains. Mandatory compliance with NPDES Construction General Permit requirements would involve implementation of erosion and stormwater and water quality control measures, which would prevent substantial adverse effects on water quality during construction."

Section 5.5.3.7 presents the direct and indirect effects of Alternative 4, The People's Project, on surface water hydrology and water quality. Draft EIR/EIS page 5.5-54 explains that components unique to Alternative 4 would have a reduced land-based disturbance area compared to the proposed project and therefore, construction of Alternative 4 would have a reduced potential for soil erosion and risk of inadvertent releases of hazardous chemicals during general construction activities.

However, as identified on the same page in Section 5.5.3.7, Alternative 4 would result in an increased level of impact on offshore water quality from construction activities compared to the proposed project which proposes no construction on the seafloor. Offshore in MBNMS, Alternative 4 would result in approximately 43,200 square feet (approximately 1 acre) of disturbance on the seafloor from installation of the open ocean intake, outfall pipeline and diffuser, and laying of 1,100 feet of intake pipeline and 700 feet of brine discharge pipeline on the seafloor, ballasted with concrete collars and protected with riprap armoring. The conclusion of significant and unavoidable impacts on water quality during construction of Alternative 4 is due to the substantially increased size of the Alternative 4 in-water construction area and the lack of available details regarding construction techniques designed to avoid or minimize the degradation of water quality within MBNMS.

Selfridge2-5 The analysis supporting the conclusion that the proposed project would have a less-than-significant impact on impedance or redirection of flood flows (Impact 4.3-9) was provided on Draft EIR/EIS pages 4.3-116 and 4.3-117 and is summarized in Section 5.5.3.2 on page 5.5-35. The analysis supporting the conclusion that Alternative 4 would have a significant and unavoidable impact on impedance or redirection of flood flows was provided in Draft EIR/EIS Section 5.5.3.7 on page 5.5-57. This impact does not concern the potential impacts of flood flows on the project's or an alternative's facilities. Rather, it concerns whether the facilities

would impede or redirect flood flows. For the proposed project, only the subsurface slant wells and portions of the Source Water Pipeline, Castroville Pipeline, and new Transmission Main would be constructed in a 100-year flood hazard area. These underground facilities would not impede or redirect flood flows after they have been constructed. Based on the limited information available at this time regarding project design and flood hazard mitigation, the placement of the Alternative 4 desalination plant above ground within the 100-year flood hazard area could impede or redirect flood flows at this location.

Selfridge2-6 Draft EIR/EIS Section 5.5.3.2 presents a summary of the direct and indirect effects of the proposed project on surface water hydrology and water quality that are fully described in Section 4.3.5. Impact 4.3-10 is presented in its entirety for the proposed project on page 4.3-117 which explains tsunami damage is typically confined to low-lying coastal areas, and under the proposed project, only the subsurface slant wells and the Castroville Pipeline in unincorporated Monterey County would be located in areas subject to flooding from a tsunami. These facilities and associated mechanical vaults and electrical enclosures would be located underground and/or designed to withstand inundation as a result of a tsunami. The impact of the proposed project is summarized on page 5.5-35 of the Draft EIR/EIS: "The subsurface slant wells at CEMEX, and the Castroville Pipeline would be located in areas subject to flooding from a tsunami. Because the presence of onsite personnel would be minimal, operation of the subsurface slant wells and pipeline operations and maintenance would not expose personnel or structures to significant risks from flooding in the event of a tsunami."

EIR/EIS Section 5.5.3.7 presents the direct and indirect effects of Alternative 4, The People's Project, on surface water hydrology and water quality. Draft EIR/EIS explains page 5.5-57 that the Alternative 4 desalination plant would be located in a flood hazard area that has been designated as Zone A by FEMA, indicating the base flood elevations have not been determined. Based on limited project design and flood hazard mitigation information, the Draft EIR/EIS concluded that the risk of exposure of people or structures to loss, injury, or death from flooding due to a tsunami at the Alternative 4 desalination plant would be significant. See Master Response 15 regarding the Lead Agencies' coordination with the People's Project proponent to obtain project information.

Impact assessment for tsunami damage does not rely on historical data of past tsunami occurrence, but instead relies on projections from government agencies that assess potential community exposure to tsunami hazards. Whether a tsunami has occurred in the past 100 years is irrelevant to the assessment.

Selfridge2-7 Draft EIR/EIS Section 5.5.3.2 presents a summary of the direct and indirect effects of the proposed project on surface water hydrology and water quality that are fully described in Section 4.3.5. Impact 4.3-11 is presented in its entirety for the proposed project on page 4.3-118 and is summarized on page 5.5-35:

"Portions of the Source Water Pipeline, new Transmission Main, and Castroville Pipeline would be constructed in a 100-year flood hazard area. However, these facilities would be placed underground and would not impede or redirect flood flows. The electrical control cabinet at the slant wells would divert flood flows to the sandy areas immediately surrounding the cabinet, still within the CEMEX active mining area, and would not affect other properties or structures."

Section 5.5.3.7 presents the direct and indirect effects of Alternative 4, The People's Project, on surface water hydrology and water quality. Pages 5.5-57 and 5.5-58 of the Draft EIR/EIS explain how a new pump house on the existing caisson, as proposed by this alternative, would require the caisson to remain in place, potentially exposing adjacent properties to flooding from sea level rise. Mitigation would be required to address the flooding, including a coastal retreat strategy or a plan to armor the caisson, and in so doing, the applicant must demonstrate that flooding will not occur. However, while the applicant may propose such measures or provide model analyses to demonstrate compliance with Coastal Act requirements related to armoring, erosion, and sea level rise resilience, there is insufficient project design and flood hazard mitigation information available for Alternative 4 at this time to conclude that the risk of exposure of people or structures to loss, injury, or death from flooding due to sea level rise would not be significant. See Master Response 15 regarding the Lead Agencies' coordination with the People's Project proponent to obtain project information.

Regarding potential impacts of the proposed project with respect to flooding due to sea level rise, see response to comment PTA-6 in Section 8.6.16.

Selfridge2-8 See Master Response 15 regarding the status of alternative desalination projects; in particular, see Section 8.2.15.2 regarding the availability of cultural resources surveys or studies for the People's Project.

Selfridge2-9 See Master Response 15 and response to comment Selfridge2-8. If cultural resource surveys or studies have been or would be performed for Alternative 4, they may satisfy the requirements of Mitigation Measure ALT-CUL-1 (conduct subsurface investigation). However, because no such reports have been made available to the Lead Agencies for review, they cannot conclude at this time that this mitigation measure would not be required to reduce impacts of Alternative 4 to a less-than-significant level.

Selfridge2-10 The Lead Agencies relied not solely on the impact summary in Table 5.6-1, but on the extensive analysis in Chapter 4, Section 5.5, the Draft EIR/EIS appendices, and the referenced materials to make the preliminary determination in Section 5.6 that Alternative 5a is the environmentally superior/preferred alternative. See Master Response 15, Section 8.2.15.2 regarding the Lead

Agencies' coordination with the People's Project proponent to obtain project information.

Selfridge2-11 See response to comment Selfridge1-6.

8.7.22.3 Responses to Comments from Nancy Selfridge– Letter 3

Selfridge3-1 Master Response 3, Water Rights, Section 8.2.3.2 describes the sequence of approvals vis-a-vis water rights: The substance of CalAm's legal claim to water rights is addressed in EIR/EIS Section 2.6, and in Master Response 3, Section 8.2.3.4. Since under the legal construct, an appropriative right to developed water is a right that exists based upon the facts at hand, and need not be formally established in advance, there is no possibility for the Lead Agencies to insist that CalAm obtain or perfect water rights prior to project approval. See also Master Response 8, Project Source Water and Seawater Intrusion.

The issue of ratepayer liability is outside the scope of the CEQA and NEPA; however, as described in EIR/EIS Section 1.5.4.1, the CPUC decision to grant or deny a Certificate of Public Convenience and Necessity for the project (i.e., project approval) would follow a process after certification of the EIR during which the Commission will consider any other issues that have been established in the record of the proceeding, including but not limited to economic issues, social impacts, specific routing and alignments, and the need for the project. Therefore, comments regarding ratepayer liability are relevant to and will be considered as part of that proceeding.

Selfridge3-2 See Master Response 11 regarding the test slant well. Draft EIR/EIS Section 3.2.11 explains that the test slant well was drilled at 19 degrees below horizontal, is 724 feet long, and is screened for 450 linear feet at depths corresponding to both the Dune Sand Aquifer and the underlying 180-Foot-Equivalent Aquifer of the Salinas Valley Groundwater Basin. The same EIR/EIS section explains that "The nine new permanent slant wells would be approximately 900 to 1,000 feet long and drilled at approximately 14 degrees below horizontal to extend offshore to a distance of 161 to 356 feet seaward of the MHW line (except #8, which would not extend past the MHW line) and to a depth of 190 to 210 feet beneath the seafloor." The test slant well is screened in the Dune Sands and 180-FTE Aquifers – the same aquifers the proposed slant wells would be screened in. Therefore, the proposed slant wells would not be "hundreds of feet deeper" than the test slant well. See also Master Response 12, The North Marina Groundwater Model (v. 2016), which provides clarification on the groundwater modeling data that is the basis for the EIR/EIS conclusions on groundwater impacts.

Selfridge3-3 See Master Response 3, Water Rights, Section 8.2.3.5.

Selfridge3-4 See Master Response 11, CalAm Test Slant Well, Section 8.2.11.4.

Selfridge3-5 See Master Response 3, Water Rights, Section 8.2.3.5.

Selfridge3-6 This comment addresses the operation of the test slant well pursuant to its existing permits that were issued by the CA Coastal Commission, and is outside the scope of this EIR/EIS. For more details about the permitting and operation of test slant well, see Master Response 11, CalAm Test Slant Well, Sections 8.2.11.1, 8.2.11.2 and 8.2.11.3. Regarding beneficial uses of water, see Master Response 3, Water Rights, Section 8.2.3.5. Master Response 8, Project Source Water and Seawater Intrusion, explains the slant wells at CEMEX would initially extract the water that is held in the surrounding sediments (ambient groundwater) and as pumping continues, the wells would extract increasing proportions of infiltrating recharge from the ocean and the ocean recharge would gradually replace the ambient groundwater within the capture zone. The capture zone is defined as a localized area at the coast. The impacts of the proposed project on the Ag Land Trust wells are described in Draft EIR/EIS Section 4.4.5.2 and in Table 4.4-10.

Selfridge3-7 The Final EIR/EIS has not been altered in such a way as a result of this comment or other comments on the Draft EIR/EIS that identify new or substantially more severe significant environmental impacts that were not previously identified in the Draft EIR/EIS. Nor has the Final EIR/EIS identified new feasible mitigation measures or project alternatives to reduce significant impacts, or new mitigation measures that the project proponent refuses to incorporate into the project. Furthermore, the comments on the Draft EIR/EIS have not raised issues or presented data so as to cause the Lead Agencies to conclude that the Draft EIR/EIS was fundamentally flawed. For these reasons, the EIR/EIS need not be recirculated for further public review.

8.7.23 Responses to Comments from Jan Shriner

Shriner-1 See Master Response 11, CalAm Test Slant Well, Sections 8.2.11.2, 8.2.11.3, and 8.2.11.7, and EIR/EIS Section 3.2.1.1.

Shriner-2 Table 1 in the Coastal Retreat Study (EIR/EIS Appendix C2) presents the erosion rate data sources that were included when the consultants to the Lead Agencies established historic shoreline change trends that were used in the development of dune erosion profiles. The erosion profiles were developed by the consultants as described in Appendix C2, and not by CalAm; CalAm provided the locations of proposed project infrastructure where pipes or outfalls would cross the erosion profiles as explained in the text on page 7 of EIR/EIS Appendix C2.

Shriner-3 The average annual erosion rates cited in the comment were not used in the EIR/EIS because the natural system is too complicated to rely on a single number. The annual rates were calculated by the commenter by taking the results of the year 2060 horizontal dune erosion profile presented in Appendix C2 on page 7, and dividing it by 46 years (from 2014 to 2060). The methodology for projecting future vertical and horizontal erosion profiles that is used in the EIR/EIS is described in Section 3 of Appendix C2. The analysis considered localized erosion (rip currents), long-term erosion, and sea level rise to develop the erosion profiles.

Shriner-4 The Coastal Retreat Study (Appendix C2) is described in EIR/EIS Section 4.2.4.5 and Figures 4.2-7 and 4.2-8 present the erosion profiles and envelopes for the test slant well and the production wells, respectively. The wellhead of the test slant well is shown in Figure 4.2-7 to be at 30 feet (NAVD) above mean sea level and behind (inland) of the "2040, 100-Year Storm Event" line. Note 4 on Figure 4.2-7 explains the test slant well location is based on a "geologic cross section" that was ground-truthed and provided in GIS format. The blue pipe in the panorama photo provided by the commenter is the discharge pipe that connects the test slant well to the outfall; the test slant well is aligned perpendicular to the discharge pipe just off to the left. The yellow posts in the foreground of the photo are protecting the monitoring wells (MW-1), which are located about 170 feet inland from the surf zone, and 230 feet closer to the beach than the discharge pipe; the test slant well is therefore, located about 400 feet inland from the surf zone and the other nine wells are proposed to be located approximately 500 feet further inland. Mitigation Measure 4.2-9 is a Slant Well Abandonment Plan in the event coastal erosion threatens to expose the slant well.

The current situation is not flatter and closer than the EIR/EIS states because the location was ground-truthed and provided in GIS format and not assumed from an unscaled photo; therefore, the test slant well is not at eminent risk of exposure from coastal erosion that would require the well to be removed before the snowy plover season. As noted by Special Condition 3(b) of the CDP that was issued by the CCC for the test slant well, project-related construction including site preparation,

equipment staging, and installation or removal of equipment or wells, shall not occur between February 28 and October 1 of any year (to protect nesting snowy plover). If the test slant well cannot be removed by February 28, 2018, and it has not been approved to be converted to a permanent well, CalAm, will need to apply to the CCC for an extension of the CDP.

Shriner-5 The vertical to horizontal scale in Figures 4.2-7 and 4.2-8 is 1:6 as shown on the x and y axes, and is not intended to be misleading. Rather, this is a standard practice that enables the entire section to be printed on one page and, more importantly, it better visually illustrates the subsurface details. For example, the preliminary AEM data that was presented at the August 7, 2017 Regular MCWD Board Meeting and Joint Board/Groundwater Sustainability Agency Meeting utilized a vertical exaggeration of 1:15. If printed at a 1:1 scale, the vertical view section would be compressed and the details of the subsurface would not be visible. The comment is correct regarding the test slant well elevation; the test slant well wellhead is shown in Figure 4.2-7 to be at 30 feet (NAVD) above sea level and behind (inland) of the 2040, 100-Year Storm Event line as of January 7, 2016.

Shriner-6 The paragraphs quoted in the comment are from EIR/EIS Section 4.2, Geology, Soils, and Seismicity, and are addressing Impact 4.2-10: Accelerate and/or exacerbate natural rates of coastal erosion, scour, or dune retreat, resulting in damage to adjoining properties or a substantial change in the natural coastal environment. As explained in EIR/EIS Section 3.2.1.1, the slant wells would be located on a retired portion of the CEMEX property and would not affect the existing sand mining operations. CalAm has coordinated with CEMEX on the locations of the proposed slant wells and associated infrastructure so as to not interfere with the existing sand mining operations.

Many people in the community, especially the City of Marina, believe the CEMEX sand mining operation should be shut down, and it will be, effective 2020; see Master Response 14, CEMEX Settlement Agreement. The text cited in the comment from page 147 is in EIR/EIS Section 3.2.1.1 (project description) and “page 374” is on page 7 of EIR/EIS Appendix C2 (Analysis of Historic and Future Coastal Erosion with Sea Level Rise). Page 374 reads as follows: “It is important to note that actual sea level rise and the effects are not known, and that relatively high values were used in this study. Also, interventions may change shore recession.” The intervention may well be the closure of the sand mining operation.

The ongoing erosion at CEMEX is not a cumulative project (see EIR/EIS Section 4.1.7); it is a baseline condition against which the impacts of the proposed project are evaluated, and as noted in EIR/EIS Section 4.2.4.5, the Coastal Retreat Study considered historic erosion and assumed there would be no changes to existing sand mining practices. The proposed project slant wells would not contribute to coastal erosion because they would be removed prior to exposure and therefore, prior to it having an influence on coastal erosion “resulting in damage to adjoining

properties or a substantial change in the natural coastal environment." The conclusion for Impact 4.2-10 is therefore, determined to be less than significant. See also Master Response 14, Section 8.2.14.1, which addresses anticipated changes to existing sand mining practices at CEMEX, and the resulting effect on coastal erosion.

Figure 5.1 is in EIR/EIS Appendix E2 and presents the North Marina Groundwater Model cells that would be "flooded" as a result of sea level rise in 2073, while EIR/EIS Figure 3-3a presents the slant well locations at CEMEX (Figure 3-13, referenced by the comment, is a map of the Castroville Pipeline Optional Alignment and is not relevant to this comment). Appendix E2 Figure 5.1 and EIR/EIS Figure 3-3a serve different purposes, and sea level rise is only one component used in the development of the vertical and horizontal erosion profiles (see response to comment Shriner-3). The erosion hazard zones at the CEMEX site and at the Potrero Road site are presented side by side in Figure 3 in Appendix C2 and the comment is correct – the slant well locations at the CEMEX site would be impacted before and more severely than slant wells at the alternative location at Potrero Road. However, as shown on EIR/EIS Figures 4.2-7 (profile), the test slant well at CEMEX is located behind (inland of) the 2040, 100-Year Storm Event line and would be abandoned if necessary, prior to exposure to coastal erosion, as discussed in the response to comment CEMEX-8. The remaining proposed slant wells at CEMEX would be located behind (inland of) the 2060, 100-year Storm Event line, as shown on Figure 4.2-8. (The erosion profile for the Potrero Road site is shown on Figure 7 in EIR/EIS Appendix C2.)

EIR/EIS Figures 4.2-7 and 4.2-8 present both vertical and horizontal retreat profiles at CEMEX, including new corresponding bottom contours and depths in the sand of the intake pipes. Note 1 explains these envelopes of erosion consider seasonal changes in beach width, localized erosion (rip currents), long-term erosion, and accelerated erosion caused by sea level rise, and each of these factors is important in defining the profile shape and location at a given time; see EIR/EIS Section 4.2.4.5. For this reason, the analysis identified a projected future profile and an extremely eroded profile (lower envelope) for each future time horizon: years 2010, 2040 and 2060. The future profile is the current profile eroded at the historic rate, with added erosion caused by sea level rise. The lower profile envelope represents a highly eroded condition, which could occur from a combination of localized erosion (rip currents), a large winter storm, and seasonal changes. The purpose of these figures is to identify if and when coastal retreat is anticipated to occur independent of the MPWSP, and the analysis indicates the slant wells would not impact, accelerate, or exacerbate the rate of coastal erosion, because they would be removed prior to exposure and therefore, prior to it having an influence on coastal erosion as explained in Section 4.2, Impact 4.2-10 (see Draft EIR/EIS pages 4.2-68 through 4.2-72). No change has been made to the EIR/EIS in response to this comment.

The MPWSP would not contribute to any ongoing impact caused by the CEMEX ponds as explained in Section 4.4, Impact 4.4-3 (Draft EIR/EIS pages 4.4-70 through

4.4-72). The impacts relative to the MRWPCA outfall are discussed in Section 4.3, Impacts 4.3-4 and 4.3-5.

Shriner-7 The Monterey Downs project has been removed from the list of cumulative projects in EIR/EIS Table 4.1-2.

Shriner-8 The Notice of Availability (NOA) of the Draft EIR/EIS was published on January 13, 2017, and included an announcement that "[t]he open house/public meetings will include a brief presentation on the contents and conclusions of the Draft EIR/EIS and interested parties will be provided an opportunity to interact with technical staff and preparers of the Draft EIR/EIS." The Lead Agencies' consultant staff was directed to help reviewers of the Draft EIR/EIS to navigate the document in order to facilitate the review of the lengthy and complicated document. As noted in response to comment Shriner-3, the EIR/EIS did not use a single erosion rate because the natural system is too complicated to rely on a single number. Regardless, the reported behavior of the Applicant's Project Manager towards the commenter at a Lead Agency-hosted public meeting on the Draft EIR/EIS is unfortunate. The Lead Agencies and their consultants work independently from the Applicant, and is not monitored or otherwise influenced by employees of CalAm.

Shriner-9 It is not clear what this comment is referring to, or what was said on February 15, 2017. Master Response 8, Project Source Water and Seawater Intrusion, may respond to the concerns raised in this comment. See also responses to comments MCWD-Hopkins Groundwater Consultants (HGC) in Section 8.5.2.2.

Shriner-10 At the request of several agencies and members of the public, the Lead Agencies extended the comment period by an additional 30 days, and written comments on the Draft EIR/EIS were accepted from January 13 through March 29, 2017, for a total review period of 75 days.

Shriner-11 The comment does not provide any specifics on how or why the EIR/EIS alternatives analysis is inadequate. CEQA Guidelines Section 15126.6(d) and the NEPA Regulations (40 CFR § 1502.14) emphasize the selection of a reasonable range of alternatives that meet the objectives of and/or purpose and need for the project, and the comparative assessment of the impacts of the alternatives to allow for public disclosure and informed decision-making. EIR/EIS Chapter 5 provides a thorough and comprehensive analysis of alternative project components (see Sections 5.1 through 5.3) and project alternatives (see Sections 5.4 and 5.5), including the No Project/No Action alternative, consistent with the provisions of CEQA and NEPA.

Shriner-12 The comment does not provide any specifics on what peer-reviewed science may have been inadequately addressed. The CPUC engaged the Lawrence Berkeley National Laboratories to peer review the 2015 version of the North Marina Groundwater Model ($NMGWM^{2015}$) performed by Geoscience for the April 2015 MPWSP Draft EIR (see EIR/EIS Appendix E1); the Monterey Peninsula Regional Water Authority (aka the Mayors' Authority) engaged GeoSyntec to peer review the

2016 version of the North Marina Groundwater Model ($NMGWM^{2016}$) performed by HydroFocus and the brine discharge modeling performed by Dr. Phil Roberts; Trussell Technologies, on behalf of the MRWPCA, engaged in a peer review of the CEQA/NEPA brine discharge modeling. Consultants to the Lead Agencies have collaborated with the Hydrogeologic Working Group (HWG) as explained in Master Response 5, The Role of Hydrogeologic Working Group and its Relationship to the EIR/EIS, and have reviewed and considered the results of the MCWD-sponsored ERT study performed by the Stanford University post-graduate program (see Master Response 9, Electrical Resistivity Tomography (ERT) and Airborne Electromagnetic (AEM)).

8.7.24 Responses to Comments from Roy Thomas

Thomas-1 Potential beneficial impacts on terrestrial biological resources dependent on the Carmel River are discussed in Section 5.5.6.3. The need for the proposed project is predicated on State Water Resources Control Board (SWRCB) Order 95-10, which requires CalAm to reduce and terminate surface water diversions from the Carmel River in excess of its legal entitlement of 3,376 acre-feet per year (afy) (see EIR/EIS Section 1.3). Section 2.2.3 further explains SWRCB Order 95-10 and how it directed CalAm to obtain appropriative rights to the Carmel River water that was being unlawfully diverted, obtain water from other sources and make one-for-one reductions of the unlawful diversions, and/or contract with other agencies that had appropriative rights to divert and use water from the Carmel River. The proposed project represents one possible method of achieving the requirements of SWRCB Order 95-10; the alternatives, including the No Project Alternative, represent other options. Regardless of which alternative ultimately is selected, CalAm's surface water diversions from the Carmel River in excess of its legal entitlement will be reduced and terminated in compliance with SWRCB Order 95-10. The beneficial impacts of implementation of SWRCB Order 95-10 are analyzed in the Order.

However, as explained in EIR/EIS Section 5.5.3.3 and 5.5.6.3, the No Project alternative would result in a more beneficial impact on Carmel River resources as compared to the proposed project or another action alternative, because in the event that the Cease and Desist Order (CDO) milestones are not met, diversions from the Carmel River would be curtailed sooner than if milestones are met through project or another action alternative approval and implementation. This analysis is provided to address the difference in intensity of impacts between the No Project Alternative and an action alternative.

Thomas-2 As discussed in EIR/EIS Section 3.2.4, the ASR-5 and ASR-6 wells would be used to provide additional injection/extraction capacity for both desalinated product water and Carmel River supplies, and to increase system reliability: "These improvements would not affect CalAm's maximum allowable surface water diversions from the Carmel River for injection into the groundwater basin." Consequently, there would be no change in effect on the Carmel River from the implementation of ASR-5 or ASR-6.

Thomas-3 Water flowing in the Carmel River channel is the surface expression of groundwater that flows through the water-bearing river alluvium known as the Carmel River Aquifer. The aquifer is underlain and bordered by non-water bearing bedrock that creates the river bed and bank. The groundwater that occupies and is transmitted through the river alluvium is referred to as underflow, some of which is extracted by CalAm's groundwater production wells. As noted in SWRCB Order 95-10 (SWRCB, 1995) Section 3.3, depth to water in the wells ranges from 3 to 30 feet. Therefore, CalAm's diversion wells on the Carmel River are not deep wells; they extract

underflow which is in direct contact with the surface flows and recharge time is minimal. Water Rights Permits 20808A and 20808C include conditions that establish limits on diversions to the ASR system, including a requirement that minimum mean daily instream flows in the Carmel River be maintained for the protection of fisheries, wildlife, and other instream uses.

Thomas-4 Final EIR/EIS Section 3.2.3.5 (was formerly Draft EIR/EIS Section 3.2.3.6) and Table 3-1, explain that the proposed Carmel Valley Pump Station (CVPS) would provide the additional pressure needed to pump water already within the system, through the existing Segunda Pipeline to fill the Segunda Reservoir via a 100 hp pump. See also response to comment Beech2-17 in Section 8.7.2.2. The CVPS would not affect CalAm's maximum allowable surface water diversions from the Carmel River; see response to comment Thomas-2, Thomas-3 and Thomas-6.

Thomas-5 As explained in EIR/EIS Section 3.4.2, CalAm proposes to use the ASR system to store water during wet periods. As noted in Table 3-6, the Subsurface Intake System and MPWSP Desalination Plant would operate 24 hours per day, 365 days per year. Injection of desalinated product water and Carmel River supplies into the ASR system would occur during the wet season, typically from December through April or May. Water would be extracted from the ASR system typically from May through November.

Thomas-6 See response to comment Thomas-1. As a result of compliance with SWRCB Order 95-10, CalAm's surface water diversions from the Carmel River will be held to a legal limit of 3,376 afy. Compliance with the Order would restore the spring, summer and fall flows on the Carmel River.

Thomas-7 As was described in Draft EIR/EIS Section 3.2.3.5, Terminal Reservoir would have stored potable water supplies from a variety of sources, including Carmel River supplies, desalinated product water, and ASR product water from the Seaside Groundwater Basin. However, Terminal Reservoir has been removed from the proposed project (see Final EIR/EIS Section 1.6); therefore, the EIR/EIS analysis reflects this change.

Thomas-8 As noted in EIR/EIS Section 1.3.1, the primary objectives of the proposed project are to develop water supplies for the CalAm Monterey District service area to replace existing Carmel River diversions in excess of legal entitlement (see Section 2.2.3), to reduce pumping from the Seaside Groundwater Basin and to allow CalAm to meet its obligation to pay back the Seaside Groundwater Basin (see Section 2.2.4), to meet peak month demand of CalAm's Monterey District service area customers (see Sections 2.3.1 and 2.3.2), to serve existing vacant legal lots of record (see Section 2.3.2.2, formerly Draft EIR/EIS Section 2.3.3.3), and to accommodate tourism demand under recovered economic conditions (see

Section 2.3.2.1, formerly Draft EIR/EIS Section 2.3.3.2). Construction is expected to be complete in June 2020 and operations would begin immediately thereafter.

Thomas-9 EIR/EIS Section 4.6.2 presents the regulatory framework for terrestrial biological resources and draws conclusions about the proposed project's consistency with these regulatory requirements. The Federal Endangered Species Act (FESA) is discussed in Section 4.6.2.1.

EIR/EIS Section 4.5.2 presents the regulatory framework for marine biological resources; consistency with the Magnuson-Stevens Fishery Conservation and Management Act is discussed in Section 4.5.2.1. MBNMS, a Lead Agency for the EIR/EIS, is also in consultation with the National Marine Fisheries Service and U.S. Fish and Wildlife in compliance with the FESA and the Magnuson-Stevens Act; see EIR/EIS Section 7.1. See also response to comment Thomas-1.

Thomas-10 As explained in EIR/EIS Section 2.4.2, CalAm's total adjudicated right to Seaside Groundwater Basin groundwater will be 1,474 afy. Repayment of the water that CalAm has pumped from the Seaside Basin in excess of its adjudicated right would occur over 25-years as agreed to between CalAm and the Seaside Basin Watermaster; payback would start when CalAm secures additional supplies. The payback would occur as "in-lieu" replenishment, which means CalAm would pump only 774 afy during the 25-year repayment period, leaving the 700 afy balance of their 1,474 afy adjudicated right in the ground to replenish the basin. EIR/EIS Table 2-4 presents assumed quantities provided by CalAm's water supply sources with and without the GWR project and during and after the Seaside Groundwater Basin replenishment period. The desalination plant was sized assuming only 774 afy would be available from the Seaside Groundwater Basin for 25 years. As shown, the amount of supply available from the Carmel River would be the same during and after the replenishment period.

Thomas-11 See response to comment Thomas-3. During the winter months, CalAm is allowed under Water Rights Permits 20808A and 20808C to extract water for diversion to ASR, and the water is diverted from the underflow of the Carmel River, not from deep wells. The difference in the flows between the gages is more likely due to the permitted diversion of flows to ASR, than to restoring the groundwater. For example, as reported to the MPWMP Board of Directors on April 19, 2017, since the start of Water Year 2017 (October 2016) through March 2017, runoff was 325 percent of average, and 1,510 acre-feet had been diverted from the Carmel River for injection and storage in the Seaside Basin ASR (MPWMD, 2017).

Thomas-12 The proposed project would allow CalAm to be in compliance with its water rights on the Carmel River. EIR/EIS Section 2.4.3 discusses the volume and timing of diversions from the Carmel River to the ASR system.

Thomas-13 As presented in EIR/EIS Table 3-1 and Section 3.2.3.9, the Ryan Ranch-Bishop and Hidden Hills Interconnection Improvements would allow CalAm to convey

MPWSP water supplies to the Ryan Ranch, Bishop, and Hidden Hills satellite water systems by constructing new pipelines that would connect to existing booster stations, and by making improvements to existing booster stations. Since Carmel River water and MPWSP desalinated product water would be injected into the ASR system, it is possible that these communities could receive Carmel River ASR water as part of their water supply. As CalAm ratepayers, these communities would contribute to CalAm's operating expenses in some fashion via the rate structure. See EIR/EIS Section 1.5.4 for an explanation of how the decision-makers would address cost issues.

Thomas-14 See response to comment Thomas-1.

Re: Monterey Peninsula Water Supply Project (MPWSP) (A1204019)

Dear CPUC Commissioners and Sanctuary Agency Officials:

The two most alarming deficiencies in California American Water Company's proposed desal project are 1) poor science around the 'first of its kind' slant well ocean intake; and 2) lack of water rights.

These signed requests were collected after the DEIR/EIS was released. I am transmitting them widely so that more public officials become aware of these shortcomings. It is urgent that at least two very specific issues are clarified: FORM1-1

1. There have been NO successful, completed slant wells for subsurface ocean desalination anywhere in the U.S. or the world. There was only one attempted project at Dana Point, CA. State agencies require a feasibility study of this new technology. With an untested and experimental design, the *highest standard* of scientific testing must be made. There is a more accurate method of mapping the saltwater intrusion in the Salinas Valley Groundwater Basin (called Electrical Resistivity Tomography--ERT) but this method is NOT used in the DEIR environmental review of impacts. ERT imaging will be completed in mid-2017. Such scientific data and observations must be included in the DEIR evaluation of impacts and the question of 'no harm' from the project. FORM1-2

2. Cal-Am has no water rights in the Salinas Groundwater Basin but they intend to pump another water district's groundwater. The fundamental determination of legal water rights must be made now before further infrastructure investment and before more project approvals. FORM1-3

Additional concerns include possible litigation and delay, lack of contingency planning, and continued pressure from the State Cease and Desist Order.

Ratepayers are facing huge new costs, regardless of success, delay or failure. I and other signers request your support in pursuing these issues. Sooner, rather than later. FORM1-4

Thank you for your attention.

Sincerely,

Michael Baer

Re: Monterey Peninsula Water Supply Project (MPWSP)

Dear Commissioners and Agency Officials:

I request the CPUC deny approval of the draft Environmental Impact Report (DEIR) and deny certification for the Monterey Peninsula Water Supply Project (MPWSP) until at least two very specific issues are clarified:

- There have been NO successful, completed slant wells for subsurface ocean desalination anywhere in the U.S. or the world. There was only one attempted project at Dana Point, CA. State agencies require a feasibility study of this new technology. With an untested and experimental design, the *highest standard* of scientific testing must be made. There is a more accurate method of mapping the saltwater intrusion in the Salinas Valley Groundwater Basin (called Electrical Resistivity Tomography-ERT) but this method is NOT used in the DEIR environmental review of impacts. ERT imaging will be completed in mid-2017. Such scientific data and observations must be included in the DEIR evaluation of impacts and the question of 'no harm' from the project.

- Cal-Am has no water rights in the Salinas Groundwater Basin but they intend to pump another water district's groundwater. The fundamental determination of legal water rights must be made now before further infrastructure investment and before more project approvals.

- Additional comments: PLEASE MAKE THE WATER RIGHTS DETERMINATION WITH GREAT URGENCY. IT IS ONLY COMMON SENSE TO DO THIS BEFORE INCURRING EVEN MORE POTENTIALLY STRANDED COSTS TO BE BORNE BY RATEPAYERS.

FORM1-5

Thank you for your attention to this matter.

Sincerely,
(Signature) [signature]

Dear Commissioners:

Attached is a CD containing 791 scanned letters signed by individual Monterey Bay citizens, like me, who wish to express concerns regarding the Cal-Am Slant Well project (MPWSP). These letters are signed by unaffiliated, private citizens, mostly from the City of Marina and Ord Communities, and are NOT specifically related to the DEIR public comments. However, the issues are vital to us as well as to other area interests. I hope you will review them to understand our concerns.

I would appreciate confirmation of receipt of these CDs at jhofmann@redshift.com when they have been distributed to your commissioners.

FORM2-1

Thank you very much,

Juli Hofmann

Re: Monterey Peninsula Water Supply Project (MPWSP)

Dear Commissioners:

I request the CPUC deny approval of the draft Environmental Impact Report (DEIR) and deny certification for the Monterey Peninsula Water Supply Project (MPWSP) for the following reasons:

- Cal-Am has no water rights in the Salinas Valley Groundwater Basin (SVGB) but they intend to pump water from this district to their Peninsula customers; the SVGB water district already has serious concerns of the adequacy of its aquifers to meet the needs for current and future water. This is not considered in the environmental review! FORM2-2
- Cal-Am's project represents an ***environmental injustice*** that blatantly ignores the rights and welfare of Marina, a small city of 21,000 with a working class and diverse population. FORM2-3
- Cal-Am's project assumes that compromising the Salinas Valley Groundwater Basin is inconsequential over the needs of a wealthier, more politically influential jurisdiction. FORM2-4

Re: Monterey Peninsula Water Supply Project (MPWSP)

Dear Commissioners:

I request the CPUC deny approval of the draft Environmental Impact Report (DEIR) and deny certification for the Monterey Peninsula Water Supply Project (MPWSP) for the following reasons:

- Cal-Am's project proposes pumping millions of gallons of water per day from our already over-drafted Salinas Groundwater Basin...much more per day than Marina Coast Water District currently pumps! FORM2-5
- No considerations are given to our own region's fragile and limited groundwater resources! FORM2-6
- The 180' and 400' aquifers are already over-drafted. The 900' aquifer is currently a primary water source but due to its small storage and/or recharging rates, this last aquifer may be at risk. Cal-Am has failed to prove that the region's water sources will not be harmed by their massive pumping! FORM2-7

Additional Comments:

Thank you for your kind attention to this matter.

Re: Monterey Peninsula Water Supply Project (MPWSP)

Dear Commissioners:

I request the CPUC deny approval of the draft Environmental Impact Report (DEIR) and deny certification for the Monterey Peninsula Water Supply Project (MPWSP) for the following reasons:

- Saltwater intrusion is a real threat to the region's water supplies; there will be enormous amounts of water pumped by Cal-Am and pumping causes seawater intrusion. FORM2-8
- There is a much more accurate method of mapping the saltwater intrusion in the Salinas Valley Groundwater Basin (called Electrical Resistivity Tomography-ERT) but this method is NOT used in Cal-Am's environmental review! FORM2-9
- This information is needed to prove Cal-Am will do "no harm" to our groundwater sources.
- Until such ERT imaging is completed, we request a delay in approval of the environmental review.

Additional Comments:

Thank you for your kind attention to this matter.

Sincerely,

Re: Monterey Peninsula Water Supply Project (MPWSP)

Dear Commissioners:

I request the CPUC deny approval of the draft Environmental Impact Report (DEIR) and deny certification for the Monterey Peninsula Water Supply Project (MPWSP) for the following reasons:

- Cal-Am has not proven with any high levels of certainty that their project will not damage or cause injury to the Salinas Groundwater Basin...the "life blood" of this region's groundwater source. FORM2-12

- Even with significant saltwater intrusion, the region has responsibly managed its water sources. Water remains affordable, and Marina Coast Water District has embarked on alternative projects to secure water in the future; Cal-Am will undermine all such plans! FORM2-13

- Cal-Am must give written assurances for monetary compensation to Salinas Groundwater Basin ratepayers should their project damage the regional water supply. Without this, Cal-Am will be allowed to gamble with another's districts water supply without contemplating paying damages in the future to injured parties! FORM2-14

Re: Monterey Peninsula Water Supply Project (MPWSP)

Dear Commissioners:

I request the CPUC deny approval of the draft Environmental Impact Report (DEIR) and deny certification for the Monterey Peninsula Water Supply Project (MPWSP) for the following reasons:

- Cal-Am has no water rights in the Salinas Groundwater Basin but they intend to pump another district's groundwater and transport this water to their Peninsula customers. The fundamental determination of legal water rights must be made now before any further project approvals! FORM2-15

- Cal Am plans to extract high volumes of water from one source (Marina) and return a small portion of this water to another area (Castroville). This goes against ordinances that prohibit groundwater extraction and exportation and there is no scientific proof that there is any direct benefit to the groundwater of Marina and the Ord community by such action. FORM2-16

- Groundwater from Marina and Ord communities must stay in and be used for Marina and the Ord communities! FORM2-17

Re: Monterey Peninsula Water Supply Project (MPWSP)

Dear Commissioners:

I request the CPUC deny approval of the draft Environmental Impact Report (DEIR) and deny certification for the Monterey Peninsula Water Supply Project (MPWSP) for the following reasons:

- Cal-Am has failed to prove, as required by law, "no harm" to our local groundwater. FORM2-18
- Cal-Am failed to establish accurate and comprehensive baseline information before installing the test slant well. The model that Cal-Am uses to predict "harm" uses this inaccurate and incomplete information! FORM2-19
- Cal-Am's test slant well is showing that less seawater and more aquifer water than expected is being pumped. This means that Cal-Am expects to pump a larger portion of fresh water from the 180 foot aquifer and there is miscalculation of important predictions...this not acceptable science! FORM2-20

Re: Monterey Peninsula Water Supply Project (MPWSP)

Dear Commissioners:

I request the CPUC deny approval of the draft Environmental Impact Report (DEIR) and deny certification for the Monterey Peninsula Water Supply Project (MPWSP) for the following reasons:

- Cal-Am's slant well project is **not** just ocean intake as they have promoted to the public. Cal-Am's slant wells will absolutely be in the 180' aquifer, a source of water for our region, and they have clouded this critical fact! FORM2-21

- Current test slant well results show greater than predicted groundwater, rather than ocean water, has been drawn from the test slant well. This is taking precious water from aquifers that belong to the Salinas Valley Groundwater Basin! FORM2-22

- Saltwater intrusion has degraded the quality of our aquifer water; we need to know precisely where all leakages of saltwater could occur to lower aquifers and the "ERT" imaging can provide this much needed information. The approvals of the environmental review should **not** be done until we have this ERT study completed! FORM2-23

Additional Comments:

Thank you for your kind attention to this matter.

Re: Monterey Peninsula Water Supply Project (MPWSP)

Dear Commissioners:

I request the CPUC deny approval of the draft Environmental Impact Report (DEIR) and deny certification for the Monterey Peninsula Water Supply Project (MPWSP) for the following reasons:

- There have been NO successful, completed slant wells for subsurface ocean desalination anywhere in the U.S. or the world; there is only one attempted project at Dana Point, CA. There has been no serious evaluation of the Dana Point project included in the environmental review. "Those who do not know the past, are doomed to repeat it". FORM2-24
- Cal-Am's test slant well itself produced results that did not meet the projected targets and the pumping during the testing had to be stopped multiple times for unexpected occurrences; this is truly sloppy science! FORM2-25
- For such an untested, experimental design, the highest standards of scientific testing must be applied; Cal-Am is simply not doing this! FORM2-26

Re: Monterey Peninsula Water Supply Project (MPWSP)

Dear Commissioners:

I request the CPUC deny approval of the draft Environmental Impact Report (DEIR) and deny certification for the Monterey Peninsula Water Supply Project (MPWSP) for the following reasons:

- Cal-Am has not proven with any high levels of certainty that their project will not damage or cause injury to the Salinas Groundwater Basin...the "life blood" of this region's groundwater source.

- Even with significant saltwater intrusion, the region has responsibly managed its water sources. Water remains affordable, and Marina Coast Water District has embarked on alternative projects to secure water in the future; Cal-Am will undermine all such plans!

- Cal-Am must give written assurances for monetary compensation to Salinas Groundwater Basin ratepayers should their project damage the regional water supply. Without this, Cal-Am will be allowed to gamble with another's districts water supply without contemplating paying damages in the future to injured parties!

Additional Comments: we need evidence on this ~~the~~ Cal Am is not trust worthy - I need proof to save my water

FORM2-30

Thank you for your kind attention to this matter.

Sincerely,

Moira LaMountain (Print Name)

Re: Monterey Peninsula Water Supply Project (MPWSP)

Dear Commissioners:

I request the CPUC deny approval of the draft Environmental Impact Report (DEIR) and deny certification for the Monterey Peninsula Water Supply Project (MPWSP) for the following reasons:

- There have been NO successful, completed slant wells for subsurface ocean desalination anywhere in the U.S. or the world; there is only one attempted project at Dana Point, CA.
- With an untested, experimental design the *highest standard* of scientific testing must be made; Cal-Am has used "sloppy science" and created unproven "theories" to minimize the impact on saltwater intrusion in the region.
- Serious questions are being raised about Cal-Am's models and the data coming out of their test slant well; with the high risk to the Salinas Valley Groundwater Basin, no approvals should be made without first having all the facts!

Additional Comments: We need evidence. Cal Am is not trustworthy!

Thank you for your kind attention to this matter.

Sincerely,

Moira LaMountain (Print Name)

Re: Monterey Peninsula Water Supply Project (MPWSP)

Dear Commissioners:

I request the CPUC deny approval of the draft Environmental Impact Report (DEIR) and deny certification for the Monterey Peninsula Water Supply Project (MPWSP) for the following reasons:

- Cal-Am's project proposes pumping millions of gallons of water per day from our already over-drafted Salinas Groundwater Basin...much more per day than Marina Coast Water District currently pumps!
- No considerations are given to our own region's fragile and limited groundwater resources!
- The 180' and 400' aquifers are already over-drafted. The 900' aquifer is currently a primary water source but due to its small storage and/or recharging rates, this last aquifer may be at risk. Cal-Am has failed to prove that the region's water sources will not be harmed by their massive pumping!

Additional Comments: Please do the right thing. We need evidence. Cal Am's not trustworthy.

Thank you for your kind attention to this matter.

Sincerely,

Moira LaMountain (Print Name)

Re: Monterey Peninsula Water Supply Project (MPWSP)

Dear Commissioners:

I request the CPUC deny approval of the draft Environmental Impact Report (DEIR) and deny certification for the Monterey Peninsula Water Supply Project (MPWSP) for the following reasons:

- Cal-Am has failed to prove, as required by law, "no harm" to our local groundwater.
- Cal-Am failed to establish accurate and comprehensive baseline information before installing the test slant well. The model that Cal-Am uses to predict "harm" uses this inaccurate and incomplete information!
- Cal-Am's test slant well is showing that less seawater and more aquifer water than expected is being pumped. This means that Cal-Am expects to pump a larger portion of fresh water from the 180 foot aquifer and there is miscalculation of important predictions...this not acceptable science!

Additional Comments: IT IS WELL PAST TIME TO STOP THE ASSAULT ON MARINA'S WATER SUPPLY BY THE THREE PIECE SUIT PARASITES AT CAL AM / CONGLOMERATE.

FORM2-31

Thank you for your kind attention to this matter.

8.8.1 Responses to Comments from Form Letter 1

Form Letter 1 consists of 149 one-page letters, received as a package and consisting of several common statements as well as hand-written comments added by individual signers. All unique comments have been identified and addressed in responses below.

Form1-1 The Lead Agencies acknowledge receipt of the letters and provide responses below where comments included enough specificity to allow for a substantive response.

Form1-2 Master Response 11, CalAm Test Slant Well, Section 8.2.11.8 discusses the new and evolving slant well technology and specifically addresses the test well at Dana Point. EIR/EIS Section 4.4.1.4 presents ERT and the work of Dr. Rosemary Knight; Master Response 9, Electrical Resistivity Tomography (ERT) and Airborne Electromagnetics (AEM), presents supplemental information on ERT/AEM and clarifies its use as a method to help characterize water quality and seawater intrusion along the coast of Monterey Bay. Master Response 3, Water Rights, Section 8.2.3.5 further addresses the issue of harm and injury.

Form1-3 EIR/EIS Section 2.6 addresses water rights. See also Master Response 3, Section 8.2.3.2 for a discussion of the sequence of approvals vis-à-vis water rights, and Section 8.2.3.7 for an explanation of the proposed project's potential effects on water supplies used by the Marina Coast Water District.

Form1-4 Possible litigation is outside of the scope of this CEQA and NEPA analysis. The comment does not provide sufficient explanation of what is meant by contingency planning to permit a response. EIR/EIS Section 2.2.3 describes the SWRCB Order 95-10 and the associated Cease and Desist Order. See also Master Response 3, Water Rights. Regarding ratepayer issues, see response to comment PWN2-22 in Section 8.6.17.

Form1-5 See Master Response 3, Section 8.2.3.2 for a discussion of the sequence of approvals vis-à-vis water rights. Regarding ratepayer issues, see response to comment PWN2-22 in Section 8.6.17.

Form1-6 EIR/EIS Section 4.2.4.5 describes the Coastal Retreat Study (Appendix C2); see also responses to comments Shriner-4 in Section 8.7.23 and PTA-6 in Section 8.6.16. EIR/EIS Section 4.18 evaluates energy conservation and Section 4.11 addresses greenhouse gas emissions. Regarding ratepayer issues, see response to comment PWN2-22 in Section 8.6.17.

Form1-7 EIR/EIS Section 4.4.5.2 addresses the proposed project's impact on seawater intrusion in the Salinas Valley Groundwater Basin. See also Master Response 8, Project Source Water and Seawater Intrusion.

Form1-8 Thank you for your comment. This comment does not concern the adequacy of the environmental review included in the EIR/EIS, but will be considered by decisionmakers, as discussed in Section 1.5.

Form1-9 Master Response 3, Section 8.2.3.7 addresses the proposed project's potential effects on water supplies used by the Marina Coast Water District.

Form1-10 Master Response 3, Section 8.2.3.2 provides a discussion of the sequence of approvals vis-à-vis water rights.

8.8.2 Responses to Comments from Form Letter 2

Form Letter 2 consists of 791 one- or two-page letters, received as a package and consisting of several common statements as well as hand-written comments added by individual signers. All unique comments have been identified and addressed in responses below.

Form 2-1 The Lead Agencies acknowledge receipt of 791 form letters reflecting the concerns of certain citizens from the City of Marina and Ord communities.

Form 2-2 EIR/EIS Section 2.6 addresses the issue of water rights as one of project feasibility. See also Master Response 3, Water Rights, Section 8.2.3.2 for a discussion of the sequence of approvals vis-à-vis water rights and Section 8.2.3.7 for an explanation of the proposed project's potential effects on water supplies used by MCWD.

Form 2-3 Environmental justice, including potential disproportionately high and adverse impacts on minority and low-income populations, is addressed in EIR/EIS Section 4.20, Socioeconomics and Environmental Justice. See also responses to comments Marina-5 through 10, 36, 37, 39, 45 through 83, 132 and 133 in Section 8.5.1 for specific discussions of environmental justice concerns in the City of Marina.

Form 2-4 EIR/EIS Section 4.4.5.2 presents the analysis of potential impacts of the proposed project on groundwater resources in the Salinas Valley Groundwater Basin, regardless of jurisdictional boundaries, and concludes that impacts would be less than significant.

Form 2-5 The proposed project would involve more slant well pumping per day than is currently being pumped by the Marina Coast Water District. The water pumped by the proposed project would be brackish, and the project proposes to return to the groundwater basin the freshwater component that originated in the basin. As such, the EIR/EIS concludes that the proposed project would not significantly impact the Salinas Valley Groundwater Basin. As described in EIR/EIS Section 3.2.1.1, the proposed slant wells at CEMEX would pump 24.1 million gallons per day (mgd), or approximately 27,000 acre feet per year (afy). EIR/EIS Section 5.6.2 explains that the Lead Agencies found Alternative 5a to be the environmentally superior alternative; it would pump 15.5 mgd or approximately 17,500 afy (see EIR/EIS Section 5.4.7.2). The water drawn by the wells is expected to be close to 95 percent ocean water and whatever portion of the water that originated in the groundwater basin (five percent) would be returned to the groundwater basin as desalinated water (see EIR/EIS Sections 2.6.2 and 4.4.2.2 and Master Response 4, The Agency Act and Return Water). In comparison, MCWD pumped 4,200 afy of potable water in 2015 (MCWD, 2016).

Form 2-6 See response to comment Form2-4 and Master Response 7, The Deeper Aquifers of the Salinas Valley Groundwater Basin.

Form 2-7 See response to comment Form2-4 and Master Response 7, The Deeper Aquifers of the Salinas Valley Groundwater Basin.

Form 2-8 See response to comment Form2-4. See also Master Response 7, The Deeper Aquifers of the Salinas Valley Groundwater Basin and Master Response 8, Project Source Water and Seawater Intrusion.

Form 2-9 EIR/EIS Section 4.4.1.4 presents Electrical Resistivity Tomography (ERT) and the work of Dr. Rosemary Knight; Master Response 9, Electrical Resistivity Tomography (ERT) and Airborne Electromagnetics (AEM), presents supplemental information on ERT/AEM and clarifies its use as a method to help characterize water quality and seawater intrusion along the coast of Monterey Bay. Master Response 3, Water Rights, Section 8.2.3.5 further addresses the issue of harm and injury.

Form2-10 Master Response 11, Section 8.2.11.8, discusses the new and evolving slant well technology and specifically addresses the test well at Dana Point. EIR/EIS Section 4.4.4 presents the approach to analysis of potential impacts on groundwater resources.

Form2-11 EIR/EIS Appendix E2 explains that the groundwater model used in the EIR/EIS to evaluate impacts on groundwater resources was prepared by the CEQA/NEPA team, and it is not a CalAm model. See Master Response 12, The North Marina Groundwater Model (v.2016), and Master Response 11, CalAm's Test Slant Well. The CPUC decision-making process is explained in EIR/EIS Section 1.5.4. EIR/EIS Section 4.4.5.2 presents the analysis of potential impacts of the proposed project on groundwater resources in the Salinas Valley Groundwater Basin, and concludes that impacts would be less than significant.

Form2-12 EIR/EIS Section 4.4.4 presents the approach to analysis of potential impacts on groundwater resources and Section 4.4.5.2 presents the analysis of potential impacts of the proposed project on groundwater resources in the Salinas Valley Groundwater Basin, and concludes that impacts would be less than significant. See also Master Response 3, Water Rights, Section 8.2.3.5 for a discussion of harm or injury.

Form2-13 Master Response 3, Water Rights, Section 8.2.3.7, presents an explanation of the proposed project's potential effects on water supplies used by MCWD.

Form2-14 EIR/EIS Section 4.4.5.2 presents Applicant Proposed Measure 4.4-3, Groundwater Monitoring and Avoidance of Damage. This measure is not required to reduce a potential impact to less than significant, but would ensure that CalAm would monitor changes in the groundwater surface elevations caused by the proposed pumping at the slant wells through a voluntary program and use of new groundwater monitoring wells. If it is determined that a nearby active groundwater well has been damaged or otherwise negatively affected by the project pumping of the slant wells, the project applicant shall coordinate with the well owner to arrange for an interim water supply

and begin developing a mutually agreed upon course of action to repair or deepen the existing well, restore groundwater yield by improving well efficiency, provide long term replacement of water supply, or construct a new well.

Form2-15 EIR/EIS Section 2.6 addresses water rights. See also Master Response 3, Water Rights, Section 8.2.3.2 for a discussion of the sequence of approvals vis-à-vis water rights, and Section 8.2.3.7 for an explanation of the proposed project's potential effects on water supplies used by the Marina Coast Water District.

Form2-16 See response to comment Form2-4, Master Response 2 Master Response 3, Master Response 4 and Master Response 8.

Form2-17 Master Response 11, Section 8.2.11.8 discusses the new and evolving slant well technology and specifically addresses the test well at Dana Point. EIR/EIS Section 4.4.4 presents the approach to analysis of potential impacts on groundwater resources. EIR/EIS Section 4.4.1.4 presents ERT and the work of Dr. Rosemary Knight; Master Response 9, Electrical Resistivity Tomography (ERT) and Airborne Electromagnetics (AEM) presents supplemental information on ERT/AEM and clarifies its use as a method to help characterize water quality and seawater intrusion along the coast of Monterey Bay. Master Response 3, Water Rights, Section 8.2.3.5 further addresses the issue of harm and injury.

Form2-18 EIR/EIS Section 4.4.5.2 presents the analysis of potential impacts of the proposed project on groundwater resources. See also EIR/EIS Section 2.6 and Master Response 3, Water Rights, for a discussion of "harm".

Form2-19 The reporting of test slant well baseline data is described in Master Response 11, CalAm Test Slant Well, Section 8.2.11.4, and how the test slant well data were used in the groundwater modeling is described in Master Response 12, The North Marina Groundwater Model (v. 2016), Section 8.2.12.2. See also EIR/EIS Appendix E2, Section 4.2, Test Slant Well Pumping, for an example where real-world monitoring data is utilized to compare measured drawdown with the drawdown calculated with the superposition model. EIR/EIS Appendix E2 explains the groundwater model used in the EIR/EIS and demonstrates why this model consists of the best available information.

Form2-20 Master Response 11, CalAm Test Slant Well, Section 8.2.11.5, presents the results of the test slant well pump test; see also EIR/EIS Appendix E3. EIR/EIS Section 4.4.5.2 evaluates impacts of the propsed project on the Salinas Valley Groundwater Basin and considers the portion of source water that might have originated in the groundwater basin to be between zero and 12 percent. The actual percentage of water that would be returned to the Basin would be determined annually based on measured values in the production wells. See also Master Response 3 and Master Response 8.

Form2-21 The EIR/EIS is explicit about where the wells would be located in the groundwater basin. Section 3.2.1.1, specifically Table 3-1 explains, the slant wells would draw water from groundwater aquifers that extend beneath the ocean floor (the Dune Sand Aquifer and the 180-Foot-Equivalent Aquifer of the Salinas Valley Groundwater Basin) for use as source water for the MPWSP Desalination Plant. Impact 4.2-8 explains that the slant wells would be screened at depths corresponding to both the Dune Sand Aquifer and the underlying 180-Foot-Equivalent Aquifer of the Salinas Valley Groundwater Basin. Impact 4.2-10 explains the wells would extend to the west beneath the seafloor and be screened in the Dune Sand Aquifer and the 180-Foot Equivalent Aquifer. See also Figure 4.4-3 for a hydrogeologic cross section that shows the test slant well penetrating the Dune Sand and 180-Foot-Equivalent aquifers. See also Master Response 8.

Form2-22 See response to comment Form2-20, and Master Response 3, Water Rights.

Form2-23 See responses to comments Form2-8 and Form 2-9

Form2-24 Slant well technology is discussed in Master Response 11, CalAm Test Slant Well.

Form2-25 See Master Response 11, which explains why the testing was stopped.

Form2-26 See Master Response 11.

Form2-27 Master Response 3, Water Rights, Section 8.2.3.7 presents an explanation of the proposed project's potential effects on water supplies used by MCWD.

Form2-28 See Master Response 3.

Form2-29 See Master Response 11. Also see Chapter 4.4.1.2 for the baseline discussions of local and regional hydrogeolgy, including seasonal variations.

Form2-30 The EIR/EIS analysis relies on the best available information and was prepared by the CPUC and MBNMS as the CEQA and NEPA Lead Agencies.

Form2-31 Master Response 3, Water Rights, Section 8.2.3.7 presents an explanation of the proposed project's potential effects on water supplies used by MCWD.

Form2-32 Master Response 3, Water Rights, Section 8.2.3.7 presents an explanation of the proposed project's potential effects on water supplies used by MCWD.

PUBLIC COMMENTS:

(Time noted: 4:22 p.m.)

GARY CURSIO: My name is Gary Cursio, and I am here representing the Coalition of Peninsula Businesses as well as the Monterey County Hospitality Association. I would like to thank the Commission for all they have done along the process, keeping us moving forward, helping us get an extension to the CDO, speaking on our behalf. It is all very much appreciated and noted. Thank you for that.

The Monterey County Hospitality Association is made up of 250 members and over 25,000 hospitality employees, and we are their trade association.

The reason all of us fought so hard to extend the CDO was to allow time for this EIR process to run its course and conclude. The EIR findings, which are largely the same as the DEIR released in 2015, show that this project, which is made up of 6.4 million gallons per day, along with the groundwater recharge project, to be environmentally sensitive and feasible. Therefore, the Coalition of Peninsula Businesses and the Monterey County Hospitality Association ask that you please move forward with approvals so that we can solve our water supply shortage and stay within the new deadlines set by the CDO.

Transcript-1 (Cursio)

Thank you.

CHARLES GARDNER: Thank you. Okay. Margaret Ann is next, followed by John Tilley, and then Elizabeth Billingsley.

MARGARET ANN COPPERNOLL: Wow. Quite an introduction.

Good afternoon, and thank you so much for inviting us to come here today. My name is Margaret Ann Coppernoll. I'm a Marina resident.

I'm here today to plead with the CPUC to deny the certification of the MPWSP and to deny approval of this Draft EIR. The reason is that this desal project is infeasible and irreparable harm is being done and will be done. Cal Am has no groundwater rights, making its project, from the start, infeasible. None of the arguments presented qualify Cal Am with groundwater rights. Those water rights belong to the jurisdiction that has lead responsibility. That jurisdiction is Marina Coast Water District, a publicly-owned water purveyor that has a decades-long golden track record of providing fresh potable water to its customers at affordable prices and rewards them with incentives for their water conservation efforts.

Cal Am has inserted its test slant well into Marina Coast Water District's freshwater aquifer, the perched dune sand aquifer. This aquifer provides a natural barrier against seawater intrusion. As science shows, overpumping causes seawater intrusion. The DEIR report states that Cal Am is currently drawing from this aquifer, not the subsurface out in the ocean as the project design depicted. The EIR tells us that the desal project intends to continue drawing from the dune sand aquifer once its other nine slant wells are constructed.

Transcript-2 (Coppernoll)

This project is in violation of the City of Marina's Coastal Land Use Plan, as the DEIR points out. The project is in violation of the CEQA Chapter 9.2 requirement to prove it will do no irreparable harm. It's already doing irreparable harm by taking water that it has no right to take and diminishing Marina's water supply.

The dune sand aquifer is a perched freshwater aquifer that naturally prevents saltwater intrusion. Field research studies have scientifically demonstrated through electrical resistivity tomography, or ERT, that freshwater exists along with saltwater-intruded water in the various geologic, stratographic layers of the subsurface areas of the Salinas Valley groundwater basin aquifers.

Marina Coast Water has done a first-class job in restoring fresh water through sustainable groundwater management plans and programs. Per the report, the desal project is undermining those efforts by pumping 2,100 gallons of water per minute out of the dune sand aquifer, water that ends up back in the bay. This squandering action is unlawful.

The project's goal to construct pipelines that will extract Salinas Valley groundwater basin water out of its jurisdiction and transport it to another area is also unlawful. Providing another water source to the Peninsula is an honorable objective, but it is not honorable to usurp another jurisdiction's water rights in the process.

I plead with you to be fair, to do the morally right thing, to protect Marina's lawful groundwater jurisdiction from this invasion into its water supply system. Please, please deny certification and approval until authentic scientific data can be obtained and any irreparable harm to Marina's water supply system could be averted.

The United Nations has declared water to be a basic human right. California supports this policy that every human being has a basic right to affordable water for drinking, sanitary, and cooking needs. Water is God's gift to mankind and should not be viewed as a for-profit commodity for investors.

Transcript-2 (Coppernoll) cont.

Thank you, and God bless all of you and our communities.

CHARLES GARDNER: So John Tilley, followed by Elizabeth Billingsley, and Harvey Biala.

JOHN TILLEY: Hello. My name is John Tilley. I'm with the Peninsula Coalition of Businesses also, and I'm also involved with the Monterey Commercial Property Owners Association.

I'm really pleased about the EIR coming through to see that this progress has been made. It's very important to know that the projects that are in place have been blessed in this manner. I was very thrilled to see the portfolio of water projects that were part of our application are being well-viewed and that the CDO was extended. And thank you very much for any help you offered in that regard.

I have two main reasons why I'm very supportive of this proposed water project. One is this thing about the community, which means the people that are employed where Cal Am

Transcript-3 (Tilley)

serves. And when I see the number of people coming to this Peninsula every day to work and I think about what would happen if the water supply project was not available, it really concerns me that so many lives would be affected in such a negative way.

Another way I think about this as a very, very positive step forward is as an environmentalist, which I am deeply involved with the environmental projects in the area and very supportive of the health of the Carmel River. The idea that we can limit the amount of the water coming off the river through these projects thrills me. The fact that we can restore the natural course of the river, the volume of water there, the habitat for the many animals that survive there is such a great thing to have. We're blessed in this area with abundant, natural beauty, and I am really thankful that these projects are in place to protect our environment and also to protect our community.

Transcript-3 (Tilley) cont.

Thank you very much.

CHARLES GARDNER: Thank you.

Okay. Elizabeth Billingsley, Harvey Biala followed by Kathy Biala.

ELIZABETH BILLINGSLEY: Hello, everybody. I'm Elizabeth Billingsley, a Peninsula resident for 55 years, but now I'm upset about this EIR. How could the California Public Utilities Commission listen to all of Cal Am's sob stories about the current plight of no water when they did nothing to responsibly renew their own water sources? Now you will allow them to destroy Marina Coast Water District's only water source that 33,000 people are dependent on? Really?

In your environmental review there is no mention about the Salinas Valley groundwater basin needs for our people. We have more undeveloped land than anybody here in the Peninsula, and Cal Am just takes -- talks about the Peninsula needs. Does Cal Am care if we cannot meet our own future water needs and we do not [sic] have the legal rights to this water?

Cal Am has no right to our water, period. You will end up having yet another destroyed water source left by Cal Am if you allow them to take our water illegally. Add us to the Cal Am's list of Carmel River and Seaside groundwater basin of destroyed water resources that Cal Am has brought upon their ratepayers. Marina says "No" to Cal Am.

Transcript-4 (Billingsley)

Thank you.

CHARLES GARDNER: Thank you very much.

So Harvey Biala, Kathy Biala, and then Hebard Olsen.

HARVEY BIALA: My name is Harvey Biala, and I'm a resident of Marina.

Cal Am describes a proposed project as an ocean intake system with subsurface slant wells extending offshore, leading us to believe Cal Am will be taking ocean water for the desalination

Transcript-5 (H. Biala)

project. There is a diagram explained at public meetings, and it seems to depict this and imply that the slant wells will be pumping water safely out from under the ocean floor. This is completely misleading and we are outraged that this is put before the public in this deceptive manner.

In the DEIR there is a diagram that clearly shows the slant well is in the 180-foot aquifer. How dare Cal Am suggest otherwise. Our aquifers are connected to the ocean across the entire region. Cal Am cannot illegally take 27,000 acre feet per year from our water sources and claim no harm will be done to an already over-drafted and fragile groundwater system.

By the way, Marina Coast Water District is currently managing 4,000 acre feet per year, which is one-seventh of what the Cal Am project is proposing to be pumping.

Cal Am has not bothered to understand Marina and Ord communities' future needs for our water. The DEIR lists pages of the Peninsula's needs for single-family affordable housing and commercial needs, but there is absolutely no mention of what we are struggling with to accommodate our future growth and water needs in Marina. We have a university expecting to grow to 12,000 students. We have, as yet, an unopened flagship medical veterans facility. We have commitments to build in excess of 2,000 more homes and so much more. And we are wondering how to provide water for all this development without the water grab from Cal Am. Where is this considered in the DEIR? Why does Cal Am's Peninsula needs -- why does Cal Am's Peninsula needs take precedence over ours when we have water rights and they do not?

This is truly an example of environmental injustice in which a powerful and predatory mega-corporation is allowed to dominate a small, economically challenged, and diverse community to meet the needs of a wealthier, more politically influential population.

Transcript-5 (H. Biala) cont.

Thank you.

CHARLES GARDNER: Kathy Biala, Hebard Olsen, and then Tom McMahon.

KATHY BIALA: My name is Kathy Biala, and I'm a resident of Marina.

First, I want to stress that Cal Am has no legal water rights in the Salinas Valley groundwater basin. The issue of groundwater rights must be determined before any further project approvals.

Secondly, because this specific type of slant well technology is experimental, a high level of scientific scrutiny is required. But basic scientific methodology has been breached in the Cal Am project. Among these are:

Cal Am's assumption that the 180-foot aquifer contains only unusable brackish water is a falsehood on two counts. Brackish water is valuable in a desalination process because it contains a portion of fresh water by definition and, hence, has great value to the local water purveyor, Marina Coast Water District.

Transcript-6 (K. Biala)

Further, an MCWD hydrogeologist has discovered a perched fresh water aquifer on the Armstrong property not addressed in Cal Am's assertion of no harm. How can Cal Am's model predict no harm to our basin without an accurate baseline of where the freshwater is?

Cal Am has shown a complete disregard for the electrical resistivity tomography, the ERT for shorthand, that can image very large portions of the groundwater basin up to depths below the 900-foot aquifer in a 3D mapping. By contrast, Cal Am, who knew about the ERT at least two years ago, is obtaining data from only nine vertical monitoring wells, builds a model from this limited data, and then claims no harm to our basin.

The test well study has not been completed, and yet still this DEIR is to be approved? This is very absurd. Any Cal Am claims of no harm are mere conjecture at this point until the test is completed.

Large numbers of pumping stoppages have occurred with significant lapses in data collection, and yet no questions have been raised as to whether this is a valid study under such conditions.

Two major data variances in the test slant well have already occurred. One, exceeding the acceptable water drawdown level of more than one foot that was later explained away by the impact of agricultural pumping; two, not reaching a projected salinity level of 96 percent in the threshold well, meaning that currently 93 percent salinity is 7 percent aquifer water being pumped.

This model is highly faulty as it did not factor in, before the testing began, the impacts of the agricultural pumping nor identify levels of uncertainty for unexpected results. This is shoddy science.

MCWD will initiate the ERT in May. If you approve this project without the benefits of an ERT study, you will likely face compelling legal challenges based on the facts revealed by the ERT. Do not approve this project until an ERT is completed and the data applied to the existing model. What is at stake is an entire regional water supply.

Transcript-6 (K. Biala) cont.

Thank you.

CHARLES GARDNER: Thank you.

Hebard Olsen, then Tom McMahon, and then Peter Mounteer.

HEBARD OLSEN: I'm Hebard Olsen and I live in Monterey.

And since Cal Am does not have rights to the water that they are putting in the system, I'm going to be turning the tap on and getting stolen water.

Now the question is how can I cure that problem? That's getting rather difficult. When they did their test well, they had water drawn from a mile or so away from the well on the land.

Transcript-7 (Olsen)

I would like to not have the project approved until they can serve me water that they actually own, not water that they have stolen from Marina and whoever else is out in that area.

Second, I would like to know if they have got in their budget sufficient money to pay for the damage to Marina after they get -- run their well for a while.

It seems to me that the original EIR should not be approved and that one of the alternatives that takes water from Moss Landing should be the one that's considered, not any of the ones that take water from Marina.

Transcript-7 (Olsen) cont.

CHARLES GARDNER: Thank you. Tom McMahon, Peter Mounteer, and then Brian Leneve.

TOM McMAHON: Good afternoon. My name is Tom McMahon. I am with the Pacific Grove Downtown Business Improvement District. I'm also a Pacific Grove representative with the Coalition of Peninsula Businesses, and I'm the owner and general manager of Monterey Bay Laundry.

I don't want to come here tonight and speak about hypotheticals. I want to speak about the reality of what we face in the business community and as a resident on the Monterey Peninsula. It was no more than about 90 days ago that we were facing the termination or the effective date of the CDO which threatened to completely shut off -- or virtually completely shut off the water supply to the Monterey Peninsula. Now, I think we all sat at that time and said, "Well, it's unlikely. I don't think they are going to do that." And we hoped and worked very hard in order to get that CDO date pushed out, and we were effective in doing that.

But, in the meantime, it's important for people to realize that, particularly from the business community, if you look at the business community in Pacific Grove, we need investment. Our business community is anemic. We need investment. But we cannot get investment when we have a huge question mark associated with whether or not water is going to be available to these businesses.

Transcript-8 (McMahon)

At a very personal level, I can tell you that we shut down two operations -- two laundry operations, one in Pacific Grove and one in Monterey, due exclusively to the fact of the question mark associated with whether or not we were going to have water available. We were looking at the need to invest significantly in the business, and the question mark introduced too much of a risk for us to be able to make that investment, given the fact that we were unsure of what our water supply would be.

This is not hypothetical. This is happening now. There are businesses now that either cannot operate within our community or cannot invest in our community or can't perform what -- the duties or what they're attempting to do as a business because of that question mark with the water.

I really urge you to approve the EIR so we can solve our water supply issue and allow the community of Pacific Grove, Monterey, Carmel to be able to grow and thrive. Right now we can't do that.

Transcript-8 (McMahon) cont.

Thank you.

CHARLES GARDNER: Thank you.

So we have Peter Mounteer, Brian Leneve, and then Rene Poskoff.

PETER MOUNTEER: Good afternoon. My name is Peter Mounteer. I am the marketing and events manager at the Pacific Grove Chamber of Commerce, and I'm here today on behalf of that organization and its membership.

We represent over 400 businesses and individuals, many of whom who have a strong interest and a sound water supply solution for the Monterey Peninsula area. We ask that you please move forward with approvals to the environmental impact report so that we can solve our water supply shortage and stay within the new deadlines set by the Cease and Desist Order.

The groundwater impacts are shown to be less than significant. The modeling has been peer-reviewed and undergone intense testing to confirm its accuracy. Subsurface intakes conform to state policy on desal plants. They avoid harm to the environment and they are a feasible technology, given the geology of the Cemex site. Solving this problem is of urgent importance to our community and health of the Carmel River.

The environmental impact report shows that the collaboration that has taken place between Cal Am, the cities, the Monterey Regional Water Pollution Control Agency, the Monterey Peninsula Water Management District, environmental groups, and other stakeholders has arrived at a suite of projects that provides a sustainable, reliable water supply and protects the water and river environment of the Monterey Peninsula.

Transcript-9 (Mounteer)

Thank you.

CHARLES GARDNER: So Brian Leneve and then Rene Poskoff.

BRIAN LENEVE: Good evening. Thanks for this opportunity to talk. I don't have any prepared statements, so I may be stumbling through this a little bit.

I am Brian Leneve. I'm a resident of Carmel. I'm a ratepayer of Cal Am, and I'm also the president of the Carmel Steelhead Association, and I'm also an environmentalist.

I believe this is a good project. We have worked to support it since the beginning. Since 1995, steelhead in the Carmel River have been waiting for some sort of a break to get more water into the river. This is the closest they have come to it. Without this project, the steelhead will continue to suffer, they will continue to decline, and they become extinct.

Transcript-10 (Leneve)

As an environmentalist, I like the slant well intakes. I believe it's an environmentally superior way of taking water from the ocean. Two speakers from me talked about the hypothetical. There's a lot of people here from Marina tonight talking about hypothetically how this may affect the groundwater. In Marina, however, that's hypothetical. They don't want to listen to the studies or read the studies in the EIR. But we support this EIR. We believe it's a way forward for the environment and statistically the steelhead.

Transcript-10 (Leneve) cont.

Thank you.

CHARLES GARDNER: Rene Poskoff.

RENE POSKOFF: Good afternoon. I'm representing the Coalition of Peninsula Businesses as well as the Monterey County Hospitality Association and the 22,000 people that it employs. And the Coalition of Peninsula Businesses and MCHA have been working very diligently over the past -- I lost track of the number of years, as I'm sure maybe you have, on this project, but I won't repeat all the great reasons that already have been stated. But we're very much in support of it. We think it's needed, and we urge you to move forward.

Our community -- and when I say "community," I really talk about both. We're residents, all 22,000 people that work in the hospitality industry and our business people, but they are residents and business people. And we need this project. We urge you to move forward.

And the only other statement really I would make is that I know there's a lot of conversation about the cost of water, and we all understand that. But there's one thing which is scarier than expensive water, and that is not having water at all. Because without it, as an individual, as a resident, or a business, we can't -- we can't support our industry, and we need it. So we urge you to move forward.

Transcript-11 (Poskoff)

Thank you for your time.

CHARLES GARDNER: Thank you. That's the conclusion of the list that I have. Is there anybody else who would like to provide comments who hasn't signed up already? Okay. Is there anyone who has additional -- has commented but they have additional comments?

HEBARD OLSEN: Yes, I do. Here.

CHARLES GARDNER: If you could just repeat your name for the court reporter, that would be great.

HEBARD OLSEN: I'm Hebard Olsen again. And I forgot to mention the fact that Marina's water is from a non- -- a temporary system. The Army, when they turned the system over, they determined that the system, the water source, is not -- should not be a permanent water source. So we have a problem that's brewing, and this Cal Am project will add to that problem and make its fruition more likely.

Transcript-12 (Olsen)

Marina actually has some desalination and they might have to turn to totally desalinated water, moving an expense to them from our -- from the project of Cal Am. So that's not fair to them.

And, again, I said that I would be drawing on -- water that I'm getting from my tap would be stolen water, and how do I feel about that.

Transcript-12 (Olsen) cont.

CHARLES GARDNER: Okay. Thank you. Anyone else have additional comments?

Okay. I think what we'll do is go off the record.

(Time noted: 4:44 p.m.)

(Time noted: 5:26 p.m.)

CHARLES GARDNER: Okay. So we have a couple of people who have come and want to provide comments, so we're going to go back on the record to receive those comments. We have Jody Hansen and then Michael Baer. So we've asked people to stick to three minutes, but there's only two of you, so -- but you might lose us after five or so.

So, Jody, would you like to provide some comments?

JODY HANSEN: Thank you. My name is Jody Hansen. I'm the president and CEO of the Monterey Peninsula Chamber of Commerce. I'm here this evening representing the Coalition of Monterey Peninsula Businesses as well as the Chamber.

We are in strong support of this project. It's very important for our community. You're going to hear from a lot of different groups today and many of them saying that this EIR has problems. And there's no such thing as a perfect EIR. And having been at the last CPUC meeting where we knew that it may not have been the last, but where we heard that the EIR was going to take longer, it's going to take an additional year, and the staff was talking about making it bulletproof, well, we know that this project is not perfect. And it can't be made bulletproof when we have a community that is always looking for the problems with projects.

Solving this problem is of urgent importance to our community and the Carmel River. We saw that taking the dam down has been a huge difference for the Carmel River, and we're looking at getting the desal project finished so that we can allow that river to become healthy again.

The EIR shows that the collaboration that has taken place between Cal Am, the cities, MRWPCA, MPWMC, environmental groups, and other stakeholders has arrived at a suite of projects, this portfolio of projects that provides a sustainable, reliable water supply and protects the river and the wider environment of the Monterey Peninsula.

Transcript-13 (Hansen)

We, as a coalition of Peninsula businesses, represent the business community that actually provides a lot of economic stability for this area, and without water we're in a world of hurt and we go into a real possible economic downfall again.

So I think this is where we have to look at ways to mitigate the EIR and be creative, if we need to be. The PUC has been extremely diligent and thorough in its study of the environmental impacts of the MPWSP. The end analysis is extremely important, which is demonstrated by its comprehensiveness and depth. We're glad to see this level of study, glad this milestone has been reached, and we're looking forward to a speedy decision on the project.

Transcript-13 (Hansen) cont.

Thank you very much.

CHARLES GARDNER: Thank you. Michael?

MICHAEL BAER: Hello. I'm Michael Baer. I'm a resident of Monterey Peninsula and I'm a ratepayer.

The level of distrust, I want to just -- that's kind of the theme. Well, first of all, you've got five years of history, at least, with this project, 4,000 pages of a document, and I'm supposed to say something in three minutes. So the idea is to take one thread as an example and, you know, not try and cover everything.

But the theme is distrust both of Cal Am and the PUC. And we've been talking about this for years and people complain. And I think the poor turnout is reflective of people -- of the distrust, not of the lack of interest of what's been doing on. And there's been letters to the editor, you know, all the time for years.

So I want to take this slant well as the theme, the thread, for which I want to talk about why there's such distrust. In 2014, Cal Am told us that they would run a test slant well continuously for up to two years for a cost of about $4,000,000. In the original Coastal Commission permit it said that they would decommission that slant well, cap it and bury it. And because it was identified as a temporary experimental test, the CEQA regulations were waived. Now it is designated as a back-up production well. So it's a way for them to get around some CEQA regulations back in 2014.

The costs have grown to over $12,000,000 at the last count, and the last count was several months ago. That fact falls between the cracks. I just want to highlight that. Like when we come to a ratepayer argument, we can't really say, "Oh, by the way, you tripled the costs on the slant well." And here we are at the EIR. We can't really talk about costs. But we paid that $12,000,000, which was originally slated at $4,000,000, and I'm sure it will be higher before this is all done.

Transcript-14 (Baer) cont.

It was supposed to be continuous tests up to 24 months. But in those 24 months there have been three major stoppages, one of 14 weeks, one of 8 weeks, and, most recently, one of three weeks, and more than a dozen other stoppages from a couple of hours to several days.

The State Water Resources Control Board, when they agreed to this, were under the impression this would be a subsurface intake system -- subocean intake system. But the current slant well does not draw water from beyond the mean high tide line. It draws it out from the aquifer. And even though the other production wells are described as extending beyond the high tide to some extent, it raises the question: What did this test well actually test if this slant well is not representative of the other ones?

In the Executive Summary there's been some omissions. The EIR skips over the fact that Dennis Williams had conflicts of interest. He was the hydrogeologist doing some of the modeling in the original EIR, and he has an international patent on slant wells. So he gains -- if this is successful, he stands to gain a tremendous amount of money from that, and yet he remains on the hydrological working group collecting all the data that's being used in the model, and there's questions about whether or not that is accurate which I won't go into here.

Transcript-14 (Baer) cont.

The other thing that was omitted was that the Marina City Council denied the CDB permit for the slant well, finding that the prepared negative declaration for that project was insufficient and that a full EIR should be required for that -- an EIR should be required for that test slant well, which was subsequently overruled by the Coastal Commission.

So you can kind of get this idea where this distrust comes from. We're told one thing in the beginning. It doesn't turn out that way.

And just -- finally, I would just say that we have a hard time believing, many of us, that the impact on the groundwater will be insignificant as this EIR states. I'm talking 25,000,000 gallons a day coming out of the 180-foot aquifer for 40 years. The modeling is very impressive. It's hard to understand as a layman. You know, you have to rely on the experts. But given the level of distrust, we don't believe this is -- I don't believe -- and there's many like me who don't believe this is a sustainable source water.

I guess that's all I have for today.

THE COURT: All right. Thank you, Mike.

Okay. Anybody else arrive? Okay. So we'll go off the record again. Thanks.

(Time noted: 5:35 p.m.)

(Time noted: 6:37 p.m.)

THE COURT: So we have three more people that have arrived that would like to provide comments. So we're going back on the record.

In order, we have Jan Shriner, Herbert Cortez, Julie Hofmann. So we've been asking people to keep it to three minutes, but there's certainly more time if you need. You don't have to keep it to that. So if you want to start?

JAN SHRINER: Thank you. Thank you for the opportunity. I need to say that I am on the board of the Marina Coast Water District. It's a volunteer elected position, but today I'm here speaking as a resident of Marina, not in that official capacity and in no way authorized by the board. I sit on other boards and collaborative working groups, but none of them have authorized me to speak on their behalf. So it's Jan Shriner as a Marina resident.

Some of the things that -- I was just looking over this really briefly, skimming through. I'm glad in some ways to see that this schematic of 3-13 shows that these intake lines are not actually going offshore and under the bay. But I read in the text on page 3.8 that they are actually going offshore under the bay. So it's confusing there. They say, in the paper, 161 feet to 356 feet, except for Number 8. On the schematic Number 8 is not labeled, but none of them appear to be any different than one another.

One of our biggest concerns in Marina is our erosion rate. On this site it is found to be the highest erosion rate of the continent. We have a scientist locally who estimates that up until two years ago the erosion rate was 220,000 cubic feet per year. Now he estimates, it's been in the paper, it's either 350- or 380,000 cubic feet per year. The State Parks uses an erosion rate of something like 7 feet per year as far as how far it's moving away from the water. I know when you go to the site at Reservation Road you will see the parking lot falling into the bay. I know the Marina Coast Water District beach office is falling into the bay.

Transcript-15 (Shriner)

When I run out to this site, I can see the low spot is this landfill. There is kelp already around the road of the sediment ponds. So it's very concerning to me about erosion.

We love our publicly water -- publicly owned water in Marina. Our community water rates are the lowest in the region. We appreciate an accessible, transparent process in Marina. A lot of us participate. And in this case, for the EIR, the online link is extremely difficult to locate. Some of us are lucky enough to have picked up disks.

But assumptions for models that were undisclosed until Friday, February 10th, and I was able to kind of ask some scientists last night about it, some of them don't know their assumptions off the top of their head. When you come to a public workshop, I would like them to be able to rattle off: What are the erosion rates that went into the model? What are the historical pumping data that went into the model? They were only able to say, "Try Appendix E2," or, you know, "Try Appendix C1," things like this, kind of like vague. It's not accessible for the public, and maybe we expect too much.

Recently, the previous Thursday, one week before today, I went to a DOGGR presentation. It's California State Department of Conservation, Division of Oil Gas Geothermal Resources. The presentation was for an aquifer exemption of untreated wastewater injection into the

Lombardi and Aurignac sands of the Salinas Valley groundwater basin. The public were told not to worry, that we would never be using these aquifers, the future of the Salinas Valley groundwater basin is rosy, and the cite -- the cited examples included locating a desal project in Moss Landing.

This is a state organization. This is our aquifer. We need better communication among the agencies. I told them I wanted to be in the room when they informed Cal Am that the desal project will be located in Moss Landing. Because this whole Draft EIR appears to me to be in Marina with an alternative explored, bruskly, at Potrero Road and two or three other options in Moss Landing. The decision has not yet been made, but I would prefer to see it moved at least to Potrero Road, but then there is the problem with the groundwater rights, right? That's the first reason why it got located here, supposedly so slant wells could take seawater, but these intakes do not go offshore, not according to this schematic.

So please work on your process. Of course, we'll be reading some more of these things. And I appreciate the time that you gave us, or three minutes, to be here today.

Transcript-15 (Shriner) cont.

CHARLES GARDNER: Thank you, Jan.

Herbert, are you ready? And then, Julie, you're up next.

HERBERT CORTEZ: So I would like the following concerns to be added to the record.

Before I begin, I do want to mention about the current violation that I see with the CPUC and this public hearing. It's violation of Resolution ALJ 252. According to the rules, the public should have had a chance to sign up to speak before 10:00 a.m., and that was not the case. I have documentation and screenshots about 8:30 in the morning trying to sign up for the public hearing. This is an official CPUC hearing, is my understanding, and so the rules should have been applied to this hearing. So I will present that at the end of my discussion.

So to begin with, I do want to say that the current draft environmental impact report, I want to address what Cal Am has said in the past three public hearings about super-positioning modeling. That's what it is, it's modeling. This super-position modeling which they speak of so highly does not address the deep aquifer of Marina Coast Water District.

And before I continue with this statement, I must say that I'm also a Marina Coast Water District board member. I do not speak on their behalf. I'm speaking as a concerned resident of Marina and Monterey County in that they did not authorize me to make any of these statements.

But I do want to add that I find it very interesting that if you're going to address the super-position modeling of being able to see how much groundwater is taken and put back, that you cannot address the big -- the deep aquifer, which is 900 feet, and I think that's crucial to this discussion. So they want to show you the 180- and the 400-foot aquifer because they think, according to their terms, it's not water that's of beneficial use. But they don't show you and

Transcript-16 (Cortez)

they don't tell you scientifically -- and it's proven and cited -- that there's leakage from the 180, 400, and deep aquifer. So if you're super-positioning focus on the 180 and 400, it should include the deep aquifer which is 900 feet, and that's not addressed. So that's my first concern about the Draft EIR.

My second concern about the Draft EIR is that they don't focus on the Hopkins groundwater analysis that was done in 2015 that finds freshwater in the 180-foot aquifer. So the reason why that's important is because the case that Cal Am is making to the public is that this is water that's not of beneficial use. Well, of course, if the public keeps hearing, "well, this is not in use and someone is going to come and make it better," well, that's great. The problem is this is fresh water, and that fresh water is used to help us support saltwater intrusion.

Now, if they develop slant wells and they continue putting in slant wells, well, guess what? That's more saltwater intrusion. And if you aren't going to do that, then you should put in your Draft EIR that's how the Hopkins groundwater analysis is proven wrong, or there is no fresh water there, and their super-position modeling is not addressed. And I think that's really important.

Okay. My third point about the Draft EIR is the following. It goes back to this conversation and this image and perception to the public regarding beneficial use of this area. Now, my understanding is that you had in the morning -- not in the morning -- but early afternoon you had constituents from pro business in Monterey, and, of course, they want that water. But you know who else needs that water? The people who live in Marina, the growing population that's about to increase in the next 20 to 30 years, which is forecasted by Fort Ord, by the Marina Coast Water District, and the Monterey Regional Water Pollution Control.

So if the issue is that the water is not of beneficial use, why would there be a memorandum of understanding between these agencies -- a state agency, a county agency and a federal agency -- about the long-term use of this water? That's not addressed in this Draft EIR. And this is public documentation in which they can see the analysis of use of what's needed -- freshwater, groundwater, brackish water -- and it's not addressed in the EIR.

And so this image and perception that has gone on for the past two weeks and possibly more about the fact that this water is not of beneficial use needs to be stopped. It should be on the record that if they are going to keep saying that, they should document it and make sure that it's available for all eyes.

Now, my final thing that I want to say before I leave is I was really concerned about not being able to sign up in public. And the reason why is because I live in Marina, yet we're here in Carmel. The reason why I found out that this was happening, it wasn't because of Cal Am's great public push to have public participation, it was because I went to the Marina City Council, and the Marina City Council probably asked Cal Am to come and make a presentation.

Transcript-16 (Cortez) cont.

So I'm here today to say that I really want this resolution that I think there's a violation of ALJ 252 to be corrected, because this is a long-term activist concern that I have, because this is just a draft. This is a long-term project for Cal Am. There will be more people like me speaking up. There will be more knowledgeable people understanding exactly what a Draft EIR is and what false perceptions are from Cal Am. So I would like that corrected.

Transcript-16 (Cortez) cont.

So with that said, thank you very much.

CHARLES GARDNER: Julie Hofmann.

JULIE HOFMANN: Julie Hofmann, a Marina resident.

I think secure water is a good thing. And I like parts of this DEIR, you know, as far as recovering wastewater and some of the other groundwater replenishment.

But I think that if anyone has looked at a map and seen all of these straws that are in the Salinas Valley water basin, you have an idea of how much there are impacts already to that water supply. And Marina sits on the very end of that water supply. And now we have a Draft EIR that really disregards Marina's role in being at the end of that waterline.

There's a big do-no-harm requirement in this Draft EIR as I have read it, and I have a problem with some of the data. I understand this is going to use millions of gallons of water. The way I first heard about this was going to be a desal project, but yet the closer I read the DEIR, I understand that quite a bit of groundwater will be taken up. This is the way slant wells work. It helps desal the water a little bit before it gets there.

I think that we need better information before we go wading into this project. Maybe slow this train wreck down a little and start considering how Marina will be impacted by this. It's really interesting to me that the second location on Potrero Road has more information in the DEIR about impacts to the Elkhorn slough than there are for Marina.

I think that the biggest problem that I have with the slant wells is there just isn't any slant wells with any sort of reliability or historical evidence as working with desal. There aren't any in California, there aren't any in the United States, and there aren't in the world that I can find that provide drinking water to a tap of a paying customer. So we need to really look at that before we start putting 10 slant wells into the end of the Marina aquifer.

I have heard about this ERT data, and it's sort of like a CAT scan for the groundwater. And rather than relying on data from small wells poked around and modeling from the data pulled from those different places and interpretating -- interpolating, as I understand it, the difference between this point and this point and kind of making up a number here, we could have a much better idea of what's actually going on in our groundwater.

And I do understand that Marina Coast Water is paying to have this done. And I think that the CPUC should delay this project until we can see that modeling and see that data, and

Transcript-17 (Hofmann)

maybe Cal Am should use that data to give us a complete picture of the groundwater before we sallie forth. So we need the complete data.

I'm very worried about the mitigation to going into a project like this that's using so much of the groundwater and doesn't seem to have much data to really tell us what's going on with the water. And we need to be really sure before we go into this, because this is a long-term issue. We're at the end of the line. There is increased water needs everywhere along the Salinas Valley. We could end up with saltwater intrusion simply from that alone, without the slant wells at the end of the water line here.

Transcript-17 (Hofmann) cont.

So let's be sure about these slant wells. I just see high costs and failure to provide water in the long-term, and I see harm to the Marina aquifer with the information as it's been provided so far.

Thank you.

THE COURT: Thank you.

Is there anybody else who has arrived?

Okay. Let's go of on the record again and we'll see if anyone else arrives.

(Time noted: 6:49 p.m.)

(Time noted: 7:27 p.m.)

CHARLES GARDNER: So we will go back on the record to receive further comments.

If you could state your name.

GEORGE RILEY: Yes, I will. George Riley from Monterey. I've been active in water issues in Monterey for ten years, at least. I have no idea what was said tonight, but I'm going to guess that they were concerned about the lack of water rights in the project. I know this is supposed to be on the EIR, and I don't know everything that might be related to the EIR exactly, I'm sure they were concerned about the fact that the project is located within another public agency, the water district. And I worry about invasion, and without water rights and without being invited, that's become a real issue.

I do think that the PUC structure for the public participation hearings restricts the comments that are made to you and the information that you get. Those who are residents here and those who are ratepayers here get the whole picture. We get the silo that comes from San Clemente Dam. We get the silo that comes from returned water or -- I don't know. It's 15,070.19, I think, of the 38 or 39 million dollars of money that Cal Am gets. It's a decision made by the PUC that supports Cal Am and doesn't support the ratepayers. We get the different silos altogether here because we pay the bills.

Transcript-18 (Riley)

But we think that the general approach to public participation hearings is that you create a silo that some of the stuff that's said here doesn't apply. You're talking about an EIR, we're talking about the cost on the ratepayers, and that doesn't apply, or another case that doesn't apply.

So the dilemma that I think the ratepayers here feel and the public comment that I'm suspecting that you heard tonight represents an impact on ratepayers that is presented to you in silos, to us in the composite, and that's the dilemma we have.

And I feel like two things that are still outstanding on the EIR process and the project in general is the lack of water rights and poor science. I am convinced that the feasibility analysis that's required by the state for the slant well idea is based on very skimpy science and that we would like to advocate a more serious approach, a more expansive approach to science which includes the ERT -- you know what I'm talking about -- process and that's outside the schedule.

So we're -- as ratepayers, I think we're going to be advocating two things: One, figure out what the schedule is on how to determine the water rights issue; and, second, to figure out where a better approach to science can apply to the whole evaluation of the approach. Side issues are going to be invading another jurisdiction, seawater intrusion in general, maybe a few more, but you get my gist.

Transcript-18 (Riley) cont.

And I probably have run out of three minutes. Thank you very much.

CHARLES GARDNER: You can continue.

GEORGE RILEY: I don't know that there's a whole lot more to be said. But I do think the main thing I want to say is ratepayers here, whether it's commercial or residential, we represent residential -- I mean, I'm speaking on behalf of residential victims -- that there's a general unfairness between the commercial rates and the ratepayer rates. The commercial rates have no financial incentive to save money anymore after they changed the rate structure for them.

It's our position that once they have reached a certain category of installation of water-saving devices, once they have reached this level of that, then they can use all the water they want and have no financial incentive to save water. Just the opposite applies to residential. Just the opposite. And so we think there's an unfairness there. But that doesn't apply to the EIR. That's the dilemma. That's an example of the dilemma that I think we face.

And we keep paying the bills. And Cal Am has had several projects that have gone nowhere, and they incur costs, and they go to the PUC, and the PUC approves. And every example of this over the past ten years has been that Cal Am can go to the PUC: We have a failed project, but we were conscientious about what we were trying to do, we were within the objectives of what we were trying to accomplish, we were trying to get there, but we failed. Sorry we didn't deliver something. And then what happens to the extended costs? They come

to the ratepayers. Not once has the PUC decided that there's somebody sharing that cost beyond stockholders. Not once. So that's a real rub to the ratepayers.

The San Clemente Dam example. I know I'm way over the basic topic. I appreciate that you're not going to call three minutes. The San Clemente Dam is another example where the ALJ recommended in the proposed decision a certain level of reimbursement to Cal Am. The commissioner assigned to that project reversed -- absolutely, totally reversed that decision and even added to it the benefit to Cal Am. And even Cal Am was surprised at how generous the PUC decision was. And the ratepayers pay all that bill.

So even when Cal Am -- even when the PUC gets all the facts, hears all the information, takes into account all of the evidence that's been submitted, comes to a conclusion that Cal Am did not deserve but a certain amount, then the Commission -- and this is why the Commission is in our cross-hairs as well. I mean, Cal Am is a problem to us; the PUC is also similar in the cross-hairs. A single commissioner, relatively brand new, and subject to nine -- if my memory is right, there are about 14 or 15 ex parte meetings in that process -- nine of them, if I remember right, was with this one commissioner -- documented in the ex parte reports -- and this one commissioner turns around and says, "We will reverse the proposed PUC decision, reverse it." And even Cal Am was saying hallelujah. And the ratepayers pay for it.

I mean, so we suffer from decisions that you make, Cal Am proposes, and Cal Am consistently represents to the public that the PUC demands this, the PUC ordered us to do this.

We know the process. Cal Am goes to the PUC, they ask for this, you approve this, and then they came back and say, "The PUC orders us to do this." They do not take responsibility for their own role in it. I mean, we know this. I mean, this is what we're up against.

And we would just like you to hopefully consider a little more -- you have got a bad history as far as ratepayers are concerned locally in the past ten years -- I've only been active about ten years -- and I'm amazed at how many decisions and opportunities I have had to be critical of Cal Am or the PUC and what decisions they have made, but somewhere in there there's got to be some attention given to the ratepayers, and I think they have been ignored, and I don't even know how that applies to the EIR. But, anyway, thank you for the time.

(Time noted: 7:35 p.m.)

CERTIFICATE OF COURT REPORTER

The foregoing public hearing was held before me, KELLI A. RINAUDO, Certified Shorthand Reporter, License No. 6411, RMR, CRR, CCRR, and RDR, for the State of California.

The public comments were taken by me in machine shorthand at the time and place therein named, and thereafter, under my direction transcribed into longhand.

I further certify that I am not of counsel or attorney for either or any of the parties to said hearing, nor in any way interested in the outcome of the cause named in said caption, and that I am not related to any party thereto.

Dated March 2, 2017.

8.9.1 Responses to Public Meeting Verbal Comments

The verbal comments from the public hearing on February 16, 2017 were transcribed. The numbering in the response to comments includes the commenter's last name in parenthesis.

Transcript-1
(Cursio) This comment does not concern the adequacy of the environmental review included in the EIR/EIS, but will be considered by decisionmakers, as discussed in Section 1.5.

Transcript-2
(Coppernoll) The CPUC's consideration of the EIR/EIS and the proposed project is described in EIR/EIS Section 1.5.4.1. Water rights, the feasibility of the proposed project, the issue of harm, and effects on the Marina Coast Water District (MCWD) supply are addressed in Master Response 3, Water Rights. See also response to comment Coppernoll-1.

The existing test slant well currently draws water from the brackish Dune Sand Aquifer and the 180-Foot Equivalent (FTE) Aquifer, neither of which are perched at this location. Contrary to the comment, the water being drawn by the slant test well is not fresh. Sampling of the test slant well water reveals the salinity of the pumped water has varied over time, ranging from 25,400 mg/L of TDS at start-up in April 2015 (76 percent ocean water salinity) to 31,800 mg/L in November 2016 (95 percent ocean water salinity); see Master Response 11, CalAm Test Slant Well. As described in EIR/EIS Table 3-1, the proposed slant wells would draw water from groundwater aquifers that extend beneath the ocean floor (the Dune Sands Aquifer and the 180-Foot-Equivalent Aquifer of the Salinas Valley Groundwater Basin) for use as source water for the MPWSP. See Master Response 2, Source Water Components and Definitions.

The perched groundwater-bearing zone referred to in the comment is located inland of the proposed slant wells. Groundwater flows to the edge of this zone and "waterfalls" into the underlying Dune Sand or 180-Foot Aquifer formations. The edge of the perched layer occurs 1.5 miles inland from the capture zone of the proposed slant wells. There is no evidence that the groundwater in the perched zone is reversing seawater intrusion or providing "protection" against seawater intrusion. This is evident in the fact that there is documented seawater intrusion further inland, which has been occurring for decades and continues to occur today See also response to MCWD-Hopkins Groundwater Consultants (HGC) Section 8.5.2.2.

EIR/EIS Section 4.4.5.2 presents the analysis of potential impacts of the proposed project on groundwater resources in the Salinas Valley Groundwater Basin, including the risk of seawater intrusion, and concludes that impacts would be less than significant. See also Master Response 8, Project Source Water and Seawater

Intrusion.The EIR/EIS acknowledges that components of the proposed project would be inconsistent with the City of Marina LCLUP. See Impact 4.6-4 in Section 4.6, Terrestrial Biological Resources. See also responses to comments Marina-94 and MCWD-150.

Master Response 3, addresses Marina's Water Rights.

Numerous resource protection programs throughout the SVGB (e.g. the Castroville Seawater Intrusion Project and the Salinas Valley Water project) have been developed by the Monterey County Water Resources Agency to promote groundwater recharge; EIR/EIS Section 4.4.1.3 describes these groundwater enhancement programs in the SVGB. The suggestion that groundwater quality has been restored through sustainable groundwater management plans and programs of the MCWD is inaccurate. Ceasing of groundwater pumping in the 180-Foot Aquifer and transferring MCWD pumping to the deeper aquifers was done out of necessity (see Master Response 7, the Deeper Aquifers of the SVGB, Section 8.2.7.1) and was not a deliberate effort by MCWD to restore that aquifer. See response to comment MCWD-HGC in Section 8.5.2.2. See also Master Response 6, Sustainable Groundwater Management Act and Master Response 9, Electrical Resistivity Tomography (ERT) and Airborne Electromagnetics (AEM).

Transcript-3
(Tilley) This comment does not concern the adequacy of the environmental review included in the EIR/EIS, but will be considered by decisionmakers, as discussed in Section 1.5.

Transcript-4
(Billingsley) EIR/EIS Section 1.1 explains that CalAm is proposing the MPWSP to develop water supplies for CalAm's Monterey District service area (Monterey District). Section 1.3 presents the need for the project: to replace existing water supplies that have been constrained by legal decisions affecting the Carmel River and Seaside Groundwater Basin water resources. Therefore, the focus of the analysis on water demand (EIR/EIS Section 2.3) is on CalAm's Monterey District and not on other areas that may or may not need water; see also response to comment Biala1-30. See Master Response 3, Water Rights, specifically, Section 8.2.3.7 regarding effects on MCWD's water supply. EIR/EIS Section 4.4.5.2 presents the analysis of potential impacts of the proposed project on groundwater resources in the Salinas Valley Groundwater Basin, and concludes that impacts would be less than significant.

Transcript-5
(H. Biala) As described in EIR/EIS Table 3-1, the proposed slant wells would draw water from groundwater aquifers that extend beneath the ocean floor (the Dune Sands Aquifer and the 180-Foot-Equivalent Aquifer of the Salinas Valley Groundwater

Basin) for use as source water for the MPWSP. See also Master Response 2, Source Water Components Defined, and Master Response 3, Water Rights, regarding water rights, harm, and effects on MCWD's water supply.

See response to comment Biala1-30 regarding consideration of other service area's water needs. Consistent with NEPA and CEQA, the EIR/EIS analyzes the project as it was proposed by CalAm, the applicant; likewise, the project objectives within the EIR/EIS (see Section 1.3) reflect the purposes for which CalAm proposed the project. EIR/EIS Section 4.4, Groundwater Resources, analyzes the physical impacts of the proposed project on the quality and quantity of water in the regional aquifers that could be affected by the project, thus providing data as to whether and how the water sources of other water users could be affected.

Environmental Justice is addressed in EIR/EIS Section 4.20, Socioeconomics and Environmental Justice.

Transcript-6
(K. Biala) See Master Response 3, Water Rights, Section 8.2.3.2, Sequence of Approvals. See response to comment Marina-11 regarding slant well technology. See Master Response 2, Source Water Components and Definitions, and Master Response 3, Water Rights, Section 8.2.3.7 regarding the effects on MCWD's water supply.

The perched groundwater-bearing zone referred to in the comment is located inland of the proposed slant wells. Groundwater flows to the edge of this zone and "waterfalls" into the underlying Dune Sand or 180-Foot Aquifer formations. The edge of the perched layer occurs 1.5 miles inland from the capture zone of the proposed slant wells. There is no evidence that the groundwater in the perched zone is reversing seawater intrusion or providing "protection" against sea water intrusion. This is evident in the fact that there is documented seawater intrusion further inland, which has been occurring for decades and continues today.

EIR/EIS Section 4.4.5.2 presents the analysis of potential impacts of the proposed project on groundwater resources in the Salinas Valley Groundwater Basin, including the risk of seawater intrusion, and concludes that impacts would be less than significant. See also Master Response 8, Project Source Water and Seawater Intrusion, response to comment Transcript-2, and MCWD-HGC in Section 8.5.2.2. See Master Response 9, Electrical Resistivity Tomography (ERT) and Airborne Electromagnetics (AEM). Results of the test slant well are presented in Master Response 11, CalAm Test Slant Well, and EIR/EIS Appendix E3. See Master Response 12, The North Marina Groundwater Model (V. 2016), Section 8.2.12.1.

Transcript-7
(Olsen) See Master Response 3, Water Rights, Sections 8.2.3.5 and 8.2.3.7. EIR/EIS Impact 4.4-3 concludes that impacts associated with changes in groundwater levels during operation of the MPWSP would be less than significant. However, CalAm

has voluntarily proposed Applicant Measure 4.4-3. If it is determined that a nearby active groundwater well has been damaged or otherwise negatively affected by the project pumping of the slant wells, the project applicant shall coordinate with the well owner to arrange for an interim water supply and begin developing a mutually agreed upon course of action to repair or deepen the existing well, restore groundwater yield by improving well efficiency, provide long term replacement of water supply, or construct a new well. CalAm would be bound to implement this mitigation measure through the Mitigation Monitoring and Reporting Program (CEQA Guidelines Section 15097), which ensures that measures included in an EIR to mitigate or avoid significant environmental effects are implemented.

Alternative projects at Moss Landing are described in EIR/EIS Section 5.4 and evaluated in Section 5.5.

Transcript-13
(Hansen) This comment does not concern the adequacy of the environmental review included in the EIR/EIS, but will be considered by decisionmakers, as discussed in Section 1.5.

Transcript-14

(Baer) The EIR/EIS is based on the best available information. See Master Response 11, CalAm Test Slant Well, Sections 8.2.11.2 and 8.2.11.3, which summarize the Coastal Development Permit and CEQA and NEPA review processes for the test slant well; see also Section 8.2.11.5 which describes the long-term pump test and the outages. See also EIR/EIS Appendix E3.

In a letter dated September 26, 2012, the CPUC requested an opinion from the SWRCB on whether CalAm has a credible legal claim to extract feedwater for the proposed MPWSP in order to inform the CPUC's determination regarding the legal feasibility of the MPWSP; the CPUC did not request a water rights determination. The SWRCB acknowledged in their review that the information provided to the SWRCB does not allow staff to definitively address the issue of how the proposed project would affect water rights in the Basin since it was unknown at that time which aquifer(s) the wells will extract water from, and further complicating the analysis, the relationship of the aquifers in the well area to surrounding low-permeability aquitards was uncertain. The results of the test slant well long-term pump test, and the information sought by the SWRCB in their July 2013 Final Report, are summarized in EIR/EIS Appendix E3.

As described in EIR/EIS Table 3-1, the proposed slant wells would draw water from groundwater aquifers that extend beneath the ocean floor (the Dune Sands Aquifer and the 180-Foot-Equivalent Aquifer of the Salinas Valley Groundwater Basin) for use as source water for the MPWSP.

EIR/EIS Section ES.8 explains that the groundwater model and results presented in the April 2015 Draft EIR, which relied on the work of Dr. Williams, have been revised in response to public concerns about potential conflict of interest. See also Master Response 5, The Role of the Hydrogeologic Working Group and its Relationship to the EIR/EIS, Section 8.2.5.6.

Finally, EIR/EIS Section 4.4.5.2 concludes that the impacts of the proposed project pumping on groundwater resources would be less than significant (not "insignificant" as the comment states) according to specified significance criteria. While the proposed project would extract 24.1 mgd of source water from the Dune Sands Aquifer and 180-FTE Aquifer (see Master Response 8, Project Source Water and Seawater Intrusion), and the Environmentally Preferred Alternative (Alternative 5a) would extract 15.5 mgd of source water, it would be 90 percent ocean water in the first few months of project pumping and 95 percent ocean water within 5 years of project pumping; see Master Response 4, The Agency Act and Return Water, Section 8.2.4.3 as well as EIR/EIS Appendix E3. See Master Response 12, The North Marina Groundwater Model (v. 2016).

Transcript-15
(Shriner) EIR/EIS Table 3-1 explains that the proposed slant wells would draw water from groundwater aquifers that extend beneath the ocean floor (the Dune Sands Aquifer and the 180-Foot-Equivalent Aquifer of the Salinas Valley Groundwater Basin). The proposed location of the slant wells is shown on EIR/EIS Figure 3-3a, and lengths of permanent slant wells seaward of 2020 Mean High Water are shown in Table 3-2 and Figure 3-3b. The Coastal Retreat Study conducted for the EIR/EIS is included as Appendix C2, and is explained in EIR/EIS Section 4.2.1.3; see also response to comment Shriner-3 and PTA-6.

EIR/EIS Appendix A1 is the Draft EIR/EIS distribution list. In addition to the direct mailing of 392 CDs, a notice of availability (NOA) was mailed to all property owners and residences within 300-feet of any proposed or alternative facility; the NOA provided the web address containing the Draft EIR/EIS for download, and announced the locations of hard copies for public review. Announcements regarding the availability of the Draft EIR/EIS, with links to the document, were provided in a regional newspaper (the Monterey Herald), a local newspaper (the Carmel Pinecone) and in the Federal Register.

Assumptions for the groundwater model were disclosed and reviewed with the public approximately 4.5 months prior to the release of the Draft EIR/EIS. The September 1, 2016, CPUC-sponsored workshop at the Sunset Center in Carmel-by-the-Sea included a presentation and discussion on EIR/EIS Appendix E2, North Marina Groundwater Model Review, Revision, and Implementation for Slant Well Pumping Scenarios. Copies of the presentations that were made at the workshop continue to be available at: http://www.cpuc.ca.gov/Environment/info/esa/mpwsp/comms_n_docs.html.

The Draft EIR/EIS NOA that was published on January 13, 2017 included an announcement that "[t]he open house/public meetings will include a brief presentation on the contents and conclusions of the Draft EIR/EIS and interested parties will be provided an opportunity to interact with technical staff and preparers of the Draft EIR/EIS." The Lead Agencies and consultant staff were directed to help reviewers navigate the Draft EIR/EIS in order to facilitate the public's review of the lengthy and complicated document.

EIR/EIS Chapter 5 presents the alternatives' analysis, including analysis of alternatives at Moss Landing and Potrero Road. A detailed screening of components was provided in EIR/EIS Section 5.1 through 5.3. EIR/EIS Section 5.4 describes a total of eight whole alternatives, including the proposed project, the No Project Alternative, and Alternatives 1 through 5b; the alternatives are evaluated in EIR/EIS Section 5.5. The environmentally superior/environmentally preferred alternative (Alternative 5a, Reduced Project 6.4-mgd Desalination Plant - Intake Slant Wells at CEMEX) is described in EIR/EIS Section 5.6.

Transcript-16

(Cortez) The Public Hearing on the Draft EIR/EIS was not a CPUC Commission Meeting. Therefore, rules described in CPUC Resolution ALJ 252 did not apply; see response to comment Cortez-1.

See Master Response 1, EIR/EIS Authorship: this EIR/EIS was prepared by the CPUC as the CEQA Lead Agency, by NOAA's MBNMS as the NEPA Lead Agency. Likewise, the Lead Agencies, and not CalAm, hosted the EIR/EIS public meetings.

Regarding superposition modeling, see Master Response 12, The North Marina Groundwater Model (v. 2016), particularly Section 8.2.12.3. The deeper aquifer is evaluated in EIR/EIS Section 4.4.5.2; see also Master Response 7, the Deeper Aquifers of the SVGB, particularly Section 8.2.7.2. Regarding freshwater in the 180-FTE Aquifer, see Master Response 2, Source Water Components and Definitions, as well as response to comment MCWD-HGC in Section 8.5.2.2. EIR/EIS Appendix E2 Section 5.3 explains that slant well pumping effects on the inland movement of saltwater were assessed using the 2016 version of the North Marina Groundwater Model (NMGWM$^{2016)}$ and MODPATH. Without slant well pumping, the particles representing saltwater would continue to migrate inland. With slant well pumping, the movement of saltwater is in response to the regional background gradient and drawdown created by slant well pumping. The EIR/EIS therefore, utilized the superposition NMGWM^{2016} without the regional gradient to isolate changes in saltwater movement due solely to slant well pumping.

See Master Response 3, Water Rights, regarding the beneficial uses of water, and specifically Section 8.2.3.7 regarding effects of the proposed project on MCWD's water supply. What MOU the comment is referring to between a state agency, a county agency and a federal agency is not clear, but may be referring to the three party planning agreement. EIR/EIS Table 4.2 identifies Project No. 31 as the MCWD RUWAP Desalination Element, and discusses the three-party planning effort involving Fort Ord, MCWD and MRWPCA: The three party planning (TPP) effort will explore the most cost effective and technically efficient mix of advanced treated water, conservation, desalination, groundwater recharge and recovery, and other water sources, options, and alternatives to provide the 973 afy of augmented water, and whether more or less than 1,427 afy of advanced treated water is necessary to serve the Ord Community. The FORA Board will utilize the TPP study in developing a preferred water augmentation mix and deciding which additional water augmentation project(s) should be developed by MCWD.

Transcript-17

(Hofmann) EIR/EIS Section 4.4.5.2 describes potential operational impacts of the proposed project on groundwater resources in the Salinas Valley Groundwater Basin. See also Master Response 3, Water Rights, Section 8.2.3.7 regarding the effects of the

proposed project on MCWD's water supply. See Master Response 11, CalAm Test Slant Well, and response to comment Marina-11, in Section 8.5.1, regarding slant well technology. See Master Response 9, Electrical Resistivity Tomography (ERT) and Airborne Electromagnetics (AEM) regarding the use of ERT data.

EIR/EIS Section 4.4.5.2 presents the technical analysis of impacts of the proposed project's operation on groundwater resources, and is supported by Appendices C3 Section 4.4.4 (regional geologic setting), Section 4.6.6 (hydrostratigraphy), Section 5.2 (groundwater quality, CEMEX area), as well as Appendix E2 (groundwater modeling), and Appendix E3, Section 1.2 (hydrogeologic conceptual model).

outfall, ES-4, ES-12, ES-13, ES-14, ES-15, ES-19, ES-29, ES-45, 1-6, 1-7, 3-11, 3-17, 3-19, 3-22, 3-29, 3-30, 3-50, 3-58, 3-66, 4.1-3, 4.1-4, 4.1-19, 4.2-2, 4.2-16, 4.2-22, 4.2-67, 4.2-70, 4.2-71, 4.2-77, 4.3-2, 4.3-11, 4.3-12, 4.3-21, 4.3-28, 4.3-35, 4.3-43, 4.3-44, 4.3-53, 4.3-63, 4.3-66, 4.3-68, 4.3-69, 4.3-70, 4.3-71, 4.3-73, 4.3-74, 4.3-75, 4.3-76, 4.3-84, 4.3-85, 4.3-87, 4.3-89, 4.3-91, 4.3-93, 4.3-94, 4.3-96, 4.3-97, 4.3-104, 4.3-105, 4.3-106, 4.3-107, 4.3-108, 4.3-109, 4.3-126, 4.3-127, 4.3-132, 4.5-1, 4.5-2, 4.5-7, 4.5-10, 4.5-25, 4.5-28, 4.5-34, 4.5-37, 4.5-42, 4.5-43, 4.5-44, 4.5-45, 4.5-46, 4.5-49, 4.5-54, 4.5-62, 4.5-63, 4.5-65, 4.5-66, 4.5-69, 4.5-70, 4.5-71, 4.5-72, 4.5-73, 4.5-79, 4.5-81, 4.6-124, 4.6-268, 4.6-271, 4.7-35, 4.8-3, 4.8-11, 4.8-13, 4.13-1, 4.13-6, 4.13-13, 4.13-15, 4.13-22, 4.13-23, 4.13-24, 4.13-25, 4.13-26, 4.13-27, 4.13-28, 4.13-29, 4.13-30, 4.13-38, 4.13-39, 4.13-40, 4.13-41, 4.13-43, 5.1-5, 5.2-1, 5.3-5, 5.3-6, 5.3-10, 5.3-19, 5.3-20, 5.3-21, 5.3-22, 5.3-23, 5.3-24, 5.3-25, 5.3-26, 5.3-27, 5.3-29, 5.3-37, 5.3-38, 5.3-39, 5.3-40, 5.3-41, 5.3-49, 5.3-50, 5.3-51, 5.3-53, 5.4-2, 5.4-3, 5.4-35, 5.4-43, 5.4-45, 5.4-47, 5.4-48, 5.4-52, 5.4-56, 5.4-63, 5.5-20, 5.5-23, 5.5-30, 5.5-31, 5.5-32, 5.5-35, 5.5-36, 5.5-44, 5.5-47, 5.5-48, 5.5-49, 5.5-50, 5.5-54, 5.5-55, 5.5-58, 5.5-60, 5.5-61, 5.5-62, 5.5-64, 5.5-69, 5.5-71, 5.5-74, 5.5-76, 5.5-113, 5.5-115, 5.5-117, 5.5-118, 5.5-119, 5.5-123, 5.5-128, 5.5-129, 5.5-135, 5.5-157, 5.5-158, 5.5-160, 5.5-164, 5.5-165, 5.5-196, 5.5-197, 5.5-198, 5.5-199, 5.5-213, 5.5-265, 5.5-266, 5.5-267, 5.5-268, 5.5-269, 5.5-270, 5.5-271, 5.5-272, 5.5-273, 5.5-274, 5.5-275, 5.5-276, 5.5-277, 5.5-278, 5.5-279, 5.5-280, 5.5-290, 5.5-292, 5.5-298, 5.5-320, 5.5-322, 5.5-337, 5.5-339, 5.6-5, 5.6-6, 5.6-7, 5.6-17, 6-48, 6-49, 6-51, 6-57, 6-58, 6-59, 6-60, 6-61

ozone, 4.10-3, 4.10-5, 4.10-6, 4.10-9, 4.10-10, 4.10-11, 4.10-12, 4.10-13, 4.10-17, 4.10-18, 4.10-23, 4.10-24, 4.10-26, 4.10-27, 4.10-32, 4.11-2, 4.11-4, 5.5-218, 5.5-220, 5.5-221, 5.5-222, 5.5-223, 5.5-224, 5.5-225, 5.5-226, 5.5-228, 5.5-229, 5.5-230, 5.5-231, 5.5-232, 5.5-233, 5.5-368, 5.6-3, 6-2, 6-40, 6-53

Project objectives, ES-1, ES-3, 1-1, 1-5, 5.1-3, 5.4-1, 5.4-8, 5.4-11, 5.4-12, 5.4-14, 5.4-21, 5.4-39, 5.4-50, 5.4-52, 5.4-59

proposed action, ES-1, ES-4, ES-21, ES-27, 1-2, 1-3, 1-6, 1-7, 1-13, 1-18, 3-1, 3-63, 4.1-11, 4.1-12, 4.2-36, 4.3-91, 4.4-1, 4.4-66, 4.4-71, 4.4-72, 4.4-73, 4.5-1, 4.10-1, 4.10-14, 4.11-22, 4.18-9, 5.1-2, 5.1-3, 5.1-5, 5.3-1, 5.5-50, 5.5-261, 5.5-340, 5.5-373, 5.6-9, 5.6-15, 6-1, 6-10, 6-12

Purpose and Need, ES-1, ES-3, ES-4, 1-1, 1-3, 1-5, 1-6, 5.1-2, 5.1-3, 5.1-4, 5.2-1, 5.3-1, 5.3-4, 5.3-49, 5.4-1, 5.4-34, 5.4-50, 5.6-1, 5.6-2, 5.6-3, 5.6-6, 5.6-7

radius of influence, 2-38, 2-39, 4.4-51, 4.4-52, 4.4-58, 4.4-92, 4.4-95

Range of alternatives, 1-15, 5.1-2, 5.1-6

Salinas Valley Groundwater Basin, ES-17, 2-2, 2-18, 2-23, 2-31, 2-32, 3-9, 3-17, 3-18, 3-37, 3-38, 4.1-18, 4.2-66, 4.4-1, 4.4-3, 4.4-4, 4.4-6, 4.4-17, 4.4-18, 4.4-19, 4.4-24, 4.4-31, 4.4-32, 4.4-33, 4.4-42, 4.4-107, 4.4-113, 4.13-5, 4.13-15, 5.3-9, 5.3-11, 5.3-12, 5.4-14, 5.5-8, 5.5-13,

5.5-15, 5.5-17, 5.5-19, 5.5-21, 5.5-22, 5.5-40, 5.5-45, 5.5-53, 5.5-83, 5.5-109, 5.5-121, 5.5-131, 5.5-152, 5.5-157, 5.5-162, 5.5-178, 5.5-181, 5.5-183, 5.5-194, 5.5-196, 5.5-198, 5.5-209, 5.5-212, 5.5-214, 5.5-223, 5.5-226, 5.5-229, 5.5-238, 5.5-240, 5.5-242, 5.5-252, 5.5-256, 5.5-259, 5.5-270, 5.5-272, 5.5-275, 5.5-288, 5.5-291, 5.5-295, 5.5-307, 5.5-309, 5.5-311, 5.5-318, 5.5-319, 5.5-321, 5.5-328, 5.5-329, 5.5-330, 5.5-336, 5.5-337, 5.5-339, 5.5-346, 5.5-347, 5.5-349, 5.5-356, 5.5-361, 5.5-364, 5.5-367, 5.5-374, 5.5-377, 5.5-385, 6-5, 6-12, 6-19, 6-36, 6-37

salinity, ES-15, ES-22, ES-34, 3-58, 4.3-2, 4.3-7, 4.3-8, 4.3-9, 4.3-10, 4.3-11, 4.3-22, 4.3-26, 4.3-27, 4.3-29, 4.3-33, 4.3-34, 4.3-57, 4.3-59, 4.3-60, 4.3-68, 4.3-69, 4.3-70, 4.3-71, 4.3-73, 4.3-74, 4.3-75, 4.3-76, 4.3-77, 4.3-78, 4.3-79, 4.3-83, 4.3-84, 4.3-85, 4.3-86, 4.3-87, 4.3-88, 4.3-89, 4.3-91, 4.3-92, 4.3-93, 4.3-94, 4.3-95, 4.3-96, 4.3-105, 4.3-126, 4.4-8, 4.4-27, 4.4-70, 4.4-106, 4.5-2, 4.5-6, 4.5-9, 4.5-17, 4.5-21, 4.5-43, 4.5-46, 4.5-52, 4.5-54, 4.5-55, 4.5-56, 4.5-57, 4.5-58, 4.5-59, 4.5-60, 4.5-62, 4.5-67, 4.5-68, 4.5-70, 4.5-71, 4.5-73, 4.5-77, 4.5-79, 4.5-80, 4.5-81, 4.6-73, 4.6-250, 4.13-26, 4.13-40, 4.20-18, 5.3-2, 5.4-45, 5.5-29, 5.5-31, 5.5-38, 5.5-42, 5.5-47, 5.5-48, 5.5-49, 5.5-50, 5.5-52, 5.5-53, 5.5-55, 5.5-60, 5.5-61, 5.5-62, 5.5-63, 5.5-64, 5.5-69, 5.5-71, 5.5-72, 5.5-74, 5.5-76, 5.5-81, 5.5-115, 5.5-117, 5.5-120, 5.5-123, 5.5-124, 5.5-126, 5.5-128, 5.5-129, 5.5-132, 5.5-133, 5.5-135, 5.5-269, 5.5-278, 5.6-5, 5.6-7, 5.6-10, 6-49, 6-50, 6-60

Sea level rise, ES-19, ES-22, ES-35, 3-19, 4.2-22, 4.2-23, 4.2-30, 4.2-37, 4.2-40, 4.2-46, 4.2-49, 4.2-50, 4.2-69, 4.2-77, 4.3-12, 4.3-16, 4.3-57, 4.3-60, 4.3-121, 4.3-122, 4.3-130, 4.4-55, 4.4-57, 4.4-58, 4.4-76, 4.4-77, 4.4-78, 4.4-80, 4.11-1, 4.11-2, 4.11-18, 5.3-31, 5.3-37, 5.3-43, 5.5-27, 5.5-29, 5.5-33, 5.5-34, 5.5-39, 5.5-43, 5.5-51, 5.5-57, 5.5-68, 5.5-89, 5.6-10, 6-54

Seaside Groundwater Basin, ES-1, ES-2, ES-3, ES-7, ES-11, ES-13, ES-16, 1-5, 1-6, 1-8, 1-9, 2-1, 2-2, 2-3, 2-4, 2-5, 2-7, 2-8, 2-9, 2-10, 2-17, 2-18, 2-19, 2-20, 2-25, 2-47, 2-48, 2-49, 3-2, 3-12, 3-28, 3-29, 3-45, 3-60, 3-61, 3-62, 3-67, 3-69, 3-70, 4.1-3, 4.1-4, 4.1-23, 4-35, 4.2-3, 4.2-66, 4.2-79, 4.2-80, 4.3-111, 4.3-112, 4.4-1, 4.4-3, 4.4-15, 4.4-23, 4.4-24, 4.4-27, 4.4-35, 4.4-43, 4.4-44, 4.4-58, 4.4-59, 4.4-81, 4.4-108, 4.4-109, 4.4-112, 4.4-113, 4.6-126, 4.6-268, 4.13-11, 4.13-15, 4.15-29, 4.18-16, 5.1-4, 5.1-5, 5.2-2, 5.2-4, 5.2-6, 5.2-7, 5.3-11, 5.4-2, 5.4-3, 5.4-5, 5.4-6, 5.4-7, 5.4-8, 5.4-10, 5.4-12, 5.4-50, 5.4-52, 5.4-57, 5.5-6, 5.5-8, 5.5-15, 5.5-19, 5.5-22, 5.5-30, 5.5-83, 5.5-113, 5.5-174, 5.5-190, 5.5-203, 5.5-218, 5.5-235, 5.5-246, 5.5-283, 5.5-303, 5.5-314, 5.5-343, 5.5-373, 5.5-374, 5.5-375, 5.5-376, 5.5-377, 5.5-379, 5.5-380, 5.5-381, 5.5-382, 5.5-383, 5.5-384, 5.5-385, 5.6-2, 6-5, 6-9, 6-13, 6-18, 6-19, 6-20, 6-36, 6-39, 6-41, 6-45, 6-55

Seawater intrusion, ES-17, 2-8, 2-34, 2-36, 2-37, 2-39, 2-42, 2-43, 4.1-18, 4.4-16, 4.4-19, 4.4-22, 4.4-24, 4.4-31, 4.4-34, 4.4-35, 4.4-43, 4.4-44, 4.4-47, 4.4-60, 4.4-63, 4.4-69, 4.4-70, 4.4-89, 4.4-90, 4.4-91, 4.4-105, 4.4-106, 5.5-84, 5.5-86, 5.5-87, 5.5-95, 5.5-97, 5.5-99, 5.5-101, 5.5-102, 5.5-375, 5.5-378, 6-39, 6-41, 6-45, 6-46, 6-48

Squid, 4.3-8, 4.5-2, 4.5-8, 4.5-10, 4.5-12, 4.5-15, 4.5-20, 4.5-21, 4.5-24, 4.5-25, 4.5-39, 4.5-41, 4.5-59, 4.5-68, 4.5-73, 4.5-74, 4.5-79, 5.3-38, 5.5-111
