Table 5.5-18 provides a breakdown of demand associated with existing and anticipated land uses assumed for the MPWSP. **Table 5.5-19** shows water supplies that would be available with the MPWSP, compared with the service area demands shown in **Table 5.5-18**, as well as two estimates of the SVGB return water obligation associated with operating the proposed 9.6-mgd desalination plant. **Table 5.5-19** illustrates available and surplus supply (or deficit) during the Seaside Groundwater Basin replenishment period, assuming a 6 percent or 12 percent return water obligation. As shown, under either of these return water scenarios, the available supply would meet demand associated with existing land uses and water entitlements (12,845 afy), with a surplus of 209 or 1,829 afy depending on the return water obligation.

[13] Although demand in 2010 is slightly less than the current 10-year average demand (12,351 afy) CalAm assumes this is the appropriate level of demand for planning purposes to ensure the proposed action is sized appropriately to meet peak demands as required by state regulations; see Section 2.3 in Chapter 2 for more information.

[14] For the first 25 years of MPWSP operation, CalAm would provide in-lieu replenishment of the Seaside Groundwater Basin in repayment of groundwater CalAm has pumped from the basin in excess of CalAm's adjudicated right, as discussed in Chapter 2, Section 2.2.4. Replenishment would occur at a rate of 700 afy. During the replenishment period, available supply from the Seaside Groundwater Basin would be limited to 774 afy; at the end of the replenishment period, available supply would equal CalAm's adjudicated right of 1,474 afy.

[15] Existing annual service area demand now includes the 325 afy Pebble Beach entitlement, and 325 afy was therefore, removed from the anticipated future demand.

TABLE 5.5-18
EXISTING AND ANTICIPATED DEMAND
(ACRE-FEET PER YEAR)

Demand Component	MPWSP Demand Assumptions	Demand Associated with Existing Land Uses and Water Entitlements	Demand Associated with Anticipated Development
Existing Annual System Demand	12,270	12,270	-
Pebble Beach Water Entitlements	325	325	
Hospitality Industry Rebound Economic Recovery	500	250[a]	250
Legal Lots of Record	1,180		1,180
Total	**14,275**	**12,845**	**1,430**

NOTES:
[a] A comparison of commercial sector demand prepared for this analysis suggests that demand by the hospitality industry under improved economic conditions may be lower than identified by CalAm; refer to text discussion for more information.

NOTES: mgd = million gallons per day; Seaside GW Basin = Seaside Groundwater Basin; SVGB = Salinas Valley Groundwater Basin

[a] Includes 325 afy for Pebble Beach water entitlements.
[b] Water supply sources include: Carmel River (3,376 afy), Seaside Groundwater Basin (774 afy), Aquifer Storage and Recovery Project (1,300 afy), Sand City Coastal Desalination Plant (94 afy), and the proposed MPWSP Desalination Plant (10,750 afy), as shown in Table 2-4 of Chapter 2.

SOURCE: Table 2-4, Table 6.3-4.

The 1,430 afy of MPWSP supply that would serve anticipated development, shown in **Table 5.5-18**, is about 40 percent of 3,526 afy, the 2006 estimate of future demand as revised based on updated information and about half of 2,820 afy, the 2006 estimate of future demand as updated and reduced by an additional 20 percent.

The MPWSP would not directly contribute to the creation of additional housing or jobs within the area it serves as it is limited to the construction and operation of water supply facilities and infrastructure. But the proposed project would indirectly support growth by removing some water

supply limitations as an obstacle to growth, thereby enabling a degree of growth under the approved general plans within the area served by the MPWSP.

The cities and county in the area served by the proposed project have the authority to approve or deny development projects and to impose mitigation to address significant environmental impacts associated with development projects within their respective jurisdictions. In addition, numerous federal, state, regional, and local agencies are specifically charged with protecting environmental resources, and ensuring that planned development occurs in a sustainable manner. Together, these agencies exercise the authority to reduce the effects of development on the environment. Some unavoidable impacts would still, however, be expected to occur.

Cumulative Analysis

The geographic scope for the cumulative analysis of indirect growth inducement consists of the CalAm Monterey District service area jurisdictions and other areas of Monterey County that could experience similar indirect growth inducement. The baseline environmental setting against which the MPWSP is being analyzed includes the effects of existing, operational water supply projects identified in Table 4.1-2 such as the Seaside Groundwater Basin Aquifer Storage and Recovery projects (Nos. 29 and 30), and Sand City Coastal Desalination Plant (No. 6), which are assumed in water supply planning undertaken for the proposed project (as discussed in Chapter 2, Section 2.4 and shown in Table 2-4). The CalAm Slant Test Well at CEMEX (No. 47) is assumed to be used for production of the proposed MPWSP supply.

Several of the planned future cumulative projects identified in Table 4.1-2 would provide new sources of potable water supply in Monterey County. Growth induced by one or more of these cumulative water supply projects in combination with the proposed project would result in secondary effects of growth in Monterey County that are similar to, but would likely be more severe and widespread than, those summarized above in Table 6.3-9; these impacts include increased traffic, noise, and air pollution and loss of open space and biological resources.

Other water projects listed in Table 4.1-2, would either provide non-potable recycled water supply or enhance groundwater recharge. Projects providing recycled water could offset demand for potable supply that is currently used for non-potable uses, thereby making that potable supply available for other uses including growth. Projects capturing and diverting stormwater runoff to enhance groundwater recharge would primarily improve surface water quality and help stop seawater intrusion, but may overtime increase the availability of groundwater supply. These projects could contribute to the growth-inducing impacts of the cumulative potable supply projects described above by increasing the availability of existing potable supplies and groundwater.

5.5.21.3 Indirect Growth Inducing Effects of No Project Alternative

The No Project Alternative would deliver less water than the proposed project, would not be able to reliably serve existing customers, and therefore, would have no indirect growth inducing effects associated with the provision of water supply and it would not achieve the benefits of the proposed project in terms of providing minor amounts of additional water to accommodate some growth. The No Project Alternative water supplies of 11,314 afy, through September 2018, would

be reduced by 1,000 af annually to 6,380 afy by January 2022. This supply could not serve the baseline demand of 12,595 afy – or 11,335 afy, assuming ongoing implementation of conservation programs reduced demand to this amount by 2021 – and the implementation of Stage 3 Conservation Measures and Stage 4 Rationing would be required.

5.5.21.4 Indirect Growth Inducing Effects of Alternative 1 – Slant Wells at Potrero Road)

Operational Impacts

The indirect growth-inducing impact of Alternative 1 would be similar to that of the proposed project, although slightly decreased because source water pumped under this alternative is expected to include more groundwater that originated from inland aquifers than the proposed project, requiring a higher percentage of water to be returned to the SVGB. Therefore, less desalinated product water likely would be available to support growth. With CalAm's other supply sources, water supplies would total 16,294 afy, shown in **Table 5.5-20**, the same as for the proposed project (shown in **Table 6.3-4** in Section 6.3, Growth Inducement, of Chapter 6, Other Considerations). After meeting existing service area demand and entitlements of 12,845 afy and an assumed 6 percent SVGB return water obligation,[16] 1,829 afy would be available for other uses during the 25-year Seaside Groundwater Basin (SGB) replenishment period.

Although the precise amount of the return water obligation is not currently known, this analysis assumes that Alternative 1, like the MPWSP, would provide enough supply to meet the level of service area demand that CalAm proposes to meet, 14,275 afy. The surplus shown in **Table 5.5-20** indicates that Alternative 1 would have some operational flexibility needed to meet the *peak demands* that would be associated with the anticipated average annual demand, including about 1,430 afy of water for anticipated future development – that is, water for growth. As discussed in Section 6.3.5.3, this level of growth is consistent with the growth planned for in the adopted land use plans of service area jurisdictions. The environmental consequences of planned growth have been addressed in adopted local land use plans and their associated CEQA documents, as well as in other, project-specific documentation, as discussed in Section 6.3.6. Some of the identified indirect effects of this growth would be significant and unavoidable while other effects would be significant but can be mitigated.

Assuming a 6 percent SVGB return water obligation, this alternative would not provide enough supply to meet the estimated 3,526 afy of additional service area demand associated with general plan buildout (discussed in Section 2.5.3 of Chapter 2 and shown in **Table 2-5**). Following the conclusion of the Seaside Groundwater Basin replenishment period, an additional 700 afy of supply would be available to meet additional demands; however, it would still not meet projected future demands in the CalAm service area. This additional supply could provide CalAm added operational flexibility or could be used to serve a degree of additional growth still within the levels of approved general plans.

[16] The 6 percent return water obligation assumed here is an example of what the return obligation could be. The SVGB return water obligation will be based on observed values of the source water. Groundwater modeling performed for this EIR/EIS simulated scenarios with 0, 3, 6, and 12 percent of the source water extracted via subsurface slant wells being returned to the SVGB (see Section 4.4, Groundwater Resources).

TABLE 5.5-20
ALTERNATIVE 1 – SLANT WELLS AT POTRERO ROAD WATER SUPPLIES AND DEMANDS DURING SGB REPLENISHMENT PERIOD: TWO FUTURE DEMAND SCENARIOS (ACRE-FEET PER YEAR)

	Supply Compared to MPWSP-Anticipated Demands	Supply Compared to Updated MPWMD Estimate of Future Supply Needs
Existing/Other CalAm Supplies[a]	5,544	5,544
Supply provided by Alternative 1	10,750	10,750
Total Supplies	**16,294**	**16,294**
Minus Existing Service Area Demand (Table 6.3-3)	12,845	12,845
Minus SVGB Return Obligation (Assuming 6% Return Obligation)[b]	1,620	1,620
Supply Available for Other Use (Supplies Minus Existing Demand and Return Obligation)	**1,829**	**1,829**
Minus Future Demands: Two Scenarios	1,430[c]	3,526[d]
Surplus or (Deficit)	**399**	**(1,697)**

NOTES: SGB = Seaside Groundwater Basin; SVGB = Salinas Valley Groundwater Basin; afy = acre feet per year

[a] Existing/Other CalAm supplies consist of 3,376 afy from the Carmel River, 774 afy from the Seaside Groundwater Basin, 1,300 afy from the Aquifer Storage and Recovery Project, 94 afy from the Sand City Coastal Desalination Plant. At the end of the 25-year Seaside Groundwater Basin replenishment period CalAm's supply from that the groundwater basin will increase by 700 afy to 1,474 afy.
[b] The SVGB return water obligation will be based on the observed amount of fresh water component in the source water. The percentage of return water required for pumping at the Potrero Road site (this alternative) is expected to be higher than the percentage of return water that would be required for pumping at the CEMEX site (the MPWSP).
[c] Demand associated from anticipated development CalAm proposes to meet with the MPWSP (see Section 6.3.5.1 and Table 6.3-3).
[d] MPWMD's 2006 estimate of future water supply needs updated by more recent information (see Section 6.3.5.3 and Table 6.3-8).

SOURCE: Table 2-4, Table 6.3-3, Table 6.3-8.

While the above analysis discloses the indirect growth inducing impact of Alternative 1 associated with a 6 percent SVGB return water obligation, the analysis in Section 5.5.4.3, which describes the impacts of Alternative 1 on groundwater resources, suggests that a higher return water percentage would be necessary under Alternative 1. In the event that the return water obligation is determined to be 12 percent (the highest return value simulated), after meeting existing demand and entitlements only 209 afy would be available for other uses, which would not meet either future demand scenario and, therefore, Alternative 1 would not fully meet the project objective/need for water, some of which was to support limited growth (e.g., legal lots of record). The indirect growth inducing impact of this alternative assuming a 12 percent SVGB return would result in a ***reduced impact conclusion*** compared to the proposed project, less than significant.

Cumulative Analysis

The geographic scope for the cumulative analysis of indirect growth inducement impacts of Alternative 1 is Monterey and Santa Cruz Counties. The cumulative impact would be similar to that described for the MPWSP in Section 6.3.7. Of the planned sources of new potable water supply for Monterey County and other areas identified in **Table 4.1-2**, the DeepWater Desal Project (No. 34) could combine with Alternative 1 to have cumulative growth inducing impacts in

the areas that would be served by these projects. If both projects were approved, Alternative 1 would supply water to the CalAm service area, as described under operational impacts above, and the entire 25,000 afy produced by the DeepWater Desal Project would be provided to the city of Salinas in Monterey County and to areas of Santa Cruz County.

In addition, the RUWAP Desalination Element (No. 31 in **Table 4.1-2** in Section 4.1) would serve the Marina Coast Water District's Ord Community with approximately 1,000 afy of potable supply. Through an agreement with FORA and the MRWPCA, an additional 1,400 afy of potable supply from the Pure Water Delivery and Supply Project (No. 35) would meet the build-out needs of the Ord Community, which is contiguous with CalAm's service area. The Granite Ridge Water Supply Project (No. 33) would increase water supply availability for the area of northern Monterey County that it would serve. The Interlake Tunnel Project (No. 24) would reduce the amount of water spilled at Nacimiento Dam by allowing water from Nacimiento Reservoir to be stored at San Antonio Reservoir for later use. This project would enhance flood control, provide environmental benefits, and offset groundwater pumping. However, because this project would provide groundwater recharge, this analysis assumes it could indirectly augment supply available for groundwater users, including municipal supply that could serve additional growth. Although the primary purpose of the Salinas Valley Water Project Phase II (No. 1) is to combat seawater intrusion by providing a new source of surface water to offset groundwater consumption, the availability of a reliable surface water supply provided by this project could induce growth by removing supply reliability limitations as an obstacle to urban development.

Growth induced by these cumulative water supply projects in combination with Alternative 1 would result in secondary effects of growth that are similar to, but would likely be more widespread in Monterey and Santa Cruz Counties than those summarized in **Table 6.3-9** in Section 6.3 for the CalAm service area only. These impacts include increased traffic, noise, and air pollution and loss of open space and biological resources.

Other water projects listed in **Table 4.1-2**, including the RUWAP Recycled Water Project (No. 35), West Broadway Stormwater Retention Project (No. 41), Del Monte Boulevard Dry Weather Diversion Project (No. 44), Pacific Grove Local Water Project (No. 22), Pacific Grove Recycled Water Project (No. 23), and Monterey Pacific Grove Area of Special Biological Significance (ASBS) Stormwater Management Project (No. 45), would either provide non-potable recycled water supply or enhance groundwater recharge. As described for the MPWSP, projects providing recycled water could offset demand for potable supply that is currently used for non-potable uses, thereby making that potable supply available for other uses, including growth. Projects capturing and diverting stormwater runoff to enhance groundwater recharge would primarily improve surface water quality and help stop seawater intrusion, but may overtime increase the availability of groundwater supply. These projects would eliminate an impediment to growth; some of the impacts of that growth were determined by the general plan EIRs to be significant and unavoidable and could contribute to the growth inducing impacts of Alternative 1 and the DeepWater Desal project by increasing the availability of existing potable supplies and groundwater. Because Alternative 1 would have a significant and unavoidable impact, it would have a significant contribution to significant and unavoidable cumulative impacts of indirect growth inducement.

5.5.21.5 Indirect Growth Inducing Effects of Alternative 2 – Open Water Intake at Moss Landing

Operational Impacts

The indirect growth-inducing impact of Alternative 2 would be similar to, but greater than, that of the proposed project because this alternative would produce the same amount of desalinated product water and no desalinated water would need to be returned to the SVGB. As under the MPWSP, with CalAm's other supply sources, water supplies would total 16,294 afy, shown in **Table 5.5-21**.

TABLE 5.5-21
ALTERNATIVE 2 – OPEN OCEAN INTAKE AT MOSS LANDING WATER SUPPLIES AND DEMANDS DURING SGB REPLENISHMENT PERIOD: TWO FUTURE DEMAND SCENARIOS (ACRE-FEET PER YEAR)

	Supply Compared to MPWSP-Anticipated Demands	Supply Compared to Updated MPWMD Estimate of Future Supply Needs
Existing/Other CalAm Supplies[a]	5,544	5,544
Supply provided by Alternative 2	10,750	10,750
Total Supplies	**16,294**	**16,294**
Minus Existing Service Area Demand (Table 6.3-3)	12,845	12,845
Supply Available for Other Use (Supplies Minus Existing Demand)	**3,449**	**3,449**
Minus Future Demands: Two Scenarios	1,430[b]	3,526[c]
Surplus or (Deficit)	**2,019**	**(77)**

NOTES: SGB = Seaside Groundwater Basin; afy = acre feet per year

[a] Existing/Other CalAm supplies consist of 3,376 afy from the Carmel River, 774 afy from the Seaside Groundwater Basin, 1,300 afy from the Aquifer Storage and Recovery Project, 94 afy from the Sand City Coastal Desalination Plant. At the end of the 25-year Seaside Groundwater Basin replenishment period CalAm's supply from that the groundwater basin will increase by 700 afy to 1,474 afy.
[b] Demand associated from anticipated development CalAm proposes to meet with the MPWSP (see Section 6.3.5.1 and Table 6.3-3).
[c] MPWMD's 2006 estimate of future water supply needs updated by more recent information (see Section 6.3.5.3 and Table 6.3-8).

SOURCE: Table 2-4, Table 6.3-3, Table 6.3-8.

After meeting existing service area demand and entitlements of 12,845 afy, 3,449 afy would be available to support growth in the CalAm service area during the 25-year Seaside Groundwater Basin replenishment period. This is substantially more than the 1,430 afy of anticipated future development demand CalAm proposes to meet with the MPWSP and similar to the estimated 3,526 afy of additional service area demand associated with general plan buildout (discussed in Section 2.5.3 of Chapter 2 and shown in **Table 2-5**). While this alternative appears to almost meet projected future general plan demands, water use does not occur at an average rate throughout the year (as discussed in Section 2.3.2), and it is unlikely this alternative could provide the operational flexibility to meet the peak demands associated with general plan buildout.

In any event, the growth inducing impact of Alternative 2 would be greater than the proposed project because Alternative 2 would remove water supply limitations as an obstacle to growth to a greater extent than would the MPWSP. The environmental consequences of planned growth that would be supported by this alternative have been addressed in the adopted land use plans and

associated CEQA documents of service area jurisdictions, as discussed in Section 6.3.6. Some of the identified indirect effects of this growth would be significant and unavoidable while other effects would be significant but can be mitigated.

Following the conclusion of the Seaside Groundwater Basin replenishment period, an additional 700 afy of supply will be available to meet demands in the CalAm service area. This additional supply could provide CalAm added operational flexibility to meet peak demands or it could be used to serve a degree of additional growth.

The greater indirect growth inducing impact of this alternative would result in an ***increased impact conclusion*** compared to the proposed project, significant and unavoidable.

Cumulative Analysis

The cumulative scenario for Alternative 2 would be the same as described above for Alternative 1. The contribution of Alternative 2 to significant and unavoidable cumulative impacts of indirect growth inducement would be significant and would be increased compared to the proposed project and Alternative 1 as a result of the greater amount of water available for growth under Alternative 2, as shown in **Table 5.5-21**.

5.5.21.6 Indirect Growth Inducing Effects of Alternative 3 – Monterey Bay Regional Water Project (DeepWater Desal)

Operational Impacts

The indirect growth-inducing impact of Alternative 3 would be greater than that of the proposed project because this alternative would produce about 14,000 afy more desalinated water. Assuming CalAm purchased 10,750 afy (9.6 mgd) from DeepWater Desal for use in the CalAm service area, CalAm supplies would total 16,294 afy, as shown in **Table 5.5-22**. Because no desalinated water would need to be returned to the SVGB, more water would be available to the service area; after meeting existing demand and entitlements of 12,845 afy, 3,449 afy would be available under Alternative 3 to support growth in the CalAm service area during the 25-year Seaside Groundwater Basin Replenishment period. This is substantially more than the 1,430 afy of anticipated future demand CalAm proposes to meet with the MPWSP and similar to the estimated 3,526 afy of service area demand associated with general plan buildout (discussed in Section 2.5.3 of Chapter 2 and shown in **Table 2-5**).

Assuming CalAm purchased 10,750 afy for use in the CalAm service area, the remaining 14,250 afy produced by Alternative 3 would be available for other areas of Monterey and Santa Cruz Counties. Other areas that may be served by this alternative include the city of Salinas, the unincorporated community of Castroville, other areas of northern Monterey County, and areas of Santa Cruz County.

Therefore, the indirect growth-inducing impact of Alternative 3 would be greater than the MPWSP because this alternative would remove water supply limitations as an obstacle to growth in a much larger area of the region as well as within CalAm's service area. The environmental consequences

TABLE 5.5-22
ALTERNATIVE 3 – DEEPWATER DESAL WATER SUPPLIES AND DEMANDS DURING SGB REPLENISHMENT PERIOD: TWO FUTURE DEMAND SCENARIOS (ACRE-FEET PER YEAR)

Supplies/Demands	Supply Compared to MPWSP-Anticipated Demands	Supply Compared to Updated MPWMD Estimate of Future Supply Needs
Existing/Other CalAm Supplies[a]	5,544	5,544
Alternative 3 Water Provided to CalAm Service Area/Purchased From DeepWater Desal Project[b]	10,750	10,750
Total Supplies to CalAm Service Area	**16,294**	**16,294**
Minus Existing Service Area Demand (Table 6.3-3)	12,845	12,845
CalAm Service Area Supply Available for Other Use (Supplies Minus Existing Demand)	**3,449**	**3,449**
Minus Future Service Area Demands: Two Scenarios	1,430 [c]	3,526 [d]
Surplus or (Deficit) within CalAm Service Area	**2,019**	**(77)**
Supply Available for Other Areas[e]	**14,250**	**14,250**

NOTES: SGB = Seaside Groundwater Basin; mgd = million gallons per day; afy = acre feet per year

[a] Existing/Other CalAm supplies consist of 3,376 afy from the Carmel River, 774 afy from the Seaside Groundwater Basin, 1,300 afy from the Aquifer Storage and Recovery Project, 94 afy from the Sand City Coastal Desalination Plant. At the end of the 25-year Seaside Groundwater Basin replenishment period CalAm's supply from that the groundwater basin will increase by 700 afy to 1,474 afy.

[b] Supply to the CalAm Service area assumes DeepWater Desal LLC would provide, and CalAm would purchase, 9.6 mgd, or 10,750 afy of desalinated water from the DeepWater Desal Project.

[c] Demand associated from anticipated development CalAm proposes to meet with the MPWSP (see Section 6.3.5.1 and Table 6.3-3).

[d] MPWMD's 2006 estimate of future water supply needs updated by more recent information (see Section 6.3.5.3 and Table 6.3-8).

[e] The DeepWater Desal Project would produce 25,000 afy of desalinated product water. After delivering 9.6 mgd (10,750 afy) 14,250 afy would be available to other areas of Monterey and Santa Cruz Counties.

SOURCE: Table 2-4, Table 6.3-3, Table 6.3-8.

of planned growth in the CalAm service area that would be supported by this alternative have been addressed in the adopted land use plans and associated CEQA documents of service area jurisdictions, as discussed in Section 6.3.6 (discussed in Section 6.3.6). Some of the identified indirect effects of this growth would be significant and unavoidable while other effects would be significant but can be mitigated.

Because information is not currently available about how much and where the remaining 14,250 afy of water produced by this alternative may be used, whether for replacement supplies or for growth, the consistency of this supply with planned growth in areas that would receive it cannot be definitively assessed. But because of the amount of water that would be available, impacts would likely be significant and unavoidable. The separate EIR/EIS that is being prepared for the DeepWater Desal project will provide more detailed analysis on this topic.

Following the conclusion of the Seaside Groundwater Basin replenishment period, another 700 afy of supply would be available to the CalAm service area. This additional supply could provide CalAm greater operational flexibility, could be used to serve a degree of additional growth, or could prompt CalAm to reduce the amount of water it purchases from DeepWater Desal, in which case more desalinated product water from DeepWater Desal would be available to other areas.

Therefore, the indirect growth inducing impact of this alternative would result in an ***increased impact conclusion*** compared to the proposed project, significant and unavoidable.

Cumulative Analysis

The geographic scope for the cumulative analysis of indirect growth inducement impacts of Alternative 3 is Monterey and Santa Cruz Counties. Of the planned sources of new potable water supply for Monterey County identified in **Table 4.1-2**, the GWR Project (No. 59) could combine with Alternative 3 to have cumulative growth inducing impacts in the areas that would be served by these projects. If both projects were approved, it is assumed that Alternative 3 would supply water to the CalAm service area equivalent to the production of a 6.4 mgd plant, or about 7,170 afy, supplementing the water that would be supplied by the GWR project, and the remaining 17,830 afy produced by Alternative 3 would be provided to the city of Salinas, the unincorporated community of Castroville, other areas of Monterey County and areas of Santa Cruz County.

In addition, the other projects in the cumulative scenario, described above for Alternative 1, could induce growth by removing supply reliability limitations as an obstacle to urban development. Growth induced by these cumulative water supply projects in combination with Alternative 3 would result in secondary effects of growth in Monterey and Santa Cruz Counties that are similar to, but would likely be more severe and widespread than, those summarized in **Table 6.3-9**. These impacts include increased traffic, noise, and air pollution and loss of open space and biological resources.

The overall cumulative impact would be significant and unavoidable. While the total amount of water available for growth would be reduced under the Alternative 3 cumulative scenario compared to the proposed project scenario (because only the Alternative 3 desalination plant would be built, compared to building it and the proposed project), the contribution of Alternative 3 to significant and unavoidable cumulative impacts of indirect growth inducement would be significant and increased compared to the proposed project and Alternatives 1 and 2 as a result of the greater amount of water available for growth under Alternative 3, as shown in **Table 5.5-22**.

5.5.21.7 Indirect Growth Inducing Effects of Alternative 4 – People's Moss Landing Desalination Project

Operational Impacts

The indirect growth-inducing impact of Alternative 4 would be greater than that of the proposed project because this alternative would provide substantially more water. Based on the 13,400 afy the People's Moss Landing Project proposes to deliver from its proposed 12 mgd desalination plant, supplies under this alternative would total 18,944 afy, as shown in **Table 5.5-23**. This is substantially more than the proposed project's 16,294 afy, and because no desalinated water would need to be returned to the SVGB, the entire supply would be available for use. After meeting existing demand and entitlements of 12,845 afy in the CalAm Monterey District service area, 6,099 afy would be available to support growth in the region during the Seaside Groundwater Basin Replenishment period. This is more than three times the amount that would be available under the proposed project (1,829 afy), assuming a 6 percent return water obligation, and would be almost

twice the 3,526 afy estimate of future Monterey District service area demand under general plan buildout (discussed in Section 2.5.3 of Chapter 2 and shown in **Table 2-5**). This alternative would provide substantially more water than needed to meet demand associated with General Plan buildout in the CalAm service area, based on currently available information.[17] Although surplus supply could be delivered to other users in the region, the growth that could be supported in the Monterey District service area by this alternative would be beyond the level evaluated in adopted land use plans and would likely have impacts related to increased density (such as increased traffic and noise) or the development of new land areas (such as loss of open space, wildlife habitat, and agricultural land), potentially resulting in impacts that are more severe than those identified in the EIRs of adopted land use plans and plan elements. The separate EIR/EIS that is being prepared for the People's Project will provide more detailed information on this topic.

TABLE 5.5-23
ALTERNATIVE 4 – PEOPLE'S PROJECT WATER SUPPLIES AND DEMANDS DURING SGB REPLENISHMENT PERIOD: TWO FUTURE DEMAND SCENARIOS (ACRE-FEET PER YEAR)

Supplies/Demands	Supply Compared to MPWSP-Anticipated Demands	Supply Compared to Updated MPWMD Estimate of Future Supply Needs
Existing/Other CalAm Supplies[a]	5,544	5,544
Alternative 4 Water Provided to CalAm Service Area/Purchased From People's Project [b]	13,400	13,400
Total Supplies	**18,944**	**18,944**
Minus Existing Service Area Demand (Table 6.3-3)	12,845	12,845
Supply Available for Other Use (Supplies Minus Existing Demand)	**6,099**	**6,099**
Minus Future Demands: Two Scenarios	1,430[c]	3,526[d]
Surplus or (Deficit)	**4,669**	**2,573**

NOTES: SGB = Seaside Groundwater Basin; mgd = million gallons per day; afy = acre feet per year

[a] Existing/Other CalAm supplies consist of 3,376 afy from the Carmel River, 774 afy from the Seaside Groundwater Basin, 1,300 afy from the Aquifer Storage and Recovery Project, 94 afy from the Sand City Coastal Desalination Plant. At the end of the 25-year Seaside Groundwater Basin replenishment period CalAm's supply from that the groundwater basin will increase by 700 afy to 1,474 afy.
[b] Supply assumes the People's Project would provide, and CalAm would purchase, 12 mgd, or 13,400 afy of desalinated water from the People's Project.
[c] Demand associated from anticipated development proposed to be met by the MPWSP (see Section 6.3.5.1 and Table 6.3-3).
[d] MPWMD's 2006 estimate of future water supply needs updated by more recent information (see Section 6.3.5.3 and Table 6.3-8).

SOURCE: Table 2-4, Table 6.3-3, Table 6.3-8.

Following the conclusion of the Seaside Groundwater Basin replenishment period, an additional 700 afy of supply would be available, which would support an even greater degree of growth beyond that anticipated in jurisdictions' general plans.

Therefore, the indirect growth inducing impact of this alternative would result in an ***increased impact conclusion*** compared to the proposed project, significant and unavoidable.

[17] As discussed in more detail in Section 2.5.3.4, General Plan Buildout, of Chapter 2, the future demand estimate assumed in this analysis, 3,526 afy, is based on MPWMD's 2006 estimate of future water supply needs as updated by more recent information.

Cumulative Analysis

The cumulative scenario for Alternative 4 would be the same as described above for Alternative 1. Of the planned sources of new potable water supply identified in **Table 4.1-2**, the DeepWater Desal Project (No. 34) could combine with Alternative 4 to have cumulative growth inducing impacts in the areas that would be served by these projects. If both projects were approved, Alternative 4 would supply water to the CalAm service area, as described under operational impacts above, and the entire 25,000 afy produced by the DeepWater Desal Project would be provided to the city of Salinas and other areas in Monterey and Santa Cruz Counties. The contribution of Alternative 4 to significant and unavoidable cumulative impacts of indirect growth inducement in the CalAm Service District would be significant and would be increased compared to the proposed project or Alternatives 1 through 3 as a result of the greater amount of water available for growth as shown in **Table 5.5-23** and would be cumulatively considerable and the same as the proposed project for the other areas of Monterey and Santa Cruz counties.

5.5.21.8 Indirect Growth Inducing Effects of Alternatives 5a and 5b

Operational Impacts

The indirect growth-inducing impact of both Alternative 5a and 5b would be less than that of the proposed project because neither alternative would provide enough water to support growth. Neither Alternative 5a nor 5b would provide enough supply to meet both existing demand and the SVGB return water obligation associated with operation of the subsurface slant wells. Supplies provided by Alternatives 5a and 5b with CalAm's other supplies would total 12,711 afy during the 25-year Seaside Groundwater Basin replenishment period, as shown in **Table 5.5-24**. This amount is less than existing service area demands and entitlements of 12,845 afy, and is unlikely to provide the operational flexibility needed to meet peak demands that would be associated with an annual average demand of 12,711 afy. After meeting existing demands and entitlements to the extent feasible, no supply would be available for other uses or for the 6 percent return water obligation assumed in considering the project alternatives.[18] Furthermore, as described for Alternative 1, modeling analysis of pumping at the Potrero Road site suggests that a higher return water percentage would be necessary under Alternative 5b; perhaps closer to 12 percent. Under Alternative 5b, using a 12 percent assumption for the return water obligation, the deficit in available return water would be that much greater than the 6 percent obligation assumed for Alternative 5a (2,084 afy rather than 1,042 afy). Considering that neither alternative is expected to provide enough supply to meet existing demands or the SVGB return water obligation associated with operation of the subsurface slant wells, neither alternative would provide water to support future growth. They would therefore not remove water supply limitations as an obstacle growth and would not be growth inducing. Following the conclusion of the Seaside Groundwater Basin replenishment period, another 700 afy of supply would be available to the CalAm service area. This additional supply could provide CalAm greater operational flexibility to meet peak demands and to meet some of its return water obligation.

[18] As stated in Chapter 2, the SVGB return water obligation will be based on the amount of fresh water in the source water. In order to consider the effect of the return water for this EIR/EIS, groundwater modeling simulated scenarios with return water obligations representing 0, 3, 6, and 12 percent of the source water (see Section 4.4, Groundwater Resources).

TABLE 5.5-24
ALTERNATIVE 5 – REDUCED DESALINATION PLANT WATER SUPPLIES AND DEMAND DURING SGB REPLENISHMENT PERIOD: TWO FUTURE DEMAND SCENARIOS (ACRE-FEET PER YEAR)

Supplies/Demands	Supply Compared to MPWSP-Anticipated Demands	Supply Compared to Updated MPWMD Estimate of Future Supply Needs
Existing/Other CalAm Supplies[a]	5,544	5,544
6.4-MGD Desalination Plant Production[b]	7,167	7,167
Total Supplies	**12,711**	**12,711**
Minus Existing Service Area Demand (Table 6.3-3)	12,845	12,845
Minus SVGB Return Obligation (Assuming 6% Return Obligation)[c]	1,042	1,042
Supply Available for Other Use or (Deficit) (Supplies Minus Existing Demand and Return Obligation)	**(1,176)**	**(1,176)**
Minus Future Demands: Two Scenarios (Tables 6.3-3 and 6.3-8)	1,430[d]	3,526[e]
Surplus or (Deficit)	(2,606)	(4,702)

NOTES: SGB = Seaside Groundwater Basin; SVGB = Salinas Valley Groundwater Basin mgd = million gallons per day

[a] Existing/Other CalAm supplies consist of 3,376 afy from the Carmel River, 774 afy from the Seaside Groundwater Basin, 1,300 afy from the Aquifer Storage and Recovery Project, 94 afy from the Sand City Coastal Desalination Plant. At the end of the 25-year Seaside Groundwater Basin replenishment period CalAm's supply from that the groundwater basin would increase by 700 afy to 1,474 afy.
[b] Assumed annual supply is based on a 6.4-mgd desalination plant operating at full capacity.
[c] Alternative 5 includes two alternatives – Alternative 5a and Alternative 5b. Both consist of a 6.4-mgd desalination plant. Source water for Alternative 5a would be from slant wells at the CEMEX site. Source water for Alternative 5b would be from slant wells at the Potrero Road site. The SVGB return water obligation will be based on the amount of the fresh water component of the source water. The return water estimate shown here is based on a 6 percent return water obligation as an example. The 6 percent return water obligation is assumed for Alternative 5a. The percentage of return water required for pumping at the Potrero Road site (Alternative 5b) is expected to be higher than for pumping at the CEMEX site (Alternative 5a).
[d] Demand associated from anticipated development CalAm proposes to meet with the MPWSP (see Section 6.3.5.1 and Table 6.3-3).
[e] MPWMD's 2006 estimate of future water supply needs updated by more recent information (see Section 6.3.5.3 and Table 6.3-8).

SOURCE: Table 2-4, Table 6.3-3; Table 6.3-8.

Neither Alternative 5a nor 5b would fully meet current demands and entitlements and therefore would not provide water to support growth. The indirect growth inducing impact of Alternative 5 would result in a ***reduced impact conclusion*** compared to the proposed project, less than significant.

Cumulative Analysis

The geographic scope for the cumulative analysis of indirect growth inducement impacts of Alternatives 5a and 5b is Monterey and Santa Cruz Counties. The cumulative impact would be similar to that described for the MPWSP. Of the planned sources of new potable water supply for Monterey County and other areas identified in **Table 4.1-2**, the GWR Project (No. 59) and DeepWater Desal (No. 34) could combine with Alternative 5 to have cumulative growth inducing impacts in the areas that would be served by these projects. If the three projects were approved, CalAm would purchase 3,500 afy of GWR Project water to supplement the water produced by Alternative 5. Together, water supplies from Alternative 5 and the GWR Project, with CalAm's other sources, would total 16,211 afy. This is slightly less than the MPWSP alone would provide,

but the total volume of SVGB return water obligation under Alternatives 5a and 5b would be smaller compared to the proposed project and Alternative 1, respectively, due to the reduced pumping volume of the smaller desalination plant. Under the cumulative scenario, the GWR Project would provide water to the CalAm service area, and the entire 25,000 afy produced by the DeepWater Desal project would be provided to the city of Salinas in Monterey County and to areas of Santa Cruz County.

In addition, the other projects in the cumulative scenario, described above for Alternative 1, could induce growth by removing supply reliability limitations as an obstacle to urban development. Growth induced by these cumulative water supply projects in combination with Alternative 5 would result in secondary effects of growth that are similar to, but would likely be more widespread in Monterey and Santa Cruz Counties than those summarized in **Table 6.3-9**. These impacts include increased traffic, noise, and air pollution and loss of open space and biological resources.

After meeting existing service area demand and entitlements of 12,845 afy, Alternative 5a, in combination with the water purchase agreement with the GWR Project, would result in 2,324 afy available for other use. This is more than the 1,430 afy of anticipated future demand CalAm proposes to meet with the MPWSP, and therefore is assumed to provide substantial flexibility to meet associated peak demands; available supply would not be enough to meet the estimated 3,526 afy of service area demand associated with general plan buildout. Alternative 5b in combination with the GWR Project, assuming a 12 percent SVGB return water obligation, would result in 1,282 afy available for other use. Given that this is slightly less than the future demand CalAm proposes to meet with the MPWSP, Alternative 5b with the GWR project is also assumed to provide less flexibility to meet peak demands, and also would not provide enough supply to meet the estimated service area demand associated with general plan buildout. Both Alternatives 5a and 5b combined with GWR Project water could support a degree of growth that would result in potentially significant impacts. The overall cumulative impact would be significant and unavoidable. The contribution of Alternative 5a and 5b to significant and unavoidable cumulative impacts of indirect growth inducement would be significant and would be similar to the proposed project as a result of the total amount of water available for growth under Alternative 5a and 5b in combination with the GWR Project.

5.6 Environmentally Superior/Environmentally Preferred Alternative and NOAA-Preferred Alternative

This section presents a summary comparison of the overall potential environmental impacts of the proposed project and alternatives in order to identify an environmentally superior alternative under CEQA and an environmentally preferred alternative under NEPA, and the NOAA-preferred alternative. Environmental advantages and disadvantages of each alternative are discussed. Section 5.5 addresses the individual impacts associated with each alternative by topic and by individual impact. The alternatives, as described in Chapter 3 (Description of Proposed Project) and Section 5.4, are the proposed project, no project/no action, Alternative 1 (Slant Wells at Potrero Road), Alternative 2 (Open-Water Intake at Moss Landing), Alternative 3 (Monterey Bay Regional Water Project (MBRWP or DeepWater Desal Project)), Alternative 4 (People's Moss Landing Water Desalination Project (People's Project)), Alternative 5a (Reduced Project 6.4-mgd Desalination Plant - Intake Slant Wells at CEMEX), and Alternative 5b (Reduced Project 6.4-mgd Desalination Plant - Intake Slant Wells at Potrero Road).

The analysis of alternatives presented in this section and Section 5.5, taken together with the analysis of the proposed project in Chapter 4, provide a basis to identify the environmentally superior alternative under CEQA (CEQA Guidelines Section 15126.6) and the environmentally preferred alternative under NEPA (40 CFR 1502.14(e)). Although NEPA CEQ regulations (40 CFR §1505.2) require the identification of the "environmentally preferable" alternative for the Record of Decision (ROD), this Final EIR/EIS identifies the environmentally preferred alternative for informational purposes. In this document, the environmentally superior/ environmentally preferred alternative is the alternative identified as meeting most of the basic project objectives, similar to satisfying the primary purpose and need, and resulting in the fewest or least severe combination of significant environmental impacts. CEQA Guidelines Section 15126.6 provides that if the No Project Alternative is the environmentally superior alternative, the EIR shall also identify an environmentally superior alternative among the other alternatives. Here, the No Project Alternative may technically qualify as the environmentally superior/ environmentally preferred alternative because it would involve the least amount of impact on the existing physical environment. However, it would not meet most of the basic project objectives; it would have considerable economic and socioeconomic consequences (e.g., severe water conservation measures), and could result in different impacts than the proposed project or other alternatives given the failure of the No Project Alternative to supply sufficient water for customers within the CalAm service area. For this reason, the discussion below focuses on selecting another environmentally superior/environmentally preferred alternative from among the alternatives (including the proposed MPWSP) presented in this EIR/EIS.

It is important to recognize that the selection of the environmentally superior/environmentally preferred alternative is not always a straight-forward and formulaic exercise. In some cases, including here, no alternative stands out from the others as eliminating all significant and unavoidable, long-term environmental effects. There are environmental tradeoffs among the alternatives and even within resource issue areas or topics, making it difficult to summarize the

net effect of the alternatives. As such, considerable weighing among the severity of impacts of the alternatives and professional judgment as to the relative importance of topical impact areas is necessary. Such judgment, while based on reasoning grounded in the scientific study that comprises the EIR/EIS, can be subjective. This means that, although this EIR/EIS identifies an environmentally superior/environmentally preferred alternative, the CPUC and MBNMS decision-makers could ultimately come to a different conclusion as to which alternative is the environmentally superior alternative based on applying different weights to various impact areas. For example, one primary area of concern for MBNMS is marine biological resources and potential impacts on these resources from brine discharge and impingement/entrainment. However, in this Final EIR/EIS, MBNMS and CPUC have both identified the same alternative as the environmentally superior/environmentally preferred alternative, and MBNMS has determined that the environmentally preferred alternative is also the NOAA-preferred alternative under NEPA, as discussed in Section 5.6.2, below.

5.6.1 Summary and Comparison of Impacts of Alternatives

While most of the alternatives have impacts that are similar to the proposed MPWSP for most of the topical areas identified in Sections 5.5, there are several impacts that are unique to certain alternatives, or the impacts are more or less severe than the proposed MPWSP, that factor heavily into the selection of the environmentally superior/environmentally preferred alternative. **Table 5.6-1** presents the impact conclusion for each impact statement, for every topical area evaluated, for the proposed project and for all alternatives, and provides a relative impact severity for each alternative (increased, decreased, or same) compared to the proposed project. **Table 5.6-1** also allows for a comparison of the proposed project and other action alternatives to the No Action Alternative; beneficial impacts are highlighted in green.

5.6.1.1 Overview and Assumptions

The alternatives evaluated in this EIR/EIS would produce different quantities of water and are placed into three categories: (a) those that would produce more water than CalAm needs to meet the project objectives/purpose and need (Alternatives 3 and 4); (b) those that would produce less water (Alternatives 5a and 5b), and; (c) those that would produce the same water as the proposed project (Alternatives 1 and 2). The alternatives that provide more water than the proposed project have been sized by their proponents to serve regional needs and that is acknowledged in the comparisons. The alternatives that are smaller than the proposed project would not completely meet the project purpose and need for water, but would reduce the severity of impacts commensurate with their smaller capacities. Since the GWR project EIR was certified and approved by the MRWPCA in October 2015, and the CPUC in September 2016 authorized CalAm to purchase 3,500 afy of the GWR supply for extraction from the Seaside Groundwater Basin, GWR is assumed in the No Action alternative and analyzed as a cumulative project with several of the alternatives, including the 6.4 mgd desalination plant in Alternatives 5a and 5b. While CalAm is seeking approval of the 9.6 mgd project (proposed project), CalAm proposes to move forward with a 6.4 mgd desalination plant (Alternative 5a and 5b) if the GWR project is successfully implemented. In case the GWR project faces hurdles that would impair its ability to supply the additional 3,500 afy of water for CalAm's customers in a timely manner, CalAm also

seeks contingency approval for the 9.6 mgd desalination plant. Therefore, in order to make a meaningful comparison, the methodology of choosing the environmentally superior, or preferred alternative, includes the following:

1. The combination of Alternative 5a or 5b with the already-approved GWR project would size these alternatives to meet the purpose and need, and the cumulative environmental effects of the 6.4 mgd desalination plant in combination with the impacts of the GWR project are considered in the comparison, and;

2. Identifying two environmentally superior/environmentally preferred alternatives; one without, and one with the GWR Project.

5.6.1.2 Proposed Project (9.6 mgd MPWSP) Significant Impacts

To provide a basis for comparison, the proposed project would result in the following significant and unavoidable impacts in the issue areas of terrestrial biology, transportation, air quality, noise, and growth-inducement[1]:

- Disturbance within the CEMEX mining facility in areas that are designated as "primary habitat" under the City of Marina Local Coastal Program (LCP), and construction and operation of portions of the Source Water Pipeline, new Desalinated Water Pipeline, and new Transmission Main, in vegetation communities within the coastal zone designated as primary habitat, would be in conflict with the City of Marina's LCP Land Use Plan (LUP) policies, and; significant contribution to cumulatively inconsistencies with the City of Marina LCPLUP policies.

- Significant cumulative construction impacts on traffic and transportation, given the size of the MPWSP, along with the number of cumulative projects and uncertainty regarding overlap in project construction timing.

- Short-term construction emissions in excess of MBUAPCD significance thresholds for ozone and NO_2 standards on sensitive receptors; associated conflict with the intent of the 2012 Air Quality Management Plan due to these short-term exceedances; and cumulatively considerable contribution to construction emissions.

- Project-specific and cumulative nighttime noise impacts on sensitive receptors from the installation of the Castroville Optional Alignment and drilling and development of the ASR-5 and ASR-6 Wells.

- Indirect growth inducement by removing, to some extent, water supply limitations as an obstacle to growth in CalAm's Monterey District service area. The environmental consequences of this planned growth have been addressed in adopted local plans and the associated CEQA review as well as in other, project-specific, documentation. Some of the identified indirect effects of this growth are significant and unavoidable; others are significant but can be mitigated.

- Cumulatively significant contribution to secondary growth effects in Monterey County including increased traffic, noise, and air pollution and loss of open space and biological resources.

[1] Proposed project impacts from greenhouse gas emissions are no longer considered in this chapter because the impact determination in Section 4.11, Greenhouse Gas Emissions, has been reduced to less than significant with mitigation due to CalAm's commitment to the GHG Reduction Plan.

Alternative 5a, which is a reduced-size project with components at the same locations as the proposed project, would result in the same impacts listed above for the proposed project. However, the severity of impacts would be slightly reduced due to the smaller project size.

None of the alternatives would avoid all of the above-listed significant unavoidable impacts of the proposed project and several alternatives would result in additional significant impacts, as noted below. There were varying degrees of significance in impacts on terrestrial biological resources due to the differences in locations of alternative components. And while the physical impacts on terrestrial biological resources could be mitigated to less than significant, the inconsistency with Marina's LCPLUP policy would remain significant and unavoidable. All of the action alternatives would result in significant and unavoidable construction noise and air quality impacts, including from temporary cumulatively considerable contributions to health effects on sensitive receptors, similar to the proposed project and in some cases, more severe than the proposed project.

5.6.1.3 Key Impact Differences Between Alternatives

The following discussion summarizes key differences in the significant environmental impacts among the alternatives and the proposed project, including consideration of resource impacts that are of particular importance to MBNMS.

Three of the alternatives would use screened, open water intakes, which would reduce or avoid several proposed project impacts but result in new significant impacts. These alternatives would have similar or increased impacts compared to the proposed project with regard to air quality, greenhouse gas (GHG) emissions, traffic, and noise. The key differences in impacts pertaining to open water intakes included in Alternative 2 (Open-Water Intake at Moss Landing), Alternative 3 (DeepWater Desal Project), and Alternative 4 (People's Project), compared to the proposed project include:

- The construction of a new open water intakes would require the use of barges and other activities in the waters of MBNMS, including the placement of ballast rock on the seafloor, and could result in temporary and permanent direct and indirect effects on marine habitat and associated marine biological resources, as well as historical resources (i.e., shipwrecks) in Monterey Bay, resulting in significant and unavoidable impacts.
- The construction and operation of new intake facilities, located within a ravine of the Monterey Submarine Canyon, could result in temporary and permanent direct and indirect effects due to unstable slopes and the potential for landslides on the seafloor as well as alteration of the seafloor and oceanic processes such as sediment transport, resulting in potentially significant impacts.
- Operation of screened open-water intakes would result in long-term direct and indirect effects on marine biological resources within MBNMS in Monterey Bay as a result of impingement and entrainment, resulting in a significant and unavoidable impact.
- Operation of these open water intake alternatives would avoid less than significant direct or indirect effects on groundwater resources because of the absence of slant well pumping for source water.

The following impacts are unique to Alternative 3 (DeepWater Desal Project) and Alternative 4 (People's Project):

- Due to the proximity of live-aboard boats in Moss Landing Harbor, construction activities would result in exposure of more sensitive receptors to substantial pollutant concentrations from construction equipment emissions, resulting in a significant and unavoidable impact.
- Alternatives 3 and 4 would have potentially significant and unavoidable impacts related to PM_{10} emissions, which could result in significant and unavoidable environmental justice impacts.
- Operation of a new, brine-only outfall (no co-mingling with wastewater or other diluent flows) could result in long-term direct and indirect effects on water quality related to increased levels of salinity and concentrations of certain constituents, resulting in a significant and unavoidable impact.
- Each of these alternatives would produce more desalinated water than the proposed MPWSP, resulting in more water being available that would remove an impediment to growth in the three-county region resulting in a significant and unavoidable impact:
  - Alternative 3 (DeepWater Desal) would produce 22 mgd
  - Alternative 4 (People's Project) would produce 12 mgd

The following impacts are unique to Alternative 3 (DeepWater Desal Project):

- Operation of the co-located data center and emergency generators would result in substantial total net operation GHG emissions resulting in a significant and unavoidable impact.
- Operation of the co-located data center would require the use of substantial quantities of energy that would constrain local or regional supplies and require additional capacity, resulting in a significant and unavoidable impact.
- Operation of emergency generators would use large amounts of fuel in a manner that would be unnecessary and wasteful, resulting in a significant and unavoidable impact.

The following impacts are unique to Alternative 4 (People's Project):

- Construction of the desalination plant could impact (currently unsurveyed) historical resources, resulting in a significant and unavoidable impact.
- Operation and siting of the intake pumping facilities on top of the existing caisson at the existing shoreline could result in long-term direct effects on coastal erosion and scour processes that could expose adjacent properties to coastal flooding and a change in sediment transport, resulting in potentially significant impacts.
- Operation and siting of the desalination plant facilities within a 100-year flood zone could cause long-term direct effects related to redirection of flood flows, resulting in a significant and unavoidable impact.
- Operation and siting of the intake pumping facilities on top of the existing caisson would result in impacts on the visual quality of the shoreline in Moss Landing and interrupt views of MBNMS resources, resulting in potentially significant impacts.

The following impact would be unique to slant well pumping at Potrero Road (Alternative 1 and 5b):

- Operation of the slant wells at Potrero Road for a 6.4 mgd desalination plant (Alternative 5b) would lower groundwater levels in the Dune Sands/Perched-A aquifer in the Moss Landing area; operation of the wells for a 9.6 mgd desalination plant (Alternative 1) would additionally lower groundwater levels in the 180- and 400-Foot Aquifers, thereby capturing groundwater that would have otherwise flowed into Elkhorn Slough. The direct and indirect permanent effects on marine and terrestrial biological resources at Elkhorn Slough from the lowering of groundwater levels would result in significant and unavoidable impacts.

5.6.2 Determination of Environmentally Superior/ Environmentally Preferred and NOAA-Preferred Alternative

Based on current information, Alternatives 3 and 4 would each produce more water than the proposed MPWSP and while they would each meet most of the project objectives and purpose and need, these alternatives would not generally reduce or avoid the potential significant environmental impacts of the proposed MPWSP. Both alternatives would have a greater impact on the seafloor and generally on marine biological resources within MBNMS than the proposed project as a result of new screened open water intake and outfall structures, and Alternative 3 would use substantially more energy (because of the co-located data center) that would result in increased air quality and GHG impacts. In addition, the water that these alternatives would produce would exceed CalAm's needs, and would be available for use in the region. That use is unknown and could eliminate an impediment to growth which would result in additional impacts. For these reasons, neither Alternative 3 nor Alternative 4 is the environmentally superior/environmentally preferred alternative.

The proposed project, Alternative 1 (Slant Wells at Potrero Road), and Alternative 2 (Open Water Intake at Moss Landing) would each provide 9.6 mgd of desalinated water and each would meet the project objectives and purpose and need. Alternative 2 would have greater impacts on the seafloor than the proposed project or Alternative 1, as a result of the construction of a new intake, and operation of an open water intake would result in long-term marine biological impacts from impingement and entrainment. The operational impacts would be mitigable, but the proposed project and Alternative 1 would avoid the impacts by using subsurface intakes. The impacts of the subsurface intakes at Potrero Road (Alternative 1), however, would have a greater impact on groundwater levels in the Dune Sands, 180- and 400-Foot Aquifers, resulting in greater impacts on marine and terrestrial biological resources at Elkhorn Slough than pumping at CEMEX (proposed project). Therefore, neither Alternative 1 nor Alternative 5b would offer overall environmental advantages over the proposed project or reduced-size alternative (Alternative 5a).

Alternative 5b (Reduced Desal with Slant Wells at Potrero Road) would have similar but reduced groundwater level impacts at Elkhorn Slough in the Dune Sands Aquifer compared to Alternative 1. Although it would avoid impacts on marine and terrestrial biological resources at the proposed CEMEX site, the impacts on Elkhorn Slough biological resources were determined to be of

greater magnitude. Therefore, Alternative 5b would not offer overall environmental advantages over the proposed project or Alternative 5a.

The proposed project would offer the following environmental advantages over other alternatives of the same or larger size (Alternatives 1, 2, 3, and 4):

- Use of an existing outfall and co-mingling of brine with wastewater;
- No construction on the seafloor;
- Meets Ocean Plan Water Quality objectives for salinity within a very short distance;
- Avoids impingement and entrainment of marine organisms associated with an open water intake;
- Less than significant impacts on groundwater resources, surface water resources and marine biological resources; and
- Consistency with the Ocean Plan and MBNMS Desalination Guidelines.

While the proposed project would cause significant and unavoidable construction impacts on air quality and cumulative traffic during construction, the construction impacts would be temporary. While the proposed slant wells at CEMEX would be inconsistent with the City of Marina's LCPLUP policy (and thereby would therefore also result in a significant and unavoidable cumulative impact on terrestrial biological resources when considered with the test slant well at the CEMEX site), Coastal Act Section 30260 encourages coastal-dependent industrial uses and provides for resolution of conflicting Coastal Act policies where such development is concerned. Therefore, the proposed project would be the environmentally superior/environmentally preferred alternative that meets the project objectives and purpose and need without the GWR Project.

Alternative 5a would result in similar environmental advantages (see above) and would result in a reduced severity of some of the potential impacts of the proposed project (smaller footprint, less energy, reduced impacts on groundwater levels). But, as a standalone project, it would not meet the project objectives or purpose and need in terms of providing adequate water supply in the CalAm Monterey District Service Area. Assuming that the GWR Project is implemented and producing water, the combination of Alternative 5a and GWR would meet the project objectives. The cumulative effects of Alternative 5a and GWR may be greater for some of the construction-related impacts (air quality, traffic, noise), and some of the footprint-related impacts (all of the GWR facility footprints plus the footprint of Alternative 5a) and some impacts would remain the same (inconsistency with City of Marina LCPLUP policy). However, some of the operational impacts would be reduced compared to the proposed project because the 3,500 afy provided by the GWR Project would require less energy than producing it by desalination, resulting in reduced impacts on air quality. The reduced capacity desalination plant would require less source water from the slant wells, resulting in a reduction in the severity of impacts on groundwater levels, and the GWR Project would provide additional irrigation supplies to CSIP that would benefit the groundwater basin. For these reasons, assuming that the GWR Project is fully funded and successfully implemented so as to meet its purposes, Alternative 5a would be the

environmentally superior alternative under CEQA, the environmentally preferred alternative under NEPA and the NOAA-preferred alternative.

Given a choice between the proposed MPWSP and Alternative 5a paired with the GWR Project, this EIR/EIS identifies Alternative 5a as the environmentally superior/environmentally preferred and NOAA-preferred alternative. While it is true that implementing Alternative 5a and the GWR Project would result in a larger facility footprint than the proposed project alone, the pairing of Alternative 5a and the GWR Project would result in reduced operational energy use and reduced impact on air quality compared to the proposed project. Not only would the combination of Alternative 5a and the GWR Project result in reduced effects on groundwater levels influenced by fewer slant wells and less volume of pumping, the GWR Project would provide water to the CSIP growers that would benefit the groundwater basin. In addition, Alternative 5a paired with the GWR Project would be consistent with the 2016 California Action Plan seeking integrated water supply solutions, the Governor's drought proclamations, the CPUC Water Action Plan goal of promoting water infrastructure investment, and the Ocean Plan and MBNMS Desalination Guidelines.

Impact	Proposed Project 10 Slant Wells at CEMEX	No Action	Alt. 1: Slant Wells at Potrero Road	Alt. 2: Open Water Intake at Moss Landing	Alt. 3: Deep Water Desal	Alt. 4: People's Project	Alt. 5: Reduced Size Desal
Section 4.2: Geology, Soils, and Seismicity							
Impact 4.2-1: Substantial soil erosion or loss of topsoil during construction.	**LSM**	**NI ↓**	**LSM ↑**	**LSM ↑**	**LSM ↑**	**LSM ↑**	**LSM ↓**
Impact 4.2-2: Exposure of people or structures to substantial adverse effects related to fault rupture.	**LS**	**NI ↓**	**LS =**	**LS =**	**LS =**	**LS =**	**LS =**
Impact 4.2-3: Exposure of people or structures to substantial adverse effects related to seismically-induced groundshaking.	**LS**	**NI ↓**	**LS =**	**LS =**	**LS =**	**LS =**	**LS =**
Impact 4.2-4: Exposure of people or structures to substantial adverse effects related to seismically-induced ground failure, including liquefaction, lateral spreading, or settlement.	**LS**	**NI ↓**	**LS =**	**LS =**	**LS =**	**LS =**	**LS =**
Impact 4.2-5: Exposure of people or structures to substantial adverse effects related to landslides or other slope failures.	**LS**	**NI ↓**	**LS =**	**LS =**	**LS =**	**LS =**	**LS =**
Impact 4.2-6: Exposure of people or structures to substantial adverse effects related to expansive soils.	**LS**	**NI ↓**	**LS =**	**LS =**	**LS =**	**LS =**	**LS =**
Impact 4.2-7: Exposure of structures to substantial adverse effects related to corrosive soils.	**LS**	**NI ↓**	**LS =**	**LS =**	**LS =**	**LS =**	**LS =**
Impact 4.2-8: Exposure of people or structures to substantial adverse effects related to land subsidence.	**NI**	**NI ↓**	**NI =**	**NI =**	**NI =**	**NI =**	**NI =**
Impact 4.2-9: Exposure of people or structures to substantial adverse effects related to alternative wastewater disposal systems.	**LS**	**NI ↓**	**LS =**	**LS ↓**	**LS ↓**	**LS ↓**	**LS =**
Impact 4.2-10: Accelerate and/or exacerbate natural rates of coastal erosion, scour, or dune retreat, resulting in damage to adjoining properties or a substantial change in the natural coastal environment.	**LSM**	**NI ↓**	**NI ↓**	**NI ↓**	**NI ↓**	**SU ↑**	**5a: LSM = 5b: NI ↓**
Impact 4.2.11: Degrades the physical structure of any geologic resource or alters any oceanographic process, such as sediment transport, that is measurably different from pre-existing conditions.	**NI**	**NI ↓**	**NI =**	**SU ↑**	**SU ↑**	**SU ↑**	**NI =**
Impact 4.2-C: Cumulative impacts related to Geology, Soils, and Seismicity.	**LSM**	**NI ↓**	**LSM =**	**SU ↑**	**LSM =**	**SU ↑**	**LSM =**

ALTERNATIVES IMPACT SUMMARY

Impact	Proposed Project 10 Slant Wells at CEMEX	No Action	Alt. 1: Slant Wells at Potrero Road	Alt. 2: Open Water Intake at Moss Landing	Alt. 3: Deep Water Desal	Alt. 4: People's Project	Alt. 5: Reduced Size Desal
Section 4.3: Surface Water Hydrology and Water Quality							
Impact 4.3-1: Degradation of water quality associated with increased soil erosion and inadvertent releases of hazardous chemicals during general construction activities.	LS	LS↓	LS ↑	LS ↑	SU ↑	SU ↑	LS ↓
Impact 4.3-2: Degradation of water quality from construction-related discharges of dewatering effluent from open excavations and water produced during well drilling and development.	LSM	NI ↓	LSM ↑	LSM =	LSM ↑	LSM ↓	LSM ↓
Impact 4.3-3: Degradation of water quality from discharges of treated water and disinfectant from existing and newly installed pipelines during construction.	LS	NI ↓	LS ↑	LS =	LS ↑	LS ↓	5a: LS = 5b: LS ↑
Impact 4.3-4: Violate water quality standards or waste discharge requirements or degrade water quality from increased salinity as a result of brine discharge from the operation of the MPWSP Desalination Plant.	LSM	NI ↓	LSM =	LSM =	LSM ↑	SU ↑	LSM =
Impact 4.3-5: Violate water quality standards or waste discharge requirements or degrade water quality as a result of brine discharge from the operation of the MPWSP Desalination Plant.	LSM	NI ↓	LSM =	LSM =	LSM ↑	SU ↑	LSM =
Impact 4.3-6: Degradation of water quality due to discharges associated with maintenance of the subsurface slant wells and the ASR -5 and ASR-6 Wells.	LS	NI ↓	LS =	LS ↑	LS ↑	LS ↑	LS ↓
Impact 4.3-7: Alteration of drainage patterns such that there is a resultant increase in erosion, siltation, or the rate or amount of surface runoff.	LS	NI ↓	LS ↓	LS ↓	LS ↑	LS ↓	LS =
Impact 4.3-8: Alteration of drainage patterns such that there is an increase in flooding on- or offsite or the capacity of the stormwater drainage system is exceeded.	LS	NI ↓	LS ↑	LS ↓	LS ↑	LS ↓	LS ↓
Impact 4.3-9: Impedance or redirection of flood flows due to the siting of project facilities in a 100-year flood hazard area.	LS	NI ↓	LS ↓	LS =	LS ↓	SU ↑	5a: LS = 5b: LS ↓
Impact 4.3-10: Exposure of people or structures to a significant risk of loss, injury, or death from flooding due to a tsunami.	LS	NI ↓	LS ↓	LS =	LS ↓	SU ↑	LS =
Impact 4.3-11: Exposure of people or structures to a significant risk of loss, injury, or death from flooding due to sea level rise.	LS	NI ↓	LS ↓	LS =	LS ↓	SU ↑	LS =
Impact 4.3-C: Cumulative impacts related to Surface Water Hydrology and Water Quality.	LSM	NI ↓	LSM =	LSM =	LSM ↑	SU ↑	LSM =

ALTERNATIVES IMPACT SUMMARY

Impact	Proposed Project 10 Slant Wells at CEMEX	No Action	Alt. 1: Slant Wells at Potrero Road	Alt. 2: Open Water Intake at Moss Landing	Alt. 3: Deep Water Desal	Alt. 4: People's Project	Alt. 5: Reduced Size Desal
Section 4.4: Groundwater Resources							
Impact 4.4-1: Deplete groundwater supplies or interfere substantially with groundwater recharge such that there would be a net deficit in aquifer volume or a lowering of the local groundwater table level during construction.	**NI**	**NI =**	**NI =**	**NI =**	**NI =**	**NI =**	**NI =**
Impact 4.4-2: Violate any water quality standards or otherwise degrade groundwater quality during construction.	**LS**	**NI ↓**	**LS =**	**LS ↑**	**LS ↑**	**LS ↑**	**LS =**
Impact 4.4-3: Deplete groundwater supplies or interfere substantially with groundwater recharge such that there would be a net deficit in aquifer volume or a lowering of the local groundwater table level during operations so as to expose well screens and pumps.	**LS**	**NI ↓**	**LS ↓**	**LS ↓**	**LS ↓**	**LS ↓**	**5a: LS ↓ 5b: LS =**
Impact 4.4-4: Violate any water quality standards or otherwise degrade groundwater quality during operations.	**LSM**	**NI ↓**	**LS ↓**	**LS ↓**	**LS ↓**	**LS ↓**	**5a: LSM = 5b: LS ↓**
Impact 4.4-C: Cumulative impacts related to Groundwater Resources.	**LS**	**NI ↓**	**NI ↓**	**NI ↓**	**NI ↓**	**NI ↓**	**5a: LS = 5b NI ↓**
Section 4.5: Marine Resources							
Impact 4.5-1: Result in a substantial adverse effect, either directly or through habitat modifications, including direct disturbance, removal, filling, hydrological interruption, or discharge, on any marine species, natural community, or habitat, including candidate, sensitive, or special-status species identified in local or regional plans, policies, regulations or conservation plans (including protected wetlands or waters, critical habitat, essential fish habitat (EFH); or as identified by the CDFW, USFWS, and/or NMFS during construction	**LS**	**NI ↓**	**LS ↑**	**SU ↑**	**SU ↑**	**SU ↑**	**LS ↓**
Impact 4.5-2: Threaten to eliminate a marine plant or animal wildlife community or cause a fish or marine wildlife population to drop below self-sustaining levels during construction.	**LS**	**NI ↓**	**LS ↑**	**LS ↑**	**LS ↑**	**LS ↑**	**LS ↓**
Impact 4.5-3: Interfere substantially with the movement of any native marine resident or migratory fish or marine wildlife species or with established native resident or migratory marine wildlife corridors, or impede the use of native marine wildlife nursery sites during construction.	**LS**	**NI ↓**	**LS ↑**	**LS ↑**	**LS ↑**	**LS ↑**	**LS ↓**
Impact 4.5-4: Result in a substantial adverse effect, either directly or through habitat modifications, including direct disturbance, removal, filling, hydrological interruption, or discharge, on any marine species, natural community, or habitat, including candidate, sensitive, or special-status species identified in local or regional plans, policies, regulations or conservation plans (including protected wetlands or waters, critical habitat, essential fish habitat (EFH); or as identified by the CDFW, USFWS, and/or NMFS during operations.	**LS**	**NI ↓**	**SU ↑**	**SU ↑**	**SU ↑**	**SU ↑**	**5a: LS = 5b: SU ↑**

TABLE 5.6-1 (Continued)
ALTERNATIVES IMPACT SUMMARY

Impact	Proposed Project 10 Slant Wells at CEMEX	No Action	Alt. 1: Slant Wells at Potrero Road	Alt. 2: Open Water Intake at Moss Landing	Alt. 3: Deep Water Desal	Alt. 4: People's Project	Alt. 5: Reduced Size Desal
Section 4.5: Marine Resources (cont.)							
Impact 4.5-5: Threaten to eliminate a marine plant or animal wildlife community or cause a fish or marine wildlife population to drop below self-sustaining levels during operations.	**LS**	**NI ↓**	**LS =**	**LS ↑**	**LS =**	**LS =**	**LS ↓**
Impact 4.5 6: Interfere substantially with the movement of any native marine resident or migratory fish or marine wildlife species or with established native resident or migratory marine wildlife corridors, or impede the use of native marine wildlife nursery sites during operations.	**LS**	**NI ↓**	**LS =**	**LS ↑**	**LS =**	**LS =**	**LS ↓**
Impact 4.5-C: Cumulative impacts on Marine Resources.	**LS**	**NI ↓**	**LS =**	**SU ↑**	**NI ↓**	**SU ↑**	**LS ↓**
Section 4.6: Terrestrial Biological Resources							
Impact 4.6-1: Result in substantial adverse effects on species identified as candidate, sensitive, or special-status, either directly or through habitat modification, during construction.	**LSM**	**LSM↓**	**LSM =**	**LSM ↓**	**LSM ↑**	**LSM =**	**LSM =**
Impact 4.6-2: Result in substantial adverse effects on riparian habitat, critical habitat, or other sensitive natural communities during construction.	**LSM**	**LSM ↓**	**LSM =**	**LSM ↓**	**SU ↑**	**LSM =**	**LSM =**
Impact 4.6-3: Result in substantial adverse effects on federal wetlands, federal other waters, and/or waters of the State during construction.	**LSM**	**NI ↓**	**LSM =**	**LSM =**	**LSM ↑**	**LSM ↑**	**LSM =**
Impact 4.6-4: Be inconsistent with any local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance with local tree ordinances.	**SU**	**NI ↓**	**SU ↓**	**SU =**	**SU =**	**SU =**	**SU =**
Impact 4.6-5: Introduce or spread an invasive non-native species during construction.	**LSM**	**LSM ↓**	**LSM =**	**LSM =**	**LSM =**	**LSM =**	**LSM =**
Impact 4.6-6: Result in substantial adverse effects on candidate, sensitive, or special-status species during project operations.	**LSM**	**↓**	**LSM =**	**LSM ↓**	**LSM =**	**LSM =**	**LSM =**
Impact 4.6-7: Result in substantial adverse effects on riparian habitat, critical habitat, or other sensitive natural communities during project operations	**LSM**	**↓**	**SU ↑**	**LSM ↓**	**LSM =**	**LSM =**	**5a: LSM = 5b: SU ↑**
Impact 4.6-8: Result in substantial adverse effects on federal wetlands, federal other waters, and waters of the State during project operations.	**LSM**	**NI ↓**	**LSM =**	**NI ↓**	**LSM =**	**LSM =**	**LSM =**
Impact 4.6-9: Introduce or spread an invasive non-native species during project operations.	**LSM**	**NI ↓**	**NI ↓**	**NI ↓**	**NI ↓**	**NI ↓**	**5a: LSM = 5b: NI ↓**

TABLE 5.6-1 (Continued)
ALTERNATIVES IMPACT SUMMARY

Impact	Proposed Project 10 Slant Wells at CEMEX	No Action	Alt. 1: Slant Wells at Potrero Road	Alt. 2: Open Water Intake at Moss Landing	Alt. 3: Deep Water Desal	Alt. 4: People's Project	Alt. 5: Reduced Size Desal
Section 4.6: Terrestrial Biological Resources (cont.)							
Impact 4.6-10: Conflict with the provisions of an adopted Habitat Conservation Plans, natural community conservation plans or other approved local, regional, or state habitat conservation plan.	**LSM**	**NI ↓**	**LSM =**	**LSM =**	**LSM =**	**LSM =**	**LSM =**
Impact 4.6-C: Cumulative impacts related to Terrestrial Biological Resources.	**SU**	**LS ↓**	**SU =**	**SU =**	**LSM ↓**	**SU =**	**SU ↑**
Section 4.7: Hazards and Hazardous Materials							
Impact 4.7-1: Create a significant hazard to the public or the environment through the routine transport, use, or disposal of hazardous materials during construction.	**LS**	**NI ↓**	**LS ↑**	**LS ↑**	**LS ↑**	**LS ↑**	**LS ↓**
Impact 4.7-2: Encountering hazardous materials from other hazardous materials release sites during construction.	**LSM**	**LSM ↓**	**LSM =**	**LSM ↑**	**LSM ↑**	**LSM ↑**	**LSM =**
Impact 4.7-3: Project facilities would be located on a known hazardous materials site.	**LS**	**NI ↓**	**LS =**	**LS ↑**	**LS ↑**	**LS ↑**	**LS =**
Impact 4.7-4: Handle hazardous materials or emit hazardous emissions within 0.25 mile of schools during construction.	**LS**	**NI ↓**	**LS =**	**LS =**	**LS =**	**LS =**	**LS =**
Impact 4.7-5: Increase risk of wildland fires during construction.	**LS**	**NI ↓**	**LS =**	**LS =**	**LS =**	**LS =**	**LS =**
Impact 4.7-6: Create a significant hazard to the public or the environment through the routine transport, use, disposal, or accidental release of hazardous materials during project operations.	**LS**	**NI ↓**	**LS =**	**LS =**	**LS ↑**	**LS ↑**	**LS ↓**
Impact 4.7-C: Cumulative impacts related to Hazards and Hazardous Materials.	**LSM**	**LS ↓**	**LSM =**	**LSM ↑**	**LSM ↑**	**LSM ↑**	**LSM =**
Section 4.8: Land Use, Land Use Planning, and Recreation							
Impact 4.8-1: Consistency with applicable plans, policies, and regulations related to land use and recreation that were adopted for the purpose of mitigating an environmental effect.	**LS**	**NI ↓**	**LS =**	**LS =**	**LS =**	**LS =**	**LS =**
Impact 4.8-2: Disrupt or preclude public access to or along the coast during construction.	**LSM**	**NI ↓**	**LSM ↑**	**LSM ↑**	**LSM ↑**	**LSM ↑**	**5a: LSM = 5b: LSM ↑**
Impact 4.8-C: Cumulative impacts related to Land Use, Land Use Planning, and Recreation.	**LSM**	**NI ↓**	**LSM =**	**LSM =**	**LSM =**	**LSM =**	**LSM =**

TABLE 5.6-1 (Continued)
ALTERNATIVES IMPACT SUMMARY

Impact	Proposed Project 10 Slant Wells at CEMEX	No Action	Alt. 1: Slant Wells at Potrero Road	Alt. 2: Open Water Intake at Moss Landing	Alt. 3: Deep Water Desal	Alt. 4: People's Project	Alt. 5: Reduced Size Desal
Section 4.9: Traffic and Transportation							
Impact 4.9-1: Temporary traffic increases on regional and local roadways due to construction-related vehicle trips.	**LSM**	**NI ↓**	**LSM ↑**	**LSM ↑**	**LSM ↑**	**LSM ↑**	**5a: LSM = 5b: LSM ↑**
Impact 4.9-2: Temporary reduction in roadway capacities and increased traffic delays during construction.	**LSM**	**NI ↓**	**LSM ↑**	**LSM ↑**	**LSM ↑**	**LSM ↑**	**5a: LSM = 5b: LSM ↑**
Impact 4.9-3: Increased traffic safety hazards for vehicles, bicyclists, and pedestrians on public roadways during construction.	**LSM**	**NI ↓**	**LSM ↑**	**LSM ↑**	**LSM ↑**	**LSM ↑**	**5a: LSM = 5b: LSM ↑**
Impact 4.9-4: Impaired emergency access during construction.	**LSM**	**NI ↓**	**LSM ↑**	**LSM ↑**	**LSM ↑**	**LSM ↑**	**5a: LSM = 5b: LSM ↑**
Impact 4.9-5: Temporary disruptions to public transportation, bicycle, and pedestrian facilities during construction.	**LSM**	**NI ↓**	**LSM ↑**	**LSM ↑**	**LSM ↑**	**LSM ↑**	**5a: LSM = 5b: LSM ↑**
Impact 4.9-6: Increased wear-and-tear on the designated haul routes used by construction vehicles.	**LSM**	**NI ↓**	**LSM ↑**	**LSM ↑**	**LSM ↑**	**LSM ↑**	**5a: LSM = 5b: LSM ↑**
Impact 4.9-7: Parking interference during construction.	**LSM**	**NI ↓**	**LSM ↑**	**LSM =**	**LSM =**	**LSM =**	**5a: LSM = 5b: LSM ↑**
Impact 4.9-8: Long-term traffic increases on regional and local roadways during project operations and maintenance.	**LS**	**NI ↓**	**LS =**	**LS =**	**LS =**	**LS =**	**LS =**
Impact 4.9-C: Cumulative impacts related to Traffic and Transportation.	**SU**	**NI ↓**	**SU =**	**SU =**	**SU =**	**SU =**	**SU =**

TABLE 5.6-1 (Continued)
ALTERNATIVES IMPACT SUMMARY

Impact	Proposed Project 10 Slant Wells at CEMEX	No Action	Alt. 1: Slant Wells at Potrero Road	Alt. 2: Open Water Intake at Moss Landing	Alt. 3: Deep Water Desal	Alt. 4: People's Project	Alt. 5: Reduced Size Desal
Section 4.10: Air Quality							
Impact 4.10-1: Generate emissions of criteria air pollutants and contribute to a violation of an ambient air quality standard during construction.	**SU**	**LSM ↓**	**SU ↑**	**SU ↑**	**SU ↑**	**SU =**	**SU =**
Impact 4.10-2: Construction activities could conflict with implementation of the applicable air quality plan.	**SU**	**NI ↓**	**SU ↑**	**SU ↑**	**SU ↑**	**SU =**	**SU =**
Impact 4.10-3: Expose sensitive receptors to substantial pollutant concentrations and/or *Coccidioides immitis* (Valley Fever) spores or create objectionable odors affecting a substantial number of people during construction.	**LS**	**NI ↓**	**LS ↑**	**LS ↑**	**SU ↑**	**SU ↑**	**LS =**
Impact 4.10-4: Long-term increase of criteria pollutant emissions that could contribute to a violation of an ambient air quality standard during operations.	**LS**	**NI ↓**	**LS =**	**LS ↑**	**LSM ↑**	**LS ↑**	**LS ↓**
Impact 4.10-5: Expose sensitive receptors to substantial pollutant concentrations or create objectionable odors affecting a substantial number of people during operations.	**LS**	**NI ↓**	**LS =**	**LS ↑**	**LSM ↑**	**LS ↑**	**LS ↓**
Impact 4.10-C: Cumulative impacts related to Air Quality.	**SU**	**LS ↓**	**SU ↑**	**SU ↑**	**SU ↑**	**SU ↑**	**SU =**
Section 4.11: Greenhouse Gas Emissions							
Impact 4.11-1: Incremental contribution to climate change from GHG emissions associated with the proposed project.	**LSM**	**LSM ↓**	**LSM ↑**	**LSM ↑**	**SU ↑**	**LSM ↑**	**LSM ↓**
Impact 4.11-2: Conflict with the Executive Order B-30-15 Emissions Reduction Goal.	**LSM**	**NI ↓**	**LSM ↑**	**LSM ↑**	**SU ↑**	**LSM ↑**	**LSM ↓**
Impact 4.11-3: Conflict with AB 32 Climate Change Scoping Plan.	**LSM**	**NI ↓**	**LSM ↑**	**LSM ↑**	**SU ↑**	**LSM ↑**	**LSM ↓**
Impact 4.11-C: Cumulative impacts related to Greenhouse Gas Emissions.	**LSM**	**LS ↓**	**LSM ↑**	**LSM ↑**	**SU ↑**	**LSM ↑**	**LSM ↓**
Section 4.12: Noise and Vibration							
Impact 4.12-1: Cause a substantial temporary or periodic increase in ambient noise levels in the project vicinity during construction.	**SU**	**NI ↓**	**SU ↑**	**SU ↑**	**SU ↑**	**SU ↑**	**5a: SU = 5b: SU ↑**

TABLE 5.6-1 (Continued)
ALTERNATIVES IMPACT SUMMARY

Impact	Proposed Project 10 Slant Wells at CEMEX	No Action	Alt. 1: Slant Wells at Potrero Road	Alt. 2: Open Water Intake at Moss Landing	Alt. 3: Deep Water Desal	Alt. 4: People's Project	Alt. 5: Reduced Size Desal
Section 4.12: Noise and Vibration (cont.)							
Impact 4.12-2: Expose people to or generate noise levels in excess of standards established in the local general plan, noise ordinance, or applicable standards of other agencies during construction.	**LSM**	**NI ↓**	**LSM ↑**	**LSM ↑**	**LSM ↑**	**LSM ↑**	**5a: LSM = 5b: LSM ↑**
Impact 4.12-3: Exposure of people to or generation of excessive groundborne vibration during construction.	**LSM**	**NI ↓**	**LSM ↓**	**LSM ↓**	**LSM ↓**	**LSM ↓**	**5a: LSM = 5b: LSM ↓**
Impact 4.12-4: Consistency with the construction time limits established by the local jurisdictions.	**LSM**	**NI ↓**	**LSM =**	**LSM =**	**LSM ↑**	**LSM =**	**5a: LSM = 5b: LSM ↓**
Impact 4.12-5: Substantial permanent increases in ambient noise levels in the project vicinity above levels existing without the project during operations.	**LSM**	**NI ↓**	**LSM =**	**LSM =**	**LSM ↑**	**LSM ↑**	**LSM =**
Impact 4.12-6: Expose people to or generate operational noise levels in excess of standards established in the local general plan, noise ordinance, or applicable standards of other agencies during operation.	**LS**	**NI ↓**	**LS =**	**LS =**	**LS =**	**LSM ↑**	**LS =**
Impact 4.12-C: Cumulative impacts related to Noise and Vibration.	**SU**	**NI ↓**	**SU ↑**	**SU ↑**	**SU ↑**	**SU ↑**	**5a: SU = 5b: SU ↑**
Section 4.13: Public Services and Utilities							
Impact 4.13-1: Disrupt or relocate regional or local utilities during construction.	**LSM**	**NI ↓**	**LSM ↑**	**LSM ↑**	**LSM ↑**	**LSM ↑**	**5a: LSM = 5b: LSM ↑**
Impact 4.13-2: Exceed landfill capacity or be out of compliance with federal, state, and local statutes and regulations related to solid waste during construction.	**LSM**	**NI ↓**	**LSM ↑**	**LSM ↑**	**LSM ↑**	**LSM ↑**	**5a: LSM = 5b: LSM ↑**
Impact 4.13-3 Exceed landfill capacity or be out of compliance with federal, state, and local statutes and regulations related to solid waste during operations.	**LS**	**NI ↓**	**LS =**	**LS =**	**LS ↑**	**LS ↓**	**LS =**

TABLE 5.6-1 (Continued)
ALTERNATIVES IMPACT SUMMARY

Impact	Proposed Project 10 Slant Wells at CEMEX	No Action	Alt. 1: Slant Wells at Potrero Road	Alt. 2: Open Water Intake at Moss Landing	Alt. 3: Deep Water Desal	Alt. 4: People's Project	Alt. 5: Reduced Size Desal
Section 4.13: Public Services and Utilities (cont.)							
Impact 4.13-4: Exceed wastewater treatment requirements of the Central Coast RWQCB, or result in a determination by the wastewater treatment provider that it has inadequate treatment or outfall capacity to serve the project.	**LSM**	**NI ↓**	**LSM =**	**LSM =**	**LS ↓**	**LS ↓**	**LSM =**
Impact 4.13-5: Increased corrosion of the MRWPCA outfall and diffuser as a result of brine discharge associated with project operations.	**LSM**	**NI ↓**	**LSM =**	**LSM =**	**NI ↓**	**NI ↓**	**LSM =**
Impact 4.13-C: Cumulative impacts related to Public Services and Utilities.	**LSM**	**NI ↓**	**LSM =**	**LSM =**	**LSM ↓**	**LSM ↓**	**LSM =**
Section 4.14: Aesthetic Resources							
Impact 4.14-1: Construction-related impacts on scenic resources (vistas, roadways, and designated scenic areas) or the visual character of the project area and its surroundings.	**LS**	**NI ↓**	**LS =**	**LS =**	**LS =**	**LSM ↑**	**LS =**
Impact 4.14-2: Temporary sources of substantial light or glare during construction.	**LSM**	**NI ↓**	**LSM ↑**	**LSM ↑**	**LSM ↑**	**LSM ↑**	**LSM =**
Impact 4.14-3: Permanent impacts on scenic resources (vistas, roadways, and designated scenic areas) or the visual character of the project area and its surroundings.	**LSM**	**NI ↓**	**LSM =**	**LSM ↓**	**LSM ↓**	**LSM =**	**LSM =**
Impact 4.14-4: Permanent new sources of light or glare.	**LSM**	**NI ↓**	**LSM =**	**LSM =**	**LSM ↑**	**LSM ↑**	**LSM =**
Impact 4.14-C: Cumulative impacts related to Aesthetic Resources.	**LSM**	**NI ↓**	**LSM =**	**LSM =**	**LSM =**	**LSM =**	**LSM =**
Section 4.15: Cultural and Paleontological Resources							
Impact 4.15-1: Cause a substantial adverse change in the significance of a historical resource as defined in Section 15064.5 of the CEQA Guidelines or historic properties pursuant to 36 CFR 800.5 during construction.	**NI**	**NI =**	**NI =**	**NI =**	**NI =**	**SU ↑**	**NI =**
Impact 4.15-2: Cause a substantial adverse change during construction in the significance of an archaeological resource pursuant to Section 15064.5 of the CEQA Guidelines or historic properties pursuant to 36 CFR 800.5.	**LSM**	**LSM ↓**	**LSM ↑**	**LSM ↑**	**LSM ↑**	**LSM ↑**	**5a: LSM = 5b: LSM ↑**
Impact 4.15-3: Directly or indirectly destroy a unique paleontological resource or site, or unique geological feature during construction.	**LS**	**NI ↓**	**LS ↑**	**LS ↑**	**LS ↑**	**LS ↑**	**5a: LS = 5b: LS ↑**

TABLE 5.6-1 (Continued)
ALTERNATIVES IMPACT SUMMARY

Impact	Proposed Project 10 Slant Wells at CEMEX	No Action	Alt. 1: Slant Wells at Potrero Road	Alt. 2: Open Water Intake at Moss Landing	Alt. 3: Deep Water Desal	Alt. 4: People's Project	Alt. 5: Reduced Size Desal
Section 4.15: Cultural and Paleontological Resources (cont.)							
Impact 4.15-4: Disturbance any human remains, including those interred outside of formal cemeteries, during construction.	**LSM**	**NI ↓**	**LSM ↑**	**LSM ↑**	**LSM ↑**	**LSM ↑**	**5a: LSM = 5b: LSM ↑**
Impact 4.15-C: Cumulative impacts related to Cultural and Paleontological Resources.	**LS**	**LS ↓**	**LS =**	**LSM ↑**	**LSM ↑**	**LSM ↑**	**LSM =**
Section 4.16: Agricultural Resources							
Impact 4.16-1: Result in changes in the existing environment that, due to their location or nature, could temporarily disrupt agricultural activities or result in the permanent conversion of farmland to non-agricultural use.	**LSM**	**NI ↓**	**LSM =**	**LSM =**	**LSM ↑**	**NI ↓**	**LSM =**
Impact 4.16-2: Convert Prime Farmland, Unique Farmland, or Farmland of Statewide Importance to non-agricultural use.	**LS**	**NI ↓**	**LS =**	**LS =**	**LS ↑**	**NI ↓**	**LS =**

	6.4-1 Assessment of Project Conformity with Guidelines for Desalination Plants in Monterey Bay National Marine Sanctuary

This chapter addresses other considerations required by CEQA and NEPA, including the potential for the proposed project to have unavoidable significant impacts; the irreversible or irretrievable commitment of resources; the relationship between short-term uses of the project and long-term productivity; growth-inducing effects of the project; and project consistency with MBNMS Desalination Guidelines.

6.1 Significant and Unavoidable Environmental Effects

Section 15126.2(b) of the CEQA Guidelines requires that an EIR identify significant environmental effects that cannot be avoided by the proposed project, including those that can be mitigated, but not to a less-than-significant level. CEQ Regulations 40 CFR Section 1502.16 states that the EIS environmental analysis shall include any adverse environmental effects which cannot be avoided should the proposal be implemented. The analysis in Chapter 4 identifies all adverse impacts associated with the proposed project/proposed action and those impacts that

cannot be avoided. The analysis in Chapter 4 determined that the proposed project would result in impacts related to noise, air quality, terrestrial biological resources, and cumulative traffic impacts that, even with implementation of mitigation measures, would remain significant and unavoidable. These impacts are summarized below:

- Nighttime noise impacts on residential receptors during installation of the Castroville Pipeline Optional Alignment 1 and during drilling and development of the ASR-5 and ASR-6 Wells would remain significant and unavoidable, even with implementation of mitigation measures. See Section 4.12, Noise and Vibration, for additional information on this impact.

- Nighttime construction could contribute to a significant unavoidable cumulative impact. In the absence of detailed information regarding cumulative project construction equipment and exact construction phase timing, a quantitative assessment of cumulative nighttime noise impact cannot be reasonably estimated. However, it is conservatively assumed that the potential exists for residual (post-mitigation) MPWSP pipeline construction noise to combine with that of one or more of five cumulative projects in Table 4.1-2 (Nos. 31, 35, 38, 45, and 51) to cause nighttime noise levels to exceed the sleep interference threshold. As a result, temporary cumulative increases in nighttime construction noise could result in a significant cumulative nighttime noise impact. No additional mitigation within the scope of this EIR/EIS is available to further reduce this potential impact. Therefore, MPWSP nighttime construction noise could have a significant contribution to a significant cumulative effect. See Section 4.12, Noise and Vibration, for additional information on this impact.

- Short-term air emissions associated with construction of the proposed project could contribute to an exceedance of state and/or federal standards for ozone and NO_x, which could increase the susceptibility of sensitive individuals to respiratory infections and is a significant impact. Such exceedances in ozone would also be inconsistent with the Monterey Bay United Air Pollution Control District's 2012 Air Quality Management Plan (AQMP). Implementation of mitigation measures would not reduce project-related NO_x emissions (a precursor to ozone) to a level below the significance threshold, therefore resulting in significant and unavoidable impacts with regard to violations of air quality standards and compliance with the AQMP. See Section 4.10, Air Quality, for additional information on these impacts.

- Project construction NO_x emissions, in combination with cumulative project emissions, would violate ambient air quality standards and conflict with implementation of the applicable air quality plan, even with implementation of mitigation measures**.** The proposed project's incremental contribution to the cumulative impact would be significant. No further feasible mitigation measures are available to reduce the project's contribution to cumulative impacts.

- Several proposed facilities would occur in areas that may qualify as Primary and Secondary Habitat according to the City of Marina Local Coastal Land Use Plan (LCLUP). These facilities, which include the subsurface slant wells, and portions of the Source Water Pipeline, new Desalinated Water Pipeline, new Transmission Main, and the staging area at Beach Road, would be inconsistent with the City of Marina's LCLUP Policy 25 that prohibits development in Primary Habitat that is not protective of and dependent upon that habitat. The LCLUP states, "Primary habitat areas shall be protected and preserved against any significant disruption of habitat values and only uses dependent on those resources shall be allowed within those areas (City of Marina, 1982)." Implementation of mitigation

measures would reduce impacts on special-status species habitat. However, given that project facilities proposed for such habitats are not resource-dependent, and because the LCLUP policy provides no exception to the requirements that development within such habitats be resource-dependent, potential conflicts with this policy would remain unresolved. The effect would be significant and unavoidable. See Section 4.6, Terrestrial Biological Resources, for additional information.

- As described above, construction of some of the proposed components would be inconsistent with the City of Marina LCLUP Policy 25. The test slant well at the CEMEX site is a cumulative project that is within the geographic scope of this analysis. The test slant well was also determined to be inconsistent with the City of Marina LCLUP. Implementation of the proposed project would have a significant contribution to the cumulative impact related to inconsistencies with the City of Marina LCLUP. No mitigation measures are available that would reduce this impact to less than significant. See Section 4.6, Terrestrial Biological Resources, for additional information.

- Given the size of the MPWSP, along with the number of cumulative projects and uncertainty regarding cumulative project construction timing, the MPWSP transportation impacts could contribute substantially to cumulative local and regional traffic and roadway capacity disruptions, a cumulatively significant impact. Implementation of Mitigation Measure 4.9-C (Construction Traffic Coordination Plan), could reduce cumulative impacts, however there is no guarantee that local agencies would participate in such coordination efforts. Therefore, the project's incremental contribution to potential significant cumulative effects would be significant, even with implementation of mitigation measures. See Section 4.9, Traffic and Transportation, for additional information.

- The proposed project would indirectly support growth by removing some water supply limitations as an obstacle to growth, thereby enabling a degree of growth under the approved general plans within the area served by the MPWSP. The project's effect would be significant and unavoidable and its contribution to cumulative indirect growth-inducement would also be significant and unavoidable. See Section 6.3, Growth-Inducing Impacts, for additional information.

6.2 Significant Irreversible Changes and Short-Term versus Long-Term Uses

In accordance with CEQA Section 21100(b)(2)(B), CEQA Guidelines Sections 15126(c) and 15126.2(c), and CEQ Regulations 40 CFR Section 1502.16, the purpose of this section is to identify significant irreversible environmental changes and commitments of resources that would be caused by implementation of the proposed project. In addition, NEPA (40 CFR §1502.16) requires an EIS to include analysis of the relationship between short-term uses of the environment and the maintenance and enhancement of long-term productivity.

6.2.1 Irreversible Changes

A resource commitment is considered irreversible when primary or secondary impacts from its use limit future use options. Irreversible commitment applies primarily to nonrenewable resources, such as minerals or cultural resources, and to those resources that are renewable only over long time spans, such as soil productivity. A resource commitment is considered

irretrievable when the use or consumption of the resource is neither renewable nor recoverable for use by future generations. Irretrievable commitment applies to the loss of production, harvest, or natural resources. The proposed project would involve two types of resources: (1) general industrial resources including fuels and construction materials; and (2) project-specific resources such as land, biotic and cultural resources at the project facility sites. This section identifies any resources that would be lost permanently as a result of undertaking the project.

Implementation of the proposed project would result in a significant irreversible commitment of natural resources during construction and operation through the use of fossil fuels, energy and materials such as concrete, steel, and plastics.

During the life of the project, the land used for the facilities would be committed to the project. Project components, including the slant wells, desalination plant, ASR-5 and 6 Wells, and Carmel Valley Pump Station, would permanently occupy approximately 30 acres of land, via physical siting and security fencing. This land could be used for other purposes in the future; however, the baseline condition of the land would either be irretrievable or renewable in an undeterminable timeframe. Siting of the slant wells would displace sensitive dune habitat and designated mineral resources; the desalination plant would displace non-native grassland; the ASR-5 and 6 Wells could displace central maritime chaparral plant communities, including special-status species; and the Carmel Valley Pump Station site could displace non-native grassland with coastal live oak woodland fringe.

Accidents, such as the release of hazardous materials, could trigger irreversible environmental damage. As discussed in Section 4.7, Hazards and Hazards Materials, construction and operation of the proposed project would involve limited quantities of miscellaneous hazardous substances, such as gasoline, diesel fuel, solvents, paints, and other chemicals. An accidental spill of any of these substances could affect water and/or groundwater quality and, if a spill were to occur of significant quantity, the release could pose a hazard to construction workers, the public, and the environment. Improper storage, use, handling, or accidental spilling of such materials could result in a hazard to the public or the environment. However, compliance with the various regulations regarding the safe transport, use, and storage of hazardous materials (see Section 4.7.2, Regulatory Framework) as well as the National Pollutant Discharge Elimination System General Construction Permit requirements would ensure that public health and safety risks are maintained at acceptable levels. Therefore, significant irreversible changes from accidental releases are not anticipated.

6.2.2 Short-Term versus Long-Term Uses

This section compares the short- and long-term environmental effects of the project. Short-term impacts would result from constructing the various project components. These actions would result in temporary adverse impacts related to soils, air quality, terrestrial biology, water quality, noise, hazardous materials, traffic and transportation, aesthetics, agriculture, energy consumption, and the daily influx of construction workers. The siting and operation of various project components could result in long-term adverse impacts related to terrestrial biological resources, greenhouse gas emissions and the indirect effects of induced growth. All of these short-term and long-term impacts are addressed in Chapter 4 and feasible mitigation measures are identified that

would result in a reduction of many impacts to a less than significant level. On balance, impacts would not substantially affect the maintenance and enhancement of long-term environmental productivity, nor pose long-term risks to health or safety.

6.3 Growth-Inducing Impacts

6.3.1 Introduction

This section addresses the indirect growth inducement potential of the proposed MPWSP. Refer to Section 4.19, Population and Housing, for an analysis of the MPWSP's potential direct effects on growth[1]. Direct and indirect growth-inducing effects of the alternatives are addressed in Section 5.5. This section describes the relationship between land use planning and water supply; identifies the regulatory framework for the analysis; describes the assumptions used in the analysis; and discloses the MPWSP's potential to induce growth indirectly. The study area for this analysis consists of the area that would be served by the proposed project – CalAm's Monterey District service area (Monterey District)– which encompasses most of the Monterey Peninsula, and Monterey County. In particular, the MPWSP would provide water supply to customers served by the Monterey District main distribution system and three small satellite water systems, the Ryan Ranch, Hidden Hills, and Bishop systems. The main distribution system serves the cities of Carmel-by-the-Sea, Del Rey Oaks, Monterey, Pacific Grove, Sand City, and most of the City of Seaside; the Monterey Peninsula Airport District; and the unincorporated county areas of Carmel Highlands, Carmel Valley, Pebble Beach, and the Del Monte Forest. The analysis also evaluates the proposed delivery of Salinas Valley Groundwater Basin Return Water to the community of Castroville.

Growth can be induced in several ways, such as through the elimination of obstacles to growth, through the stimulation of economic activity within the region, or through the establishment of policies or other precedents that directly or indirectly encourage additional growth. In general, a project may foster spatial, economic, or population growth in a geographic area if the project removes an impediment to growth (for example, the establishment of an essential public service, the provision of new access to an area; a change in zoning or general plan amendment approval); or economic expansion or growth occurs in an area in response to the project (for example, changes in revenue base, employment expansion, etc.).

Assessing the MPWSP's potential to indirectly induce growth means determining whether the project would indirectly support economic expansion, population growth, or residential construction, and if so, determining the magnitude and nature of the potential environmental effects of that growth.

The objectives of the MPWSP include development of water supply to enable CalAm to replace Carmel River and Seaside Groundwater Basin supplies that are currently diverted and pumped in excess of CalAm's legal rights; development of a reliable water supply for its Monterey District

[1] "Direct effects" of a proposed project are "caused by the [action or project] and occur at the same time and place," while "indirect or secondary effects" are "caused by" the action or project and are "later in time or farther removed in distance, but are still reasonably foreseeable." (CEQA Guidelines § 15358(a))

service area; and provision of sufficient water supply to serve existing vacant lots of record and accommodate tourism demand under recovered economic conditions. Water supply is one of the primary public services needed to support urban development. A water service deficiency could constrain future development, particularly if coupled with policies that constrain growth relative to water supply. Adequate water supply would play a role in supporting additional growth in CalAm's service area, but it would not be the single impetus behind such growth. Other factors that influence new development and population growth on the Monterey Peninsula include economic factors such as employment opportunities; the availability of adequate infrastructure like public schools, roadways, and sewer service; local land use policies in the affected communities; and constraints on the use of areas like floodplains and sensitive habitats.

6.3.2 Relationship between Land Use Planning and Water Supply

There is a connection between land use planning and water supply. In California, cities and counties have primary authority over land use while water suppliers, through laws and agreements, are expected – and usually required – to provide water service if water supply is available. In the areas served by CalAm, it is the responsibility of the cities or Monterey County to approve or deny development proposals. In addition, on the Monterey Peninsula, the MPWMD is responsible for allocating water to the jurisdictions within its boundary (which includes the CalAm service area), issuing water permits, and approving new water distribution systems or expansions. Therefore, when deciding whether to approve or deny development projects, including whether water would be available to serve the projects, the jurisdictions within the MPWMD's boundary take into account the MPWMD's allocation and distribution determinations and permits. Numerous laws ensure that water supply planning and land use planning proceed in an orderly fashion. The laws and agencies described below provide the regulatory and planning context in which water agencies, cities, and counties work together and produce key documents (e.g., general plans and regional projections) used in this analysis.

6.3.2.1 Regional Planning and Local Planning

AMBAG

The Association of Monterey Bay Area Governments (AMBAG) is the key regional agency involved in forecasting growth in Monterey County. Although AMBAG can forecast growth, it does not have authority to approve or deny land use plans or development projects. AMBAG is a Joint Powers Authority that serves as the federally-designated Metropolitan Planning Organization and Council of Governments for Monterey, Santa Cruz and San Benito Counties. It is governed by a Board of Directors made up of elected officials from each city and county in the region. AMBAG undertakes metropolitan-level transportation planning on behalf of the region; manages the region's transportation demand model; and prepares regional housing, population and employment forecasts that are used in a variety of regional plans (AMBAG, 2013). AMBAG's regional growth forecast, which it produces approximately every five years, supports regional planning efforts such as the Metropolitan Transportation Plan, and may be used by city and county governments in support of local planning efforts such as the development of general

plans and project review. The 2004 and 2008 forecasts describe how the existing water and sewer infrastructure constrains growth (AMBAG, 2004, 2008). AMBAG adopted a different methodology for its current (2014) forecast, which emphasizes employment growth as the primary driver of long-term population change at a regional scale. The 2014 forecast includes population, housing, and employment projections out to the year 2035 (AMBAG, 2014a). While AMBAG does not have authority to approve or deny land use plans, it does direct regional growth decisions by setting state-mandated fair-share regional housing allocations in Monterey and Santa Cruz Counties and their respective cities.[2]

General Plan Requirements

Under state law,[3] each city and county must adopt a comprehensive, long-term general plan for the physical development of the jurisdiction. The general plan is a statement of development policies, and must include land use, circulation, housing, conservation, open space, noise, and safety elements. The land use element designates the general distribution, location, and extent of land uses, and includes a statement of the standards of population density and building intensity recommended for lands covered by the plan. The city or county must prepare the water section of the conservation element in coordination with any countywide water agency and with all district and city agencies that have developed, served, controlled, managed, or conserved water of any type for any purpose in the county or city for which the general plan is prepared. Coordination among relevant agencies is required to include the discussion and evaluation of any water supply and demand information contained in any applicable urban water management plan, current capital improvement program, and related supply and demand information that has been submitted to the city or county by a water agency.[4]

6.3.2.2 Coordination of Land Use Planning and Water Supply

Urban Water Management Planning Act

The Urban Water Management Planning Act[5] requires every urban water supplier to prepare an urban water management plan (UWMP) for the purpose of "actively pursu[ing] the efficient use of available supplies."[6] In preparing the UWMP, the water supplier must coordinate with other appropriate agencies, including other water suppliers that share a common source, water management agencies, and relevant public agencies. When a city or county proposes to adopt or substantially amend a general plan, the water agency must provide the planning agency with the current version of the adopted UWMP, the current version of the water agency's capital improvement program or plan, and other information about the system's sources of water supply. The Urban Water Management Planning Act requires urban water suppliers, as part of their long-range planning activities, to make every effort to ensure the appropriate level of reliability in their

2 San Benito County is responsible for setting the fair share regional housing allocation for the cities and unincorporated area in that county.
3 California Government Code § 65300 *et seq.*
4 California Government Code § 65302(d)(1).
5 California Water Code §10610 *et seq.*
6 California Water Code §10610.4(c).

water service sufficient to meet the needs of their various categories of customers during normal, dry, and multiple dry water years.[7]

Senate Bills (SB) 610 and 221

SB 610[8] and SB 221[9] were companion legislative measures that took effect in January 2002. They require increased efforts to identify and assess the reliability of anticipated water supplies, and require increased levels of communication between municipal planning authorities and local water suppliers.

- **SB 610** requires that the CEQA documents for most large projects[10] (including those that generate water demand greater than an equivalent of 500 dwelling units or increase service connections by 10 percent) include a water supply assessment. A water supply assessment must address whether existing water supplies will suffice to serve the proposed project and other planned development over a 20-year period in average, dry, and multiple-dry year conditions, and must set forth a plan for finding additional supplies necessary to serve the proposed project. Cities and counties can approve projects notwithstanding identified water supply shortfalls if they address those shortfalls in their findings.
- **SB 221** applies when cities and counties approve new tentative subdivision maps. When they do so, the cities and counties must impose a condition on the developers, requiring them to provide a detailed, written verification from the applicable water supplier that sufficient water supply will be available to serve the proposed subdivision. Without that verification, the cities and counties cannot approve the final subdivision map. SB 221 applies to projects similar in size to those addressed in SB 610.

Senate Bill 7 of the Seventh Extraordinary Session (Senate Bill 7)

Enacted in November 2009, Senate Bill 7[11] requires all water suppliers in the State to increase the efficiency of water use. Urban water suppliers like CalAm must reduce per capita water consumption 20 percent by 2020, and must set and achieve interim targets by 2015.

State Policies Encouraging Compact and Sustainable Development

In addition to the laws promoting coordinated land use and water supply planning, several recent laws have been adopted that seek to refocus planning efforts to reduce sprawl, preserve farmland, increase the viability of public transportation, and reduce the emission of greenhouse gases. These efforts promote compact and sustainable development, which allows for the more efficient provision of public services and reduces the consumption of resources, including water. One of the cornerstones of sustainable development is efficient water use. This includes water

7 California Water Code §10610.2(a)(4)
8 Codified at California Water Code §§ 10631, 10656, 10910, 10911, 10912, and 10915, and California Public Resources Code § 21151.9.
9 Codified at California Government Code §§ 65867.5, 66455.3, and 66473.7, and California Business and Professions Code § 11010.
10 Large projects include residential developments with more than 500 units; retail uses with more than 500,000 square feet of floor space; office buildings with more than 250,000 square feet of floor space; hotels or motels with more than 500 rooms; industrial uses occupying more than 40 acres or having more than 650,000 square feet of floor area; and mixed-use projects that include any use or combination as large as the above uses.
11 Codified at California Water Code §§ 10608 and 10800-10853.

conservation and efficiency measures such as using recycled water, installing water efficient fixtures, and putting in drought-tolerant landscaping.

- **Assembly Bill (AB) 32,**[12] the Global Warming Solutions Act of 2006, was adopted with the goal of reducing greenhouse gas emissions to 1990 levels by the year 2020. Under the Act, the California Air Resources Board (CARB) adopted a scoping plan that identifies measures to reduce the energy requirements of significant greenhouse gas sources, including those associated with providing reliable water supplies. These measures include increasing water use efficiency, recycling water, and improving water system energy efficiency. CARB updated the Scoping Plan CARB in May 2014.

- **SB 375,**[13] adopted in 2008, requires each of the state's MPOs to coordinate land use and transportation planning, and to develop a "Sustainable Communities Strategy" to reduce sprawl, and to reduce greenhouse gas emissions from automobiles and light trucks. AMBAG, the MPO for the three-county region, adopted its combined Metropolitan Transportation Plan/Sustainable Communities Strategy, which is advisory, in June 2014.

- **SB 732,**[14] adopted in 2008, establishes the Strategic Growth Council, a cabinet-level committee that coordinates the activities of State agencies to improve air and water quality, protect natural resources, and assist in the planning of sustainable communities.

- **AB 857,**[15] signed into law in 2002, establishes three planning priorities for the State: promoting infill development, protecting natural resources, and encouraging efficient development patterns. These priorities are to be incorporated into the Governor's Environmental Goals and Policy Report,[16] which provides a 20- to 30-year overview of State growth and development and guides the commitment of State resources in agency plans and infrastructure projects.

- The **Regional Blueprint Planning Program** is a grant program operated by the California Department of Transportation that provides assistance to COGs in developing long-range plans with the intent of supporting greater transit use, encouraging more efficient land use, improving air quality, and protecting natural resources. AMBAG released its blueprint, *Envisioning the Monterey Bay Area: A Blueprint for Sustainable Growth and Smart Infrastructure,* in June 2011.

6.3.2.3 Water Supply Management and Planning: Monterey Peninsula Water Management District

The MPWMD was established by state statute in 1978[17] to provide integrated management of all water resources for the Monterey Peninsula. In doing so, the MPWMD must ensure that the quantity of water use does not harm public trust resources, and that all water use is reasonable and beneficial. The MPWMD manages surface and groundwater resources within its jurisdictional boundary. Its functions include:

12 Codified at California Health and Safety Code § 38500 *et seq*.
13 Codified by amending California Government Code §§ 65080, 65400, 65583, 65584.01, 65584.02, 65584.04, 65587, and 65588; amending California Public Resources Code § 21061.3; adding Government Code §§ 14522.1, 14522.2 and 65080.01; and adding Public Resources Code §§ 21159.28 and 21155 *et seq*.
14 Codified at California Public Resources Code §§ 75076, 75077, 75100 *et seq.,* and 75120 *et seq.*
15 Codified at California Government Code § 65041.1.
16 Required in California Government Code § 65041.
17 West's California Water Code, Appendix Chapters 118-1 to 118-901.

- augmenting the water supply through integrated management of surface water and groundwater resources;
- promoting water conservation;
- promoting water reuse and reclamation of stormwater and wastewater; and
- fostering scenic values, environmental qualities, native vegetation, fish and wildlife, and recreation on the Monterey Peninsula and in the Carmel River basin.

The MPWMD's responsibilities also include:

- computer modeling of water resources systems;
- hydrologic monitoring;
- issuing water permits for new connections and remodels;
- allocating water to jurisdictions and tracking its use;
- developing, implementing, and enforcing water efficiency programs and ordinances;
- determining when water supply emergencies exist and then imposing and enforcing rationing programs; and
- approving new water distribution systems and expansions.

The MPWMD includes the cities of Carmel-by-the-Sea, Del Rey Oaks, Monterey, Pacific Grove, Sand City, and Seaside, as well as the Monterey Peninsula Airport District and portions of unincorporated Monterey County (see Figure 3-1 in Chapter 3). Its boundary encompasses CalAm's Monterey District as well as other territory east of Carmel Valley Village and in the Ord Community. MPWMD is governed by a seven-member Board of Directors: five directors are elected from voter divisions; one is a member of the County Board of Supervisors; and one is an elected official or chief executive officer appointed by a committee consisting of the mayors from jurisdictions within the District boundaries.

6.3.3 Regulatory Framework

NEPA requires that an EIS discuss the direct and indirect effects of a proposed action. The potential for growth-inducing effects are indirect effects (40 CFR 1508.8). Specifically:

> Effects include:
>
> > Indirect effects, which are caused by the action and are later in time or farther removed in distance [than direct effects], but are still reasonably foreseeable. Indirect effects may include growth inducing effects and other effects related to induced changes in the pattern of land use, population density or growth rate, and related effects on air and water and other natural systems, including ecosystems.

The CEQA Guidelines require that an EIR evaluate the growth-inducing impacts of a proposed project (Section 15126.2(d)). The EIR should:

> Discuss the ways in which the proposed project could foster economic or population growth, or the construction of additional housing, either directly or indirectly, in the surrounding environment. Included in this are projects which would remove obstacles to

> population growth (a major expansion of a waste water treatment plant might, for example, allow for more construction in service areas). Increases in the population may tax existing community service facilities, requiring construction of new facilities that could cause significant environmental effects. Also discuss the characteristic of some projects which may encourage and facilitate other activities that could significantly affect the environment, either individually or cumulatively. It must not be assumed that growth in any area is necessarily beneficial, detrimental, or of little significance to the environment.[18]

Economic growth refers to the extent to which a project could cause increased activity in the local or regional economy.

Growth that is induced by a project may be consistent with adopted local or regional land use plans. In that case, a formal CEQA/NEPA review would have identified and evaluated the indirect, or secondary, effects of that planned growth and, if necessary, mitigation would have been adopted to address these effects. If a project would have growth inducement potential that is not consistent with the land use plans and growth management plans and policies for the area affected (e.g., growth beyond that reflected in adopted plans and policies), then additional adverse secondary effects of growth beyond those previously evaluated could occur. Regional and local land use plans provide for land use development patterns and growth policies that allow for the orderly expansion of urban development supported by adequate urban public services, such as water supply, roadway infrastructure, utilities, wastewater, and solid waste service. This urban development may have environmental impacts, as identified in CEQA documents prepared for adoption of local land use plans. A project that would induce “disorderly” growth that conflicts with regional and local planning could indirectly cause additional adverse environmental impacts and impacts on other public services. Thus, it is important to assess the degree to which the growth associated with a project would be consistent with regional and local planning.

6.3.4 Approach to Analysis

Based on the CEQA and NEPA discussions above, assessing the growth-inducement potential of the MPWSP involves answering the question: Would implementation of the proposed project directly or indirectly cause economic or population growth or residential construction? As indicated above, a project can have a direct or indirect growth inducement potential, or both. This chapter addresses the proposed project's indirect effects; the potential direct effects are addressed in Section 4.19, Population and Housing.

To determine the MPWSP's potential to indirectly induce growth, the proposed project was evaluated for its potential to stimulate additional housing development and the need for services as a result of increasing available water supply and providing associated infrastructure improvements. The following steps were taken to investigate the MPWSP’s growth inducement potential and to characterize the secondary effects on the environment resulting from such growth.

- **Describe the Relationship Between Land Use Planning and Water Supply.** Section 6.3.2 provides an overview of water supply and land use planning requirements in

[18] The CEQA Guidelines define indirect effects the same as NEPA, above, except that the Guidelines refer to “indirect or secondary” effects (Section 15358(a)(2)).

California to provide the reader with an understanding of the rules that govern decisions about water, land use, and growth.

- **Identify Changes in Water Supply and Characterize Growth-Inducement Potential of the Proposed Project.** Section 6.3.5 analyzes the impact of growth-inducement. It describes the water supply that the MPWSP would provide, and characterizes the proposed project's potential to support or foster growth within the service area. The section describes recent growth trends reflected in census data; presents population and housing forecasts prepared by AMBAG; and provides an overview of growth anticipated in the general plans of the jurisdictions served by the MPWSP. To evaluate the proposed project's consistency with growth anticipated by these local planning agencies, the analysis compares project supply that would be available to meet future demand with an analysis of future water needs prepared by the MPWMD in collaboration with service area jurisdictions.

  While Castroville is not in CalAm's service area, the analysis also considers the growth-inducement potential of delivering Salinas Valley Groundwater Basin return water as desalinated supply, to the Castroville Community Services District (see Section 6.3.5.4).

- **Characterize the Indirect or Secondary Effects of Planned Growth.** When the jurisdictions adopt general or specific plans, they must first perform CEQA review. Those CEQA documents have evaluated the environmental effects of planned growth. To characterize and disclose the impacts of planned growth, including the cumulative impacts of such growth, the EIRs prepared for the general plans of jurisdictions served by the proposed project are summarized in Section 6.3.6.

6.3.5 Growth-Inducement Potential

6.3.5.1 Proposed MPWSP Water Service Capacity

As described in Chapter 2, Water Demand, Supplies, and Water Rights, CalAm proposes that the MPWSP provide, along with other supply sources, sufficient water supply to:

- meet existing service area demand;
- serve development that uses existing water entitlements held in the Pebble Beach-Del Monte Forest area;
- develop vacant legal lots of record; and
- support increased water consumption at local restaurants and lodging when tourism increases under improved economic conditions.

Table 6.3-1 summarizes the water demand CalAm proposes to meet with the MPWSP, along with existing and other planned water supply sources. Of the total annual demand of 14,275 af, the estimate of existing annual system demand, 12,270 afy, is based on demand in 2010.[19] CalAm's existing demand also includes 325 afy associated with existing Pebble Beach water entitlements, as discussed below. Other demand proposed to be served by the MPWSP totals 1,680 acre-feet per year (afy). The proposed water supplies for each of these demand components are analyzed below to determine whether they would have growth-inducement effects.

[19] Although demand in 2010 is slightly less than the current 10-year average demand (12,351 afy) CalAm assumes this is the appropriate level of demand for planning purposes to ensure the proposed action is sized appropriately to meet peak demands as required by state regulations; see Section 2.3 in Chapter 2 for more information.

TABLE 6.3-1
MPWSP DEMAND ASSUMPTIONS

Demand Component	Annual Demand (acre-feet)
Existing Annual System Demand	12,270
Pebble Beach Water Entitlements	325
Hospitality Industry Rebound Economic Recovery	500
Legal Lots of Record	1,180
Total	**14,275**

SOURCE: RBF Consulting, 2013; Svindland, 2016.

Components of Water Demand to be Served by the MPWSP

Existing System Demand

Annual demand

CalAm's estimate of existing system annual demand is based on recent demand data for the areas of CalAm's Monterey District that would be served by the project: the main distribution system and the Ryan Ranch, Hidden Hills, and Bishop satellite systems, and is presented in Section 2.3.1.1. As discussed above in Section 6.3.3, a proposed project would induce growth if it would directly or indirectly foster economic or population growth, including by removing an obstacle to growth (such as a constraint on water supply) in the surrounding environment. The portion of MPWSP water used to satisfy existing annual demand would replace current withdrawals from the Carmel River and Seaside Groundwater Basin in excess of CalAm's legal rights. The portion of MPWSP supply used to meet average and peak demands of existing customers (see Section 2.3.1.2) would not be available to serve economic or population growth. Therefore, this portion of the MPWSP supply would not be growth-inducing under CEQA and NEPA because it would not remove water supply limitations as an obstacle to additional growth.

Pebble Beach Entitlements

As described in Chapter 2, Water Demand, Supplies and Water Rights, Section 2.3.1.3, the MPWMD granted water entitlements totaling 380 afy to the fiscal sponsors that underwrote development of the Carmel Area Wastewater District/Pebble Beach Community Services District (CAWD/PBCSD) wastewater reclamation project. The reclamation project now provides all of the irrigation water used on golf courses and some open space areas in the Del Monte Forest, and MPWMD estimates that it saves approximately 1,000 afy of potable water (Stoldt, 2011). In 2013, when CalAm prepared the estimate of demand associated with these entitlements, approximately 325 afy of the entitlements were unassigned. Since then, MPWMD has issued additional water permits and the remaining unassigned Pebble Beach entitlements now stand at about 304 afy (MPWMD, 2016a). Because the recently issued permits may not immediately translate to water connections or water use that is reflected in existing demand data, 325 afy is a reasonable estimate of demand associated with these entitlements.

The remaining entitlements represent an existing commitment by MPWMD to issue water permits to entitlement-holders and, as stated by the SWRCB in the CDO (SWRCB, 2016), the total entitlements represent less water than historically had been diverted from the Carmel River to serve areas now served by the wastewater project. Given that the Pebble Beach entitlements represent an existing commitment by MPWMD and duty to serve by CalAm whether or not the MPWSP is implemented, water supply limitations are not considered an obstacle to the development of the Del Monte Forest properties associated with these entitlements. Therefore, the Pebble Beach water entitlements are considered part of CalAm's existing demand and project water supply used to serve these entitlements would not be growth-inducing under CEQA or NEPA.

Other Service Area Demand

Hospitality Industry Rebound

Since the 2008 recession, the Monterey Peninsula hospitality industry, which includes hotels, restaurants and other visitor-serving businesses, has experienced lower occupancy rates – and therefore lower water use – than it had before the recession (Svindland, 2013). With the recession over, the industry expects to rebound. Industry representatives are concerned that basing the estimate of existing demand on water use in recent years will understate water needs at existing businesses during a more robust economy. CalAm estimates that a tourism rebound will increase annual demand by about 500 afy and the rebound will be evenly distributed between May and September, which is the high tourist season (RBF Consulting, 2013). CalAm based this estimate on its review of past water use by commercial sector customers (Svindland, 2013) and "recent discussions in the region" (RBF Consulting, 2013). As described in Chapter 2, Water Demand, Supplies, and Water Rights, Section 2.3.3, the MPWMD performed several comparisons of recent commercial sector water demand with earlier levels of demand, considering the years 1998 through 2011, and determined that recent demand was 194,236, or 440 afy lower than in previous years, depending on the years compared and the methodology used (refer to Chapter 2, Section 2.3.2.1 for more information).

This analysis performed several additional comparisons of commercial sector water consumption, based on annual CalAm consumption reports that the MPWMD provided for water years[20] 2003 through 2015 (MPWMD, 2008, 2013a, 2016b). **Table 6.3-2** summarizes commercial sector consumption data from these reports; the data reflect consumption in CalAm's Monterey District main distribution system and the Ryan Ranch, Hidden Hills and Bishop satellite systems. As the table shows, over this 13-year period, annual commercial sector consumption declined in all but two years; therefore, comparing the earliest years in the period with the most recent years yields the most pronounced differences. For example, consumption in 2003 was 980 af higher than in 2015. Average annual consumption for the four years before the recession (water years 2004 through 2007) was 233 af higher than average annual consumption for the four years after the recession started (2008 through 2011) and average annual consumption for the five years before the recession (water years 2003 through 2007) was 289 af higher than for the average of the five years after it started (2008 through 2012). Considering all 13 years shown, average annual consumption for the five years prior to the recession was 434 af higher than average annual

[20] A water year runs from October 1 through September 30 and is named for the year in which it ends.

consumption for the eight years since (water years 2008 through 2015), which included four drought years. Consumption in the last year before the recession (water year 2007) was higher than the year before and any year since. Since the region was experiencing a serious drought during the last four years of the 13-year record shown in Table 6.3-2, at least some of the reductions in demand shown in these years may reflect short term behavioral water conservation practices that may not be sustained during normal rainfall years.

TABLE 6.3-2
MONTEREY DISTRICT COMMERCIAL SECTOR WATER CONSUMPTION
WATER YEARS[a] 2003 THROUGH 2015

2003-2009		2010-2015	
Water Year[a]	Consumption (acre-feet)[b]	Water Year[a]	Consumption (acre-feet)[b]
2003	3,284	2010	2,857
2004	3,320	2011	2,839
2005	3,108	2012	2,770
2006	3,093	2013	2,731
2007	3,125	2014	2,498
2008	3,097	2015	2,304

Annual Average 2003-2009	3,135	Annual Average 2010-2015	2,667

NOTES:
[a] A water year runs from October 1 through September 30 and is named for the year in which it ends.
[b] Consumption shown is for the CalAm's Monterey County District excluding the Ambler, Ralph Lane, Chualar, and Toro satellite systems, which would not be served by the proposed project.

SOURCE: MPWMD, 2008; 2013a, 2016b.

MPWMD's water conservation programs have continued over this period, and have permanently reduced some consumption through, for example, the replacement of less efficient water fixtures with more efficient ones or the replacement of more water-intensive landscaping with drought-tolerant landscaping. Thus, the years just prior to the recession should better indicate the increases in commercial sector demand that could result from economic recovery and a rebound of tourism in the area than do the earlier years. MPWMD's analysis of occupancy levels and commercial sector water consumption indicated that, based on four hospitality-industry businesses in Monterey and one in downtown Carmel, occupancy levels in 2011 were about 7 percent lower than the average occupancy levels for the years 1998 to 2001. Based on this difference, and on commercial sector water consumption data, MPWMD calculated that a 7 percent increase in the average annual commercial water demand for years 2009 to 2011 would increase annual demand by about 194 af. The greatest difference MPWMD found in its analysis, which compared average commercial water use for water years 2009 through 2011 with water use in the year 2000, was 440 afy; commercial water use was 3,207 af in the year 2000, which is higher than most years shown in Table 6.3-2. Of the comparisons presented above, the greatest differences are in the comparisons that include more distant pre-recession years or include post-recession years influenced by the recent drought.

Given the permanent reductions in water consumption achieved by the ongoing conservation programs and the fact that the recent severe drought was not a factor constraining water use in the year CalAm used to represent existing annual water demand, the less extreme pre-and post-recession differences found in the above comparisons seem more likely indicators of the increased commercial sector water use that could occur in a fully recovered post-drought economy than do the more extreme differences. Therefore, based on the above considerations, increases in demand at area restaurants, lodging, and other commercial businesses from a rebounding economy may more likely be on the order of 200 or 300 afy, rather than CalAm's estimate of 500 afy.

A recent study of the economic impacts of travel in California suggests that the tourism in Monterey County may have largely returned to pre-2008 levels (Dean Runyon Associates, Inc., 2016). For example, by 2013, the California transient occupancy tax, which had decreased in the years following 2008, had surpassed 2007 levels for all but one of the Peninsula cities listed. By 2014, all of the listed Peninsula cities showed higher occupancy tax receipts than in 2008. While the increases in tax receipts reflect any increases in hotel room rates that have occurred over this period, it is assumed that the increase in occupancy tax receipts also reflect increased occupancy rates since 2008. Thus, it seems that Monterey County's hospitality industry has experienced a substantial rebound. However, because the last four years were also drought years, the water demand shown in Table 6.3-2 may be somewhat lower than what could be expected during normal rainfall years. Therefore, demand associated with hospitality industry rebound on the order of 200 to 300 afy remains a reasonable estimate for purposes of this analysis.

This rebound in demand is assumed to occur due to increased occupancy rates without any expansion in physical capacity. Because no development or expansion of physical capacity would cause those demand increases, water supply provided to meet such increases would not be considered growth-inducing under CEQA or NEPA.

To the extent that businesses were to expand, or to the extent that increased tourism in the area were to cause new businesses to open, that new development would only be possible if water supply were available. Water supply serving new or expanded businesses would remove water supply limitations as a constraint to such development and therefore would induce growth. Based on the analysis above, a portion of 500 afy capacity proposed to meet demand for the existing hospitality industry may exceed the need for this purpose. This analysis assumes that the excess water service capacity provided by the project would be available to support future growth; that would therefore be considered growth-inducing. According to the analysis above, even with economic recovery, between 200 and 300 afy of the project capacity earmarked for hospitality industry rebound may be available to serve additional growth in the service area. For simplicity's sake, this analysis assumes that about 250 afy of supply designated for rebound of the hospitality industry would likely be used for this purpose and 250 afy would be available for new development. How this surplus could be allocated is discussed below under "Assumptions Regarding Allocation and Use of MPWSP Water Service Capacity."

Vacant Legal Lots of Record

The proposed project would provide 1,181 afy of water to serve the development of vacant legal lots of record in the service area. This estimate is apparently based on an estimate presented in

CalAm's 2006 UWMP, which cited a 2001 MPWMD estimate of demand associated with vacant buildable lots of record (CalAm, 2006).[21] However, as described in Chapter 2, Water Demand, Supplies, and Water Rights, Section 2.3.2.2, the MPWMD no longer considers this a valid estimate. The most recent demand assessment prepared for MPWMD specifically on lots of record was a 2002 estimate that identified demand of 1,211 afy for lots of record in the incorporated cities of the service area. The District never adopted this estimate because it did not include demand associated with vacant lots on improved parcels in the unincorporated County areas (Stoldt, 2013). While MPWMD testified in 2013 that CalAm's estimate of 1,181 afy may therefore underestimate demand associated with lots of record (Stoldt, 2013), in 2017 MPWMD observed that development has occurred since those estimates were prepared in the early 2000s and that some vacant lots on improved parcels that were included in MPWMD's vacant lot study may never be split from the main property and developed (MPWMD, 2017). MPWMD's most recent estimate of future service area demand, prepared in collaboration with service area jurisdictions, was completed in 2006. In that estimate, the MPWMD did not evaluate demand associated with lots of record *per se,* although it included demand associated with new residential and non-residential development under general plan buildout, which would include developable lots within the respective jurisdictions. Water supply that would serve currently vacant lots of record would remove water supply limitations as an obstacle to the development of these lots and would induce growth under CEQA and NEPA. As discussed below in Section 6.3.5.3, this would not be growth beyond the level anticipated in adopted General Plans.

According to the MPWMD's methodology for calculating demand, and according to its water permit system, new demand can also be generated at developed lots of record by, for example, adding bathrooms and fixtures. For this analysis, absent the addition of new dwelling units or similar intensification of use at a given lot, supply that would meet demand associated with remodels or fixture additions at developed lots would not be considered to be removing an obstacle to new development and therefore would not be growth-inducing. In any event, because this analysis assumes that MPWSP would provide 1,181 afy that could support new development at currently vacant lots of record, this component of demand would be growth-inducing.

Assumptions Regarding Allocation and Use of MPWSP Water Service Capacity

As noted in Section 2.5.4 and above in Section 6.3.2.3, MPWMD is responsible for allocating water to the jurisdictions within its boundary. MPWMD has not prepared an allocation program for the water that the MPWSP would provide. MPWMD will start updating its water allocation program's EIR once construction has started on an identified water supply project (MPWMD, 2015). Separate from CalAm's current MPWSP application, MPWMD plans to collaborate with CalAm and the service area jurisdictions to address the allocation of water from the MPWSP. In the meantime, absent a new allocation for the MPWSP water, this analysis assumes that the MPWMD's allocation of water provided by the project would be similar to the District's current and past allocation programs. That is, for purposes of this EIR/EIS, it is assumed that supply provided by the proposed project would be used to meet existing demand within the CalAm

[21] The 2006 UWMP refers to a 2001analysis by the MPWMD that "projected an additional California American Water demand of 1,181 afy, based on a review of vacant legal buildable lots of record" (CalAm, 2006). Note that this is not CalAm's currently adopted UWMP; CalAm's current UWMP (WSC, 2012) does not include an estimate of demand associated with vacant lots of record.

service area, and that water service capacity beyond that would be allocated to the jurisdictions in general proportion to an estimate – which the MPWMD has not yet developed – of their future water supply needs. Once the water is allocated to the jurisdictions, each city and the County (for the unincorporated areas) would have the responsibility and discretion to approve or deny proposed development projects for which water was available, consistent with the jurisdiction's role as the primary land use authority (discussed in Section 6.3.2 above) and applicable land use plans, policies, regulations and laws. For example, this analysis recognizes that supply based on an estimate of demand associated with lots of record may not exclusively serve development of existing vacant lots; some portion of it could, for example, support development of lots created after the preparation of this EIR/EIS or the approval of this project, depending on the jurisdiction's internal allocation system and assuming water service capacity were available.

Similarly, because at present there is no guarantee that the 500 afy proposed to meet demand associated with hospitality industry rebound would be reserved for that use, this analysis assumes that either the MPWMD or the local jurisdictions could elect not to set aside 500 afy exclusively for use by existing businesses. Therefore, some portion of this 500 afy could actually serve new development within the service area.

As discussed in Section 2.5.4, MPWMD recently confirmed that the future allocation process has not yet been defined; refer to Section 2.5.4 regarding options MPWMD would consider regarding the allocation or reservation of MPWSP water, once the MPWSP was approved and it is clear that the project would be constructed. These considerations do not change the allocation assumptions described above for this analysis.

Conclusion: MPWSP Water Service Capacity

Along with existing and other planned water supply sources, the MPWSP would provide up to 16,294 afy during the 25-year Seaside Groundwater Basin replenishment period; an additional 700 afy of Seaside Groundwater Basin supply would be available to the CalAm service area at the end of the replenishment period.[22] Of this, 12,845 afy would serve existing service area demand and water entitlements, and another 1,680 afy is proposed to meet anticipated future demand. This includes an estimated 250 afy associated with the local hospitality industry, absent new development, assuming increased economic activity. Thus, 12,845 afy would be used to meet existing demand, water entitlements, and demand of existing business customers, and 1,430 afy would support additional development. **Table 6.3-3** provides a breakdown of demand associated with existing and anticipated land uses assumed for the MPWSP. **Table 6.3-4** shows water supplies that would be available with the MPWSP, compared with the service area demands shown in Table 6.3-3, as well as two estimates of the SVGB return water obligation associated with operating the proposed 9.6-mgd desalination plant. As discussed in Chapter 2, the SVGB return water obligation will be based on the amount of fresh water component in the source water. In order to consider the effect of the return water for this EIR/EIS, groundwater modeling

[22] For the first 25 years of MPWSP operation, CalAm would provide in-lieu replenishment of the Seaside Groundwater Basin in repayment of groundwater CalAm has pumped from the basin in excess of CalAm's adjudicated right, as discussed in Chapter 2, Section 2.2.4. Replenishment would occur at a rate of 700 afy. During the replenishment period, available supply from the Seaside Groundwater Basin would be limited to 774 afy; at the end of the replenishment period, available supply would equal CalAm's adjudicated right of 1,474 afy.

simulated scenarios with return water obligations representing 0, 3, 6, and 12 percent of the source water (see Section 4.4, Groundwater Resources).

TABLE 6.3-3
EXISTING AND ANTICIPATED DEMAND
(acre-feet per year)

Demand Component	MPWSP Demand Assumptions	Demand Associated with Existing Land Uses and Water Entitlements	Demand Associated with Anticipated Development
Existing Annual System Demand	12,270	12,270	-
Pebble Beach Water Entitlements	325	325	-
Hospitality Industry Bounce-Back	500	250[a]	250
Legal Lots of Record	1,180		1,180
Total	**14,275**	**12,845**	**1,430**

NOTES:

[a] A comparison of commercial sector demand prepared for this analysis suggests that demand by the hospitality industry under improved economic conditions may be lower than identified by CalAm; refer to text discussion for more information.

TABLE 6.3-4
WATER SUPPLIES AND DEMANDS DURING SEASIDE GROUNDWATER BASIN REPLENISHMENT PERIOD, 9.6-MGD DESALINATION PLANT WITH SVGB RETURN
(acre-feet per year)

	Existing Demand[a]		Existing and Anticipated Demand	
Supplies and Demands	6% SVGB Return	12% SVGB Return	6% SVGB Return	12% SVGB Return
Total Supplies[b]	**16,294**	**16,294**	**16,294**	**16,294**
Service Area Demand (Existing and Anticipated)	12,845	12,845	14,275	14,275
Supply Available for Other Use (Total Supplies Minus Service Area Demand)	3,449	3,449	2,019	2,019
SVGB Return (6% and 12%)	1,620	3,240	1,620	3,240
Surplus or (Deficit)	**1,829**	**209**	**399**	**(1,220)**

NOTES: mgd = million gallons per day; Seaside GW Basin = Seaside Groundwater Basin; SVGB = Salinas Valley Groundwater Basin

[a] Includes 325 afy for Pebble Beach water entitlements.

[b] Water supply sources include: Carmel River (3,376 afy), Seaside Groundwater Basin (774 afy), Aquifer Storage and Recovery Project (1,300 afy), Sand City Coastal Desalination Plant (94 afy), and the proposed MPWSP Desalination Plant (10,750 afy), as shown in Table 2-4 of Chapter 2.

SOURCE: Table 2-4, Table 6.3-3.

Table 6.3-4 illustrates available and surplus supply (or deficit) during the Seaside Groundwater Basin replenishment period, assuming a 6 percent or 12 percent return water obligation. As shown, under either of these return water scenarios, the available supply would meet existing service area demand and water entitlements and demand associated with the existing hospitality industry (12,845 afy), with a surplus of 209 or 1,8292 afy depending on the return water obligation. The table also compares available supply with the total 14,275 afy demand that the MPWSP is proposed to meet. Assuming a 6 percent SVGB return water obligation, there would be enough water to meet existing and anticipated demand. But assuming a 12 percent return water obligation, supplies would not be able to fully meet anticipated demand. Total projected demand associated with development of the Pebble Beach entitlements and lots of record would not occur immediately, however; rather, it is expected to occur gradually over time. At the end of the Seaside Groundwater Basin replenishment period an additional 700 afy of Seaside Groundwater Basin supply would be available to the CalAm service area.

Supply not used to meet existing demand, water entitlements, demand of existing business customers under more robust economic conditions, or the SVGB return water obligation would be available to support new development. New development might include development of existing vacant lots of record. Water supply capacity to serve new development would remove water supply limitations as an obstacle to such development and would be considered growth-inducing under CEQA and NEPA.

6.3.5.2 MPWSP Infrastructure Capacity

Pipeline Capacity

CalAm sized the proposed project pipelines to accommodate a range of flow volumes, including flows associated with the proposed 9.6-mgd MPWSP desalination plant, or with a 6.4-mgd desalination plant – the size of the plant that would be built if CalAm were able to purchase water from the Pure Water Monterey Groundwater Replenishment (GWR) project. The 6.4-mgd desalination plant is evaluated in Chapter 5, Alternatives, and described in Sections 5.4.7 and 5.4.8. Consistent with standard engineering practice, pipeline sizing takes into account the need to meet peak demands, since water demand fluctuates daily, monthly and seasonally over the course of a year. Refer to Chapter 2, Water Demand, Supplies, and Water Rights, Section 2.3.2, for more information regarding consideration of peak demands. **Table 6.3-5** shows the flow capacity of the proposed service area pipeline segments and the flows that would be generated by the 6.4- and 9.6-mgd plants. The table also shows that all pipelines would have the capacity to accommodate flows generated by a somewhat larger-capacity plant.

Added pumping pressure enables pipelines of a given size to accommodate the higher flows. For example, in the normal course of business, the estimated operating pressure needed to pump flows from a 9.6-mgd plant would be 132 pounds per square inch (psi) at the plant. The plant itself would comprise seven modules – six in operation plus one on standby – each of which independently produces 1.6 mgd. While CalAm does not propose to regularly run all seven modules, it might have to do so in an emergency (Svindland 2014). Running all seven modules would produce a total of 11.2 mgd: 9.6 plus 1.6. To pump that additional 1.6 mgd would require an operating pressure of 136 psi.

TABLE 6.3-5
RANGE OF FLOW VOLUMES ACCOMMODATED BY PIPELINE SEGMENT

Pipeline Segment	Pipeline Capacity (Flow Volumes Accommodated) (mgd)	Flow per Pipeline Segment for 6.4-mgd Plant[a] (mgd)	Flow per Pipeline Segment for 9.6-mgd Plant[b] (mgd)	Flow per Pipeline Segment for 11.2-mgd Plant[c] (mgd)	Flow per Pipeline Segment for 12.8-mgd Plant[d] (mgd)
Source Water Pipeline	16-30	16	24	28	30
Brine Discharge Pipeline	12-20	10	14	17	18
Salinas Valley Return Pipeline	2-4	2	3	3	4
Desalinated Water Pipeline	6-13	6	10	11	13
Transmission Main	6-13	6	10	11	13
ASR Pipeline	15	15	15	15	15

NOTES:

[a] Flow that would be generated by four 1.6-mgd reverse osmosis modules; i.e., operation of the 6.4-mgd plant not including its 1.6-mgd standby module.

[b] Flow that would be generated by six 1.6-mgd reverse osmosis modules; i.e., operation of the 9.6-mgd plant not including its 1.6-mgd standby module.

[c] Flow that would be generated by seven 1.6-mgd reverse osmosis modules; i.e., concurrent operation of all six modules of a 9.6-mgd plant and its 1.6-mgd standby module.

[d] Flow that would be generated by eight 1.6-mgd reverse-osmosis modules. While this size plant is not proposed, this column shows that all pipeline segments would have capacity, with increased pumping pressure, to accommodate flows from a 12.8-mgd plant.

SOURCE: Svindland, 2014.

The smaller 6.4-mgd plant that would be built in conjunction with purchase of GWR water would have four working modules plus one on standby; each, again, would produce 1.6 mgd. To pump flows under normal conditions, the smaller plant would require an operating pressure of 128 psi at the plant, and an additional 2 psi to pump the 8.0 mgd produced by all five units.

CalAm's initial basis for pipeline sizing assumed seven 1.6-mgd modules operating concurrently for the 9.6-mgd plant, and five 1.6-mgd modules operating concurrently for the 6.4-mgd plant. As **Table 6.3-5** shows, all of the pipeline segments would have the capacity to accommodate flows associated with a 12.8 mgd plant, which is somewhat higher than flows that would be generated by a 9.6-mgd plant plus its standby module. CalAm has noted that the lower end of the range of flows would have lower overall energy requirements (e.g., if the smaller plant were constructed) and that the pipelines' capacity to accommodate the higher end of the flows would delay the possible need for future, disruptive, pipeline expansion projects (Svindland, 2014).

Sizing the pipelines to accommodate flows beyond that needed to serve the proposed project would remove constrained pipeline capacity as an obstacle to future growth and therefore would induce growth. Additional water supply would be required to generate the higher future flows that the MPWSP pipelines could accommodate. Expanding the desalination plant to increase its production capacity beyond 9.6 mgd would require additional CEQA review and approval by the CPUC and, if more source wells were needed, NEPA review and approval by the MBNMS. In addition, before CalAm could increase production capacity, the MPWMD would need to review the proposed increase under CEQA and issue a permit under its Rule 22; CalAm would likely require other permits as well.

According to a proposed Settlement Agreement between CalAm and other parties relating to CalAm's MPWSP application, MPWMD intends to collaborate with the Monterey Peninsula Regional Water Authority, Monterey County, and CalAm to determine an accurate estimate of the added water supply capacity needed to meet the General Plan buildout projections for communities served by CalAm (CalAm et al., 2013). That process has not yet begun, however, and we cannot predict its results. Depending on the results, the proposed pipelines would accommodate some or all of the added water supply needs identified in this process. Growth anticipated in jurisdictions' General Plans is summarized below in Section 6.3.5.3 and the effects of growth under General Plan buildout that would be induced by pipeline capacity, and the added water supply the pipelines could accommodate, are evaluated in Section 6.3.6.

Permitted Desalination Plant Capacity

If CalAm does purchase water from the GWR project, it could reduce the size of its MPWSP Desalination Plant. Because the GWR project's timing and cost were uncertain when CalAm submitted its application for the MPWSP, CalAm proposes a 9.6-mgd desalination plant (proposed project), but also seeks authorization to reduce the size of the desalination plant to 6.4 mgd (Alternative 5a) and purchase water from the MRWPCA and MPWMD. The MRWPCA certified the Final EIR for the GWR project and approved the project in October 2015 and adopted an Addendum in October 2017. The CPUC authorized CalAm's entry into a water purchase agreement in September 2016. However, while the CPUC has authorized CalAm's entry into a water purchase agreement, given the possibility that the GWR project could run into financing or permitting obstructions, CalAm continues to seek approval of the 9.6-mgd desalination plant in the event that the GWR project is not developed. CalAm is not proposing a 9.6-mgd desalination plant plus the GWR water purchase and this analysis does not consider the growth inducement potential of such a combination. Refer to Chapter 5, Alternatives, for more information about the 6.4-mgd desalination plant (Alternatives 5a and 5b) and to Chapter 4, Section 4.1, Overview, for more information on the GWR project and how it is considered in this EIR/EIS.

6.3.5.3 Growth Trends and Planning Agency Projections

In evaluating the potential environmental effects of growth, a key consideration is whether the growth induced or supported by a project would be planned growth – i.e., growth that is anticipated in the adopted planning documents of the jurisdictions served by that project. This section presents census data indicating recent growth trends in service area jurisdictions, the projections of future growth prepared by the regional planning agency, and growth trends and planned development anticipated in the general plans of service area jurisdictions, and compares water supply that would be provided by the MPWSP and potentially available to serve future development with estimates of water supply needed for general plan buildout.

Service Area Growth Trends 1990-2010

Table 6.3-6 shows population and housing data from the U.S. census for the years 1990, 2000, and 2010. Except for Sand City, population in all of the cities in the service area declined between 1990 and 2000; population in the service area cities as a whole decreased by about 9 percent. The decrease in population slowed between 2000 and 2010, decreasing by 3 percent for the cities as a whole. Sand City's population increased in both decades, by 36 percent (69 new residents)

NOTES:

[a] Data are for the entire unincorporated county.

SOURCE: California Department of Finance, 2007; 2013.

between 1990 and 2000 and 28 percent (73 new residents) between 2000 and 2010. The total number of housing units in service area cities decreased by 0.6 percent between 1990 and 2000 and increased by 1 percent between 2000 and 2010. Information shown for the unincorporated county is for the entire county, not just the part in CalAm's service area. Population in unincorporated Monterey County stayed about the same over these two decades, increasing by about 1 percent between 1990 and 2000 and decreasing by about 1 percent between 2000 and 2010, while the number of housing units increased.

AMBAG Projections

In 2014, AMBAG adopted its current forecast of population, housing and employment, and its Metropolitan Transportation Plan/Sustainable Communities Strategy for the region. **Table 6.3-7** shows the growth forecast to the year 2035 for the cities in the CalAm service area and unincorporated Monterey County. Unlike AMBAG's previous forecast, which it adopted in 2008, the current forecast takes into account the 2010 census, the Sustainable Communities Strategy requirements of SB 375, and the effects of the economic downturn that occurred between 2008 and 2012. Development of the forecasts involved substantial input and feedback from the jurisdictions in the AMBAG region (AMBAG, 2014a). Although population, housing, and jobs in the service area cities and in unincorporated Monterey County were lower in 2010 than had been projected in AMBAG's 2008 forecast, AMBAG now projects faster population and housing growth rates in the service area cities over the 2010-2035 planning period compared to the previous forecast. As **Table 6.3-7** shows, the population of each service area city is projected to increase over the 2010-2035 projection period, although Carmel is projected to lose population between 2010 and 2020 before beginning to grow again. In terms of percentage increase, Sand City is projected to grow the fastest although, because of its small size, its net population increase over the 25-year projection period is smaller than that of several other service area cities. Seaside is projected to have the largest net increase in population over the projection period. Overall, the population of service area cities is projected to increase by 21 percent between 2010 and 2035. Housing stock in the cities is projected to grow at a slower pace, increasing by 12 percent over the projection period. Employment in service area cities as a whole is projected to grow faster than population, with the number of jobs increasing by almost 30 percent by 2035. Projections shown in **Table 6.3-7** for unincorporated Monterey County are for the entire unincorporated area, much of which is outside CalAm's service area. Population in the unincorporated areas of the county is projected to grow by 4 percent over the projection period, while the number of housing units is projected to increase by 2 percent, and the number of jobs is projected to increase by 9 percent.

Growth Trends and Projections in Jurisdiction Land Use Planning Documents

As discussed above in Section 6.3.5.1, the MPWSP would provide more water than needed to meet existing demand and demand associated with existing businesses. In other words, there would be water to serve additional development – water for growth. The land use plans of the jurisdictions served by CalAm establish land use development patterns and growth policies that allow for the orderly expansion of urban development supported by adequate public services and infrastructure. A project that would induce growth that was inconsistent with those plans and policies could result in adverse environmental impacts not previously addressed in the CEQA review of those plans. Therefore, the general plans of jurisdictions that would be served by the MPWSP were reviewed.

NOTES:

[a] Projections are for all unincorporated areas of Monterey County.

SOURCE: AMBAG, 2014a.

This section briefly summarizes expected growth in service area jurisdictions contained in the jurisdictions' general plans and related planning documents. The summaries include the jurisdictions' housing need allocation identified through the Regional Housing Need Allocation (RHNA) process, since that represents potential residential growth planned for in the jurisdictions' general plan housing elements. To the extent the general plans describe the jurisdiction's approach to allocating its water supply (from the allocation administered by MPWMD), that information is noted.[23] The summaries include estimates of current and projected population and housing to the extent this information is provided.

According to the general plans, except for the former Fort Ord lands that several cities have annexed,[24] most jurisdictions in the service area are largely built out, and infill development and intensification of land uses is a means of accommodating additional growth. All of the jurisdictions cite limited water supply as a key factor limiting planned development within their boundaries. Most of the general plans were adopted before the start of the 2008 economic recession and therefore do not reflect or anticipate its effects. The general plan housing elements were adopted more recently, between 2010 and 2016.

City of Carmel-by-the-Sea

- The City of Carmel-by-the-Sea adopted its General Plan, in 2003 and adopted its 2015-2023 Housing Element in December 2015 (City of Carmel, 2003, 2015a).
- Citing the U.S. Census and California Department of Finance, the Housing Element states that the city's population decreased by 11.6 percent between 1990 and 2015, and that there was a net increase of 83 housing units between 2000 and 2015.
- Noting that AMBAG's Regional Housing Need Allocation for 2014 to 2023 identified a housing need in Carmel of 31 additional housing units, the Housing Element identifies the capacity to accommodate a total of 164 additional residential units.
- The Housing Element identifies the lack of water as the primary infrastructure constraint to the development of housing in Carmel, and states that the lack of an available water supply continues to limit growth in Carmel and throughout the Monterey Peninsula region. The City allocates its share of Monterey Peninsula water supply based on policies in the General Plan's Land Use and Community Character and Housing Elements, which affirm the City's commitment to housing. Residential uses have high priority and the largest water allocation. Existing subdivided lots zoned for housing are first in line for limited water resources, except when this would preclude development of essential public services, recreational uses or facilities, or visitor-serving uses consistent with the Coastal Act. The City limits new subdivisions of land until existing subdivided lots have a secure water supply, and endorses the concept of distributing the limited water resources across many properties to prevent any single project from consuming a disproportionate share of available water, and to maximize the number of units that can be built or approved.
- According to the Housing Element, the City is close to expending its water allocation from MPWMD: the City has about 3.251 af of available water, of which about 1.67 af are in the

[23] CalAm has not proposed how the jurisdictions should allocate MPWSP water to serve vacant lots of record, for example, nor does the MPWMD dictate to the jurisdictions how they must manage the water allocated to them. To the extent the general plans included information on how the jurisdiction currently allocates its water supply, such information may provide insight on how the jurisdiction would allocate its MPWSP supply.

[24] The former Fort Ord lands are served by another water provider, Marina Coast Water District, not CalAm; therefore development planned for these lands is not a focus of this analysis.

City's reserves. The City supports efforts by the MPWMD and other agencies to expand the water supply, and it has a representative on both the MPWMD Technical Advisory Committee and the Policy Advisory Committee. Housing Element Program 3-5.6 b, Water Conservation, recognizes the need to conserve and manage the City's water resources to accommodate regional housing need. The City's Municipal Code includes specific requirements for water conservation in existing and new developments. New development projects and existing structures needing a building permit for substantial proposed construction must meet the City's water conservation requirements. The Housing Element noted that several projects were under discussion as options for providing a new water supply for the Monterey Peninsula in response to SWRCB Orders 95-10 and 2009-0060, and that a more immediate supply may be available to the city from the amendment of the Eastwood Trust water rights license. This supply is described in Chapter 2, Section 2.4.6.2, Malpaso Water Company, LLC.

City of Del Rey Oaks

- The City of Del Rey Oaks General Plan was adopted in 1997 and has a planning period of approximately 20 years (City of Del Rey Oaks, 1997a). A draft update of the Housing Element was prepared in August 2006 but not adopted. The California Department of Housing and Community Development indicates that the City has not submitted a housing element for the 2015-2023 planning period to the department for certification (California Department of Housing and Community Development, 2016).

- The General Plan estimates that the City had a population of 1,692 in 1996, and provided about 321 jobs in the City's commercial and institutional sectors. The 2010 census indicates the city had a population of 1,624 in 2010; AMBAG's 2014 forecast estimates that the city had 414 jobs in 2010.

- Buildout under the General Plan of the part of the city served by CalAm – that is, the area within the city limits before the former Fort Ord land was annexed – would result in five additional residential units, and the development of 43,500 gross square feet of retail/commercial land uses and a 205-room hotel. General Plan policies call for expanded and new revenue-generating businesses on visitor-serving and commercially zoned parcels in the City, development of commercial uses at the City's Highway 68/218 entrance, intensification of existing development, and the annexation of former Fort Ord land to provide additional sites for economic development.

- Buildout under the General Plan of the part of the city served by another water provider (i.e., the former Fort Ord land that was annexed to the city and is served by water provided via the Fort Ord Reuse Authority [FORA] and the Marina Coast Water District [MCWD]), includes development of a conference center, hotel, golf course, retail shops, a fitness center, office park, and corporate office center.

- AMBAG's Regional Housing Need Allocation for the 2014-2025 period states that Del Rey Oaks needs 27 additional housing units.[25]

- The General Plan indicates that the City had about 5.8 af of water for new land uses remaining in its allocation from MPWMD as of June 1995, but according to MPWMD's November 2013 monthly allocation report, Del Rey Oaks has no water remaining in its allocation (MPWMD, 2013b.)

[25] This housing need allocation is substantially lower than the 150 units identified for Del Rey Oaks in the previous regional housing need allocation. AMBAG's RHNA for 2007-2014 did not explain the relatively high number of units allocated to Del Rey Oaks for that period.

- The General Plan identifies water as a paramount concern for all of the jurisdictions on the Monterey Peninsula, and states that setbacks in providing additional supply, along with SWCRB's requirement that CalAm decrease withdrawals from the Carmel River, have magnified concern about the availability of water to support growth. General Plan policies call for the City to develop a water allocation program to prioritize water connections; work with the appropriate water management districts to encourage water conservation, retrofitting, education, reclamation, and reuse; consider water usage and conservation in all land use decisions; adopt and enforce a water conservation ordinance; and condition development plan approval on verification of available water service for projects.

City of Monterey

- The City of Monterey General Plan was adopted in 2005 and includes amendments through March 2016, including incorporation of the action program of the City's 2016 housing element. The City of Monterey Housing Element 2015-2023 was adopted March 16, 2016 (City of Monterey, 2016a, 2016b).

- The General Plan EIR (City of Monterey, 2004) projected that the city would have a population of about 34,660 residents at buildout, which is a 14 percent increase from the city's population in 2003 of about 30,350. As shown in **Table 6.3-7**, the 2010 census indicates that the City's population that year was 27,810; the California Department of Finance estimates that the City's population in 2015 was 28,576.

- The Housing Element states that the city is almost entirely built out and that future residential development is expected to occur through infill development – that is, through the recycling of existing sites and a limited amount of vacant land.

- AMBAG's Regional Housing Need Allocation for 2014-2023 states that Monterey needs 650 additional units. According to the City of Monterey 2015-2023 Housing Element, the City had issued permits or entitlements for 113 units since January 2015, so it needs 537 more. The Housing Element identifies a total capacity to develop 715 units based on an inventory of vacant and underutilized sites.

- The lack of available water is a primary obstacle to meeting General Plan goals; therefore, it is the goal of the City of Monterey and the General Plan to obtain a long-term, sustainable water supply. Among other things, the City is evaluating water supply options outside the present MPWMD framework (City of Monterey 2016a). The Housing Element states that all of the City's water allocation from the MPWMD has been allocated to projects. (City of Monterey, 2016b).

Presidio of Monterey

- The Presidio of Monterey is an active installation of the U.S. Department of the Army. While it is located within the Monterey city limits, the City does not govern it. Water used at the Presidio is part of MPWMD's overall allocation to the City. In 2013, the Army completed an EIS for the Presidio's Real Property Master Plan (U.S. Army, 2013a, 2013b), which replaces the 1983 Presidio of Monterey Master Plan.

- The Master Plan proposes short-range and long-range project building renovations or upgrades to be implemented over a 20-year planning horizon. The short-range project consists of Phase I of a multi-phase barracks complex project at the Presidio. The long-range projects include access control point upgrades, classroom renovations, and demolition and construction of three barracks complex projects and several instructional buildings. The EIS evaluated the environmental consequences of the short-range project at

a project level of detail and the long-range projects were evaluated at a programmatic level. As the long-range projects move forward, they may need additional NEPA review.

- The Master Plan alternative selected for implementation locates most improvements within the Presidio, with some support facilities at the Ord Military Community site in the former Fort Ord military base. The EIS and Record of Decision for the EIS (U.S. Army, 2013a, 2013b) conclude that, over the Master Plan's 20-year planning horizon, the long-range projects would increase water demand at the Presidio by an estimated 34 afy. Water for the short-range project would be provided through the Presidio's existing permit. To meet demand for the long-range projects, the EIS identifies a total of 36.9 afy from water currently used at outdated barracks that are scheduled to be demolished as part of the long-range projects, and from water credits that the Presidio has from the MPWMD. While the EIS concludes that both action alternatives of the overall Master Plan development project would have a less than significant impact with respect to water supply, it notes that future developments concerning the Cease and Desist Order and the March 2011 moratorium on water service connections could affect water supply in the Monterey Region; the EIS therefore identifies mitigation measures to reduce future water demand. Measures include conserving more water, implementing best management practices at all new facilities, and installing rainwater collection systems and purple piping (in anticipation of the availability of future recycled water supply) in all new buildings. The EIS states that the Army could also consider additional measures to ensure long term water supply at the Presidio and Ord Military Community, like contracting with current water providers for additional water along with the development of future regional water supply projects.

City of Pacific Grove

- The City of Pacific Grove adopted its General Plan in 1994, and adopted its Housing Element 2015-2023 in March, 2016 (City of Pacific Grove, 1994, 2016).

- The Housing Element states that the city has experienced a small decline in population over the past 25 years, from 16,177 in 1990 to 15,388 in 2015. The size and composition of the city's housing stock changed very little over that period, with a net increase of about 270 units. The City is almost fully built-out, with very little vacant land available for new housing development. By the 1980s, the City had recognized that further growth would occur only as infill development on vacant lots and through the intensification of existing development.[26] The 1994 General Plan estimates that a maximum of 5,431 additional residential units could be built within the city limits. Most units would be accommodated through the intensification of existing development, including almost 3,500 secondary units attached to existing single family homes. Vacant lots could accommodate a total of 105 new single-family or multi-family units. Notwithstanding this estimate, the General Plan notes that in the 10 years preceding its publication, only 42 secondary units had been built, and that this actual rate of development suggested that, apart from water supply constraints, new secondary units would be added slowly and would not number in the thousands. Past trends suggested that the other identified residential capacity also would be developed slowly. The General Plan projected that commercially-zoned vacant parcels could accommodate an estimated 270,000 square feet of commercial development, and that more than 1 million square feet of commercial development could theoretically be added by intensifying existing uses.

- AMBAG's Regional Housing Need Allocation for 2014-2023 states that Pacific Grove needs 115 additional housing units. The City's 2016 Housing Element identifies a realistic

[26] The General Plan did not contemplate the City annexing any unincorporated land except for a three-acre parcel (the Mission Linen parcel) on unincorporated county land entirely surrounded by city lands.

potential for 148 new units to be built on vacant parcels and a total potential for 210 new units to be built on vacant and underutilized sites and sites with second unit potential.

- The Housing Element identifies the lack of available water as the greatest constraint on the production of new housing in Pacific Grove, stating that lack of water supply has resulted in very little new housing construction for over a decade. It is the City's policy to continue working aggressively with MPWMD and other Monterey Peninsula cities to find long-term solutions to the water problem, to increase the water available for residential uses, and to provide for drought protection. The City is working on projects to reduce the use of potable water where feasible, such as at the city's golf course and cemetery, consistent with Housing Element Program 3.1. In 1994, when it prepared the General Plan, the City had less than 8 af of its water allocation remaining. In 2008, the City had 5 af left, and the City Council distributed most of that 5 af, which enabled construction of more than 50 residential and non-residential projects. Most of the City's allocation has been distributed and the City has established a new water wait list. As of July 2015, 12 single family dwellings were on the wait list. The Housing Element states that without a new water allocation, the City will be unable to permit any new housing construction, except for the few properties that have sufficient onsite water credits for second units.

- The 2016 Housing Element notes that although additional water supply needed to meet demand associated with buildout of the 1994 General Plan was previously estimated to be 1,264 afy, this estimate was based in part on the maximum potential for second units and that long-term demand is now expected to be less. In testimony provided to the CPUC on the MPWSP, a City representative revised the future demand estimate the City had provided MPWMD in 2006, from 1,264 afy to 500 afy (as shown in **Table 2-5** of Chapter 2).

Sand City

- The Sand City General Plan: 2002-2017 was adopted in 2002 and the City of Sand City Housing Element Update 2009-2014 was adopted in 2010 (City of Sand City, 2002, 2010).

- Describing the city's historic growth rates, the General Plan states that the city's population reached 600 in the 1960s, but then declined as industrial and commercial land uses displaced housing. Between 1970 and 2000, the city's population fluctuated, ranging from a low of 182 in 1980 to a high of 261 in 2000. As shown in Table 6.3-5, the city continued to grow over the past decade, to a population of 334 in 2010.) Due to the city's commercial and industrial land uses, its daytime population of employees and shoppers increased to almost 10,000 (LAFCO of Monterey County, 2011).

- The 2002 General Plan projects a buildout population of 1,295, and points out that this city-generated estimate is lower than the population of approximately 1,800 that had been forecasted in AMBAG 's then-current 1997 forecast. AMBAG, in turn, had based its forecast in part on the city's 1984 General Plan. The 2010 Housing Element cites AMBAG's 2008 forecast projecting that the city's population would grow dramatically between 2010 and 2015 (from 447 to 1,498) and would not change further between 2015 and 2035. The Housing Element confirms that population growth beyond what AMBAG had projected for 2015 was unlikely due to the city's small size. As shown in Table 6.3-6, AMBAG's most recent forecast also projects substantial growth for the city, especially between 2010 and 2020, and now projects that the city will reach the earlier population estimate of about 1,500 residents between 2030 and 2035. The 2002 General Plan focuses on achieving a vision for the community that includes economic diversification; active redevelopment; enhanced community appearance and image; organized and well-planned growth; elimination of land use conflicts; and cohesive residential neighborhoods.

- AMBAG's Regional Housing Need Allocation for 2007-2014 identified a housing need in Sand City of 120 additional units.[27] According to the City's 2010 Housing Element, 31 units had been built between January 2007 and February 2009, and an inventory of vacant and underutilized sites identified the capacity to accommodate a total of 277 additional units on those sites. The City expects that 60 additional units will be produced by the end of 2014 (City of Sand City, 2010).

- The General Plan states that the critical shortage of water on the Monterey Peninsula limits the availability of water for new development, and that this condition is expected to continue until either a long-term source of water is developed for the region or until Sand City develops a desalination facility as its own water supply. As of 2001, Sand City had allocated essentially all of its available water to specific development parcels. Since the General Plan was prepared, Sand City completed construction of a 300 afy desalination plant, which is operated by CalAm. While water from the desalination plant is delivered to the CalAm system, Sand City is entitled to 206 afy to support its future development: MPWMD Ordinance 132, in consideration for the delivery of 300 afy of potable water from this plant to the CalAm system, establishes a water entitlement of 206 afy from the CalAm system for Sand City, separate from the city's current water allocation; the ordinance indicates that the remaining 94 afy is permanently added to the broader CalAm's system.

Seaside

- Seaside adopted its General Plan in 2004, and adopted its General Plan Housing Element in 2011 (City of Seaside, 2004a, 2011a).

- According to the General Plan, the city will have a total of about 12,300 dwelling units, 19,800 square feet of non-residential development, and a population of about 43,000 at buildout of the General Plan, assuming the average levels of development allowed under the plan. While the General Plan's estimate does not indicate how much of this overall development is existing development and how much represents expected future growth, a comparison of the buildout estimates for housing and population with 2010 census data for Seaside indicates that under General Plan buildout the city expects to add almost 1,500 new housing units and 10,000 new residents. The General Plan identifies the need for more employment opportunities and tax-generating land uses to improve the overall quality of life in the City, and includes policies to encourage regional commercial and visitor-serving commercial development, community-serving retail development, fuller use of underutilized properties, development that helps increase the City's ratio of jobs to housing, and provision of a variety of housing types that complement employment opportunities in the community.

- AMBAG's Regional Housing Need Allocation for 2007-2014 states that Seaside needs 589 additional units.[28] The City's 2011 Housing Element says that the City can accommodate 1,113 additional units on vacant and underutilized residential and mixed use properties.

- The 2011 Housing Element states that lack of adequate water supply is one of the three primary environmental constraints to the development of housing in Seaside. The other constraints are environmental hazards on former Fort Ord lands and significant biological resources in the eastern portion of the city. General Plan policies call for cooperating with regional and local water providers to ensure that adequate water supply is available to meet

[27] AMBAG's RHNA for the 2014-2023 period (AMBAG, 2014b), which the next version of jurisdictions' Housing Elements will cover, identified a housing need in Sand City of 55 units.

[28] AMBAG's RHNA for the 2014-2023 period (AMBAG, 2014b), which the next version of jurisdictions' Housing Elements will cover, identified a housing need in Seaside of 393units.

the needs of existing development and future growth; encouraging the production and use of recycled water; protecting and enhancing local and regional groundwater and surface water resources; eliminating long-term groundwater overdraft as soon as feasible; and reviewing development proposals to ensure that adequate water supply, treatment, and distribution capacity is available to meet the needs of the proposed development.

- For the part of the city served by CalAm, which is the area that had been within the City boundaries before the City annexed the former Fort Ord lands to the north and east,[29] the portion of MPWMD's allocation that the City's had allotted for residential use has been exhausted and the City has established a waiting list pending the allocation of future supply. Part of the allocation the City had reserved for economic development in mixed use projects is still available. In a comment on the 2015 MPWSP DEIR, the City stated that a water supply assessment prepared in 2008 for the West Broadway Urban Village Specific Plan determined that water credits for the commercial areas and residential units that were being redeveloped would supply some but not all of the water needed for the specific plan, and that a net increase of 80 afy was estimated above exiting water use to accommodate full buildout of the specific plan (City of Seaside, 2015). This information refines the estimated demand for general plan buildout that was provided to MPWMD in 2006 (shown as "Future Supply Needs (2006 Estimate)" in Table 6.3-7). Therefore, Seaside's estimate of future water supply needs, shown in Table 6.3-7 and in Table 2-6 in Chapter 2, increased by 80 afy. Water for former Fort Ord lands annexed to the city is provided via the FORA and MCWD, not CalAm.[30]

Monterey County

The facts and figures presented in this section pertain to the County as a whole (or the unincorporated County as a whole, as noted), although CalAm does not serve the whole County.

- The *2010 Monterey County General Plan* (Monterey County, 2010a) was adopted in October 2010 and the *County of Monterey 2015-2023 Housing Element* (Monterey County, 2016) was adopted in January 2016. The General Plan has a 2030 planning horizon, while the EIR prepared for the General Plan (Monterey County, 2010b, 2010c) considers conditions under the plan in 2030 and under plan buildout, estimated to occur in 2092.

- The County's population increased from 247,450 in 1970 to an estimated population of 425,756 in 2014. The decade with the fastest growth was 1980-1990, during which the population increased by 22 percent. Data from the 2010 census indicate that the County's population increased by 3 percent between 2000 and 2010. The California Department of Finance's estimate of county population in 2014 (presented in the Housing Element) represents a 2.5 percent increase from 2010. The proportion of the county's population living in unincorporated areas has gradually decreased, from 29 percent in 1980 to 24 percent in 2010.

[29] The part of the city that had been within the city limits prior to the annexation of former Fort Ord lands, which is also the part of the city within the jurisdiction of the MPWMD, is variously referred to in the general plan as the southwestern portion of the city, southwest Seaside, the central core of the city, and Seaside proper. Part of this central core of the city is also served by the City-operated Seaside Municipal System, which operates three groundwater wells that serve the Del Monte Heights neighborhood.

[30] Seaside was allocated 748 af of the FORA's total supply to serve the Fort Ord annexation lands in North Seaside. The City does not expect this allocation to increase in the near future, and the General Plan identifies the use of recycled water for golf courses and other non-potable uses in North Seaside as the best option for expanding the availability of the North Seaside allocation for economic development and residential uses.

- Growth assumptions for the General Plan's 2030 planning horizon are based on AMBAG's 2004 population growth forecast, which projected that the county would grow from an estimated population of 464,847 in 2010 to 602,731 in 2030, a 30 percent increase. AMBAG projected that the population in unincorporated county areas would grow from 105,485 in 2010[31] to 135,375 in 2030, a 28 percent increase. The General Plan EIR notes that, in allocating the projected growth within the County, AMBAG considered growth trends and the availability of water among other factors. The Monterey Peninsula was projected to accommodate much lower levels of growth than the Salinas Valley due to the peninsula's greater water constraints.

- AMBAG's Regional Housing Need Allocation for 2014-2023 states that the unincorporated Monterey County needs 1,551 additional housing units. The 2016 Housing Element indicates that, since January 1, 2014, 185 units had been built, and another 2,955 units had been approved. Because those units do not completely meet the RHNA targets for affordable units, however, the County still needs 208 units of very low, low, and moderate income housing. The County determined that the remaining allocation of 208 very low, low, and moderate income units could fit within areas covered by adopted community and area plans including the Castroville Community Plan, the North County Land Use Plan, the Central Salinas Area Plan, (Chualar, King City, and San Lucas Areas) and the South County Area Plan (Bradley and San Ardo areas).

- According to the General Plan EIR, implementing the plan would increase water demand over the planning period. When the EIR was published, although CalAm's Coastal Water Project was forecasted to meet the then-current demand on the Monterey Peninsula, the General Plan EIR anticipated that new or expanded water supply facilities and new or expanded water entitlements would be needed to meet future demand on the peninsula. The General Plan prohibits new development that requires a discretionary permit, and that will use water, unless there is proof that a long-term, sustainable water supply is available to serve the development. The General Plan also requires that tentative subdivision maps be denied until the applicant provides evidence of a long-term sustainable water supply for all of the proposed lots. To ensure the accuracy and consistency of water supply evaluations, the Monterey County Health Department must coordinate with the MCWRA to develop guidelines and procedures for conducting water supply assessments and determining water availability. Other policies call for the County to work with all of the agencies responsible for managing existing and new water resources. As a mitigation measure, the General Plan EIR added a General Policy stating that the County will participate in regional coalitions to identify and support a variety of new water supply projects, water management programs, and multiple agency agreements that will provide additional domestic water supplies for the Monterey Peninsula and the Seaside basin. According to this new policy, the County's general objective is to complete the cooperative planning of these water supply alternatives within five years of adoption of the General Plan and to implement the selected alternatives within five years of that. The County recognizes, though, that timing will depend on the dynamics of the regional group. Other General Plan policies encourage the use of gray water and cisterns for commercial and multi-family residential landscaping; the use of recycled water as a potable water offset; and the establishment of ordinances that identify conservation measures to reduce demand for agricultural water and potable water.

- The Greater Monterey Peninsula Area Plan encourages development projects to get their water from public utilities or mutual water companies. If this is not possible, the County

[31] 2010 census data indicate that the County's population in 2010 was 415,057, somewhat lower than the 2004 forecast anticipated; according to the census the population of the unincorporated county in 2010 was 100,213.

should consider the cumulative effects of the development's water use on wildlife, fish, and plant communities, and the supply available to existing users.

- The Carmel Valley Master Plan requires that pumping from the Carmel River aquifer be managed consistent with the Carmel River Management Program and that all beneficial uses of the total water resources of the Carmel River and its tributaries be considered in planning decisions. Other policies support water projects designed to address future growth in the Carmel Valley and encourage the establishment of regulations limiting development in Carmel Valley to vacant lots of record and already-approved projects, unless additional water supplies are identified.

Monterey Peninsula Airport District

- The Monterey Peninsula Airport District is developing a new master plan, a process that is expected to take two years. A draft plan has been prepared, but CEQA documentation has not been completed and the new plan has not been adopted. Until a new master plan is adopted, the Airport District's 1992 Monterey Peninsula Airport Master Plan Update Final Report (Master Plan) (Monterey Peninsula Airport District, 1992) is the applicable land use planning document for airport development activities (Johnston, 2013).

- The goals of the 1992 Master Plan are to address airport requirements over a 20-year planning period. 2010 is the horizon year for specific aspects of the plan including projected airport activity and facility requirements. Based on anticipated changes in the fleet mix and projected growth in the number of passengers, annual operations (take-offs and landings), and general aviation aircraft based at the airport, the Master Plan was intended to meet the identified need for additional terminal areas, general aviation hangars, and aviation fuel storage, an expanded fire station, a larger maintenance building, and vehicle access improvements. The Master Plan includes three concepts each for the terminal area, the west end of the airport, and the northside of the airport, and recommends adoption of one of them, called "Concept C", for each of the three components. Each of the concepts would increase the area for the terminal ramp, the size of the terminal building, the number of parking places, the number of hangars, and the amount of space available for fixed-base operators, other tenants, and airport support facilities.

- Master Plan Appendix B, Utilities Inventory and Pavement Plan, reviews water service to the airport. The review states that past cases before the CPUC that concerned the adequacy of the water supply system for the Monterey Peninsula may restrict CalAm from serving new territory until additional supplies are assured, or until additional impounding reservoirs are built. The discussion concludes, however, that the airport lies completely within the water company's existing service area, that service to the airport property is long-standing, that airport water use is not excessive, and that curtailment of water for use by the Airport is not expected.

- In a discussion of past studies related to the airport, the Master Plan states that the environmental document for the 1983 Airport and Runway Development Program concluded that development of the northside industrial area would require water service that was not currently allocated to the Airport District, and that the District would need to work with MPWMD to resolve the issue to the extent possible. The Master Plan also discusses a 1987 EIR for the Comprehensive Land Use Plan for the Monterey Peninsula Airport which identified water resources as an area of controversy (Monterey Peninsula Airport District, 1992).

Comparison of Proposed Water Supply Capacity with MPWMD Estimate of Future Supply Needs

The project supply components that would provide water for future development (e.g., water for lots of record) do not directly compare to the levels of growth planned for and described in the jurisdictions' general plans. To relate the portion of MPWSP supply that would support future development to the growth anticipated in jurisdictions' adopted general plans, the MPWSP supply is compared with the estimate of future water supply needs that the MPWMD prepared in 2006 (MPWMD, 2006).[32]

The 2006 MPWMD estimate was a comprehensive assessment of long term water needs of customers in CalAm's Monterey District main distribution system based on information obtained from the service area jurisdictions. It included demand associated with expected remodels within the jurisdictions, and with anticipated development of single-family and multi-family residences, secondary units, and non-residential development expected to occur under buildout of each jurisdiction's general plan. The MPWMD translated the growth estimate provided by the jurisdictions into water demand using water use factors for different land use categories. The estimate also included repayment of any water credits owed to property owners for implementing water-saving retrofits, and a 20 percent contingency to address unforeseen water requirements. Based on this assessment, the estimated future water supply needs to support growth anticipated in the general plans of the jurisdictions in the CalAm service area totaled 4,545 afy.[33] The 2009 EIR prepared for CalAm's proposed Coastal Water Project evaluated in detail whether the growth assumptions underlying MPWMD's 2006 demand estimate were consistent with growth anticipated in the jurisdictions' general plans, and confirmed that, overall, the MPWMD's estimate of future demand was consistent with growth under the general plans.[34] That analysis is included in **Appendix J1** for reference.

Since the 2006 estimate was prepared, the future water needs of four jurisdictions have been revised, reducing the total estimate of future water needs from 4,545 to 3,526 afy. The new Monterey County General Plan, adopted in 2010, is the basis for one of the revisions; the City of Pacific Grove provided another revision, reducing its original 2006 estimate of future demand in testimony that the City provided regarding the MPWSP; the City of Seaside provided a revision that increased its estimate of future water demand; and the water entitlement that Sand City has from construction of its 300-afy desalination plant would cover roughly half of Sand City's 2006

[32] As noted in Section 2.5.3.4 of Chapter 2, Water Demand, Supplies, and Water Rights, the MPWMD plans to collaborate with CalAm and the service area jurisdictions to evaluate the added water supply capacity needed to meet general plan buildout projections. Given that this new MPWMD process has not yet started and that most of the general plans considered in the 2006 evaluation are still in effect, this EIR uses the 2006 MPWMD analysis, adjusted as noted below, as the basis for comparison.

[33] Because the jurisdictions' general plans were prepared in different years and covered different planning periods, MPWMD did not characterize its estimate of future demand as accommodating growth over a given period of time or to a given year. The estimate was intended, however, to accommodate growth reasonably expected by each jurisdiction consistent with its adopted general plan.

[34] The analysis determined that with a few exceptions, the estimates of residential growth were consistent with estimates contained in the general plans or general plan housing elements. Estimates of non-residential development were more difficult to compare because of substantial differences in the levels of detail in information submitted by jurisdictions to the MPWMD compared with information included in the general plans; to the extent the development potential could be compared, the estimates were determined to be consistent.

estimated future demand. Refer to the discussion of general plan buildout in Chapter 2, Water Demand, Supplies, and Water Rights, Section 2.5.3.4, for more information on the revised estimates.

California Water Code Section 10608 requires water suppliers to reduce per capita water consumption 20 percent by 2020, relative to baseline demand calculated under Department of Water Resources guidelines. According to CalAm's 2010 UWMP, current per capita consumption in CalAm's Monterey District is already below its 20 percent reduction target (WSC, 2012). Nevertheless, conservatively assuming that the Water Code 20 percent reduction target could apply to the water use assumptions MPWMD used in its 2006 estimate, the revised estimate of future water needs discussed above, reduced by an additional 20 percent, would be 2,820 afy. **Table 6.3-8** shows these estimates of future water supply needs.

TABLE 6.3-8
FUTURE WATER DEMAND AND AVAILABLE SUPPLIES: TWO RETURN WATER SCENARIOS
(acre-feet per year)

Future Demands and Supplies	Jurisdiction Total
Future Supply Needs (2006 Estimate)	4,545
Future Supply Needs (Revised)[a]	3,526
Future Supply Needs (Revised and Reduced by 20%)[b]	2,820
MPWSP Supply for Future Development[c] Assuming 6% SVGB Return	1,829
MPWSP Supply for Future Development[c] Assuming 12% SVGB Return	209
MPWSP Supply for Future Development[c] as % of Future Supply Needs (Revised)[d]	6 to 52%
MPWSP Supply for Future Development[c] as % of Future Supply Needs (Revised and Reduced)[d]	7 to 65%

NOTES: SVGB = Salinas Valley Groundwater Basin

[a] Future supply needs revised based on changes in future demand estimates in four service area jurisdictions (discussed in more detail in Section 2.5.3.4 of Chapter 2).

[b] Estimated future supply needs reduced by an additional 20 percent should water reduction requirements of Water Code Section 10608 apply. CalAm's Monterey District 2010 UWMP indicates that the service area has already met its 20 percent reduction target.

[c] Supply available for future development consists of MPWSP supply and CalAm's other supplies, shown in Table 2-4 of Chapter 2, minus existing demand and minus estimated SVGB return water obligations shown in Table 6.3-4.

[d] Lower percentage of supply available to meet future development needs assumes 12 percent SVGB return water obligation; higher percentage assumes 6 percent SVGB return water obligation

SOURCES: Table 2-4, Table 2-5, Table 6.3-4.

As discussed in Section 6.3.5.1 and shown in Table 6.3-4, during the 25-year Seaside Groundwater Basin replenishment period, the portion of the water supply provided by the MPWSP and other supply sources that would be available for future development – including the future development assumed for the MPWSP shown in Table 6.3-3 – would range from 1,829 afy to 209 afy after meeting estimated SVGB return water obligations of 6 percent to 12 percent, respectively. Assuming a 6 percent SVGB return water obligation, the 1,829 afy of supply that would be available to meet future needs would represent 52 percent of 3,526 afy, the 2006 estimate of future water supply needs as revised based on updated information. This 1,829 afy of available supply would represent 65 percent of 2,820 afy, the 2006 estimate of future demand as updated and reduced by an additional 20 percent. Thus, assuming a 6 percent SVGB return water obligation, available supply would meet a half to two-thirds the estimated future water supply needs of the

service area. Assuming a 12 percent SVGB return water obligation, during the Seaside Groundwater Basin Replenishment period, the 209 afy of supply that would be available to meet future needs would represent 6 percent of 3,526 afy and 7 percent of 2,820 afy, the two updates of MPWMD's 2006 estimate of future water supply needs discussed above. Thus, based on the updates of future demands and these return water assumptions, the portion of the water supply provided by the MPWSP that would be available to support future development would supply from less than 10 percent to 65 percent of the water demand associated with planned growth, depending primarily on the return water obligation. Table 6.3-8 summarizes these estimates.

The 1,430 afy of MPWSP supply that is proposed for anticipated development, shown in Table 6.3-3, is about 40 percent of 3,526 afy, the 2006 estimate of future demand as revised based on updated information and about half of 2,820 afy, the 2006 estimate of future demand as updated and reduced by an additional 20 percent.

As discussed above in this section, MPWMD's 2006 estimate of future water supply needs was generally consistent with the level of growth planned for in the adopted general plans of service area jurisdictions. The MPWSP would provide less water for growth than the 2006 estimate of future water supply needs as revised based on updated information (3,526 afy, or 2,820 afy if further reduced by 20 percent). The smaller MPWSP supply that would be available to support future development would similarly be consistent with the service area's planned growth.

6.3.5.4 Delivery of SVGB Return Water to Castroville

Delivery of SVGB Return Water to Castroville Community Services District

The community of Castroville, located north of the desalination plant and outside of CalAm's service area, would receive Salinas Valley Groundwater Basin (SVGB) return water (see **Section 2.5.1** in **Chapter 2**, **Water Demand**, **Supplies**, **and Water Rights**, and **Section 3.2.3.9** in **Chapter 3**, **Description of the Proposed Project**. The water would flow to the Castroville Community Services District (CCSD) for domestic use in lieu of groundwater pumping. The SVGB return water supply would only be used to replace, or offset, CCSD's current use of groundwater (approximately 800 afy), under the terms of the Return Water Settlement Agreement (CalAm et al., 2016b). Thus, the water provided by the desalination plant would not remove water supply constraints as an obstacle to additional development in the Castroville area and therefore would not induce growth. The pipeline that would be built to convey the desalinated product water to the CCSD system would be sized to accommodate the 800 afy volume of return water. Although increased pumping pressure can increase a pipeline's capacity, as discussed above in Section 6.3.5.2, the use of the pipeline to the CCSD would be limited to providing return water to offset CCSD's current groundwater use. Therefore, pipeline capacity is not anticipated to expand in the future, and building this pipeline would not remove an obstacle to growth in the Castroville area.

Delivery of SVGB Return Water to the Castroville Seawater Intrusion Project

Under the proposed project, the MPWSP would deliver the first 800 afy of SVGB return water to the CCSD and deliver the remaining return water to the Castroville Seawater Intrusion Project

(CSIP). The CSIP provides recycled water to farmers in the Castroville area to irrigate crops, thereby enabling reduced pumping of seawater-tainted groundwater. SVGB return water in excess of that needed for the CCSD would supplement the recycled water currently available to CSIP from the Monterey Regional Water Pollution Control Agency. Return water provided to the CSIP would be used to offset groundwater use for agricultural production; it would not contribute to domestic water supply and therefore would not be growth-inducing.

6.3.6 Secondary Effects of Growth

Impact 6.3-1: Secondary effects of planned growth.

The MPWSP would support a degree of planned growth in the jurisdictions served by the proposed project. In general, development planned and approved through the general plan process in the CalAm service area would have environmental impacts. The environmental consequences of this planned growth have been largely addressed in local plans and the associated CEQA review as well as in other, project-specific documentation. Some of the identified indirect effects of growth are significant and unavoidable; others are significant but can be mitigated.

Although most of the general plan EIRs reviewed for this EIR/EIS were prepared prior to the passage of the California Global Warming Solutions Act of 2006, and do not include assessments of impacts of greenhouse gas emissions, it is expected that planned growth in the area could contribute to significant and unavoidable increases in greenhouse gas emissions (e.g., from increased fossil fuel use for transportation and construction, increased industrial and commercial activities, residential energy use, operation of power plants, and oil refining).

The following environmental documents for city and county general plans and general plan elements were reviewed in order to identify the significant impacts associated with planned growth in the area:

- City of Carmel-by-the-Sea, 2015b. *Addendum to Initial Study/Negative Declaration, City of Carmel-by-the-Sea 2015-2023 Housing Element and Related Zoning Amendments,* November 18, 2015. (Addendum to *City of Carmel-by-the-Sea 2007-2014 Housing Element Public Review Draft Initial Study / Mitigated Negative Declaration,* April 2010.)
- City of Del Rey Oaks, 1997b. *Final Environmental Impact Report for the General Plan Update Project,* May 16, 1997.
- City of Monterey, 2004. *City of Monterey General Plan Update Draft Environmental Impact Report* and *Final Environmental Impact Report, State Clearinghouse No. 2003081011,* October 11, 2004.
- City of Sand City, 2001. *Expanded Environmental Impact Study and Proposed Negative Declaration, General Plan Update 2001-2016,* October 12, 2001.
- City of Sand City, 2009. *Sand City 2009 Housing Element Initial Study and Negative Declaration,* December 16, 2009.
- City of Seaside, 2004b. *Final Seaside General Plan EIR,* January 2004.

- City of Seaside, 2010. *Public Review Draft Initial Study/Proposed Negative Declaration for the of Seaside Local Coastal Program,* August 2010.
- City of Seaside, 2011b. *Public Review Draft Initial Study/Proposed Negative Declaration: City of Seaside Housing Element Update 2009-2014,* September 2010, adopted by the Seaside City Council January 27, 2011.
- Monterey County, 2010b, 2010c. *Monterey County General Plan Final Environmental Impact Report, SCH No. 2007121001*, March 2010, and *Revised Supplemental Materials to the Final EIR (October 15, 2010)*, October 2010.
- Monterey County Resource Management Agency, 2010. *Initial Study: Housing Element 2009-2014*, April 19, 2010.
- U.S. Department of the Army, 2013a. *Final Environmental Impact Statement, Real Property Master Plan, Presidio of Monterey, California*, February 2013.

Copies of these documents are available for review at the respective city and county planning departments.

Table 6.3-9 summarizes the environmental effects associated with planned growth in the project area, as identified in the general plan EIRs for the jurisdictions in the CalAm service area. Because the table reflects the determinations of multiple jurisdictions, some impacts are listed as both significant and unavoidable and significant but mitigable, reflecting differences among the jurisdictions in the service area. In addition, one EIR evaluates general plan impacts over two time periods: the planning horizon for the plan and buildout. As a result, some impacts were identified as significant and unavoidable, and significant but mitigable, depending on the timeframe. Under CEQA Guidelines Section 15130, the EIRs prepared for the jurisdictions' general plans evaluate the potential for development under the respective plans to contribute to cumulative impacts on the environment; significant cumulative impacts identified in the general plan EIRs are also shown in the table. **Appendix J2**, **Table J2-1** presents a more detailed summary of the growth impacts and mitigation measures identified in the EIRs for general plans in the CalAm service area. These environmental impacts are the indirect effects of growth that would be supported in part by the proposed project.

6.3.6.1 MPWSP Role in Addressing the Indirect Effects of Growth

Two jurisdictions in the area served by the proposed project – the City of Seaside and Monterey County – identified demand for, or impacts related to, water supply, including groundwater supply, as significant and unavoidable impacts of planned growth; other service area jurisdictions identify similar significant but mitigable impacts. In general, these impacts identify insufficient supply to meet demands associated with development that is planned for in the jurisdictions' general plans. Some EIRs address impacts associated with supply limitations, such as the potential risk of over-pumping groundwater resources and seawater intrusion, and many acknowledge the limitations on current supply sources imposed by SWRCB Order 95-10. With respect to the impacts of potential over-pumping of the Seaside Groundwater Basin and the associated threat of seawater intrusion, the MPWSP is sized to enable CalAm to "repay" to the groundwater basin, over a 25-year period, the amount of water it has pumped in excess of its

TABLE 6.3-9
SIGNIFICANT IMPACTS ASSOCIATED WITH PLANNED GROWTH IN THE PROJECT AREA

Significant and Unavoidable Impacts

- Degradation of visual character or quality of the area and surroundings
- Substantial new sources of light and glare
- Cumulative impacts on aesthetics, light and glare
- Conversion of farmland to non-agricultural use and cumulative loss of farmland
- Construction-related air quality impacts
- Net change in ozone precursor and particulate matter emissions
- Cumulative air quality impacts
- Effects on special status species
- Effects on riparian habitat and other sensitive natural communities
- Cumulative impacts on biological resources
- Potential effects on archaeological, paleontological, or historic resources
- Cumulative exposure to wildland fire hazard
- Increased demand for water supply and/or water storage, treatment, and conveyance facilities and associated secondary effects[a]
- Substantial depletion of groundwater supply[b]
- Increased demand on groundwater in areas experiencing or susceptible to saltwater intrusion[b]
- Cumulative impacts on surface and groundwater quality[c]
- Cumulative indirect impacts of water supply projects[a]
- Increased flood hazard and impacts from flooding
- Increases in cumulative traffic noise
- Induced population growth
- Effects on adjacent land uses of operation of new or expanded schools
- Local and regional traffic impacts
- Impacts of cumulative development on traffic
- Demand for water resources that exceed available water supply[d]
- Cumulative impacts on water supply[d]
- Contribution to cumulative greenhouse gas emissions and global climate change

Significant but Mitigable Impacts

- Adverse effects on scenic vistas
- Adverse effects on scenic or historic resources within a state scenic highway
- Degradation of visual character or quality of the area and surroundings
- Construction-related air quality impacts
- Transportation-related air quality impacts
- Exposure to increased diesel exhaust
- Emission of objectionable odors
- Effects on special-status species
- Effects on riparian habitat and other sensitive natural communities
- Effects on federally protected wetlands
- Conflicts with local policies or ordinances protecting biological resources
- Effects on a variety of biological resources
- Interference with migratory patterns or wildlife corridors
- Potential effects on migratory birds and raptors
- Introduction of exotic species
- Potential effects on archaeological, paleontological, or historic resources
- Exposure of new development to potential seismic or geologic hazards
- Creation of or exposure of new development to hazards related to soil erosion or expansive soils
- Exposure of new development to tsunami or seiche hazards

TABLE 6.3-9 (Continued)
SIGNIFICANT IMPACTS ASSOCIATED WITH PLANNED GROWTH IN THE PROJECT AREA

Significant but Mitigable Impacts (cont.)

- Potential exposure of people and development, including schools, to hazardous materials releases
- Increased risk of hazardous materials releases
- Safety hazards from development near airports
- Increased flood hazard and impacts from flooding
- Exposure of structures to increased risk of wildland fires
- Cumulative wildfire hazard exposure
- Impacts on water quality, including groundwater quality[c]
- Impacts on hydrology and surface water
- Substantial depletion of groundwater supplies[b]
- Increased demand on groundwater in areas experiencing or susceptible to saltwater intrusion[b]
- Inconsistency with zoning code
- Conflicts between incompatible land uses
- Impacts on open space areas
- Exposure of existing and new sensitive land uses to increased noise
- Increases in construction, traffic, stationary, and/or airport noise
- Potential conflicts between new development and existing or expanded recreational uses
- Effects of park construction and degradation of parks or recreational facilities
- Demand for new or expanded parks and recreational facilities
- Increased demand for law enforcement and/or fire protection services
- Effects of school construction to accommodate new development
- Local and regional traffic impacts
- Decreased parking capacity
- Increased demand for transportation alternatives
- Demand for water resources that exceed available water supply[d]
- Require construction of new water supply and treatment facilities[e]
- Increased demand for additional sewer or stormwater drainage infrastructure
- Increased demand for and Impacts of new or expanded public utilities and facilities
- Exposure of property and persons to otherwise avoidable physical harm due to climate change

NOTES:

[a] While the County General Plan EIR impact analysis identifies the impacts of providing additional water supply as *secondary* or indirect effects, Chapter 4 of this EIR/EIS evaluates the *direct* effects of constructing and operating the MPWSP in addition to the indirect effects of growth described in this chapter.

[b] The MPWSP is intended to provide sufficient supply for CalAm to reduce pumping from the Seaside Groundwater Basin to no more than CalAm's adjudicated right, and to "repay," over a 25-year period, the amount of water CalAm has pumped in excess of its adjudicated right since the adjudication, while meeting the water demands shown in Table 6.3-1.

[c] The effects of the proposed project on surface water and groundwater quality, including cumulative effects, are evaluated in Sections 4.3 and 4.4, respectively, of Chapter 4 of this EIR/EIS. As stated above in Note b, the proposed project would help eliminate the need for over-pumping of the Seaside Groundwater Basin in order to meet current demand, thereby helping to mitigate impacts on groundwater quality caused by seawater intrusion.

[d] The MPWSP would provide sufficient supply to enable CalAm to comply with the SWRCB Order 95-10 and Cease and Desist Order and the Seaside Groundwater Basin Adjudication while meeting current water demands and a degree of additional demands, as shown in Table 6.3-1 and discussed in this chapter. The MPWSP is not sized, however, to meet anticipated water demand under full buildout of the service area jurisdictions' general plans.

[e] This impact was identified in the Mitigated Negative Declaration prepared for the Sand City General Plan; since then, after completing required CEQA review Sand City constructed a desalination plant that is providing the City and the CalAm service area new source of water supply. The impacts of constructing the MPWSP are evaluated in this EIR.

SOURCES: City of Del Rey Oaks, 1997b; City of Monterey, 2004; City of Sand City, 2001; City of Seaside, 2004b; Monterey County, 2010b, 2010c; U.S. Army, 2013a.

adjudicated right since the groundwater basin was adjudicated. (Refer to Section 2.2.4 in Chapter 2, Water Demand, Supply, and Water Rights, for more information.) The supply to be provided by the MPWSP would thus help address the potential impacts of over-pumping the Seaside Groundwater Basin. The MPWSP would provide some water beyond that needed to meet existing demand (discussed above in Section 6.3.5.1) but not the full amount identified in MPWMD's 2006 assessment of future supply need, as adjusted by more recent information (discussed above in Section 6.3.5.3). The MPWSP would thus help address impacts related to a supply that does not meet current and projected future water supply needs within the service area jurisdictions. The MPWSP is not expected to fully meet projected future demands, however. With respect to the physical effects of providing additional water supply – that is, building and operating the proposed infrastructure – this EIR/EIS evaluates the potential impacts of the MPWSP and identifies mitigation measures to reduce those impacts to the extent feasible.

6.3.6.2 Authority to Mitigate Effects of Growth

CalAm, the CPUC, and MBNMS do not have the authority to make land use decisions or to approve growth. As described in Section 6.3.2, the authority to regulate growth, and by extension to mitigate the environmental effects of growth, resides primarily with land use planning agencies. **Table 6.3-10** identifies the agencies with the authority to implement measures to avoid or mitigate the environmental impacts of growth in the area served by the proposed project;[35] the agencies generally fall into two categories, as discussed below.

- Agencies with primary authority over land use planning and CEQA lead agency status for approval of land use plans, permits and other approvals.
- Agencies responsible for stewardship of environmental resources.

Implementation of Environmental Protection Measures by Land Use Planning Agencies

Cities and counties (for unincorporated areas) have the greatest authority over land use decisions within their jurisdictions, through implementation of their general plans, locally adopted ordinances and regulations to manage growth, and development approval processes. Some ordinances and policies adopted at the local level (e.g., ordinances establishing urban growth limit lines, protecting natural resources such as riparian habitat, or establishing resource conservation easements) are intended to avoid or reduce environmental impacts.

In their capacities as lead agencies under CEQA (California Public Resources Code Section 21002 and Section 21067), cities and counties also have the authority and responsibility to evaluate the environmental impacts that would result from the implementation of plans and individual development projects within their jurisdictions, and to adopt measures to mitigate any significant adverse impacts. Cities and counties must identify mitigation measures in the CEQA documents for these plans and projects, must adopt feasible measures within their authority, and must adopt programs to monitor and report on their implementation, as conditions of approval.

[35] While MBNMS does not have authority to make land use decisions, NOAA does have authority to mitigate impacts on biological resources through Section 7 and Section 10 consultation requirements, as shown in Table 6.3-9.

TABLE 6.3-10
AGENCIES WITH THE AUTHORITY TO IMPLEMENT OR REQUIRE IMPLEMENTATION OF MEASURES TO AVOID OR MITIGATE GROWTH-RELATED IMPACTS

Agency	Authority
Planning Agencies	
Cities within the Area Served by Project	***Planning and Enforcement.*** Responsible for planning, land use, and environmental protection of the area within the city's jurisdictional boundaries and adoption of the general plan governing this area. Responsible for enforcing city environmental policies through zoning and building codes and ordinances.
	CEQA. Cities typically act as the lead agency for CEQA compliance for development projects in incorporated areas; as such they bear responsibility for adopting measures to mitigate the project's significant direct and indirect impacts on the environment and programs to ensure that mitigation measures are successfully implemented.
Monterey County	***Planning and Enforcement.*** Responsible for planning, land use, and environmental protection of unincorporated areas and adoption of the general plan governing unincorporated county lands. Responsible for enforcing County environmental policies through zoning and building codes and ordinances.
	CEQA. Counties typically act as the lead agency for CEQA compliance for development projects in unincorporated areas; as such they bear responsibility for adopting measures to mitigate the project's significant direct and indirect impacts on the environment and programs to ensure that mitigation measures are successfully implemented.
Local Agency Formation Commission	Empowered to approve or disapprove all proposals to incorporate cities, to form special districts, or to annex territories to cities or special districts. Also empowered to guide growth of governmental service responsibilities.
California Coastal Commission	Issues Coastal Development Permits for development in the Coastal Zone, except where the local jurisdiction has an approved Local Coastal Program. Retains coastal development permit authority over development on the immediate shoreline, tidelands, submerged lands, and certain public trust lands, and over major public works projects.
U.S. Environmental Protection Agency	Responsible for writing regulations and setting national standards to implement a variety of federal environmental protection and human health laws. In California, EPA has delegated much of the authority to enforce the Clean Air Act, Clean Water Act and Drinking Water Quality Act to state agencies, but it retains some oversight. EPA also comments on the environmental review of projects by participating in the NEPA process.
Water Resources	
State Water Resources Control Board (SWRCB)[a]	Shares responsibility with the regional water quality control boards (RWQCBs) to protect and restore water quality; approves regional basin plans; provides support to regional boards; and administers surface water rights. Develops water quality control plans and polices where water quality issues cross regional boundaries or have statewide application.
Central Coast RWQCB	Shares responsibility with SWRCB to protect and restore water quality. Formulates and adopts water quality control plans. Implements portions of the Clean Water Act when EPA and SWRCB delegate authority, as is the case with issuance of NPDES permits for waste discharge, reclamation, and storm water drainage.
California Department of Public Health	Responsible for ensuring the purity and potability of domestic water supplies. Assists the SWRCB and the RWQCBs in setting quality standards.
Monterey Peninsula Water Management District	Responsible for managing water resources on the Monterey Peninsula. Allocates water to jurisdictions; issues permits for new or expanded water distribution systems and water connections; and adopts water conservation ordinances.
Air Resources	
California Air Resources Board[a]	Responsible for adopting and enforcing standards, rules, and regulations for the control of air pollution from mobile sources throughout the state. Also responsible for developing plans and regional reduction targets for greenhouse gas emissions.
Monterey Bay Unified Air Pollution Control District	Adopts and enforces local regulations governing stationary sources of air pollutants within the North Central Coast Air Basin. Issues Authority to Construct Permits and Permits to Operate. Provides compliance inspections of facilities and monitors regional air quality. Develops Clean Air Plans in compliance with the Clean Air Act.

TABLE 6.3-10 (Continued)
AGENCIES WITH THE AUTHORITY TO IMPLEMENT OR REQUIRE IMPLEMENTATION OF MEASURES TO AVOID OR MITIGATE GROWTH-RELATED IMPACTS

Agency	Authority
Biological Resources	
National Oceanic and Atmospheric Administration (NOAA), National Ocean Service, Office of National Marine Sanctuaries	Under NOAA's National Marine Sanctuary Program requirements, authorization by the Monterey Bay National Marine Sanctuary's superintendent is required for any permit, lease, license, approval, or other authorization issued or granted by a federal, state, or local agency for prohibited activities within the sanctuary.
National Oceanic and Atmospheric Administration Fisheries (NOAA Fisheries)	Requires consultation under Section 7 or Section 10 of the Endangered Species Act for projects that could impact endangered or threatened species under the purview of NOAA Fisheries. Prepares biological opinions on the status of species in specific areas and potential effects of proposed projects. Approves reasonable and prudent measures to reduce impacts and establishes Habitat Conservation Plans.
U.S. Fish and Wildlife Service (USFWS)	Requires consultation under Section 7 or Section 10 of the Endangered Species Act for projects which could impact endangered or threatened species. Prepares biological opinions on the status of species in specific areas and potential effects of proposed projects. Approves reasonable and prudent measures to reduce impacts and establishes Habitat Conservation Plans.
U.S. Army Corps of Engineers	Issues permits to dredge or place fill in waters of the United States, including wetlands, under the Clean Water Act. Required to consult with USFWS and NMFS regarding compliance with the federal Endangered Species Act.
California Department of Fish and Wildlife	Issues Stream Bed Alteration Agreements for projects potentially impacting waterways. If specific criteria are met, issues incidental take permits for projects that would take species listed the California Endangered Species Act. Under the Natural Community Conservation Planning Act, provides oversight for the development of regional Natural Community Conservation Plans, which aim to balance ecosystem protection and land use.

NOTE:

[a] These agencies fall under the umbrella of the California Environmental Protection Agency.

SOURCE: ESA

Implementation of Environmental Protection Measures by Resource Management Agencies

Federal, state, and regional resource-specific agencies are responsible for ensuring that impacts to specific resource categories are mitigated through the regulatory processes summarized in **Table 6.3-10**. Through their permitting authority, these agencies mitigate the impacts of proposed land uses and enforce the provisions of adopted resource protection plans (e.g., water basin plans and air basin plans). For example, the Central Coast Regional Water Quality Control Board identifies specific requirements and water quality standards for facilities by issuing waste discharge requirements, and the Monterey Bay Unified Air Pollution Control District addresses the effects of pollutant emissions by issuing permits to build and operate stationary sources of air emissions.

Conclusion

Significant and Unavoidable. The MPWSP would not directly contribute to the creation of additional housing or jobs within the area it would serve, as it is limited construction and operation of water supply facilities and infrastructure. But the proposed project would indirectly support growth by removing some water supply limitations as an obstacle to growth, thereby enabling a degree of growth under the approved general plans within the area served by the MPWSP.

The cities and county in the area served by the proposed project have the authority to approve or deny development projects and to impose mitigation to address significant environmental impacts associated with development projects within their respective jurisdictions. In addition, numerous federal, state, regional, and local agencies are specifically charged with protecting environmental resources, and ensuring that planned development occurs in a sustainable manner. Together, these agencies exercise the authority to reduce the effects of development on the environment. Some unavoidable impacts would still, however, be expected to occur.

6.3.7 Growth Inducement Potential of Cumulative Water Supply Projects

This section considers the indirect growth inducement potential of the cumulative projects identified in **Table 4.1-2**. The geographic scope for the cumulative analysis of indirect growth inducement consists of the CalAm service area jurisdictions and other areas of Monterey County that could experience similar indirect growth inducement. The baseline environmental setting against which the MPWSP is being analyzed includes the effects of existing, operational water supply projects identified in Table 4.1-2 such as the Seaside Groundwater Basin Aquifer Storage and Recovery projects (Nos. 29 and 30), and Sand City Coastal Desalination Plant (No. 6), which are assumed in water supply planning undertaken for the proposed project (as discussed in Chapter 2, Section 2.4 and shown in Table 2-4). The CalAm Slant Test Well at CEMEX (No. 47) is assumed to be used for production of the proposed MPWSP supply.

Several of the planned future cumulative projects identified in Table 4.1-2 would provide new sources of potable water supply in Monterey County. The Monterey Bay Regional Water Project (DeepWater Desal) (No. 34) would provide water to the City of Salinas as well as parts of Santa Cruz County. If both the MPWSP and DeepWater Desal were approved, water from DeepWater Desal could be used to support growth in other nearby areas such as northern Monterey County. The RUWAP Desalination Element (No. 31) would serve the Marina Coast Water District's Ord Community with approximately 1,000 afy of potable supply. Through an agreement with FORA and the MRWPCA, an additional 1,400 afy of potable supply from the Pure Water Delivery and Supply Project (RUWAP #35 in Table 4.1-2) would meet the build-out needs of the Ord Community (which is contiguous with CalAm's service area). The Granite Ridge Water Supply Project would increase water supply availability for the area of northern Monterey County that it would serve. The Interlake Tunnel project would reduce the amount of water spilled at Nacimiento Dam by allowing water from Nacimiento Reservoir to be stored at San Antonio Reservoir for later use. This project would enhance flood control, provide environmental benefits, and offset groundwater pumping. Because this project would provide groundwater recharge, this analysis assumes it could indirectly augment supply available for groundwater users, including municipal supply that could serve additional growth. Although the primary purpose of the Salinas Valley Water Project Phase II (No. 1) is to combat seawater intrusion by providing a new source of surface water to offset groundwater consumption, the availability of a reliable surface water supply provided by this project could induce growth by removing supply reliability limitations as an obstacle to urban development.

Growth induced by one or more of these cumulative water supply projects in combination with the proposed project would result in secondary effects of growth in Monterey County that are

similar to, but would likely be more severe and widespread than, those summarized above in Table 6.3-9; these impacts include increased traffic, noise, and air pollution and loss of open space and biological resources.

Other water projects listed in Table 4.1-2, including the RUWAP Recycled Water Project (No. 35), West Broadway Stormwater Retention Project (41), Del Monte Boulevard Dry Weather Diversion project (44), Pacific Grove Local Water Project (No. 22), Pacific Grove Recycled Water Project (No. 23), and Monterey Pacific Grove Area of Special Biological Significance (ASBS) Stormwater Management Project (No. 45) would either provide non-potable recycled water supply or enhance groundwater recharge. Projects providing recycled water could offset demand for potable supply that is currently used for non-potable uses, thereby making that potable supply available for other uses including growth. Projects capturing and diverting stormwater runoff to enhance groundwater recharge would primarily improve surface water quality and help stop seawater intrusion, but may overtime increase the availability of groundwater supply. These projects could contribute to the growth-inducing impacts of the cumulative potable supply projects described above by increasing the availability of existing potable supplies and groundwater.

As stated in Table 4.1-2, because the Peoples' Project would serve the same customers as the MPWSP, it is not reasonably foreseeable as a cumulative project but instead is considered an alternative to the MPWSP. The Pure Water Monterey Groundwater Replenishment (GWR) Project is not a cumulative project in the context of the proposed project or any alternative that includes a 9.6-mgd desalination plant built and operated by CalAm, because if the GWR is implemented, CalAm would not need to construct a 9.6-mgd desalination plant. The GWR Project is a cumulative project in the context of Alternatives 5a and 5b, which evaluate a 6.4-mgd desalination plant. The cumulative growth inducement of implementing the GWR and Alternative 5a or 5b and the other water supply projects discussed here would be similar to the cumulative growth inducement of the proposed project because water supply available to the CalAm service area with implementation of the GWR project plus Alternative 5a or 5b would be similar to the supply provided by the proposed project.

6.4 Project Consistency with Monterey Bay National Marine Sanctuary Desalination Guidelines

In 2010, MBNMS, in collaboration with the California Coastal Commission, California Central Coast Regional Water Quality Control Board, and NOAA Fisheries, published Guidelines for Desalination Plants in Monterey Bay National Marine Sanctuary, which was a strategy in the desalination action plan included in the 2008 MBNMS Final Management Plan (described in Section 4.5, Marine Biological Resources) (MBNMS, 2010). These non-regulatory guidelines were developed to help ensure that any future desalination plants in the sanctuary would be sited, designed, and operated in a manner that results in minimal impacts on the marine environment. They address numerous issues associated with desalination including site selection, construction and operational impacts, monitoring and reporting, plant discharges, and intake systems.

General provisions in the Guidelines outline the desired approach for developing desalination projects, demonstrating project need, designing alternatives, and complying with NEPA, including the following:

- Desalination plant proponents should pursue collaborations with other water suppliers and agencies currently considering water supply options in the area to evaluate the potential for an integrated regional water supply project. This should include an evaluation of other potential desalination locations and alternatives, as well as other forms of water supply;
- Desalination should only be considered when other preferable alternatives for meeting water needs, such as increased conservation and wastewater recycling are maximized or otherwise determined not feasible, and it is clear that desalination is a necessary component of the region's water supply portfolio;
- Project proponent should provide a complete evaluation of the need for a desalination plant. This should include a background of the water supply situation and discussion and evaluation of alternatives that have been considered to obtain the necessary volume of water; including the potential to use other economically and environmentally preferable alternatives including increased conservation, brackish water desalination, and wastewater recycling to meet some or all of the water needs of a proposed project; and
- Desalination plant proponents should provide a thorough analysis of the potential impacts on the coastal ecosystem for the proposed desalination plant and all project alternatives and plans to mitigate any potential impacts, or recover any resources that may be disturbed during construction.

The scope of this EIR/EIS analysis complies with the above Guideline provisions outlining the required elements of impact analysis. The key guidelines with specific recommendations that are relevant to the proposed project and alternatives are listed in **Table 6.4-1**, along with summaries of the proposed project and alternatives' consistency with each guideline. Potential inconsistencies associated with the alternatives are also addressed in individual issue area analyses in Section 5.5. The Guidelines are not applicable to the No Project Alternative and therefore, this alternative is not included in the table.

TABLE 6.4-1
ASSESSMENT OF PROJECT CONFORMITY WITH GUIDELINES FOR DESALINATION PLANTS IN MONTEREY BAY NATIONAL MARINE SANCTUARY

Summary of NOAA Desalination Guidelines	Summary of MPWSP Conformity with Guidelines	Section of EIR/EIS Containing Additional Information
Guidelines Regarding Cumulative Impacts (Sec. D.3, p. 5)		
Desalination plants should be designed, sited, and operated to avoid or minimize cumulative impacts. The project proponent should provide a detailed analysis on the potential cumulative effects of the proposed discharges in combination with other existing and future point sources of pollution (i.e., wastewater discharges, power plant cooling water, and other desalination plants) as well as non-point sources of pollution (i.e., large rivers and outfalls) and other seawater intakes. Where it is feasible to combine the desalination discharge with another discharge, the project proponent should compare the likely effects of the combined discharges with the two separate discharges.	**Proposed Project - Consistent**. The proposed project would utilize the existing MRWPCA treated effluent discharge pipeline, outfall, and diffuser to discharge brine into MBNMS. The dense brine discharge would be released alone during the irrigation season, and blended with varying volumes of secondary treated wastewater during the winter months. Cumulative impacts of the brine-only and combined discharges are fully analyzed in Chapter 4 of this EIR/EIS. Impacts on MBNMS resources from the brine-only and cumulative discharges would be less than significant with implementation of the proposed mitigation. The proposed project would not contribute to a cumulatively significant impact. **Alts. 1 and 2 – Consistent.** Same discharge as proposed project. **Alt. 3 – Potentially Inconsistent.** The discharge would not be combined with existing discharges.[36] **Alt. 4 – Potentially Inconsistent.** The discharge would not be combined with existing discharges. **Alt. 5a/5b – Consistent.** Same combined discharge as proposed project and less discharge due to smaller project.	• Overview, Section 4.1 • Surface Water Hydrology and Water Quality, Sections 4.3.5 and 4.3.6 • Marine Biological Resources, Section 4.5.5 • Alternatives Analysis Section 5.5.3 and 5.5.5 • Appendices D1, D2 and D3 (brine plume and water quality modeling)
Guidelines for Entrainment and Impingement (Sec. D.3, p. 6)		
All desalination plants should be designed and sited to avoid and minimize impingement and entrainment to the extent feasible. Project proponents should investigate the feasibility of using subsurface intakes as an alternative to traditional intake methods. Other options for consideration should include, but may not be limited to: vertical and radial beach wells, horizontal directionally drilled (HDD) and slant-drilled wells, seabed filtration systems and other structures beneath the sea floor. Where feasible and beneficial, subsurface intakes should be used. It must be ensured however, that they will not cause saltwater intrusion to aquifers, negatively impact coastal wetlands that may be connected to the same aquifer being used by the intake, and they must address the likelihood of increased coastal erosion in the future. Subsurface intakes have the potential to minimize or eliminate impingement and entrainment impacts and improve the performance and efficiency of a desalination project by providing a certain level of pretreatment.	**Proposed Project - Consistent**. The proposed project would utilize subsurface intakes that penetrate the sea floor of MBNMS and avoid impingement and entrainment of marine biological resources. The proposed project would have a less than significant impact on groundwater supply and recharge, and subsurface intakes would facilitate the reduction of seawater intrusion in the long term. In addition, proposed slant wells would be located inland of the modeled anticipated inland extent of coastal retreat, but the rate of retreat may vary due to unforeseen changes in climate change. Therefore, the slant wells could become located on the beach within the project lifetime, a significant impact that would be reduced to a less than significant impact with Mitigation Measure 4.2-9 (Slant Well Abandonment Plan). **Alt. 1 – Potentially Inconsistent.** Subsurface intakes would be used similar to the proposed project, but coastal wetlands may be affected by groundwater drawdown.	• Description of the Proposed Project, Section 3.2.1 • Geology and Soils, Section 4.2.5 • Groundwater Resources, Section 4.4.5 • Marine Biological Resources, Section 4.5.5 • Alternatives Analysis, Section 5.3, 5.5.4 and 5.5.5 • Appendices C1 (Sea Level Rise) and C2 (Coastal Erosion) • Appendix E2 (North Marina Groundwater Model)

[36] The proponent of this alternative is investigating the feasibility of combining discharge with the Moss Landing Power Plant, but the current proposed project is a standalone new discharge pipeline. Should a combined discharge be determined feasible, that option would be evaluated in the DeepWater Desal project CEQA/NEPA document.

TABLE 6.4-1 (Continued)
ASSESSMENT OF PROJECT CONFORMITY WITH GUIDELINES FOR DESALINATION PLANTS IN MONTEREY BAY NATIONAL MARINE SANCTUARY

Summary of NOAA Desalination Guidelines	Summary of MPWSP Conformity with Guidelines	Section of EIR/EIS Containing Additional Information
Guidelines for Entrainment and Impingement (Sec. D.3, p. 6) (cont.)		
	Alts. 2, 3, and 4 – Potentially Inconsistent. Open water intake would cause impingement and entrainment. **Alt. 5a – Consistent.** Similar to proposed project. **Alt. 5b – Potentially Inconsistent.** Drawdown effects similar to Alternative 1.	
Any impacts on essential fish habitat (EFH) and the biota it supports that cannot be avoided through project design or operations will require mitigation, as per NMFS' regulatory requirements. The necessary level of mitigation is to be determined through the use of a biologically based model, such as the habitat production foregone method, in order to account for all "non-use" impacts on affected biota. Mitigation projects should attempt to directly offset the impacted species or habitat (in-place, in-kind mitigation) although NOAA will work with the project proponent to identify appropriate mitigation if this is not possible.	**Proposed Project - Not Applicable**. Essential Fish Habitat is not present in the project study area. The proposed project does not include any construction activities on the sea floor; operation of the proposed slant wells and discharge of brine into MBNMS would not affect EFH. **Alt. 1 – Potentially Inconsistent.** Effects on Elkhorn Slough resources are identified as significant and unavoidable and no feasible mitigation has been identified. **Alts. 2, 3, and 4 – Not Applicable.** The location is not within EFH. **Alt. 5a – Not Applicable.** The location is not within EFH, same as the proposed project. **Alt. 5b –** Same as Alternative 1.	• Marine Biological Resources, Section 4.5.5 • Alternatives Analysis Section 5.5.5
Guidelines for Brine Discharge (Sec. D.3, pp. 6-7)		
All desalination plants should be designed to minimize impacts from the discharge. Project proponents should investigate the feasibility of diluting brine effluent by blending it with other existing discharges. The proponent should evaluate the use of measures to minimize the impacts from desalination plant discharges including discharging to an area with greater circulation or at a greater depth, increasing in the number of diffusers, increasing the velocity while minimizing the volume at each outlet, diluting the brine with seawater or another discharge, or use of a subsurface discharge structure.	**Proposed Project - Consistent**. The proposed project would utilize the existing MRWPCA outfall and diffuser in MBNMS to discharge brine from the desalination process. Brine would generally be discharged alone during the irrigation season, and combined with intermittent flows of treated wastewater in the non-irrigation season. Brine discharge modeling evaluated salinity and water quality impacts on receiving waters for six flow scenarios. Impacts were determined to be less than significant with implementation of Mitigation Measures 4.3-4 (Operational Discharge Monitoring Analysis, Reporting, and Compliance) and 4.3-5 (Implement Protocols to Avoid Exceeding Water Quality Objectives). **Alts. 1 and 2 – Consistent.** Same as proposed project. **Alts. 3 and 4 – Potentially Inconsistent.** The discharge would not be combined with existing discharges. **Alt. 5a/b – Consistent.** Same as proposed project.	• Surface Water Hydrology and Water Quality, Section 4.3.5 • Alternatives Analysis Section 5.5.3. • Appendices D1, D2 and D3 (brine plume and water quality modeling)

TABLE 6.4-1 (Continued)
ASSESSMENT OF PROJECT CONFORMITY WITH GUIDELINES FOR DESALINATION PLANTS IN MONTEREY BAY NATIONAL MARINE SANCTUARY

Summary of NOAA Desalination Guidelines	Summary of MPWSP Conformity with Guidelines	Section of EIR/EIS Containing Additional Information
Guidelines for Brine Discharge (Sec. D.3, pp. 6-7) (cont.)		
The project proponent should provide a detailed evaluation of the projected short-term and long-term impacts of the brine plume on marine organisms based on a variety of operational scenarios and oceanographic conditions: ● Brine plume modeling should address different types of seasonal ocean circulation patterns, including consideration of "worst case scenarios." ● Modeling results should be included, to illustrate how the plume will behave during variable oceanographic conditions. The plume model should estimate salinity concentrations at the discharge point, as well as where and when it would reach ambient ocean concentrations. The extent, location, and duration of the plume where the salinity is 10% above ambient salinity should also be provided. ● Information should be provided on the physical and chemical parameters of the brine plume including salinity, temperature, metal concentrations, pH, and oxygen levels. These water quality characteristics of the discharge should conform to California Ocean Plan requirements and should be as close to ambient conditions of the receiving water as feasible.	**Proposed Project - Consistent**. Brine plume dilution modeling was conducted for six flow scenarios, assuming no current at the sea floor and ignoring orbital velocities from waves. Additional dilution modeling was conducted for the Final EIR/EIS. Brine plume effects were evaluated for salinity levels in the pipe, adjacent to the diffuser, within the zone of initial dilution (ZID), along the sea floor to the edge of the brine mixing zone (BMZ) (+100 meters from the diffuser) and beyond. Input to the brine plume model included temperature and salinity levels within the ambient water column for three ocean circulation patterns, which encompass the range of seasonal patterns typical of this area. Brine plume effects on physical and chemical parameters, including salinity, temperature, metal concentrations, pH, and dissolved oxygen, and all constituents regulated under the Ocean Plan are addressed in Impact 4.3-4 and Impact 4.3-5. Mitigation Measures 4.3-4 (Operational Discharge Monitoring Analysis, Reporting, and Compliance) and 4.3-5 (Implement Protocols to Avoid Exceeding Water Quality Objectives) would reduce impacts on receiving waters to a less than significant impact, thus the project conforms to Ocean Plan requirements. **Alts. 1 and 2 – Consistent.** Same discharge as proposed project. **Alt. 3 – Consistent.** Concentrations of the discharges would be more than proposed project, but would conform to Ocean Plan requirements. **Alt. 4 – Potentially Inconsistent.** Brine plume modeling has not been conducted to support claim that diffuser will be effective in meeting Ocean Plan requirements. **Alt. 5a/5b – Consistent.** Same as the proposed project. Brine discharge would be slightly less volume than the proposed project, but overall findings and mitigation measures are the same as identified above.	● Surface Water Hydrology and WQ, Section 4.3.5 ● Marine Biological Resources, Section 4.5.5 ● Alternatives analysis, Section 5.5.3 and 5.5.5. ● Appendices D1, D2 and D3 (brine plume and water quality modeling)
A continuous monitoring program should be implemented to verify the actual extent of the brine plume, when deemed necessary (see Monitoring section below) and to determine if the plume is impacting EFH, critical habitat, or sanctuary resources. If it is, then mitigation for the EFH impact will be required.	**Proposed Project - Consistent**. To ensure that operational discharges are in compliance with the Ocean Plan, CalAm shall implement Mitigation Measure 4.3-4 (Operational Discharge Monitoring Analysis, Reporting, and Compliance), which requires a Monitoring and Reporting Plan that includes specific water quality monitoring protocols and frequencies to assess baseline conditions and track Project compliance. Continuous monitoring is required one year prior to commencement of operational discharges and for a minimum of five years after operational discharges commence. EFH is not present within the study area. **All Alternatives – Consistent.** The same monitoring mitigation measure identified for the proposed project would apply to all alternatives.	● Surface Water Hydrology and WQ, Sections 4.3.5 ● Alternatives Analysis Section 5.5.3

TABLE 6.4-1 (Continued)
ASSESSMENT OF PROJECT CONFORMITY WITH GUIDELINES FOR DESALINATION PLANTS IN MONTEREY BAY NATIONAL MARINE SANCTUARY

Summary of NOAA Desalination Guidelines	Summary of MPWSP Conformity with Guidelines	Section of EIR/EIS Containing Additional Information
Guidelines for Energy Use and Greenhouse Gas Emissions (Sec. D.3, p. 7)		
The project proponent should provide estimates of a facility's projected annual electricity use and the greenhouse gas emissions resulting from that use. Applicants should also identify measures available to reduce electricity use and related emissions (e.g., energy efficient pumps, low resistance pipes, use of sustainable electricity sources, etc.) and to mitigate for all remaining emissions (e.g., purchase of offsets and/or credits that are consistent with the policies and guidelines of the California Global Warming Solutions Act of 2006 (AB 32), etc.).	**Proposed Project - Consistent**. Section 4.11, Greenhouse Gas Emissions, provides estimates of the proposed project's anticipated total operational emissions, including those from indirect emissions, exhaust emissions, brine degassing emissions, annual electricity demand, and disturbance of carbon sequestration. The analysis provides the net increase in electrical power demand, and greenhouse gas emissions for CO_2, N_20, CH_4, and CO_2e. The proposed project includes numerous energy conservation measures, including energy recovery using pressure-exchanger technology, which is expected to substantially reduce overall energy consumption during the reverse osmosis process. GHG emission impacts would be less than significant with these energy saving measures and implementation of Mitigation Measure 4.11-1 (GHG Emissions Reduction Plan) that would require employment of additional energy conservation technologies and would ensure that operational energy use requirements result in net zero GHG emissions through renewable energy procurement and/or purchase of offsets. **All Alternatives – Consistent.** The alternatives analysis evaluates electricity use and associated greenhouse gas emissions for each alternative and identifies mitigation measures for alternatives.	• Project Description, Chapter 3 • Greenhouse Gas Emissions, Section 4.11.5 • Energy Conservation, Section 4.18 • Alternatives Analysis, Section 5.5.11 and 5.5.18
Guidance for Co-location with Power Plant (Sec. D.3, p. 7)		
Desalination plants proposing to co-locate with power plant once-through cooling systems should include an assessment, during the environmental documentation phase, of the impacts that would occur when the power plant cooling system does not operate, along with an analysis of alternative intake and outfall structures that would avoid or minimize these impacts.	**Proposed Project – Not applicable**. The proposed project is not co-located with a power plant. **All Alternatives – Not applicable**. None of the alternatives would be co-located with a power plant once through cooling system.	Not applicable
Guidance for Co-location with Sewage Treatment Facilities (Sec. D.3, p.8)		
In consideration of recent interest by many municipalities regarding water recycling projects, the project proponent should evaluate the continued availability and reliability of that discharge in the future due to the potential for additional wastewater recycling projects. Additionally, where treated wastewater is available for recycling, proponents should determine the feasibility of using it as the source water to be desalinated for use in groundwater recharge – i.e., indirect potable reuse.	**Proposed Project - Consistent**. MRWPCA certified the Final EIR and approved the Groundwater Replenishment Project (GWR) in October 2015. In September 2016, the CPUC authorized CalAm to purchase 3,500 afy of purified recycled water from the MRWPCA and MPWMD. If the GWR Project is successful at developing water, CalAm would build a reduced-size desalination project (6.4-mgd) (Alternative 5a) and utilize the GWR Project, which would advance treat a variety of water sources including wastewater, stormwater, food industry processing water, and impaired surface waters of the State.	• Water Demand and Supplies, Section 2.4.5, Groundwater Replenishment • Overview, Section 4.1, Table 4.1-2, Cumulative Project #59 • Alternatives, Sections 5.4.7 and 5.4.8 Reduced Project Desalination Plant

TABLE 6.4-1 (Continued)
ASSESSMENT OF PROJECT CONFORMITY WITH GUIDELINES FOR DESALINATION PLANTS IN MONTEREY BAY NATIONAL MARINE SANCTUARY

Summary of NOAA Desalination Guidelines	Summary of MPWSP Conformity with Guidelines	Section of EIR/EIS Containing Additional Information
Guidance for Co-location with Sewage Treatment Facilities (Sec. D.3, p.8) (cont.)		
	Alts. 1, 2, 3, 4 – Consistent. Since the GWR project is separate from the proposed project, it is assumed that other alternatives may be able to use resources resulting from this recycled water project. **Alt. 5a/5b – Consistent.** Same as the proposed project.	
The project proponent should provide a thorough analysis of the potential impacts on marine organisms resulting from the combined properties of the discharge, as well as how the addition of brine effluent would affect the dispersal/dilution of the wastewater effluent.	**Proposed Project - Consistent**. Impacts on marine organisms from the brine-only discharge, and a discharge of brine combined with treated wastewater effluent, are analyzed in Impacts 4.5-4, 4.5-5, and 4.5-6; proposed project impacts on marine biological resources would be less than significant. Brine plume modeling included analysis of the effects of the brine on wastewater effluent dispersal/dilution. **All Alternatives – Consistent.** Impacts on marine organisms from brine discharge associated with alternatives are analyzed and disclosed in Chapter 5 of the EIS/EIR. Chapter 5 also provides impact conclusions for each alternative.	• Surface Water Hydrology and WQ, Section 4.3.5 • Marine Biological Resources, Section 4.5.5 • Alternatives Section 5.5.5 • Appendices D1, D2 and D3 (brine plume and water quality modeling)
The project proponent should evaluate diurnal fluctuations in wastewater discharge operations. When modeling for dilution of the brine plume, it is crucial to include a "worst case scenario" analysis of the dilution properties of the combined wastewater effluent and brine plume, during lowest expected flow rates for the treated wastewater effluent. The project proponent should include an assessment of the impacts that would occur from brine discharge if the wastewater discharge were to cease.	**Proposed Project - Consistent**. Brine modeling evaluated and the EIR/EIS presents the impacts from six operational scenarios ranging from baseline wastewater-only discharges to "worst case" brine-only discharges. The brine-only discharge would exceed 2ppt for a very small area above the sea floor, and it would be less than 2 ppt above ambient at the edge of the ZID, the point at which the plume contacts the sea floor (less than 30 feet from the point of discharge). **Alts. 1 and 2 – Consistent.** Same as the proposed project. **Alts. 3 and 4 – Not Applicable.** Combined discharge is not proposed. **Alt. 5a/5b – Consistent.** Same as the proposed project, but less discharge volume.	• Surface Water Hydrology and WQ, Section 4.3.5 • Marine Biological Resources, Section 4.5.5 • Alternatives Analysis Section 5.5.3 and 5.5.5 • Appendices D1, D2 and D3 (brine plume and water quality modeling)
Guidelines for Use of Chemicals for Treatment and Cleaning (Sec. D.3, p. 8)		
The project proponent should provide a complete list of all chemicals that may be used for the desalination facilities, as well as the quantities of chemicals and how these will be stored and disposed. They should also include an evaluation of the potential for these chemicals to cause impacts on local marine organisms. This should also include a detailed spill prevention and response plan for chemicals stored at the project site.	**Proposed Project - Consistent**. A list of chemicals and their proposed annual usage in the desalination process is presented for the proposed project in Table 3-3 and Table 4.7-5 and includes standard treatment chemicals such as Sodium Hypochlorite, Sodium Bisulfite, Carbon Dioxide, Lime, Sodium Hydroxide, and Zinc Orthophosphate. Information regarding storage and disposal is in Impact 4.7-6. The desalination plant would be located approximately 1.75 miles from the MBNMS and chemical usage and storage at the desalination plant would not cause impacts on local marine organisms. CalAm would be required to implement the project in accordance with all applicable laws and regulations governing hazardous materials storage, handling, and	• Description of the Proposed Project, Section 3.2.2.4 • Hazards and Hazardous Materials, Section 4.7.5.2 • Alternatives Section 5.5.7

TABLE 6.4-1 (Continued)
ASSESSMENT OF PROJECT CONFORMITY WITH GUIDELINES FOR DESALINATION PLANTS IN MONTEREY BAY NATIONAL MARINE SANCTUARY

Summary of NOAA Desalination Guidelines	Summary of MPWSP Conformity with Guidelines	Section of EIR/EIS Containing Additional Information
Guidelines for Use of Chemicals for Treatment and Cleaning (Sec. D.3, p. 8) (cont.)		
	disposal. Chemicals used in the pretreatment process will be disposed of as sludge in a sanitary landfill. Spent cleaning solutions and waste effluent for the RO System would be discharged into a collection sump, chemically neutralized, then pumped into tank trucks and transported offsite for disposal. Spill prevention measures and a response plan would be included in the SWPPP and the Hazardous Materials Business Plan. **All Alternatives – Consistent.** The use of chemicals would be similar to the proposed project and chemical use is evaluated in the Alternatives Chapter 5. All alternatives will be required to prepare spill prevention and response plans.	
The project proponent should evaluate the feasibility of using alternative pretreatment techniques such as ozone pretreatment, subsurface intakes, and membrane filtration, aimed at reducing the use of chemicals.	**Proposed Project - Consistent**. The proposed project would use pretreatment techniques including subsurface intakes, pressure filters or multimedia gravity filters, backwash supply and filtered water equalization tanks, backwash settling basins with decanting system, cartridge filters, filtered water pumps, and backwash supply pumps. **Alt. 1 – Consistent.** Same as the proposed project. **Alts. 2, 3, and 4 – Potentially Inconsistent.** Open water intake. **Alt. 5a/5b – Consistent.** Same as the proposed project.	• Description of the Proposed Project, Chapter 3 • Alternatives description, Section 5.4
Guidelines for other Environmental and Socioeconomic Impacts (Sec. D.3, p.9)		
Desalination plants should be designed and operated to minimize impacts on recreational and commercial activities that occur within MBNMS. The project proponent should provide a thorough evaluation of the potential impacts on recreation, public access and safety, including but not limited to potential impacts on SCUBA divers, kayakers, recreational boaters, and commercial and recreational fishermen.	**Proposed Project - Consistent**. The MPWSP Desalination Plant itself would not be located within MBNMS; slant wells from onshore locations would extend into the submerged lands of MBNMS. The proposed project is consistent with regional and local plans and policies designed to promote and protect public safety and recreational opportunities. No construction or operational activities proposed by the MPWSP would impact divers, kayakers, boaters or fishermen. Public access to Fort Ord Dunes State Park could be temporarily disrupted during pipeline construction, but mitigation would ensure continued vehicular, pedestrian and bicyclist access; lateral access would not be affected. **Alt. 1 – Consistent.** Similar to the proposed project, but construction at the Potrero Road parking lot would temporarily limit vertical beach access. Alternative access routes are available and mitigation measures are identified to ensure continued access. Lateral beach access would not be affected. **Alt. 2 – Consistent.** Same as the proposed project. **Alt. 3 – Potentially consistent.** Offshore construction may affect recreational and commercial activities in MBNMS; however, the effects would be short-term.	• Land Use, Land Use Planning, and Recreation, Section 4.8 • Table 4.8-2 Applicable Regional and Local Land Use Plans and Policies Relevant to Land Use and Recreation • Alternatives Section 5.5.8

TABLE 6.4-1 (Continued)
ASSESSMENT OF PROJECT CONFORMITY WITH GUIDELINES FOR DESALINATION PLANTS IN MONTEREY BAY NATIONAL MARINE SANCTUARY

Summary of NOAA Desalination Guidelines	Summary of MPWSP Conformity with Guidelines	Section of EIR/EIS Containing Additional Information
Guidelines for other Environmental and Socioeconomic Impacts (Sec. D.3, p.9) (cont.)		
	Alt. 4 – Potentially consistent. Offshore construction may affect recreational and commercial activities in MBNMS and onshore construction at the caisson may preclude beach access. The effects would be short-term. **Alt. 5a – Consistent.** Same as the proposed project. **Alt. 5b – Consistent.** Same as Alternative 1.	
Desalination plants should not interfere with vertical or lateral public access to the shoreline or to coastal waters.	**Proposed Project - Consistent**. (See previous row) Construction of the proposed new Transmission Main would temporarily close 1 of 3 entrances to Fort Ord Dunes State Park. Implementation of Mitigation Measure 4.9-1 (Traffic Control and Safety Assurance Plan), would provide continued safe access. The subsurface slant wells would be set back from the beach at a distance that would not preclude public access on the beach. No other proposed components would interfere with vertical or lateral public access to the shoreline or coastal waters. **All Alternatives.** Same as previous row regarding public access and recreation.	• Land Use, Land Use Planning, and Recreation, Section 4.8 • Traffic and Transportation, Section 4.9 • Alternatives Section 5.5.8 and 5.5.9
Desalination plants in MBNMS should not contribute to coastal retreat and should not be designed to anticipate the possibility of installing coastal armoring at any time in the future to protect the plant or its infrastructure from the effects of coastal erosion, wave action, or sea level rise.	**Proposed Project - Consistent**. The only proposed component that could become vulnerable to coastal retreat during the project lifetime is the existing test slant well. CalAm would implement Mitigation Measure 4.2-10 (Slant Well Abandonment Plan), which would require annual monitoring of the rate of coastal retreat and abandonment of the facility when necessary. CalAm would remove the susceptible facility prior to its exposure or potential contribution to coastal retreat. No coastal armoring is planned to protect the subsurface slant wells. **Alt. 1 – Consistent.** The slant wells would be located inland of the modeled future coastal erosion and would not be subject to coastal erosion or contribute to coastal retreat. **Alt. 2 – Consistent.** No facilities are proposed within an area subject to coastal erosion or retreat. Pipelines would be 100 feet below the surface where crossing the coastline. **Alt. 3 – Consistent.** Same as Alternative 2. **Alt. 4 – Potentially Inconsistent.** Continued use and improvements of the existing Caisson in the shore zone may be subject to coastal erosion and could necessitate armoring. **Alt. 5a – Consistent.** Same as the proposed project. **Alt. 5b – Consistent.** Same as Alternative 1.	• Geology and Soils, Impact 4.2-10 • Alternatives Section 5.5.2 • Appendix C2, Analysis of Historic and Future Coastal Erosion with Sea Level Rise.

TABLE 6.4-1 (Continued)
ASSESSMENT OF PROJECT CONFORMITY WITH GUIDELINES FOR DESALINATION PLANTS IN MONTEREY BAY NATIONAL MARINE SANCTUARY

Summary of NOAA Desalination Guidelines	Summary of MPWSP Conformity with Guidelines	Section of EIR/EIS Containing Additional Information
Guidelines for other Environmental and Socioeconomic Impacts (Sec. D.3, p.9) (cont.)		
Desalination plants should be designed to minimize visual impacts on coastal resources.	**Proposed Project - Consistent**. The MPWSP Desalination Plant would minimize coastal visual impacts on resources because of its inland location. The subsurface slant wells and associated facilities at CEMEX would be located in an area with moderate aesthetic resource value. The site's dune topography and vegetation would substantially limit views of the slant well sites from locations outside of the CEMEX property, including from the beach and from Hwy 1. Views from the beach would be nearer and longer in duration compared to roadside views, but the above ground facilities would not appear dominant relative to surrounding features and would not obstruct coastal views. As a result, these facilities would minimize visual impacts on coastal resources. Furthermore, mitigation has been identified to reduce impacts on coastal views. **Alt. 1 – Consistent.** Similar to the proposed project. **Alt. 2 – Consistent.** No facilities are planned in the shore area. The intake pump station would be on Dolan Road in an industrial area. The desalination plant site is the same as the proposed project. **Alt. 3 – Consistent.** No facilities are planned in the shore area and the desalination plant site is inland of the coastal area. **Alt. 4 – Potentially Inconsistent.** The Sandholdt Road pump house structure would be visible within the coastal area and would affect scenic coastal views. Mitigation has been identified to reduce the impact to less than significant, but visual resources may still be affected. **Alt. 5a – Consistent**. Same as the proposed project. **Alt. 5b – Consistent.** Same as Alternative 1.	• Aesthetic Resources, Section 4.14.5 • Alternatives Analysis Section 5.5.14
The project proponent should provide an analysis of the potential population growth-inducing impacts of the desalination project. This should be compared for consistency with projected development patterns in relevant planning documents such as Local Coastal Programs and the County's General Plan. NOAA recommends that the freshwater production capacity of all desalination projects be consistent with established local government land use policies in county and city general plans and local coastal programs.	**Proposed Project - Consistent**. The proposed project is sized to provide existing customers with a reliable water supply, accounting for peak month demand; to accommodate tourism demand under a recovered economy; to provide supplies for vacant legal lots of record; and for Pebble Beach Entitlements. The direct effects on population and housing were determined to be less than significant. The indirect growth inducement potential of the MPWSP was evaluated in conjunction with population and housing forecasts prepared by the Association of Monterey Bay Area Governments and with projections from local General Plans or specific plans. While the MPWSP would provide sufficient supply to enable CalAm to comply with the SWRCB Order 95-10 and the Seaside Groundwater Basin Adjudication (see Table 6.3-1), it would provide some water for growth. The indirect impacts of that growth were identified in the EIRs prepared for the general and specific plans that guide that growth. **Alts. 1 and 2 – Consistent.** Same as the proposed project.	• Population and Housing, Section 4.19 • Alternatives Section 5.5.19 • Growth-Inducing Impacts, Section 6.3 • Alternatives Section 5.5.21 • Secondary Effects of Growth, Appendix J2

TABLE 6.4-1 (Continued)
ASSESSMENT OF PROJECT CONFORMITY WITH GUIDELINES FOR DESALINATION PLANTS IN MONTEREY BAY NATIONAL MARINE SANCTUARY

Summary of NOAA Desalination Guidelines	Summary of MPWSP Conformity with Guidelines	Section of EIR/EIS Containing Additional Information
Guidelines for other Environmental and Socioeconomic Impacts (Sec. D.3, p.9) (cont.)		
	Alt. 3 – Potentially Inconsistent. The substantially larger size of this alternative would allow more growth than the proposed project and it is not certain that this growth would be consistent with land use policies and general plan growth projections. **Alt. 4 – Potentially Inconsistent.** The slightly larger size of this alternative would allow more growth than the proposed project and it is not certain that this growth would be consistent with land use policies and general plan growth projections. **Alt. 5a/5b – Consistent**. Same as the proposed project.	
Guidelines for Plant Site Selection and Structural and Engineering Considerations (Sec. D.3, pp. 9-10)		
Desalination plant intakes should be sited to avoid sensitive habitats. For open-water intakes, areas of high biological productivity, such as upwelling centers or kelp forests or other dense beds of submerged aquatic vegetation should be avoided, since the entrainment and impingement impacts of a desalination plant are in large part dictated by the biological productivity in the vicinity of that intake.	**Proposed Project - Consistent for MBNMS Resources; Inconsistent for Onshore Resources**. The proposed project would include subsurface intakes under the MBNMS seafloor that avoid impingement and entrainment impacts. No construction is planned on the seafloor surface. Onshore, the proposed project would use subsurface slant wells at the CEMEX sand mining property. A thorough intake alternatives analysis identified the proposed location to minimize impacts. The wellheads would be located on the inland side of the dunes; sensitive communities and critical habitat within or adjacent to the project construction area could be temporarily (9 acres) or permanently (1 acre) impacted during construction. Slant well construction would occur outside of western snowy plover critical habitat. However, conversion of the test slant well to a permanent well and construction of aboveground facilities could indirectly impact the primary constituent elements of this critical habitat if worker foot traffic extends beyond the designated construction work area, if trash and debris is left behind following construction, or if invasive plant species are introduced or spread at the site. Implementation of mitigation measures would reduce impacts on sensitive natural communities and critical habitat resulting from slant well construction to a less-than-significant level. **Alt. 1 – Inconsistent.** The slant well location at the Potrero Road parking lot would not affect any sensitive habitat, but drawdown effects on Elkhorn Slough could affect sensitive species. **Alts. 2 and 3 – Inconsistent.** Construction and operation of a new open water intake system would impact marine biological resources. **Alt. 4 – Inconsistent.** Construction and operation of an extended open water intake system would impact marine biological resources. **Alt. 5a –** Same as the proposed project. **Alt. 5b – Inconsistent.** Same as Alternative 1.	• Description of the Proposed Project, Chapter 3 • Marine Biological Resources Section 4.5 • Terrestrial Biological Resources, Impact 4.6-2 • Alternatives Development and Screening Process, Chapter 5.3 • Alternatives Analysis Sections 5.5.5 and 5.5.6

TABLE 6.4-1 (Continued)
ASSESSMENT OF PROJECT CONFORMITY WITH GUIDELINES FOR DESALINATION PLANTS IN MONTEREY BAY NATIONAL MARINE SANCTUARY

Summary of NOAA Desalination Guidelines	Summary of MPWSP Conformity with Guidelines	Section of EIR/EIS Containing Additional Information
Guidelines for Plant Site Selection and Structural and Engineering Considerations (Sec. D.3, pp. 9-10) (cont.)		
Desalination plant discharges should not be located in or near ecologically sensitive areas, including Areas of Special Biological Significance as designated by the State Water Resources Control Board, EFH Habitat Areas of Particular Concern as designated by the Pacific Fishery Management Council, and Marine Protected Areas designated under the Marine Life Protection Act. These areas include: Elkhorn and Pescadero Sloughs, James V. Fitzgerald Marine Reserve, Año Nuevo, Pacific Grove Marine Gardens, Edward F. Ricketts, Carmel Bay, Point Lobos, Point Sur and Big Creek State Marine Conservation Areas and Marine Reserves, Julia Pfeiffer Burns Underwater Park, and the Ocean Area Surrounding the Mouth of Salmon Creek.	**Proposed Project - Consistent**. The MPWSP Desalination Plant discharges would not be located in or near ecologically sensitive areas. Furthermore, discharges would be combined with existing wastewater discharges. **All Alternatives – Consistent.** Same as proposed project.	• Description of the Proposed Project, Chapter 3 • Marine Biological Resources, Figure 4.5-5 Sanctuary Ecologically Significant Areas Designated in MBNMS • Alternatives Analysis Section 5.5.5
Areas with limited water circulation such as enclosed bays or estuaries, which can "trap" the brine discharge, should be avoided, as should EFH HAPC, such as rocky substrate and kelp forests, due to their high biological productivity. As a general rule, the stronger the hydrodynamic force, the better dilution is achieved due to faster dispersal from the natural mixing action of the ocean. Desalination plant discharges should be designed and sited to minimize impacts on marine biological resources of the sanctuary.	**Proposed Project - Consistent**. The proposed project would utilize the existing MRWPCA ocean outfall in Monterey Bay, within MBNMS. The location is on a shelf with a 1 percent slope towards the Monterey Submarine Canyon; it is not enclosed, not an estuary, and the only hard substrate is the ballast rock supporting the outfall pipe. There are no kelp beds nearby. **All Alternatives – Consistent.** Same as proposed project.	• Marine Biological Resources, Section 4.5, Figure 4.5-1 Identified Subtidal Habitats in Study Area • Alternatives Analysis Section 5.5.5
The project proponent should provide complete plans, which include detailed information on: location, depth, engineering, and configuration of intake and outfall pipes; sizing and configuration of seabed structures; proposed depth and distance from shore of the intake and discharge points; local bathymetry; and dilution zones for each discharge pipeline alternative. The pipeline placement and configuration of intake and discharge structures should be designed as to avoid sensitive biological areas in the sanctuary.	**Proposed Project - Consistent**. The proposed project would utilize an existing outfall and diffuser, and would use subsurface intakes; no proposed intake component would be constructed or placed on the surface of the sea floor. Local bathymetry and dilution zones are provided. **Alt. 1 – Consistent.** Same as the proposed project. **Alt. 2 – Inconsistent.** Construction and operation of a new open water intake system would impact marine biological resources. **Alt. 3 – Inconsistent.** Construction and operation of a new open water intake system and discharge pipeline would impact marine biological resources. **Alt. 4 – Inconsistent.** Construction and operation of an extended open water intake system and discharge pipeline would impact marine biological resources. **Alt. 5a/5b – Consistent.** Same as the proposed project.	• Description of the Proposed Project, Chapter 3, Table 3-1, Sections 3.2.1 and 3.2.2.5, Figure 3-3a MPWSP Seawater Intake System, Figure 3-3b Illustrative Cross-Sectional View of Subsurface Slant Wells • Geology and Soils, Section 4.2, Figure 4.2-7 Representative Profile at Test Slant Well, Figure 4.2-8 Representative Profile at Proposed Slant Wells • Surface Hydrology and WQ, Section 4.3, Figure 4.3-7 Brine Mixing Zone (BMZ) and Diffuser Overview • Marine Biological Resources, Section 4.5, Figure 4.5-1 Identified Subtidal Habitats in Study Area, Figure 4.5-4 Essential Fish Habitat Designated in MBNMS under Federal Regulations, Figure 4.5-5 Sanctuary Ecologically Significant Areas Designated in MBNMS, Figure 4.5-6 Marine Protected Areas along the California Coast • Alternatives Analysis Section 5.5.5 • Appendix D1, Brine Modeling

TABLE 6.4-1 (Continued)
ASSESSMENT OF PROJECT CONFORMITY WITH GUIDELINES FOR DESALINATION PLANTS IN MONTEREY BAY NATIONAL MARINE SANCTUARY

Summary of NOAA Desalination Guidelines	Summary of MPWSP Conformity with Guidelines	Section of EIR/EIS Containing Additional Information
Guidelines for Plant Site Selection and Structural and Engineering Considerations (Sec. D.3, pp. 9-10) (cont.)		
The project proponent should provide an analysis of the potential for co-location of desalination plants to make use of existing infrastructure.	**Proposed Project - Consistent**. The proposed desalination plant would be located adjacent to the MRWPCA and would use the existing outfall pipeline and diffuser. **Alts. 1 and 2 – Consistent.** Same as the proposed project. **Alt. 3 – Inconsistent.** The project would not be co-located. However, the proponent of this alternative is investigating the feasibility of combining discharge with the Moss Landing Power Plant. **Alt. 4 – Partially Consistent.** The project would rehabilitate existing intake and discharge pipeline systems. **Alt. 5a/5b – Consistent.** Same as the proposed project.	• Description of the Proposed Project, Chapter 3.
Guidelines for Desalination Plant Construction Phase (Sec. D.3, pp. 10-12)		
The project proponent should identify and provide a complete explanation of potential impacts from the construction process to the marine and coastal environment. They should also provide an evaluation of marine historical or archaeological resources that could be disturbed, and plans to mitigate any potential impacts, or recover any resources that may be disturbed during construction.	**Proposed Project - Not applicable**. The proposed desalination plant would be located approximately 1.75 miles from the coast and would not impact marine or coastal resources during the construction phase, nor would any marine historical/archaeological resources be affected. **Alts. 1, 2, and 5a/5b – Not applicable.** Same as proposed project. **Alts 3 and 4 –** Desalination plant construction impacts on the marine and coastal environment and on marine historical and archaeological resources are evaluated for each alternative in Section 5.5. Marine Biological Resources, and 5.14 Cultural and Paleontological Resources, and impacts are noted above in consistency determinations regarding intake and discharge pipelines. None of the alternative locations for the desalination plants would affect marine or coastal resources, as they are sited inland.	• Description of the Proposed Project, Chapter 3. • Alternatives Analysis Section 5.5.15
All proposed projects should provide a stormwater pollution prevention plan (SWPPP). Stormwater runoff from the site should be managed to prevent any discharge of silt or chemical contaminants to the ocean or any other surface water body. The SWRCB General Construction Storm Water Permit for Construction Activities (General Permit) is required by the Central Coast Water Board for all construction activities that disturb at least one acre of soil, including grading and stockpiling. Local jurisdictions may require additional construction permits and SWPPPs at lower disturbance thresholds. In the case of any accidental spills or construction-related impacts on marine biological resources, MBNMS and NMFS management should be notified immediately and mitigation plans developed.	**Proposed Project - Consistent**. Construction of the proposed project would be conducted under a General Construction Permit, which is implemented and enforced by the Central Coast RWQCB and requires project operators to prepare a SWPPP. The proposed project would include a Hazardous Materials Business plan (HMBP) that is required by the Hazardous Materials Release Response Plans and Inventory Act of 1985 for businesses and construction contractors that use and store hazardous materials. The HMBP includes information on hazardous material handling and storage, including containment, site layout, and emergency response and notification procedures (including MBNMS and NMFS) in the event of a spill or release. **All Alternatives – Consistent**. Alternatives would be subject to the same requirements as the proposed project.	• Surface Water Hydrology and Water Quality, Section 4.3.5 • Hazards and Hazardous Materials, Section 4.7.5 • Alternatives Analysis Section 5.5.3 and 5.5.7

TABLE 6.4-1 (Continued)
ASSESSMENT OF PROJECT CONFORMITY WITH GUIDELINES FOR DESALINATION PLANTS IN MONTEREY BAY NATIONAL MARINE SANCTUARY

Summary of NOAA Desalination Guidelines	Summary of MPWSP Conformity with Guidelines	Section of EIR/EIS Containing Additional Information
Guidelines for Desalination Plant Construction Phase (Sec. D.3, pp. 10-12) (cont.)		
Best Management Practices should be developed and adhered to in order to avoid or minimize impacts on the marine environment during the construction phase of a desalination project. This should include the use of materials and practices that minimize disturbances to the environment to the maximum extent practicable.	**Proposed Project - Consistent**. All construction activities associated with the proposed project would occur several hundred feet inland of MHW and potential impacts on the marine environment within MBNMS would be less than significant, or no impact. **Alt. 1 – Consistent.** Same as the proposed project. **Alts. 2, 3, and 4 – Potentially Inconsistent.** Offshore construction would be required and disturbance to the marine environment would occur. **Alt. 5a/5b – Consistent.** Same as the proposed project.	• Surface Water Hydrology and Water Quality, Section 4.3.5 • Marine Biological Resources, Section 4.5.5 • Alternatives Analysis Section 5.5.3 and 5.5.5
The plant construction phase should include techniques and plans to avoid impacts on maritime heritage resources of the MBNMS. This includes submerged cultural and archeological resources including shipwrecks.	**Proposed Project - Consistent**. The proposed project would not be located near any MBNMS maritime heritage resources. The existing MRWPCA outfall would be used for the discharge of brine; no new construction activities would occur on the sea floor or in a MBNMS maritime heritage resource area. **Alt. 1 – Consistent.** Same as the proposed project. **Alts. 2, 3, and 4 – Consistent.** Although shipwrecks may be present in the offshore construction area, pre-construction marine surveys would be required to determine presence and to avoid such resources. **Alt. 5a/5b – Consistent.** Same as the proposed project.	• Description of the Proposed Project, Chapter 3 • Cultural and Paleontological Resources, Section 4.15.5 • Alternatives Analysis Section 5.5.15
Project proponents should adhere to specific conditions for all construction activities occurring on the beach. See bulleted list on page 11 of MBNMS Guidelines.	**Proposed Project - Consistent**. All construction activities associated with the proposed project would occur at a minimum of several feet inland of MHW; construction materials and equipment would be delivered by existing access roads, no fill material would be discharged into waters of MBNMS. A list of anticipated required permits and approvals is presented in Chapter 3. Many of these would include specific conditions for work on or near the beach. All project construction activities would comply with specific conditions of any and all authorizations, regardless of construction location. **Alt. 1 – Consistent.** Similar to the proposed project, but construction at Potrero Road may require specific conditions. **Alts. 2 and 3 – Not Applicable.** No beach construction. **Alt. 4 – Potentially Inconsistent.** Beach construction would be required for the intake pipeline and modification of the existing caisson. **Alt. 5a – Consistent.** Same as the proposed project. **Alt. 5b – Consistent.** Same as Alternative 1.	• Description of the Proposed Project, Chapter 3. • Surface Water Hydrology and Water Quality, Section 4.3.5

TABLE 6.4-1 (Continued)
ASSESSMENT OF PROJECT CONFORMITY WITH GUIDELINES FOR DESALINATION PLANTS IN MONTEREY BAY NATIONAL MARINE SANCTUARY

Summary of NOAA Desalination Guidelines	Summary of MPWSP Conformity with Guidelines	Section of EIR/EIS Containing Additional Information
Guidelines for Desalination Plant Construction Phase (Sec. D.3, pp. 10-12) (cont.)		
Mitigation should be provided for the loss of EFH from the placement of the intake structure, delivery pipeline, and outfall structure.	**Proposed Project - Not Applicable**. The marine biological resources study area for the proposed project does not include EFH and does not include the placement of any new structure in MBNMS. The proposed project would not affect EFH. **Alt. 1 – Potentially Inconsistent.** No feasible mitigation has been identified for indirect drawdown effects on Elkhorn Slough resources. **Alts. 2, 3, and 4 – Not Applicable.** The intake and outfall pipelines are not within EFH. **Alt. 5a – Consistent.** Same as the proposed project. **Alt. 5b –** Same as Alternative 1.	● Marine Biological Resources, Section 4.5, Figure 4.5-4 Essential Fish Habitat Designated in MBNMS under Federal Regulations ● Alternatives Analysis Section 5.5.5
Monitoring (Sec. D.4, pp.12-13)		
The project proponent should develop an ongoing monitoring program to evaluate the extent of impacts from the plant's intake and discharge operations on marine biological resources. The monitoring program should focus on: a) developing a statistically acceptable baseline for the project area, b) monitoring source water for potential contaminants that may require additional treatment, c) monitoring the effluent prior to discharge to ensure it is in compliance with the California Ocean Plan d) monitoring the effects of the effluent on marine organisms within the plume, after the discharge begins, e) monitoring the impingement and entrainment effects on marine organisms, if applicable, and f) monitoring any required mitigation for unavoidable impacts to make sure the mitigation is performing as intended. The proposed monitoring system should be carried out for at least three years, with an evaluation report and cumulative impact evaluation generated each year. After the third year, the RWQCB and the MBNMS.	**Proposed Project - Consistent**. Mitigation Measure 4.3-4 (Operational Discharge Monitoring, Analysis, Reporting, and Compliance) applies to the proposed project operational discharges to ensure compliance with Ocean Plan requirements, and includes the following protocols, which are consistent with the guidelines: ● To establish baseline conditions, continuously record water quality parameters of salinity and dissolved oxygen at one hour intervals at several locations in the receiving waters of the Monterey Bay for one year prior to commencement of operational discharges (consistent with a.). ● Continue WQ monitoring for a minimum of five years once operational discharges have commenced to confirm compliance with Ocean Plan receiving water quality limitations. ● Assess changes to the benthic community composition within the Zone of Initial Dilution (ZID) through the collection of visual observation data for the first 3 years with assessment to continue an additional 2 years (consistent with d.) ● Prepare annual reports of analyses and summaries and send to RWQCB and MBNMS, and make publicly available via project website. Mitigation Measure 4.3-5 (Implement Protocols to Avoid Exceeding Water Quality Objectives) would require CalAm to perform extensive water quality assessment prior to implementation of the proposed project as well as during operation of the facility to ensure compliance with MRWPCA NPDES Permit amendment process (Order No. R3-2014-0013, NPDES Permit No. CA0048551) and includes the following protocols:	● Surface Water Hydrology and Water Quality, Section 4.3.5 ● Alternatives Analysis Section 5.5.3

TABLE 6.4-1 (Continued)
ASSESSMENT OF PROJECT CONFORMITY WITH GUIDELINES FOR DESALINATION PLANTS IN MONTEREY BAY NATIONAL MARINE SANCTUARY

Summary of NOAA Desalination Guidelines	Summary of MPWSP Conformity with Guidelines	Section of EIR/EIS Containing Additional Information
Monitoring (Sec. D.4, pp.12-13) (cont.)		
	• Quantify projected final design discharge volumes by month. • Collect samples of source waters and operational discharges and analyze for constituents listed in Table 1 of Ocean Plan. (Consistent with b. and c.) • Demonstrate compliance for the full range of regulated water quality constituents specified in the Ocean Plan and NPDES water quality requirements in the context of minimum initial dilution values at the edge of the ZID. • If results do not meet NPDES water quality requirements and Ocean Plan limitations, then MPWSP operational discharges shall not be released as proposed and would be subject to additional design features, engineering solutions, and/or operational measures to bring water quality constituents into conformance. • Additional design features and operational measures include additional pretreatment or source water, treatment of discharge, retrofitting the existing outfall to increase dilution, and flow augmentation. • The intakes would be subsurface; no impingement and entrainment effects would result. (Consistent with e.) Mitigation would be monitored in accordance with the Mitigation Monitoring and Reporting Program. (Consistent with f.) **All Alternatives – Consistent.** Monitoring programs would be required for any alternative approved by MBNMS, consistent with the provisions in this guideline.

CHAPTER 7
Report Preparation

7.1 Coordination and Consultations

Monterey Bay National Marine Sanctuary (MBNMS) has coordinated and consulted with several agencies during the National Environmental Policy Act (NEPA) process for the proposed project to meet the requirements of other federal laws. Summaries are provided below of the current status of consultations with the National Marine Fisheries Service (NMFS) under Section 7 of the Endangered Species Act (for marine species) and the Magnuson-Stevens Fishery Conservation and Management Act for Essential Fish Habitat (EFH); with the U.S. Fish and Wildlife Service under Section 7 of the Endangered Species Act (for terrestrial species); and with the State Historic Preservation Officer (SHPO) under Section 106 of the National Historic Preservation Act (NHPA). In addition, MBNMS has invited the U.S. Army (Presidio of Monterey) and the U.S. Army Corps of Engineers to be Cooperating Agencies under NEPA. See Appendix O, Agency Coordination and Consultation for documents related to consultation undertaken by MBNMS.

7.1.1 Endangered Species Act Section 7

Endangered Species Act Section 7(a)(1) directs federal agencies to use their authority to carry out programs for the conservation of threatened and endangered species. Federal agencies also must consult with NMFS under Section 7(a)(2) of the Act on activities that may affect a listed species (16 U.S.C. §1531 et seq.). These interagency Section 7 consultations are intended to assist federal agencies in fulfilling their duty to ensure that federal actions do not jeopardize the continued existence of a species or destroy or adversely modify critical habitat. In the event that NMFS determines that a proposed action would jeopardize a species or adversely modify critical habitat (81 Fed. Reg. 7214), it would suggest Reasonable and Prudent Alternatives to the proposed action.

For the proposed project, MBNMS is consulting with NMFS and USFWS as part of the Endangered Species Act Section 7 consultation process. MBNMS notified NMFS and USFWS regarding the proposed federal action in its August 26, 2015 Notice of Intent (NOI) to prepare an EIS for the proposed project (80 FR 51787, August 26, 2015) and is providing additional information about potential impacts of the proposed project addressed in this EIR/EIS. In June 2017, MBNMS prepared a Biological Assessment that provides specific information about potential impacts of the proposed project on federally listed species and designated critical habitat pursuant to the ESA, and on essential fish habitat (EFH) pursuant to the Magnuson-Stevens Fishery Conservation and Management Act (16 U.S.C. §§1801–1884). See Chapter 3, Project Description, Section 4.5, Marine Biological Resources and 4.6, Terrestrial Biological Resources.

On April 20, 2016, staff from USFWS, CDFW, MBNMS, AECOM (as a representative of CalAm, the applicant), and other consultants held a project coordination meeting.

On July 25, 2017, MBNMS sent an electronic request to USFWS to initiate consultation on the proposed project, including a copy of a Biological Assessment (BA) that describes the proposed action and evaluates the potential effects of the proposed project on listed and proposed species and designated and proposed critical habitat and makes a determination as to whether any such species or habitat are likely to be adversely affected by the project. On September 22, 2017, USFWS responded via letter with a request for additional information not found in the BA. Four more submittals were sent to USFWS responding to additional requests for information on October 13, November 13, and December 1, 2017, and February 20, 2018. MBNMS is awaiting a Biological Opinion from USFWS regarding the proposed project and its effects on subject listed species and designated critical habitats under Section 7(a)(2) of the Federal Endangered Species Act.

7.1.2 Magnuson-Stevens Fishery Conservation and Management Act Essential Fish Habitat Consultation

The Magnuson-Stevens Fishery Conservation and Management Act (16 U.S.C. §§1801–1884) establishes Essential Fish Habitat (EFH) provisions to identify and protect important habitats of federally managed marine and anadromous fish species. The Act defines EFH as those waters and substrate necessary to fish for spawning, breeding, feeding, or growth to maturity (16 U.S.C. §1802(10); 50 CFR 600.10). Federal agencies that fund, permit, or undertake activities that may adversely affect EFH are required to consult with NMFS regarding the potential effects of their actions on EFH, and respond to NMFS' recommendations (16 U.S.C. §1855). Federal agencies consult with NMFS under the Magnuson-Stevens Act as part of other existing interagency coordination processes to review proposed projects and other actions that may affect marine resource habitat.

On June 30, 2017, MBNMS sent an electronic request to NMFS to initiate consultation on the proposed project, including a copy of a Biological Assessment (BA) that describes the proposed action and evaluates the potential effects of the proposed project on EFH. Staff from NMFS, MBNMS, and their consultant had a conference call on August 9, 2017, to discuss proposed project components related to groundwater sources for the slant wells. The consultant provided additional information on August 30 and September 17, 2017, at which time NMFS determined the information was sufficient to initiate consultation. On October 23, 2017, NMFS issued a letter to MBNMS that determined the brine discharge resulting from the proposed action would adversely affect EFH by establishing mixing zones with salinity levels up to 2.0 ppt greater than ambient ocean conditions within 100 meters (328 feet) from the diffuser discharge area. However, various minimization measures to avoid or minimize impacts on federally managed fisheries will be employed. NMFS has no practical conservation recommendations to provide, in addition to what is already provided, that would further avoid or mitigate these impacts. NMFS concurred with MBNMS' conclusion that there would be no adverse effects for various life stages of fish species managed within the following Fishery Management Plans (FMP) under the Magnuson-Stevens Fishery Conservation and Management Act:

- Pacific Groundfish FMP;
- Coastal Pelagic Species FMP;
- Pacific Coast Salmon FMP, and;
- West Coast Fisheries for Highly Migratory Species FMP.

7.1.3 National Historic Preservation Act Section 106 Consultation

Federal agencies must demonstrate compliance with the National Historic Preservation Act (NHPA) (16 U.S.C. §470 et seq.). NHPA Section 106 requires a federal agency with jurisdiction over a project to take into account the effect of the proposed federal action on historic properties included on, or eligible for inclusion on, the National Register of Historic Places (16 U.S.C. §470f). Federal agencies also must provide the Advisory Council on Historic Preservation (ACHP) an opportunity to comment on the undertaking. Under NHPA Section 106, the MBNMS consults with Indian tribes as part of its responsibilities to identify, evaluate, and resolve adverse effects to historic properties affected by the Sanctuary's undertakings.

Implementation of the proposed project also requires local and state agencies to demonstrate compliance with the California Environmental Quality Act (CEQA), for which specific guidance regarding cultural resources is presented in Appendix K of the CEQA Guidelines. Local agencies may use the NHPA process to demonstrate compliance with those CEQA requirements. Analysis of impacts in this document and implementation of the mitigation measures in Section 4.15, Cultural and Paleontological Resources, provide evidence of MBNMS's compliance with Section 106 of the NHPA and NEPA as well as the California Public Utilities Commission's compliance with CEQA with respect to cultural resources. The basic steps in the Section 106 process are described in Section 4.15, Cultural and Paleontological Resources. For the proposed project, MBNMS contacted the Native American Heritage Commission (NAHC) and requested a search of the Sacred Lands File. The search identified no results, and the NAHC recommended MBNMS contact the tribes. MBNMS sent letters to those tribes on the provided contact list on June 24, 2016 (including members from the Esselen Tribe of Monterey County, Costanoan Rumsen Carmel Tribe, Ohlone/Costanoan Esselen Nation, Amah Mutsun Tribal Band, and Indian Canyon Mutsun Band). In response to the MBNMS letter, Irene Zwierlein from the Amah Mutsun Tribal Band of Mission San Juan Bautista requested additional information including whether a records search had been completed and the name of the consulting archaeologist. On behalf of MBNMS, Environmental Science Associates responded by email.

MBNMS completed follow up phone calls on March 16, 2017. MBNMS spoke with the Tribal Council Woman of the Ohlone/Costanoan Esselen Nation who requested that the letters and project location maps be resent. MBNMS also spoke with the Chairperson of the Amah Mutsun Tribal Band who was interested in project components north of the Salinas River.

Environmental Science Associates prepared a Cultural Resources Report that was included in a March 28, 2017 letter to the California State Historic Preservation Officer (SHPO) requesting concurrence on Section 106 compliance and a finding of "no adverse effect to historic properties"

for the MPWSP. The request included a description of the project location, the project objectives and need, a project description, a description of the methodology employed for the identification of historic properties, a definition of the area of potential effect (APE), the results of the record searches, a description of the field surveys and Native American consultations that were conducted for the proposed project, as well as a determination of effects. In a letter dated May 3, 2017, following review by the Office of Historic Preservation staff, the SHPO found no objections to the APE as defined by MBNMS (pursuant to 36 CFR 800.4(a)(1)), found MBNMS has documented a reasonable and good faith effort to identify historic properties within the APE (pursuant to 36 CFR 800.4(b)), and pursuant to 36 CFR 800.5(b) concurred with MBNMS that the proposed undertaking will result in no adverse effect to historic properties.

7.1.4 Coastal Zone Management Act Federal Consistency Review

The federal consistency requirement set forth in Section 307 of the Coastal Zone Management Act (CZMA) requires that activities approved or funded by the federal government that affect any land or water use or natural resource of a state's coastal zone, must be consistent with the enforceable policies of the state's federally approved coastal management program.

Under Section 307 of the CZMA (16 U.S.C. §1456), activities that may affect coastal uses or resources that are undertaken by federal agencies, require a federal license or permit, or receive federal funding must be consistent with a State's federally approved coastal management program. California's federally approved coastal management program consists of the California Coastal Act, the McAteer-Petris Act, and the Suisun Marsh Protection Act. The California Coastal Commission implements the California Coastal Act and the federal consistency provisions of the CZMA for activities affecting coastal resources outside of San Francisco Bay. Subpart D of the federal consistency regulations governs consistency review for activities requiring a federal license or permit. This section requires the applicant to conduct any required consistency review with the state coastal commission, and provide the Federal permitting agency with a consistency certification.

The Coastal Commission considers an application for a coastal development permit to cover the requirement for an applicant submitting a consistency certification to the Coastal Commission if the activity is located in state waters. Typically, the Coastal Commission will provide its response (concurrence, conditional concurrence, or objection) in its staff report for the coastal development permit.

CalAm is currently in discussions with the California Coastal Commission. In addition, a preliminary assessment of project consistency with the enforceable policies of the California Coastal Commission's coastal management program is provided in some of the resource sections within Chapter 4 to facilitate the analysis of potential impacts in these resource areas. The California Coastal Commission will make the final decision as to whether the proposed project is fully consistent.

7.2 EIR/EIS Preparers

National Oceanic and Atmospheric Administration, Monterey Bay National Marine Sanctuary

Karen Grimmer and Bridget Hoover (and Vicki A. Hill, NEPA Consultant)

CHAPTER 8
Comments and Responses on the Draft EIR/EIS

8.1 Introduction

On January 13, 2017, the CPUC and MBNMS (the CEQA and NEPA lead agencies, respectively, sometimes jointly referred to as the Lead Agencies) published and distributed the Notice of Availability (NOA) of the Draft EIR/EIS for the MPWSP, soliciting both written and oral comments on the Draft EIR/EIS by local, state, and federal agencies and by interested organizations and individuals for a 45-day public comment period starting January 13 and ending February 27, 2017. At the request of several agencies and members of the public, the Lead Agencies extended the comment period by an additional 30 days, and written comments on the Draft EIR/EIS were accepted through March 29, 2017. The Lead Agencies held a public hearing for the receipt of oral and written comments on the Draft EIR/EIS on February 16, 2017. The Lead Agencies received approximately 82 comment letters, plus 2 form letter submissions, sent through mail, hand-delivery, or email, as well as approximately 18 oral comments made to staff at the public hearing. On November 9, 2017, subsequent to the close of the Draft EIR/EIS comment period, Marina Coast Water District submitted additional comments to the Lead Agencies.

This chapter includes all written and oral comments received during the public comment period on the Draft EIR/EIS, and provides responses to all comments that address issues relevant to the EIR/EIS. Although several written comments were received late, they are responded to in this Final EIR/EIS.

This chapter fully complies with CEQA and NEPA provisions regarding response to Draft EIR/EIS comments. CEQA Guidelines Section 15088 requires lead agencies to evaluate comments on environmental issues and prepare a written response. According to Guidelines Section 15088(c), the "written response shall describe the disposition of significant environmental issues raised (e.g., revisions to the proposed project to mitigate anticipated impacts or objections). In particular, the major environmental issues raised when the lead agency's position is at variance with recommendations and objections raised in the comments must be addressed in detail giving reasons why specific comments and suggestions were not accepted. There must be good faith, reasoned analysis in response. Conclusory statements unsupported by factual information will not suffice."

40 CFR1503.4 establishes the following requirements for response to comments in a Final EIS:

(a) An agency preparing a final environmental impact statement shall assess and consider comments both individually and collectively, and shall respond by one or more of the means listed below, stating its response in the final statement. Possible responses are to:

(1) Modify alternatives including the proposed action.

(2) Develop and evaluate alternatives not previously given serious consideration by the agency.

(3) Supplement, improve, or modify its analyses.

(4) Make factual corrections.

(5) Explain why the comments do not warrant further agency response, citing the sources, authorities, or reasons which support the agency's position and, if appropriate, indicate those circumstances which would trigger agency reappraisal or further response.

(b) All substantive comments received on the draft statement (or summaries thereof where the response has been exceptionally voluminous), should be attached to the final statement whether or not the comment is thought to merit individual discussion by the agency in the text of the statement.

8.1.1 Responses to Comments Methodology and Organization

Responses to comments provided in this chapter address environmental issues raised during the review period. Responses are provided for each comment in the following sections. They are intended to provide clarification and refinement of information presented in the Draft EIR/EIS and, in some cases, to correct or update information in the Draft EIR/EIS. The text of the Draft EIR/EIS has been revised as appropriate in response to comments and to reflect new or updated information, and the revised text has been incorporated into the Final EIR/EIS in Chapters 1 through 7. Some of the text modifications are noted in Master Responses or individual responses to comments where necessary to discuss specific changes that have been made. Many places, the Master Responses or individual responses note that changes have been made to the text in Chapters 1 through 7, but the text of such changes is not set forth in the responses themselves.

8.1.1.1 Master Responses

Numerous comments on the Draft EIR/EIS raised common concerns or questions that are most appropriately answered or clarified in one comprehensive or “master” response. The Lead Agencies have provided Master Responses to address common concerns in Section 8.2. Individual comments related to these topics are referred to the pertinent Master Response. The Master Response topics include the following:

Master Response 1: EIR/EIS Authorship

Master Response 2: Source Water Components and Definitions

Master Response 3: Water Rights

Master Response 4: The Agency Act and Return Water

Master Response 5: The Role of the Hydrogeologic Working Group and its Relationship to EIR/EIS

Master Response 6: The Sustainable Groundwater Management Act

Master Response 7: The Deeper Aquifers of the Salinas Valley Groundwater Basin

Master Response 8: Project Source Water and Seawater Intrusion

Master Response 9: Electrical Resistivity Tomography (ERT) and Airborne Electromagnetics (AEM)

Master Response 10: Environmental Baseline under CEQA and NEPA

Master Response 11: CalAm Test Slant Well

Master Response 12: The North Marina Groundwater Model (v. 2016)

Master Response 13: Demand (Project Need) and Growth

Master Response 14: CEMEX Settlement Agreement

Master Response 15: Alternative Desalination Projects – Status, Information Sources, and Cumulative Scenario

8.1.1.2 Individual Responses

The Draft EIR/EIS comment letters, the public hearing transcript, and detailed responses to each comment are included in Sections 8.3 through 8.9, which organize comments and responses by category (Federal, State, and Local Agencies, Organizations, Individuals, Form Letters, and oral comments received at the public hearing). Within each category, letters are listed alphabetically. The comment letters appear first within each category, followed by a comprehensive set of responses. Comments have been delineated and numbered consecutively within each comment letter. Each individual comment is marked in the margin with the number of the comment and correlative response. Attachments to the Draft EIR/EIS comment letters and other supporting contents from the Draft EIR/EIS comment letters (e.g. resumes, product sheets, repeat form letters, etc.) are included in Appendix M. Where an individual comment is addressed by information in one or more Master Responses, the response refers to the Master Response(s). Where an individual comment is addressed by another individual response, the reader is referred to such other response to avoid duplication.

8.1.2 List of Commenters

Table 8-1 lists all agencies, organizations and individuals who provided written or oral comments on the Draft EIR/EIS. The table is organized by category (federal, state, and local agencies, organizations, individuals, and oral comments) and the section number where the comment and responses are located in Chapter 8.

8.2 Master Responses

8.2.1 Master Response 1: EIR/EIS Authorship

COMMENTS ADDRESSED IN MASTER RESPONSE 1

Ag Land Trust	Kathy Biala
California Unions for Reliable Energy (CURE)	Margaret-Anne Coppernoll
Citizens for Just Water	Juli Hofmann
Ford Ord Rec Users	

Several comments received on the Draft EIR/EIS appear to refer to CalAm as the author of the EIR/EIS, or represent that CalAm provided the analysis contained therein. For example, commenters assert that "CalAm erroneously represents," or that "CalAm states," or that "CalAm concludes" when referencing the EIR/EIS. This Master Response has been prepared to clarify that this EIR/EIS was prepared by the California Public Utilities Commission (CPUC) as the CEQA Lead Agency, by NOAA's Monterey Bay National Marine Sanctuary (MBNMS) as the NEPA Lead Agency, and by independent consultants under contract with these agencies, and not by CalAm, the project applicant.

CEQA Guidelines Section 15051(b) explains that if the proposed project is to be carried out by a non-governmental person or entity (like CalAm), the lead agency shall be the public agency with the greatest responsibility for supervising or approving the project as a whole. Under NEPA, the role of a federal lead agency is similar to the lead agency role under CEQA. See 40 CFR 1501.5. As explained in EIR/EIS Executive Summary Section ES.1, this EIR/EIS was prepared in accordance with CEQA (Cal. Pub. Res. Code §21000 et seq.), the CEQA Guidelines (Cal. Code Regs., Tit. 20, Div. 6, Ch. 3, §15000 et seq.), NEPA (42 U.S.C. §4321 et seq.,) and the NEPA implementing regulations (40 CFR Parts 1500-1508).

The analyses and conclusions in the EIR/EIS were prepared by the consultants on behalf of the Lead Agencies and were independently evaluated, reviewed, and revised by Lead Agency staff. See EIR/EIS Section 7.2 for a list that identifies consulting firms and individuals and their specific roles in the preparation of the EIR/EIS. Use of contractors is expressly approved under the NEPA regulations (40 CFR 1506.5). The analyses and conclusions in the EIR/EIS reflect the independent judgment of the Lead Agencies, and therefore, the CPUC and MBNMS are responsible for the scope, content, adequacy, and objectivity of the EIR/EIS.

8.2.2 Master Response 2: Source Water Components and Definitions

COMMENTERS ADDRESSED IN MASTER RESPONSE 2

City of Marina	David Beech
Marina Coast Water District	Kathy Biala
Monterey Peninsula Regional Water Authority	Margaret-Anne Coppernoll
Ag Land Trust	Myrleen Fisher
Citizens for Just Water	Juli Hofmann
Fort Ord Rec Users	Form Letter 2
Public Water Now	Public Meeting Verbal Comments
Water Ratepayers Association of the Monterey Peninsula	

Commenters have questioned the specifics of how the EIR/EIS uses key terms associated with and comprising the source water for the proposed desalination plant. This Master Response clarifies those definitions. The definitions also have been consolidated in Section 3.1, the introduction to the project description, to assist the reader.

To begin with, groundwater and ocean water can be described in simple geographic, locational terms as follows:

Groundwater: water located beneath the earth's surface

Ocean water: water located above the seafloor

In the context of the proposed MPWSP and for purposes of this EIR/EIS, of most importance is the chemical composition of any affected water. The reason for this is that the water chemistry indicates where the water came from (i.e., whether it started as groundwater or ocean water) and how usable it is for domestic and other purposes. The source water components are defined and used in the EIR/EIS as follows:

Fresh water: water that originated in a groundwater basin through precipitation or rivers and streams; in the context of the MPWSP, fresh water is water that originated within the Salinas Valley Groundwater Basin, identified as containing total dissolved solids (TDS) concentrations of less than 500 milligrams per liter (mg/L), consistent with the secondary drinking water standards established by the SWRCB in Title 22 California Code of Regulations, section 64449, as recommended levels of TDS.[1] TDS is the quantity of dissolved materials in a water sample and is used to quantify the amount of salts in a sample (it is a test for salinity).

Seawater: water that originated in the ocean, identified as containing 33,500 mg/L of TDS, which represents current salinity levels in Monterey Bay.

[1] "Constituent concentrations lower than the Recommended contaminant level are desirable for a higher degree of consumer acceptance." 22 Cal.Code Regs. 64449(d)(1).

Brackish water: water that is a combination of seawater and fresh water, and thus contains TDS levels between 500 mg/L and 33,500 mg/L.

Source water (also referred to as feed water): water that would be drawn into the proposed project slant wells and conveyed to the desalination facility. This water would be a combination of brackish groundwater representing the ambient conditions in the water-bearing sediments of the Dune Sand and 180-FTE Aquifers at the coast, and the seawater that is drawn in through the aquifer sediments to recharge the capture zone. The capture zone is the localized region that would contribute source water to the slant wells. (See Master Response 8, Source Water and Seawater Intrusion.)

The categories of fresh water, seawater, brackish water, and source water are consistent with the SWRCB's *Final Review of California American Water Company's Monterey Peninsula Water Supply Project*, included as EIR/EIS Appendix B2, which states on page 35 that "CalAm's proposed MPWSP would pump seawater, brackish water, and possibly a fresh water component."

8.2.3 Master Response 3: Water Rights

COMMENTS ADDRESSED IN MASTER RESPONSE 3

City of Marina	Kathy Biala
Marina Coast Water District	David Brown
Ag Land Trust	Bob Coble
California American Water Company	Margaret-Anne Coppernoll
CEMEX	Myrleen Fisher
Citizens for Just Water	David Gorman
Fort Ord Rec Users	Jane Haines
Just Water	Juli Hofmann
Land Watch Monterey County	Thomas Moore
Public Trust Alliance	Hebard Olsen
Public Water Now	Nancy Selfridge
Salinas Valley Water Coalition and Monterey County Farm Bureau	Form Letters 1 & 2
Water Ratepayers Association of the Monterey Peninsula	Public Meeting Verbal Comments
Michael Baer	

This Master Response addresses comments concerning the likelihood that CalAm would possess water rights to support the proposed project. While the topic of water rights is a legal issue, a fact-based analysis is key to the ultimate legal conclusion of whether, under the developed water doctrine, CalAm could have appropriative rights to the portion of project source water that would be drawn into the slant wells from the Salinas Valley Groundwater Basin (SVGB or Basin). The EIR/EIS explored in detail the law and the pertinent facts as they have been amassed to date in Section 2.6, Water Rights, concluding that the Lead Agencies could determine that there is a sufficient likelihood of CalAm having rights to water for the project for the purpose of determining project feasibility. Many comments on the EIR/EIS addressed such subjects as the water rights legal framework, the facts to support the conclusions reached in EIR/EIS Section 2.6, and the conclusions as to whether the project would cause harm or injury to Basin water users. Given the wide variety of comments on water rights, the comments are summarized throughout this Master Response as to particular topics for ease of organization and clarity. In addition to this Master Response, also see Final EIR/EIS Section 2.6, Water Rights, which has been updated and refined in further response to comments on the topic. For a full understanding, this Master Response should also be read in conjunction with Final EIR/EIS Section 4.4, Groundwater Resources, and Master Responses 2, Source Water Components and Definitions; 4, The Agency Act and Return Water; 7, The Deeper Aquifers of the Salinas Valley Groundwater Basin; and 8, Project Source Water and Seawater Intrusion.

8.2.3.1 Purpose of EIR/EIS Water Rights Section

The water rights analysis in the EIR/EIS provides the Lead Agencies and members of the public with data upon which to assess the likelihood that CalAm will possess water rights because, if it appeared more likely that CalAm would not have such rights, then the project may be deemed infeasible. The function of the EIR/EIS analysis of water rights is not to definitively decide whether there are water rights to support the project, nor would a decision to approve the project function as a binding decision on CalAm's water rights. As stated in the Draft EIR/EIS on page 2-30:

> If the proposed project is approved and any dispute arises as to whether or not CalAm possesses legal water rights, such dispute likely would be resolved through court action. Naturally, however, if CalAm does not have the right to the supply water for the proposed project, the proposed project could not proceed and would thus prove infeasible. This section examines whether, based upon the evidence currently available, the CPUC could conclude that there is a sufficient degree of likelihood that CalAm will possess rights to the water that would supply the desalination plant such that the proposed project can be deemed to be feasible.

Numerous commenters state that CalAm would be unable to meet its burden of proof to establish water rights for the project in a court of law, and several commenters (opining both that CalAm does and does not have sufficient water rights) have included lengthy legal analyses on the water rights topic. In developing this Master Response and other responses to comments, as well as in refining EIR/EIS Section 2.6, the Lead Agencies have reviewed and considered all authorities cited. At the same time, the level of detail and certainty for a feasibility analysis within an EIR/EIS is not the same as the more exacting level of detail, proof and legal arguments that would pertain in a court challenge on water rights. In an EIR/EIS, there is room for disagreement among experts, with the Final EIR/EIS still concluding that the project can be deemed feasible for current purposes on a water rights basis due to substantial evidence that CalAm will possess rights to the water that would supply the desalination plant.

Some commenters urge that CalAm should have a burden of proof now to establish by a preponderance of the evidence that it will possess water rights sufficient to make the project feasible. Other commenters ask what standard applies to the question within the EIR/EIS as to whether CalAm will possess water rights for the project, and seek identification of the criteria that the Lead Agencies will use to determine whether the project is feasible as to water rights. The criteria for the feasibility analysis are set forth within EIR/EIS Section 2.6. The standard of review that the decision-making bodies would apply to the conclusion of the Final EIR/EIS on this project feasibility matter is whether substantial evidence in the record supports the water rights findings. This standard of review may be different than a standard of review in any judicial challenge to the water rights of CalAm to support the project.

8.2.3.2 Sequence of Approvals Vis-à-vis Water Rights

Numerous commenters express concern that the MPWSP project review and consideration process is proceeding without CalAm having secured water rights for the project, urging that water rights should first be established before the Lead Agencies consider approval of the project.

This position may reflect a misunderstanding of the nature of an appropriative right to "developed water" under water rights law. As explained in Draft EIR/EIS Section 2.6, on page 2-29, "no government agency will formally grant water rights to CalAm for the project." There is no state or local agency with authority to approve CalAm's water rights for the MPWSP. As stated on page 35 of the State Water Resources Control Board (SWRCB) report on water rights for the MPWSP (EIR/EIS Appendix B2, referred to as the "Report"), "No permit is required by the State Water Board to acquire or utilize appropriative groundwater rights." The rights to pump and use groundwater in California in a non-adjudicated basin (such as the SVGB) are established by actual diversion, pumping and use, and are governed by a long line of court cases. In the event that one or more parties believe that the extraction and use of groundwater by another party is inconsistent with the law, the concerned parties may initiate a civil action against the extracting party to contest the right of that party to take and use groundwater. As applied here, someone could bring a legal action against CalAm challenging the right of CalAm to use SVGB groundwater incidentally withdrawn by the slant wells for the desalination project. The substance of CalAm's legal claim to water rights is addressed in EIR/EIS Section 2.6, and in this Master Response in Section 8.2.3.4, below. Since under the legal construct, an appropriative right to developed water is a right that exists based upon the facts at hand, and need not be formally established in advance, there is no possibility for the Lead Agencies to insist that CalAm obtain or perfect water rights prior to project approval.

Commenters point out that the uncertainty concerning project water rights could inhibit MPWSP construction or operation, and possibly even make the project infeasible in the end. It is true that a water rights judicial challenge, if one were to ensue, could indeed impair the ability of the project to move forward and timely meet the project objectives. It would at this juncture be speculative for the Lead Agencies to forecast whether such a judicial challenge would be filed, when it would occur, whether an injunction would be issued to halt project progress, how long resolution of it would take and what the outcome may be of such an action. Any development project, and certainly any complex project such as the MPWSP, is subject to myriad legal hurdles on the permitting and judicial fronts. It is precisely because the Lead Agencies understand that water rights is a topic of considerable interest for the MPWSP that the EIR/EIS includes a robust discussion of water rights in an effort to ascertain whether it appears likely based on the evidence in the record that CalAm will have water rights such that the project can be deemed feasible. The fact that someone could challenge CalAm's water rights (and the possible effects of such a challenge) does not in and of itself make the project infeasible; however, it is a factor that can be considered by the decision-makers in determining whether the project is viable, cost effective, and can be timely implemented.

Commenters have asked what would happen if a court were later to determine that CalAm did not have legal rights to the Basin water withdrawn by the project slant wells, and whether CalAm or the Lead Agencies would bear liability if it turns out the SVGB is harmed. If it were later determined that CalAm did not possess legal rights to some portion of the water for the MPWSP, the MPWSP would have to be somehow redesigned or relocated to accommodate the specific ruling. As made clear above, the Lead Agencies are not formally deciding in the EIR/EIS or through their approval processes, nor do they have jurisdiction to do so, that CalAm possesses water rights for the project. Thus, if a court were to determine that CalAm did not enjoy such

rights, the Lead Agencies would not be involved in such proceeding and would not bear any liability for the outcome. It is not the place of the EIR/EIS to opine as to any liability that CalAm may or may not bear in such a circumstance. Note, however, that CalAm has proposed a mitigation measure (Mitigation Measure 4.4-3, set forth in Draft EIR/EIS Section 4.4.5.2 at page 4.4-74, and also discussed in EIR/EIS Section 2.6) whereby CalAm would take steps to avoid harm (possibly including improving well efficiency, providing a replacement water supply and/or compensating the well owner for increased costs) if the MPWSP is demonstrated to adversely affect existing neighboring active wells.

8.2.3.3 Authority and Expertise of SWRCB to Opine on Water Rights

As explained in EIR/EIS Section 2.6 and in Section 8.2.3.2 of this Master Response, in response to a written request from the CPUC for expert assistance in gauging CalAm's rights to water for the project supply, the SWRCB prepared a report concerning the legal framework applicable to and the factual basis needed for CalAm to possess water rights for the project. Some commenters have questioned the authority and expertise of the SWRCB to prepare the Report. The Report on page 58-59 (EIR/EIS Appendix B2) addresses this critique, in response to a similar comment on the draft Report, as follows:

> The State Water Board is the state agency with primary responsibility for the regulatory and adjudicatory functions of the state in the field of water resources. (Wat. Code, § 174.) The water right permitting and licensing system administered by the State Water Board is limited to diversions from surface water channels and subterranean streams flowing through known and definite channels. (See *id.*, § 1200.) But the State Water Board has other authority that applies to all waters of the state, surface or underground. This includes the State Water Board's water quality planning authority, which extends to any activity or factor affecting water quality, including water diversions. (*Id.* §§ 13050 subds. (e) & (i).), 13140 et seq., 13240 et seq.; see 44 Ops. Cal. Atty. Gen. 126, 128 (1964).)
>
> The State Water Board has broad powers to exchange information with other state agencies concerning water rights and water quality, and more specific authority to evaluate the need for water-quality-related investigations. (Wat. Code, §§ 187, 13163, subd. (b).) The State Water Board also has authority to conduct or participate in proceedings to promote the full beneficial use of waters of the state and prevent the waste or unreasonable use of water. (*Id.*, § 275.) This authority includes participation in proceedings before other executive, legislative, or judicial agencies, including the [California Public Utilities] Commission. (*Ibid.*) And the State Water Board's authority to promote the full beneficial use of water and prevent waste or unreasonable use applies [to] all waters the state, including percolating groundwater. (See, e.g., SWRCG Decision 1474 (1977.)
>
> The Water Code includes procedures for court references to the State Water Board, under which the State Water Board prepares a report on water right issues before the court. (Wat. Code, §§ 2000 et seq., 2075 et seq.; see *National Audubon Society v. Superior Court* (1983) 33 Cal.3d 419, 451 [these procedures are designed to enable courts . . . "to make use of the experience and expert knowledge of the board."]; *San Diego Gas & Electric Co. v. Superior Court* (1996) 13 Cal.4th 893, 914-15 [the Commission has broad authority including judicial powers].)

> Thus, it is well within the State Water Board's authority and consistent with the execution of its statutory responsibilities to report to the [California Public Utilities] Commission on matters related to rights to diversion and use of water, including diversions of percolating groundwater. The conclusions and recommendations in this Report are not binding on the [California Public Utilities] Commission, but provide a means for the [California Public Utilities] Commission to make use of the knowledge and expertise of the State Water Board.

8.2.3.4 Description of Supply Water

Numerous commenters questioned the following statement in the Draft EIR/EIS at 2-30:

> The proposed project (MPWSP) and Alternative 5a are designed to take supply water from the ocean via underground slant wells that draw water from the earth underneath the ocean.

Commenters pointed out that some of the screens through which project supply water would be pulled into the slant wells lie under coastal land along the ocean, rather than being located under the ocean itself. In recognition of this fact, the pertinent language has been altered as follows:

> The proposed project (MPWSP) and Alternative 5a are designed to take supply water via underground slant wells that would draw water from aquifers that extend underneath Monterey Bay, and at this location, would eventually be recharged primarily by seawater.

8.2.3.5 Water Rights Analysis and Conclusions

Legal Framework

As a threshold matter, consistent with CEQA and NEPA directives and norms, the EIR/EIS (including Section 2.6) presumes that CalAm would implement the project in full conformance with laws, regulations, contracts and other legal constraints. As explained in EIR/EIS Section 2.6, and based on the SWRCB Report, CalAm would not need to secure any particular right to the seawater that would enter the slant wells for the project. As to the portion of the source water that would originate from the Basin, CalAm would need an appropriative groundwater right to retrieve and use that water. The Report outlines the factual circumstances that would need to exist in order for CalAm to possess such water right: so long as no legal user of water is harmed as a result, CalAm could withdraw for the project water that would otherwise be unused. CalAm would have rights to that water because it would be classified as "developed water" (sometimes also referred to as "salvaged water"), meaning that the new potable water would not have existed absent CalAm's efforts and actions. EIR/EIS Section 2.6 delves into the application of available facts to these criteria, concluding it is likely that CalAm would have water rights for any portion of the supply water that originated from the Basin because: (a) the water that originated from the Basin that would enter the desalination system is not currently being put to beneficial use, and; (b) the project would not injure existing legal water users per the factors outlined in the Report.

It is important to note that an appropriative groundwater right cannot and does not exist unless and until water is actually pumped and used. "To constitute a valid appropriation, three elements must always exist: (1) the intent to appropriate water and apply it to a beneficial use; (2) the

actual diversion . . . from a groundwater basin; and (3) the application of water to a beneficial use within a reasonable time." Turlock Irr. Dist. v. Zanker,140 Cal.App. 4th 1047, 1054 (2006). This means that CalAm will not actually possess water rights to the incidental water that originated in the Basin until the project is underway, and also means that those who may desire to use that water in the future through appropriation do not currently possess rights to use water in any greater amount or different manner other than their current actions.

The subsections of this Master Response below further address comments received on the water rights analysis and conclusions.

Quality of Basin Water

Some commenters question or seek proof that any water withdrawn from the Basin by the slant wells is in fact unusable to legal water users. As explained in Master Response 2, Source Water Components and Definitions, four basic types of water are pertinent to the project. The first, seawater originating from the ocean, is not at issue for water rights purposes. The second type, fresh water, is water that originated in the SVGB and has a total dissolved solids (TDS) concentration under 500 milligrams per Liter (mg/L). The third type of water is brackish water, a mix of seawater and fresh water resulting from decades of inland seawater intrusion. The fourth is source water, which is water that is drawn into the slant wells and is a combination of ambient highly brackish groundwater in the Dunes Sand and 180-Foot Equivalent Aquifers and the seawater that would recharge the slant well capture zone. The proposed slant wells at CEMEX would extract source water. As explained in EIR/EIS Section 4.4.1, the Dune Sand and 180-FTE Aquifers along the coast are hydraulically connected to the Pacific Ocean and seawater within the 180-Foot Aquifer has intruded to a maximum of approximately 8 miles inland as inferred from chloride concentrations greater than 500 mg/L as reported by the Monterey County Water Resources Agency (MCWRA). The source water that could be drawn into the supply wells is thus of very little use for irrigation or for drinking. It is thus reasonable to conclude that the water that would be drawn into the wells, including the brackish water originating in the Dune Sand and 180-Foot Equivalent Aquifers, is unusable water in its current form. Because the source water is unusable at present, it is not foreseeable that such water has potential reasonable beneficial uses. The only way for such water to become usable in any meaningful quality and quantity would be for such water to be desalinated in the same or a similar manner to the proposed project (see Section 8.2.3.7, below, for discussion of that possibility). Furthermore, as discussed in EIR/EIS Section 2.6, and further below, evidence indicates that any existing legal users of the brackish water would not be injured by the project.

The physical effects of the slant wells withdrawing the source water were projected using a calibrated groundwater model, as explained in EIR/EIS Section 4.4.4.2. See also Master Response 12, North Marina Groundwater Model (v.2016). Slant wells would initially extract the water that exists in the surrounding sediments (ambient brackish groundwater). As pumping continues, the wells would extract increasing proportions of infiltrating recharge from the ocean. The steady ocean recharge would gradually replace the ambient groundwater within the capture zone, and move within the capture zone toward the wells, but would not advance beyond the capture zone. For more information on these technical aspects of the project, see Master

Responses 8, Project Source Water and Seawater Intrusion. Given the inland groundwater gradient and the localized extent of the capture zone, the geographic extent within which water quality would be affected, would be a limited area confined to the coast and slightly inland (see Figures 8.2.8-5 and 8.2.6-4).

Commenters have questioned the conclusions of the water rights analysis in light of the sentence in Draft EIR/EIS Section 2.6 on page 2-34, that states that the groundwater modeling "cannot project the amount of Basin water that is expected to be drawn into the wells." It is true that the North Marina Groundwater Model cannot predict water quality, and is designed to show changes in water levels. The precise amount of fresh water (as a component of brackish water) that would be withdrawn by the slant wells is not a deciding factor as to whether CalAm would possess rights to the Basin water withdrawn. The SWRCB Report itself, at page 36, acknowledges that "the State Water Board is unable to estimate what percentage or proportion of water extracted from the Basin landward of the proposed well location could be attributed to fresh water sources." Yet the Report concludes at page 38, even with such uncertainty, that CalAm could possess rights to use Basin water for the project so long as "no other legal user of water is injured in the process." Thus, the question at hand is one of injury to existing legal water users. The modeled assessment of the drawdown effects of the project on aquifer levels appear sufficient for assessing injury without knowing how much of the withdrawn brackish water would consist of ocean water and how much would comprise fresh water. In any event, however, the Hydrogeologic Working Group has completed a work product that does help answer this query (EIR/EIS Appendix E3) and it is addressed in detail in Master Response 4, The Agency Act and Return Water.

Surplus Water

Commenters state that the brackish water drawn into the project slant wells would not automatically or necessarily be classified as surplus water in the water rights rubric. One argument is that such degraded water can still be used for "minor irrigation and dust control" and could be used by another possible desalination plant in the future. To the contrary, it does appear that such water can be properly characterized as surplus water. As the SWRCB Report states on page 35, "[B]ecause groundwater in the Basin is in a condition of overdraft, the only way to show there is surplus water available for export to non-overlying parcels is for a user to develop a new water source." The analysis and conclusion of EIR/EIS Section 2.6 are centered on exploring whether CalAm would have a right to Basin water on the basis of developing the water supply. As also stated in the Report (in footnote 65 on page 47), "Water that is currently unusable, both due to its location in the Basin and corresponding quality, could be rendered useable if desalinated and would thus be surplus to current water supplies in the Basin." Any water that is currently used for minor irrigation and dust control could continue to be so used and would not constitute surplus water. Section 4.4, Groundwater Resources, together with Section 2.6, Water Rights, indicate that the project would not harm such existing legal water users. Any possible future desalination plant does not currently possess appropriative groundwater rights because such plant has not already created a new water supply out of unusable surplus water, so it need not be considered in the pertinent water rights equation (but see the Effects on Marina Coast Water District subsection of this Master Response below).

Commenters criticize the water rights analysis for considering the usability of the brackish water that would make up a portion of the source water; they maintain that the Agency Act and County Ordinance 3709 do not differentiate between groundwater (no matter its quality) and "usable groundwater." However, the water rights evaluation is based upon the SWRCB Report, which does focus upon the quality (or usability, as discussed above) of the water withdrawn. The consistency of the project with the Agency Act and County Ordinance 3709 is a separate topic addressed in Master Response 4, The Agency Act and Return Water. Some commenters opine that the term "incidentally extracted useable groundwater" as used on page 40 of the Report in the Agency Act consistency discussion is different than the term "fresh water" (that may be contained within project source water) used in the EIR/EIS. However, the Report does repeatedly use the term "fresh water" in discussing the water that would be returned to the Basin as part of the project. It seems clear that the Report intended those terms to be interchangeable.

Commenters note that overlying Basin water users have been complying with Ordinance 3709 precluding pumping from the 180-Foot Aquifer and that the lack of use of such water should not classify it as "abandoned" water available for the project. However, EIR/EIS Section 2.6 does not depend on the unusable groundwater being "abandoned" to establish CalAm's rights to the source water. Some commenters further state that overlying users have voluntarily refrained from using groundwater when, in fact, they were precluded by Ordinance 3709 from doing so, and could not have used the water for domestic purposes due to its quality. In any event, the water rights analysis is based on the actual use and quality of any non-seawater withdrawn by the supply wells rather than the intent of overlying users.

Harm or Injury

A critical element of inquiry explored within EIR/EIS Section 2.6, and discussed throughout this Master Response, is harm or injury. As noted, CalAm may possess legal rights (on a developed water basis) to pump and use water that originated from the Basin so long as existing legal water users are protected from harm. Certain commenters claim that there is no substantiation for the conclusion in the water rights analysis that the project will not cause harm. However, as detailed in EIR/EIS Section 2.6, the findings related to harm or injury to groundwater users are based primarily upon the scientific analysis set forth in EIR/EIS Section 4.4, and the validated groundwater modeling that has been conducted for the project (as well as pertinent master responses). Section 2.6 does not merely apply the groundwater resources significance thresholds, but considers and applies each of the elements of possible injury to water rights as specified in the SWRCB Report. That Report was plainly based upon and grounded in legal precedent defining harm or injury.

Commenters stress the need for the water rights analysis to consider the effect of the diminution of water quality in the vicinity of the CEMEX property. EIR/EIS Section 4.4, together with Master Response 8, Project Source Water and Seawater Intrusion, explain that the diminution in water quality in the very local area of the CEMEX property would be of limited extent such as to not affect existing groundwater wells.

Some commenters state that the water rights analysis focuses on individual well owners, but fails to consider potential impacts on the region and its aquifers, alleging that "harm" and injury" are too narrowly defined and that any compensatory actions or mitigation measures should also include other stakeholders, such as MCWD, the City of Marina and the Fort Ord community. As stated in EIR/EIS Section 2.6:

> The [SWRCB] Report specifies three categories of foreseeable injuries that conceivably could be experienced by overlying water users within the area of influence of the MPWSP supply wells: "(1) a reduction in the overall availability of fresh water due to possible incidental extraction by the MWPSP; (2) a reduction in water quality in those wells in a localized area within the capture zone; and, (3) a reduction in groundwater elevations requiring users to expend additional pumping energy to extract water from the Basin." Report at 45.

It is not clear that MCWD or the City of Marina (as entities) have overlying water rights, so the harm inquiry directed by the Report above may not even apply. In any event, EIR/EIS Section 2.6 finds it reasonable to conclude that harm would not accrue to current groundwater users within the area where water levels could decline by 1 to 5 feet as a result of the project. Logically then, water users located more distant from the project slant wells, where water levels would decline by less than 1 foot (if at all), should be protected from harm or injury. Furthermore, EIR/EIS Section 4.4, fully examined more regional issues such as seawater intrusion, depletion of aquifer volume and reduction of groundwater quality, concluding in each respect that the project would not generate a significant environmental effect. While the CEQA/NEPA and water rights inquiries are not identical, the thresholds of significance employed in EIR/EIS Section 4.4 are such that application of them to the change effected by the project would encompass any resulting harm or injury.

In a similar vein, commenters state that taxpayers have invested in the improvement of the SVGB and efforts to ensure a long term, sustainable water supply, and that the proposed project would be adverse to such investments. With a similar response, the EIR/EIS demonstrates that no harm will accrue to the legal users of groundwater within the SVGB.

Waste of Water

At least one commenter linked the analysis of water demand in EIR/EIS Sections 2.1 – 2.5 with the topic of water rights, maintaining that any project supply of water in excess of the water supply needs of current water users would be a prohibited "waste" of groundwater. It is not expected that the project would produce more desalinated water than would be supplied to CalAm current and future customers. Thus, it is expected that no water would be wasted. To the extent that project water may be employed by new users or to support new land uses (such as legal lots of record or growth that has been envisioned by pertinent local general plans), it seems logical to assume that such water use would be a "reasonable and beneficial use" under the California Constitution aimed at preventing waste or unreasonable use of water.

8.2.3.6 Return Water

CalAm proposes as part of the project to return to the Basin the amount of fresh water that is contained within the brackish water withdrawn by the slant wells, by providing desalinated product water to CCSD and CSIP, in-lieu of CCSD and agricultural users pumping an equal amount of groundwater; see EIR/EIS Section 2.5.1. One purpose of the return water is to allay concerns over project compliance with a state law that precludes SVGB water from being removed from the SVGB. See Master Response 4, Agency Act and Return Water. Some commenters maintain that this return water component of the proposed MPWSP is a prerequisite to a conclusion that the project would enjoy water rights. Other commenters opine that water rights would exist without the return water component because the project generates no harm to existing legal water users that needs to be addressed through return water. The purpose of the return water element of the project is not to alleviate or address any environmental effects, and it is true that as to water rights, no harm has been shown to exist that the return must ameliorate. The return water is proposed to be returned to the same groundwater basin from which the fresh water component of the withdrawn brackish water would be derived; as such, the Basin would enjoy the benefits of such fresh water so as to stay in balance from a fresh water perspective. In any event, however, the question of whether the return water element is required to establish water rights is academic since the proposed project does include the return water elements and the project as a whole (rather than its individual parts) is the topic of the EIR/EIS and the water rights conclusions.

Certain commenters maintain that the return water component of the project is needed in order to establish water rights because of the water quality harm they state that the project would generate. The assertion is based on analysis in EIR/EIS Section 4.4 concerning changes in groundwater quality that could occur in the immediate vicinity of the slant wells and within the capture zone. There are no active wells constructed in the Dune Sands and 180-FTE Aquifers within the projected capture zone such that no existing legal water users would suffer harm. Furthermore, as noted above, the project considered as a whole does include the return water component such that the project would appear to be feasible from a water rights standpoint even if the return water element were critical to such conclusion.

8.2.3.7 Effect on Marina Coast Water District

Commenters express concern that the project will impair MCWD's ability to supply water on a long term, economic basis to the City of Marina and to Fort Ord, including through a possible future MCWD desalination plant. Some commenters state that the slant wells fall under the jurisdiction of MCWD, which is a public water agency. Many commenters appear to believe that MCWD owns, controls, or otherwise possesses legal rights to all groundwater within its service territory. This is not the case. To the extent that MCWD is currently appropriating water for its customers' beneficial use, MCWD certainly does possess the appropriative rights to such pumped water. As explained above in this Master Response, appropriative groundwater rights are based upon active use. They cannot be reserved in advance. The SWRCB Report at page 35 refers to "existing uses" and to "[p]otential overlying uses" as being implicated in a water rights analysis to demonstrate surplus water, but not to potential appropriative uses. Therefore, the fact that

MCWD may desire at some point in the future to use groundwater within the same aquifer or general location as does the proposed project, is not a factor that weighs into the current water rights inquiry for the project. Nonetheless, EIR/EIS Section 4.4.6 does contain a cumulative analysis of the combined effects of the MPWSP with a possible MCWD desalination plant. The analysis (which is necessarily of a fairly general, preliminary nature since no such MCWD plant is yet proposed) concludes that operation of both desalination projects would not adversely impact groundwater resources.

Commenters raise concerns that, in light of the dearth of water available to MCWD and its customers, and the needs of such current and future customers for a long term, sustainable water supply, it is illogical or unfair for the project to take any amount of water from the SVGB for the purpose of supplying water to CalAm's customers on the Monterey Peninsula. Such comments do not raise a water rights issue, but do engender a policy consideration that can be factored in and addressed by agencies considering approval of the project. Note that based on EIR/EIS Sections 4.4 and 2.6, and this Master Response, the proposed project would not cause significant impacts on groundwater quantity or quality in the Basin and it appears that the project would not harm current legal groundwater users. As to physical effects on MCWD's water source, please see Master Response 7, The Deeper Aquifers of the Salinas Valley Groundwater Basin, and Master Response 8, Project Source Water and Seawater Intrusion.

8.2.3.8 Implications of Annexation Agreement

In 1996, the MCWRA, the MCWD, the City of Marina, the owners of Armstrong Ranch, and then owners of the CEMEX property (RMC Lonestar) entered into an Annexation Agreement and Groundwater Mitigation Framework for Marina Area Lands ("Annexation Agreement"; MCWRA et al., 1996). The agreement established a framework for management of groundwater from the Basin and included terms and conditions for the annexation of lands (including the CEMEX properties) to MCWRA's benefit assessment zones as a financing mechanism to fund groundwater resource protection and reduction of seawater intrusion and to MCWD for water service.

Several commenters have raised the issue that Paragraph 7.2 of the Annexation Agreement limits CEMEX's (the successor owner of the Lonestar property and party to the Annexation Agreement) withdrawal and use of groundwater from the Basin to Lonestar's historical use of 500 acre-feet per year (afy). According to the comments, this same limitation should also apply to CalAm's right to pump groundwater from the CEMEX property. Many of the comments center on the argument that the Annexation Agreement was effective upon execution of the agreement by all parties in 1996, and therefore the limitations and restrictions apply to the proposed project. (Annexation Agreement, paragraph 7.2.)

The commenters are correct that the Annexation Agreement became effective on the date it was executed. It is not clear whether the parties to the Annexation Agreement are currently abiding by the agreement in that certain key objectives behind the agreement have not materialized (such as annexation of territory into MCWD). It does appear, though, that the more supportable position based upon the terms of the Annexation Agreement alone is that the 500 afy limitation on

CEMEX pumping groundwater from its property did also become effective on the effective date of the Annexation Agreement. EIR/EIS Section 2.6.4 has been revised to reflect this information.

Notwithstanding that conclusion, the commenters erroneously focus on the Annexation Agreement as a basis to argue that CalAm is restricted from withdrawing and using more than 500 afy of groundwater for the project. The parties to the Annexation Agreement whose water rights were implicated were all property owners, and the agreement relates to each of their overlying rights and uses of pumped groundwater on their properties. The MCWD 2010 Urban Water Management Plan (section 3.2.1, page 14) confirms that Lonestar's historical water use of 500 afy was an overlying water right and use.

In contrast, CalAm is not an overlying property owner subject to the Annexation Agreement and its right to withdraw and use brackish water from the Basin for the proposed project would be an appropriative right, as discussed extensively above and in EIR/EIS Section 2.6. The law distinguishes between the right to use water under an appropriative right and an overlying right. For instance, "[t]he overlying right . . . is associated with the ownership of land. Overlying rights are special rights to use groundwater under the owner's property. Appropriative rights, on the other hand, are not derived from land ownership but depend upon the actual taking of water." City of Santa Maria v. Adam, 211 Cal.App.4th 266, 278 (2006). A water rights legal treatise emphasizes this point as follows: "Unlike…overlying rights, [an] appropriative right is not dependent upon the ownership of real property. The right to use water under an appropriative right is distinct from the property through which the water flows or the land where the water is ultimately placed to beneficial use." 1 Slater, California Water Law and Policy (2017) § 2.16, at p. 2-102. Under these key distinctions, a non-property owner's right to water that is developed through pumping is an appropriative right. While it is true that the MPWSP would pump some water from the Basin through wells on CEMEX's property, CalAm is not the property owner and therefore does not have an overlying right to the groundwater. Accordingly, the limitations and restrictions in the Annexation Agreement apply only to CEMEX's use of the groundwater and would not apply to the proposed project.

Draft EIR/EIS Section 2.6.4 on page 2-41 stated that CalAm could conceivably employ an injection well on the CEMEX land to offset water pumped from the land so as to meet the requirements of the Annexation Agreement. Commenters have pointed out that such a strategy may not offset the amount of Basin groundwater withdrawn from the CEMEX land, and that such a concept was not studied in the Draft EIR/EIS. The critique is well taken and the language in Final EIR/EIS Section 2.6.4 has been amended to delete the suggestion.

8.2.3.9 Recirculation of Draft EIR/EIS

Certain commenters state that EIR/EIS Section 2.6 should be altered in various respects and then the Draft EIR/EIS should be recirculated for an additional round of public review and comment. In response to comments, some changes have been made to EIR/EIS Section 2.6. However, neither the methodologies employed nor the conclusions reached have changed in any way that implicates a significant environmental impact not identified in the Draft EIR/EIS, a substantially more severe significant environmental effect than indicated, or a new feasible alternative or

mitigation measure. Thus, there is no legal requirement based upon the water rights analysis to recirculate the Draft EIR/EIS.

8.2.4 Master Response 4: The Agency Act and Return Water

COMMENTERS ADDRESSED IN MASTER RESPONSE 4

City of Marina	Water Ratepayers of the Monterey Peninsula
Marina Coast Water District	Kathy Biala
Monterey Peninsula Regional Water Authority	Margaret-Anne Coppernoll
Monterey Peninsula Water Management District	Juli Hofmann
Citizens for Just Water	Hebard Olsen
Coalition of Peninsula Businesses	Larry Parrish
Fort Ord Rec Users	Form Letter 2
Land Watch Monterey County	Public Meeting Verbal Comments
Public Water Now	

This Master Response addresses comments concerning the proposed project's compliance with the Monterey County Water Resources Agency Act (Agency Act) and aspects of the proposed return water component of the MPWSP, including the allocation of the proposed return water to the Castroville Community Services District (CCSD) and to the Castroville Seawater Intrusion Project (CSIP). This Master Response also addresses comments on the amount of water required to be so allocated (or returned) in order to satisfy the Agency Act and to address project impacts, and discusses the likely percentage of water drawn through the proposed supply wells that would comprise the fresh water component of the source water. See Master Response 2, Source Water Components and Definitions, for definitions of all components of source water.

8.2.4.1 Agency Act Compliance and Location of Return Water

As explained in Draft EIR/EIS Section 2.6.3 on page 2-39, a state law known as the Agency Act created the Monterey County Water Resources Agency (MCWRA or Agency). Section 21 of the Agency Act is titled "Legislative findings; Salinas River groundwater basin extraction and recharge." Section 21 provides in pertinent part:

> The Legislature finds and determines that the Agency is developing a project which will establish a substantial balance between extraction and recharge within the Salinas River Groundwater Basin. For the purpose of preserving that balance, no groundwater from that basin may be exported for any use outside the basin . . .

In order to satisfy the Agency Act, CalAm has proposed that it will calculate annually (based on the total dissolved solids (TDS) concentration of the water being drawn through the slant wells) the percentage of supply water that originated in the Salinas Valley Groundwater Basin (SVGB, which is the same as the Salinas River Groundwater Basin) as fresh water, i.e., the fresh water component of the brackish water drawn by the slant wells. CalAm would then "return" to the SVGB that same amount of water by providing desalinated product water to CCSD and CSIP. As a result, the amount of fresh water that was drawn into the slant wells would be devoted to domestic and agricultural uses in lieu of CCSD and agricultural users pumping and using an equal amount of groundwater within the SVGB. Draft EIR/EIS Section 2.6.3 evaluates the likelihood

that the project would comply with the Agency Act, concluding on page 2-40 that "it appears at least preliminary reasonable to conclude that the project would be consistent with the Agency Act and the Ordinance [prohibiting groundwater extractions at a particular depth] such that those laws would not impair project feasibility."

Commenters expressed concern over the fact that the water returned to the Basin through provision of it to CCSD and to CSIP would be in a different location than the place from which the water was withdrawn. Specifically, commenters question how returning water to Castroville would benefit the water source for MCWD and state that the project would not return pumped groundwater directly to the Basin. Section 21 of the Agency Act pertains quite plainly to the "Salinas River Groundwater Basin" and states that "no water **from that basin** may be exported for any use outside the basin . . ." (emphasis added). The molecules of fresh water that would be drawn by the slant wells would have come from the SVGB. Likewise, CCSD currently pumps groundwater from the SVGB and that would be replaced by desalinated water supplied to CCSD, and agricultural users currently pump groundwater from the SVGB that would be replaced by desalinated water supplied to CSIP. The return water would be used in lieu of pumping groundwater directly from the SVGB. Thus, even though the withdrawal and the return may occur in different areas of the SVGB (roughly 4.5 miles apart), both would be within the same basin that is the subject of Agency Act Section 21. Concerning MCWD specifically, its water source is the SVGB. The relationship of the "Marina Subarea" defined by MCWD to the hydrogeographic unit of the SVGB is discussed in Master Response 6, The Sustainable Groundwater Management Act. The Agency Act concerns itself only with the SVGB as a whole, and does not regulate use of SVGB water based upon any geographic locale or administrative jurisdiction within the overall SVGB.

Furthermore, as discussed in EIR/EIS Section 2.6.3 and included as EIR/EIS Appendix B2, the SWRCB opined on page 40 of its *Final Review of California American Water Company's Monterey Peninsula Water Supply Project* ("Report") that because "the Project as proposed would return any incidentally extracted usable groundwater to the Basin … , it does not appear that the Agency Act or the Ordinance [3709] operate to prohibit the Project." Pages 39 to 40 of the SWRCB Report noted that while the word "export" is not defined in the Agency Act, "limitations on export ordinarily are not interpreted to apply to situations where the conveyance of water to areas outside a watershed or stream system is accompanied by an augmentation of the waters in that area, so there is no net export." The Report specifically stated on page 39 that the return may be through the CSIP (the return to CCSD had not been identified when the Report was drafted), supporting the notion that the return locale need not be within a particular radius of the slant wells so long as it occurs within the SVGB.

Several commenters noted that the SWRCB Report assumed that the screens for the slant wells would be located solely under the ocean, with none being located inland of the mean high tide line. Regardless, the SWRCB's evaluation of Agency Act compliance assumes that the project would withdraw some usable groundwater (i.e., fresh water) from the SVGB. In addition, the EIR/EIS both acknowledges and assumes that some of the water withdrawn by the slant wells would indeed be brackish water containing fresh water molecules subject to the return component

of the project because they originated in the SVGB. The conclusions of the EIR/EIS Section 2.6.3 analysis concerning whether the Agency Act would impair project feasibility need not be altered.

Some commenters asked whether the MCWRA has agreed that the Agency Act does not preclude project viability. It is noteworthy that MCWRA (a party to the CPUC proceeding on the project) agreed to and executed the June 14, 2016, MPWSP Desalination Return Water Settlement Agreement. That Settlement Agreement, the terms of which are incorporated into CalAm's MPWSP proposal, sets forth the return water construct as to how the return water amount would be calculated and the provision of the return water to CCSD and CSIP. The Settlement Agreement does state that CalAm shall comply with the Agency Act and that the agreement does not alter or affect MCWRA's authority under the Agency Act. Nonetheless, the fact that MCWRA is a party to the Return Water Settlement Agreement indicates some level of endorsement by MCWRA of CalAm's plan for Agency Act compliance through the proposed return, as well MCWRA's acknowledgement that Ordinance 3709 would not impair the project.

8.2.4.2 Required Amount of Return Water

Certain commenters maintain that new test well and groundwater monitoring data indicate that the proposed one-to-one return water ratio is insufficient to offset impacts on the Marina Subarea of the SVGB. For a discussion of the Marina Subarea, see Master Response 6, The Sustainable Groundwater Management Act. See Master Response 11, CalAm Test Slant Well, for information on test slant well data, and Master Response 8, Project Source Water and Seawater Intrusion, together with Section 4.4, Groundwater Resources, concerning impacts to groundwater resources. The project envisions returning to the Basin precisely the same amount of desalinated water as the amount of fresh water that is withdrawn (as a component of brackish water) by the slant wells. None of the commenters articulate precisely why a ratio different than one-to-one should be employed, nor do they indicate what ratio would be more appropriate. It is noteworthy that while the fresh water component of the source water (the amount subject to the return proposal) would be mingled with ocean water within the withdrawn brackish water (and could be separated only through the use of a desalination technology), the water returned to the SVGB in lieu of an equal amount of groundwater pumping would be desalinated, and fully potable water.

8.2.4.3 Anticipated versus Actual Amount of Return Water

Certain commenters requested further discussion of the anticipated annual volume of water that would be returned to the SVGB. While a range of annual volume of water to be returned to the SVGB was assumed in order to analyze the anticipated impact of the proposed intake system, the actual volume of return water would be calculated annually using actual water quality data from the production wells, as specified in the 2016 Return Water Settlement Agreement. Both the Settlement Agreement calculation method and the modeling estimation procedures are discussed below.

2016 Settlement Agreement Return Water Calculation Method

The method of calculating the specific volume of annual return water is set forth in Section H of the Settlement Agreement, which states the following:

> The Project's slant intake wells are designed to produce source water for treatment by the selected desalination plant ("Project Source Water Production"). To meet applicable requirements of the Agency Act, CalAm has proposed as part of the Project to make available for delivery to groundwater users overlying the SVGB a volume of water ("Return Water") equal to the percentage of SVGB groundwater in the total Project Source Water Production, as calculated on a water year basis and determined by the Agency.

The formula for calculating the annual volume of return water is described in the Settlement Agreement, Appendix D Base Return Water Obligation Methodology. The equation is as follows:

> (seawater salinity) x (percentage of seawater) + (inland water salinity) x (percentage of Salinas Basin water) = (brackish water salinity)

The formula is aimed at establishing the percentage of the project source water that represents the fresh water component (i.e., inland water per the formula) of the brackish water withdrawn by the slant wells.

The Settlement Agreement establishes as constant values that the measured seawater salinity in Monterey Bay (analyzed as TDS) is 33,500 milligrams per liter (mg/L) and the fresh (i.e., inland) water salinity is 500 mg/L. The brackish water salinity would be measured annually in the source water from the slant wells. Inserting the agreed-upon salinity concentrations:

> 33,500 x percentage of seawater + 500 x percentage of inland water = source water salinity

Since the sum of both percentages must be 100 percent, or 1, the percentage of inland water would be 1 minus the percentage of seawater. Inserting this value:

> 33,500 x percentage of seawater + 500 x (1- percentage of seawater) = source water salinity

Rearranging the equation provides:

> [33,500 x percentage of seawater] + 500 - [500 x percentage of seawater] = source water salinity
>
> or
>
> 33,000 x percentage of seawater = source water salinity - 500

Simplifying the equation provides:

> Percentage of seawater = [source water salinity - 500] / 33,000

The percentage of return water would be 1 minus the percentage of seawater, yielding:

> Percentage of return water = 1 - [(source water salinity - 500) / 33,000]

For example, if the salinity of the source water were measured at 31,076 mg/L, then:

> Percentage of return water = 1 - (31,076 - 500 / 33,000) = 0.074 or 7.4 percent return water

Hydrogeologic Working Group Evaluation of Return Water Estimates

As discussed in Master Response 5, The Role of the Hydrogeologic Working Group and its Relationship to the EIR/EIS, referred to as the Technical Group in the 2013 Large Settlement Agreement, was tasked with reaching "…agreement among the Technical Group about the studies, well tests, field work, modeling, monitoring, and other data analyses most appropriate to assess and characterize whether and to what extent the proposed operation of the MPWSP may adversely affect the SRGB [Salinas River Groundwater Basin] and the water supply available to legal water users thereof ("Hydrogeologic Study")."

Included in the tasks performed by the Hydrogeologic Working Group (HWG) was the evaluation of the methods and procedures used for developing the North Marina Groundwater Model (NMGWM). As described in Section 4.4.4.2, Groundwater Modeling, and Appendix E2, within the area to be modeled (model domain), the input parameters for the model included quantifying the volumes of water entering into the model domain from all sources (e.g., precipitation, seawater intrusion, agricultural return water, and infiltration from streams) and quantifying the volumes of water leaving the model domain (e.g., groundwater flow out of the model domain and agricultural pumping). The volume of return water is also an input parameter to the NMGWM because, although the return water would be extracted from and returned to the same basin, the location of the extraction (the slant wells) would not be the same as the location where the return water would be returned to the basin (CCSD distribution system or CSIP).

As previously discussed, the actual volume of return water would be calculated annually based on the salinity of the source water extracted by the slant wells, and would be expected to vary with time and season. Although the exact volume of return water would not be known prior to initiating the seawater extraction system, the return water volume was expected to be more than 0 percent but less than 12 percent, based on preliminary groundwater model runs and calculations. To account for the variable return water volumes, the 2016 version of the NMGWM (NMGWM^{2016}) was run with pumping scenarios that included representative return water volumes of 0, 3, 6, and 12 percent of the total source water volume. The HWG, as part of its Hydrogeologic Investigations, has since evaluated several approaches to return water estimates and has confirmed that the actual return water volume is expected to fall between 0 to 12 percent, as discussed below.

Return Water Estimates

As required by the 2013 Large Settlement Agreement and defined in the Hydrogeologic Workplan, the HWG was tasked with evaluating the test well study data, and ultimately preparing a report of its findings. The Technical Report prepared by the HWG (HWG, 2017; included in Final EIR/EIS as Appendix E3) includes two return water estimation methods. The first approach involves development of an analytical equation to describe mixing of water within the capture zone;[1] the second approach involves numerical modeling using the existing CEMEX Model. These methodologies are described further below. The Lead Agencies have independently reviewed the two methodologies and agree that the approaches and the input assumptions appear reasonable. The two methods – the Analytical Method and the CEMEX Model – confirm that the

[1] The capture zone is the localized region that would contribute source water to the slant wells. (See Master Response 8, Project Source Water and Seawater Intrusion).

range of 0 to 12 percent return water used in the EIR/EIS and the NMGWM^{2016} was reasonable. The HWG Technical Report (EIR/EIS Appendix E3) presents the calculated percentage of ocean water within the source water, referred to as the Ocean Water Percentage (OWP), in Section 2.2.3 and Appendix G of the report for each of the two methods. Since the OWP includes both the seawater in the source water as well as the seawater within the brackish water withdrawn by the supply wells, and in accordance with the formula in the Settlement Agreement, the return water percentage would be equal to 100 percent (or 1) minus the percentage of ocean water.

Calculation of OWP Using Analytical Method

This approach uses an analytical equation to calculate the percentage of ocean water based on the water and salinity budgets within the capture zone of the proposed slant wells. The water budget represents the steady-state inflows and outflows after equilibrium is reached from project pumping. The results show that equilibrium would be reached several months to a few years after the project pumping begins. The steady-state water inflows to the capture volume are seawater inflow from Monterey Bay and recharge from precipitation on the land surface overlying the capture zone. The steady-state water outflow from the capture zone is the pumping from the project wells.

The analytical method was generally calibrated by using the first 1.6 years (April 2015 through October 2016) of data collected from the test slant well and assumed groundwater gradients that were consistent with those used in the EIR/EIS and specifically within the NMGWM^{2016}. The major conclusions of the analytical method of calculating OWP, for the 6.4 mgd and the 9.6 mgd desalination facility options, are listed below:

- The long-term equilibrium OWP is estimated to range from 96 to 99 percent.
- Based on the range of assumptions considered, the continuous pumping time to reach 90 percent ocean water is estimated to range from about 4 months to 1.7 years.
- Based on the range of assumptions considered, the continuous pumping time to reach 95 percent ocean water is estimated to range from about 6 months to 3.1 years.

Thus, based upon the HWG calculations, the return water percentage is likely to be no more than 10 percent within the first 2 years of project slant well pumping, decreasing to no more than 5 percent within 6 months to roughly 3 years. Longer term, it appears that the return water percentage would be between 1 percent and 4 percent, well within the 0 to 12 percent range studied in the EIR/EIS.

Calculation of OWP Using CEMEX and North Marina

As discussed in Section 2.2.3.2 of the HWG Technical Report, the analytical method discussed above cannot accurately predict salinity in the early months of project pumping (prior to equilibration) because the capture zone is transient (i.e., it starts with a smaller area and increases with time until equilibrium is reached). Therefore, the CEMEX Model (see description in EIR/EIS Section 4.4.4.2, Groundwater Modeling) and NMGWM^{2016} were used to provide data to compare with the results of the analytical method. Use of the models allows for additional detail in the early months of the pumping scenarios since the CEMEX Model can provide transient

water quality data. The results for these early months of project pumping indicate a higher percentage of ocean water in the project source water than that predicted by the analytical method. As pumping continues, however, the results from the CEMEX Model and NMGWM^{2016} are consistent with the long-term pumping results from the analytical method. The analysis predicts that the percentage of ocean water will rise to 90 percent within 90 days of the initiation of full-scale pumping and the percentage of ocean water will reach 95 percent within 5 years.

Based upon calculation of the OWP using the groundwater models, it appears that the return water percentage would be no more than 10 percent within the first year of project pumping and would drop to no more than 5 percent within 5 years of project pumping.

Conclusion

In conclusion, both the analytical method and CEMEX modeling approaches to estimating the percent of return water confirm that the anticipated actual annual volume of return water could be 10 percent in the first few months of project pumping and would be no more than 5 percent within 5 years of project pumping. The 0 to 12 percent range used in the EIR/EIS and the NMGWM^{2016} is consistent with these conclusions, appears conservative, and no edits to the analysis relevant to return water presented in the Draft EIR/EIS are necessary.

8.2.5 Master Response 5: The Role of the Hydrogeologic Working Group and its Relationship to the EIR/EIS

COMMENTERS ADDRESSED IN MASTER RESPONSE 5

Marina Coast Water District	Charles Cech
Ag Land Trust	Bruce Delgado
Public Water Now	Margaret-Anne Coppernoll
Michael Baer	Jan Shriner
David Beech	Public Meeting Verbal Comments
Kathy Biala	

This Master Response discusses the background that led to the formation of the Hydrogeologic Working Group (HWG), identifies the members and the stakeholders each member represents, describes the roles and activities conducted by the HWG, describes the relationship of HWG work products to the CEQA/NEPA analysis, and discusses alleged conflicts of interest.

8.2.5.1 2013 Settlement Agreement

A Settlement Agreement was reached in 2013 wherein several parties to CPUC Proceeding A.12-04-019 affirmed their belief that, consistent with the Public Utilities Code Section 1002(a), the MPWSP would serve the public convenience and necessity. The 2013 Settlement Agreement was reached between California American Water Company (CalAm) and 10 parties, later expanded to 16 parties.[1] Parties to the 2013 Settlement Agreement represent diverse interests including: ratepayers, environmental groups, business groups, local government governments and government agencies, as well as other key stakeholders on the Monterey Peninsula. The Marina Coast Water District is a party to the proceeding, but is not a party to the 2013 Settlement Agreement. The City of Marina was not a party when the 2013 Settlement Agreement was executed and therefore, did not sign the 2013 Settlement Agreement; the City was granted party status in March 2017. Note that the 2013 Settlement Agreement is actually dated July 31, 2013, although it was submitted into the proceeding on August 6, 2013.

8.2.5.2 Establishment and Role of HWG

The HWG, referred to as the Technical Group in the 2013 Settlement Agreement, was established by the parties to the 2013 Settlement Agreement, and not by the CPUC. Within the Agreement, the parties with diverse interests agreed that CalAm's hydrogeologist and technical team would work with the Salinas Valley Water Coalition's (SVWC) and Monterey County Farm Bureau's

[1] CalAm, City of Pacific Grove, Coalition of Peninsula Businesses, County of Monterey, CPUC Division of Ratepayer Advocates (DRA), LandWatch Monterey County, Monterey County Farm Bureau (MCFB), Monterey County Water Resources Agency (MCWRA), Monterey Peninsula Regional Water Authority (MPRWA), Monterey Peninsula Water Management District (MPWMD), Monterey Regional Water Pollution Control Agency (MRWPCA), Planning and Conservation League Foundation, Salinas Valley Water Coalition (SVWC), Sierra Club, and Surfrider Foundation (collectively, the Parties)

(MCFB) assigned hydrogeologists, and other technical experts designated by CalAm. As stated in Section 5 of the 2013 Settlement Agreement, the purpose of the HWG is:

> …to reach agreement among the Technical Group about the studies, well tests, field work, modeling, monitoring, and other data analyses most appropriate to assess and characterize whether and to what extent the proposed operation of the MPWSP may adversely affect the SRGB [Salinas River Groundwater Basin] and the water supply available to legal water users thereof ("Hydrogeologic Study"). The 10 Parties agree that the purpose of this Section 5 is intended to avoid litigation regarding the scope of and methodology used to develop the Hydrogeologic Study and the Technical Report.

The Hydrogeologic Study's Work Plan and Technical Report are described further below in Section 8.2.5.4, HWG Activities and are included in EIR/EIS Appendix E3.

8.2.5.3 HWG Members

The HWG is a collaborative body and does not have an executive director, a manager, a chief hydrogeologist, or any other leader; all work is shared and openly peer reviewed by all HWG members. As previously noted, CalAm and the SVWC designated experts to represent their interests. The HWG members and the entities they represent are:

- The SVWC and the MCFB are jointly represented by Tim Durbin and Martin Feeney, as independent consultants.
- CalAm is represented by Peter Leffler (Ludorff and Scalmanini) and Dr. Dennis Williams, assisted by his staff at Geoscience Support Services (Geoscience).

HWG members are paid by the entities they represent.

Additional Participants at HWG Meetings

Other participants attended some or all of the HWG meetings, but not as formal members of the HWG. Independent consultant Barry Keller participated in some meetings on behalf of CEMEX, the property owner of the proposed source water intake site. Rich Svindland and Ian Crooks participated in some HWG meetings as additional representatives for CalAm. These participants were also paid by the entities they represent. MCWD did not have a representative on the HWG because it was not a signatory to the 2013 Settlement Agreement that established it. The City of Marina did not become a party to the proceeding until March 2017. The Monterey County Water Resources Agency (MCWRA) and the Monterey Peninsula Water Management District (MPWMD) were both settling parties and agreed to accept the SVWC and MCFB representation. Representatives from the MCWRA participated in one or two of the HWG meetings that were attended by members of the CEQA/NEPA team. In addition, the CEQA/NEPA team participated in the HWG, as described below.

8.2.5.4 HWG Activities

As previously noted, the parties to the 2013 Settlement Agreement agreed that the CalAm and SVWC/MCFB hydrogeologists and technical teams would develop a joint Work Plan to conduct

the Hydrogeologic Study described in Section 5 of the 2013 Settlement Agreement, for the proposed source water intake site consistent with the study recommendations presented in the State Water Resources Control Board's (SWRCB) July 31, 2013, Final Review of California American Company's Monterey Peninsula Water Supply Project (included as Appendix B2 in the EIR/EIS). The HWG did not consider administrative or political boundaries (e.g., city, county, or agency areas of jurisdiction), water rights issues, legal issues, or financial considerations.

The Work Plan is titled *Monterey Peninsula Water Supply Project, Hydrogeologic Investigation Work Plan* and dated August 2, 2013. The Work Plan was referenced in the Draft EIR/EIS in Section 4.4 Groundwater Resources. Section 5.2 of the 2013 Settlement Agreement also states that, "The Technical Group will review and evaluate the data and results of the Hydrogeologic Study, and will prepare a Technical Report presenting the findings and conclusions of the Technical Group." The HWG prepared the *Draft Monterey Peninsula Water Supply Project Hydrogeologic Investigation, HWG Hydrogeologic Investigation Technical Report*, dated July 27, 2017, which is referenced in and employed in the analysis of EIR/EIS Section 4.4, Groundwater Resources. The 2013 Work Plan as well as the 2017 Technical Report are included in the Final EIR/EIS in Appendix E3.

Although the Work Plan and the Technical Report are published by Geoscience since the Settlement Agreement states (at Section 5.1, pages 9 and 10) that CalAm will implement and carry out the Hydrogeologic Study, the work products (Work Plan and Technical Report) represent the collaborative work of the entire HWG, not merely Geoscience or CalAm.

The HWG developed the Work Plan as a collaborative plan of investigation to assess the hydrogeologic conditions in the project area. The Work Plan provided a phased approach to progressively investigate the hydrogeology and the potential effects of the project on aquifers from the use of subsurface slant wells for obtaining feedwater supply. The Work Plan described the Hydrogeologic Study approach and methodologies, including the purpose, locations, and methodologies for installing exploratory borings and monitoring wells; the purpose and methods for collecting and analyzing soil and groundwater samples; the aquifer testing methodology using the test slant well; the development of the conceptual model of site conditions; and the development of the groundwater models. The Work Plan was updated several times as new information became available. The final Work Plan, cited above, incorporated comments and recommendations by members of the HWG, and covered the investigative steps the HWG agreed were needed to consider the anticipated effects of the project. The final Work Plan became the hydrogeology investigation roadmap and resulted in the implementation of the fieldwork and modeling efforts conducted for the MPWSP.

8.2.5.5 Relationship to CEQA/NEPA Analysis

As described above, the HWG resulted from the 2013 Settlement Agreement with a purpose independent of the EIR/EIS. However, the topics addressed by the HWG overlap with some of the environmental topics and inquiries considered by the EIR/EIS, and the Lead Agencies were able to gain valuable data from the work of the HWG. The CEQA/NEPA team engaged with the HWG to observe the implementation of the Work Plan, to understand the test slant well data, and to take

advantage of the individual and collective knowledge of the HWG members to inform the CEQA/NEPA analysis of groundwater resources. The CEQA/NEPA team members that participated in HWG meetings were Eric Zigas and Michael Burns (Environmental Science Associates), Peter Hudson (Sutro Science), and John Fio and Steve Deveral (HydroFocus). The CEQA/NEPA team members attended 10 monthly meetings with the HWG between December 10, 2015, and January 27, 2017 in order to understand the results of the Hydrogeologic Study.

As the Hydrogeologic Study progressed, at each meeting attended by the CEQA/NEPA team, the HWG discussed the status and preliminary results for various tasks of the Hydrogeologic Study, enabling the CEQA/NEPA team to understand the preliminary and final results, and provided the opportunity to ask questions to clarify understandings and assumptions. Concurrently, the CEQA/NEPA team provided feedback to assist the HWG and the groundwater modelers in understanding the significance criteria to be employed in the EIR/EIS. The CEQA/NEPA team obtained feedback from the HWG as to the groundwater aquifer characterization and the groundwater modeling assumptions (this is noted in Footnote 34 on Draft EIR/EIS page 2-35). The HWG also reviewed and commented on the portion of the August 19, 2016, Draft North Marina Groundwater Model Technical Memo that was prepared by HydroFocus for the Lead Agencies and presented at the September 1, 2016, public Groundwater Modeling Workshop that was hosted by the CPUC in Carmel.

The primary topics discussed during the meetings attended by the CEQA/NEPA team included the ongoing test slant well monitoring results, characterization of the hydrogeologic baseline, the Monthly Reports prepared pursuant to the Coastal Development Permit Special Condition 11, the CEMEX Modeling being performed by Geoscience for CalAm, and the 2016 version of the North Marina Groundwater Model ($NMGWM^{2016}$) being utilized by HydroFocus for the Lead Agencies. Other topics discussed included: the December 2015 site visit to the Castroville Community Services District, and the Ag Land Trust wells; the approach to modeling sea level rise; scaling issues between the regional Salinas Valley Integrated Ground and Surface Water Model (SVIGSM), the $NMGWM^{2016}$ and the focused CEMEX model; model boundaries and boundary conditions; recharge and infiltration rates; the Seaside Basin divide; and Salinas Valley Return Water estimation methods.

The Lead Agencies prepared the EIR/EIS independent from the HWG, using independent judgment in evaluating the information provided by the HWG to help inform the EIR/EIS. The Lead Agencies considered and incorporated information and data generated by the HWG, as appropriate, into the EIR/EIS after subjecting it to peer review. The EIR/EIS impact analysis conclusions and mitigation measures were not shared or discussed with the HWG prior to January 2017 publication of the Draft EIR/EIS.

8.2.5.6 Potential Conflicts of Interest and Independent Judgment

Several commenters expressed concern that one or more conflicts of interest among the Lead Agencies and their consultants, the Applicant and its consultants, and the HWG may compromise the integrity of the CEQA/NEPA analysis and decision-making process. Three characterizations of potential conflicts of interest have been raised in comments:

1) that Dr. Dennis Williams, the President of Geoscience, holds one or more patents related to slant well technology that CalAm could or might use in the construction of the MPWSP;

2) that Geoscience, while under contract to the CPUC, also had a contractual relationship with CalAm, which raised concerns over the credibility and accuracy of the groundwater modeling, and concerns that the use of the NMGWM^{2016} does not reflect the independent judgment of the Lead Agencies; and

3) that the role of Geoscience, and of Dr. Williams in particular, on the HWG presented a potential or perceived conflict of interest with respect to the HWG work products and HWG input on information sources relied on in the EIR/EIS, and/or that HWG and Geoscience work products were relied on in a way that does not reflect the independent judgment of the Lead Agencies.

Although only the third item is directly related to the HWG itself, this section of Master Response 5 addresses these issues as well as the actions taken by the CPUC in response to these concerns. The second and third items are addressed together, as commenters have raised similar concerns about both Geoscience and the HWG, although they are not the same organization.

Financial Conflict of Interest Related to Patents

Dr. Williams, the President of Geoscience, is a member of the HWG and holds certain patents on slant well technology, specifically, the methodology for constructing the slant well subsurface feedwater supply system. Certain entities contacted the CPUC during the comment period for the 2015 MPWSP Draft EIR, and opined that having Geoscience conduct the project modeling and developing the design of the subsurface intake system using technology for which Dr. Williams holds the patents might constitute a conflict of interest. The opinions were that Dr. Williams would have a vested interest in the MPWSP using his technology and would gain financially by its use. Upon being apprised of the potential for a conflict of interest, a CPUC Administrative Law Judge (ALJ) issued a July 14, 2015, ruling in Proceeding A.12-04-019, requesting data from Geoscience and CalAm about patents held by Geoscience relating to the MPWSP.

Geoscience and CalAm both responded to the ruling in a document dated July 28, 2015 and titled *Response of Geoscience Support Services, Inc. to Administrative Law Judge's Ruling Requesting Data on Ratemaking and Geoscience Patents.* As explained in their responses, both parties maintained that Dr. Williams never intended to seek royalties or payments regarding his patent for slant wells in connection with the prior Coastal Water Project or the MPWSP, and no royalties were paid to Dr. Williams. Nevertheless, to provide the CPUC and CalAm customers with certainty on this issue, CalAm entered into a *Patent License and Non-Assertion Agreement* with Dr. Williams in his personal capacity and as president and owner of Geoscience. The agreement makes clear, as described in the Geoscience Response to Request No. 1f, "that Cal-Am, along with its contractors, the overseeing public entity, and end-users, are fully licensed to use, in connection with the MPWSP and for no additional charge, the technology that Geoscience has provided and is providing to CalAm . . . [P]er the terms and conditions of the Agreement, Geoscience and Dr. Williams have granted a royalty-free, fully paid-up license to make and use the slant well systems and methods . . . [A]lso per the terms and conditions of the Agreement,

Geoscience and Dr. Williams have covenanted not to assert . . . any claim of patent infringement respecting the slant well systems and methods being made and used as part of the MPWSP."

Geoscience Groundwater Model and Independent Review of Geoscience and HWG Work Products and Input

As noted in EIR/EIS Section 1.4.3, to address questions about the accuracy and credibility of the groundwater modeling performed by Geoscience (referred to as NMGWM^{2015}), the CPUC extended the public comment period on the April 2015 Draft EIR, made the groundwater data files available for public review, and employed the Lawrence Berkeley National Laboratory (LBNL) to conduct an independent evaluation of that data. In addition, the CPUC engaged with Monterey Bay National Marine Sanctuary (MBNMS, or Sanctuary) as co-lead agency and prepared an updated EIR/EIS that used an independent groundwater modeling consultant, HydroFocus, that had no prior connection to the MPWSP, as discussed below.

The results of LBNL's independent evaluation are provided in EIR/EIS Appendix E1, Section 2. As described therein, LBNL found that its simulation results matched Geoscience's results, which were presented in Appendix E2 of the April 2015 Draft EIR. LBNL's evaluation reproduced some of the groundwater modeling outputs exactly, while others showed small differences that can be attributed to computer round-off and cancellation errors. LBNL found that there were shortcomings in the Geosciences hydrostratigraphic model and simulation inputs that could potentially change the impact assessments. Chief among these was the absence of the Fort Ord-Salinas Valley Aquitard (FO-SVA), which hydraulically separates the Dune Sand and 180-Foot Equivalent (180-FTE) aquifers from greater than about 2 km east of the proposed extraction site.

Although the LBNL review indicated that the NMGWM^{2015} was correctly run and could be improved with the addition of input on the FO-SVA, in July 2015, the CPUC elected to terminate its relationship with Geoscience and proceed with the understanding that Geoscience's role was limited to being a consultant to CalAm, the Applicant. CalAm submitted the Geosciences model (NMWMG^{2015}) as applicant-provided information to the CPUC. The CPUC subsequently contracted with HydroFocus, a groundwater modeling consultant, to independently review, revise, and continue to develop and use the model for purposes of the revised Draft EIR/EIS. HydroFocus was selected because of its experience; because it had no existing or recent relationship with CalAm, Salinas Valley stakeholders, or any party to the CPUC proceeding; and because it would have no involvement with the design, construction, or operation of the MPWSP. As noted by HydroFocus in Section 1 of EIR/EIS Appendix E2, HydroFocus was charged with reviewing the NMGWM^{2015} to:

- Confirm reported hydraulic properties (horizontal and vertical hydraulic conductivity and specific storage), specified stresses (recharge and pumping), boundary conditions, and model-calculated groundwater levels and fluxes.
- Update the NMGWM^{2015} using new information from borehole, monitoring well, and slant well pumping test data (the update is referred to as the NMGWM^{2016}).
- Evaluate the NMGWM^{2016} by assessing history matching results (October 1979 through September 2011) and slant well pumping test results (April 2015 through January 2016).

- Employ the NMGWM^{2016} to calculate drawdown from proposed slant well pumping.
- Characterize sensitivity of the NMGWM^{2016} results to model assumptions and parameter values.

Revisions made to the NMGWM^{2015} by HydroFocus are described in EIR/EIS Appendix E2 at Section 3.0, specifically in Table 3.1, and were made independent from, but are consistent with, the LBNL recommendations. Thus, the credibility of the original model was confirmed by LBNL's independent review, and subsequently the accuracy of the groundwater modeling was improved as a result of the revisions made by HydroFocus.

The CPUC has properly exercised independent judgment under Public Resources Code section 21082.1(c)(3). A lead agency has the discretion to adopt materials that it chooses, such as those drafted by the applicant or its consultants, so long as the lead agency independently reviews, evaluates, and exercises judgment over that documentation and issues it raises and addresses. (*Friends of La Vina v. County of Los Angeles* (1991) 232 Cal.App.3d 1446; Pub. Resources Code, §21082.1, subd. (c); Cal. Code Regs., tit. 14, §15084, subd. (e).) The lead agency also has the discretion to resolve factual issues and to make policy decisions. As an example, "[i]f the determination of a baseline condition requires choosing between conflicting expert opinions or differing methodologies, it is the function of the agency to make those choices based on all of the evidence." (*Save Our Peninsula Committee v. Monterey County Board* (2001) 87 Cal.App.4th 99, 120; citing *Barthelemy v. Chino Basin Municipal Water District* (1995) 38 Cal.App.4th 1609, 1617.) Even if an entire EIR is initially prepared by the project applicant or a third party (such as the NMGWM^{2015} prepared by Geoscience as CalAm's consultant) and subsequently adopted by the lead agency, that does not mean that the lead agency failed to exercise its independent judgment. (*City of Poway v. City of San Diego* (1984) 155 Cal.App.3d 1037, 1042.)

Under NEPA regulations, materials may also be prepared by the applicant or a third-party contractor as long as the agency independently evaluates the information submitted and the agency is responsible for its accuracy (40 CFR § 1506.5).

Here, the Lead Agencies and their CEQA/NEPA experts relied on HydroFocus' superposition modeling report (Appendix E2); the Lead Agencies independently reviewed the report, and made an independent conclusion in the EIR/EIS about the proposed project's potential impacts on groundwater resources. It is irrelevant that Geoscience prepared the NMGWM^{2015}, or that the HWG reviewed and commented on the August 19, 2016, Draft NMGWM Technical Memo, because the analyses and the conclusions in the EIR/EIS reflect the independent judgment of the Lead Agencies.

8.2.6 Master Response 6: The Sustainable Groundwater Management Act

COMMENTERS ADDRESSED IN MASTER RESPONSE 6

City of Marina	Public Water Now
Marina Coast Water District	Margaret-Anne Coppernoll
Monterey County Water Resources Agency	Just Water

This Master Response addresses comments regarding the Sustainable Groundwater Management Act (SGMA) and about whether the proposed MPWSP would be consistent with the requirements of SGMA. Specifically, commenters requested information on how the MPWSP would avoid causing the undesirable results cited in SGMA, and discussed below. Commenters asked whether SGMA may place restrictions on pumping that would prevent implementation of the MPWSP. Commenters also requested the recent updated groundwater basin designation information in response to SGMA and requested information on which entity would serve as the Groundwater Sustainability Agency (GSA) for which subbasin.

This Master Response, therefore, provides supplemental information that expands on the discussion of groundwater basins and SGMA as presented in the Draft EIR/EIS. However, the information presented in this Master Response does not change the representation of SGMA in EIR/EIS Section 4.4.2.2, nor does it change the impact significance determinations, as explained in Section 8.2.6.3 of this Master Response.

8.2.6.1 Sustainable Groundwater Management Act

As summarized in EIR/EIS Section 4.4.2.2, SGMA became effective January 1, 2015, gives local agencies the authority and obligation to manage groundwater in a sustainable manner, and allows for limited State intervention when necessary to protect groundwater resources. SGMA establishes a definition of sustainable groundwater management, establishes a framework for local agencies to develop plans and implement strategies to sustainably manage groundwater resources, prioritizes basins (ranked as high- and medium-priority) with the greatest problems (i.e., the undesirable results as discussed below), and sets a 20-year timeline for implementation.

SGMA requires the creation of a GSA for medium- and high-priority groundwater basins in accordance with Water Code §10723 et seq. Each GSA is responsible to develop and implement a Groundwater Sustainability Plan (GSP) in accordance with Water Code §10727 et seq. Each GSP is expected to describe how users of groundwater within the basin would manage and use groundwater in a manner that can be sustainably maintained during the planning and implementation horizon without causing undesirable results. SGMA defines undesirable results as follows:

- Chronic lowering of groundwater levels indicating a significant and unreasonable depletion of supply

- Significant and unreasonable reduction of groundwater storage
- Significant and unreasonable seawater intrusion
- Significant and unreasonable degraded water quality, including the migration of contaminant plumes that impair water supplies
- Significant and unreasonable land subsidence that substantially interferes with surface land uses
- Depletions of interconnected surface water that have significant and unreasonable adverse impacts on beneficial uses of the surface water

Section 8.2.6.3 of this Master Response refers to revisions that have been made in Final EIR/EIS Section 4.4.5.2 (Impacts 4.4-3 and 4.4-4), to document how and why the proposed MPWSP would not conflict with the SGMA-defined undesirable results.

8.2.6.2 Basins and Subbasins

Commenters requested the recent updated groundwater basin designation information in response to SGMA; this discussion is provided in response to those comments.

General Discussion

As discussed in EIR/EIS Section 4.4.1.2, the Salinas River Valley extends from the headwaters around the La Panza Range and Lake Nacimiento northwestward to the Pacific Ocean. The western coastline extent of the Valley extends from Moss Landing and Elkhorn Slough in the north to the City of Monterey in the south; the Valley is underlain by the Salinas Valley Groundwater Basin (SVGB). EIR/EIS Section 4.4.1.1 provides a discussion of groundwater terminology and concepts including basins, basin boundaries, and groundwater divides. The designation and delineation of groundwater basins is the responsibility of the California Department of Water Resources (DWR). The DWR has delineated several basins and subbasins within the Valley.

The designation of groundwater basins has evolved over time as new information has become available. As shown on EIR/EIS Figure 4.4-1, the basin boundaries designated by the DWR in 2012 (colored polygons) differ from the basin boundaries designated by DWR in 1946 (black outlines). Note that the names of the subbasins have also evolved over time. Local agencies such as the Monterey County Water Resources Agency (MCWRA) have used some different basin names and delineations based on their locally available information and understanding of basin boundaries. The proposed source water intake system, for example, would be located in the 180/400 Foot Aquifer Subbasin, the boundaries of which generally coincide with those of the SVGB Pressure Area (or Subbasin) traditionally recognized by MCWRA and DWR. The basin borders are described in EIR/EIS Section 4.4.1.2.

With the implementation of SGMA, DWR reviewed all of the basins statewide and assigned priorities for establishing GSAs and implementing GSPs. Entities desiring to become a GSA must submit an application to the DWR that justifies why they would qualify as a GSA, defines the basin or subbasin over which they propose to develop and implement a GSP, and proposes any

basin boundary changes based on technical data that justifies boundary changes. The DWR then reviews the submittal and either accepts the proposed GSA or rejects the submittal, informing the stakeholders as to the reasons and directing them to resolve the issues. In some cases, multiple entities have submitted proposals to the DWR to become GSAs for the same area or for areas that overlap. The DWR may accept one GSA submittal and reject the other(s), or reject all submittals and direct the stakeholders to resolve their differences. In cases where no entity proposes to become the GSA, the DWR would assign an entity, typically the county, as the GSA. Information on the current status of the formation of GSAs and the boundaries of basins and subbasins is provided by the DWR on its SGMA website at http://water.ca.gov/groundwater/sgm/index.cfm. The website is continually updated as new information becomes available.

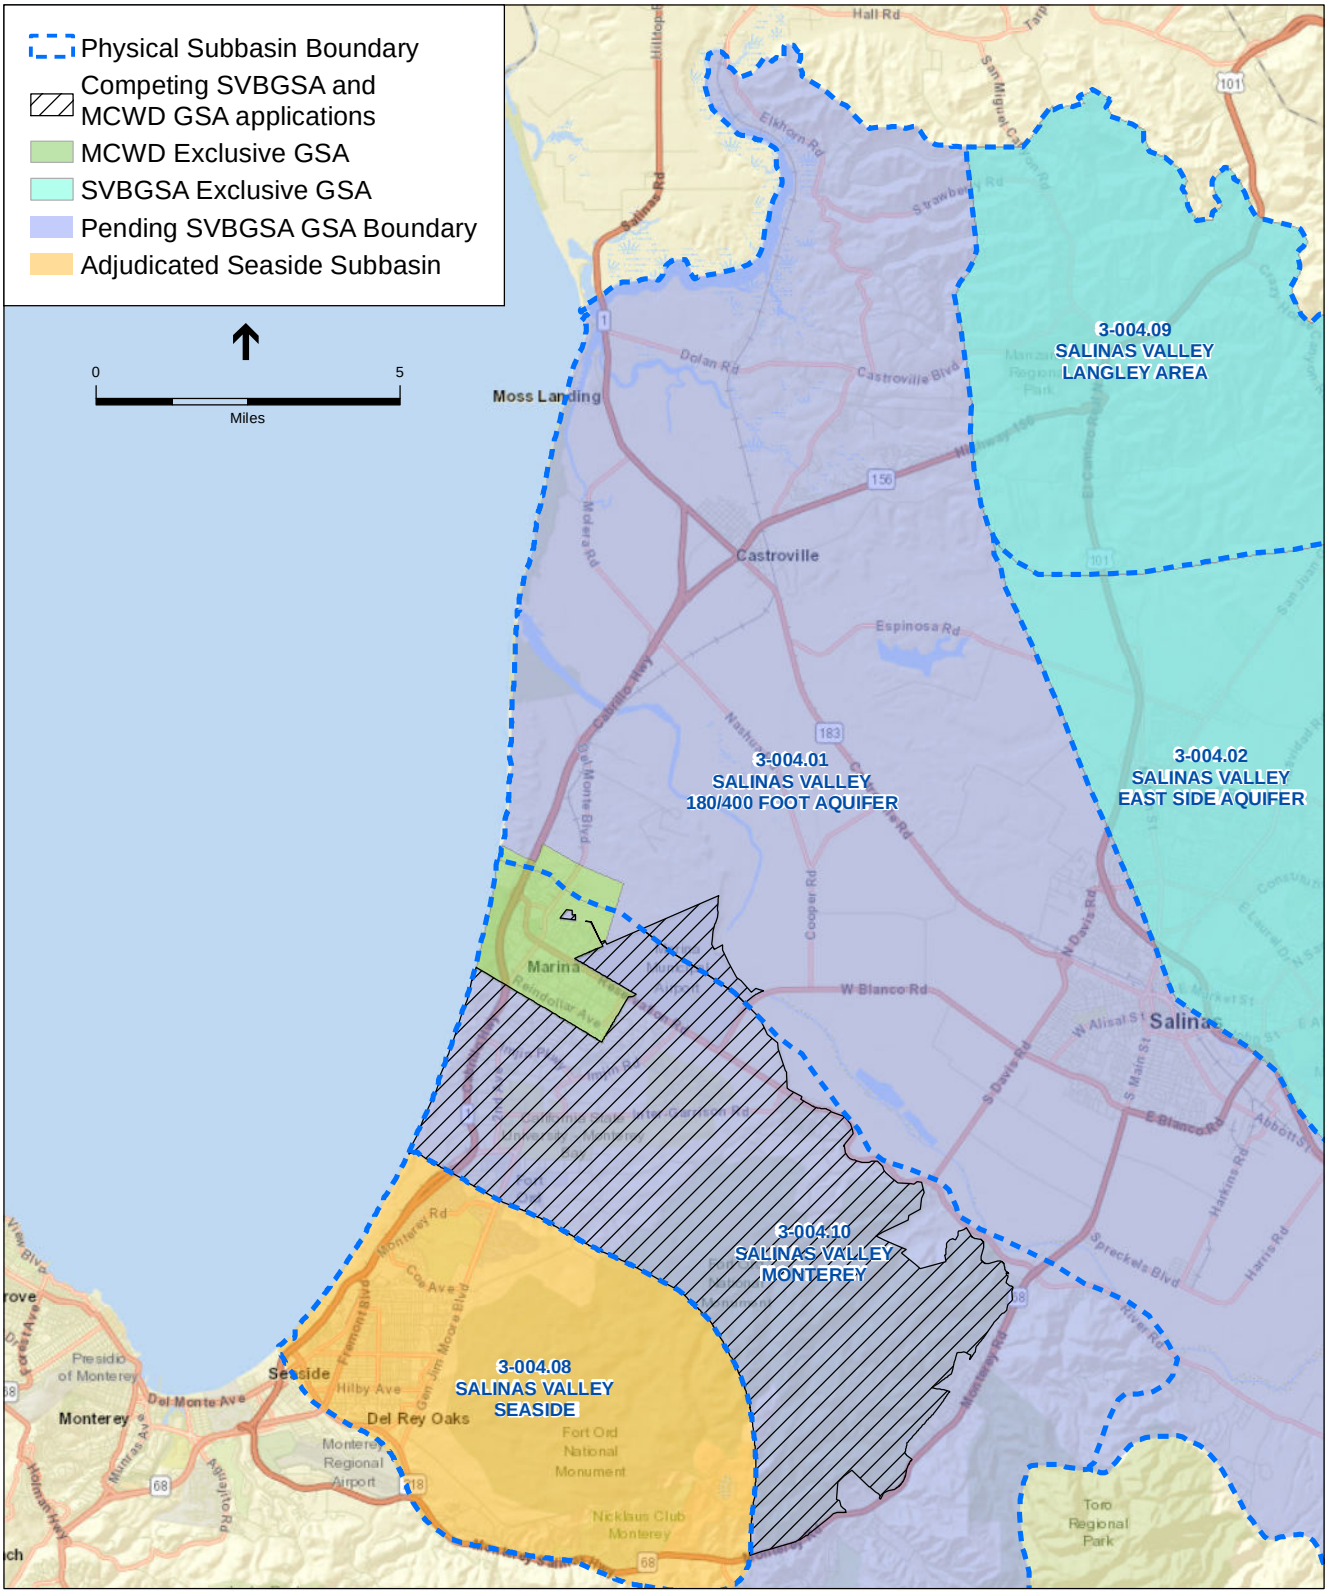
The subbasin assignments may be based on physical conditions (e.g., a groundwater divide within the overall basin), or administrative or jurisdictional boundaries (e.g., the service area of a water district whose boundaries may have no correlation to physical boundaries). It is important to note that the DWR, as authorized under SGMA, will require that each entire basin achieve sustainable groundwater conditions, regardless of how many GSAs or subbasins may exist within a given basin. Consequently, for basins that have multiple GSAs and/or subbasins, the GSAs will need to cooperate with each other to achieve sustainability on a basin-wide basis. As an ongoing process subsequent to the publication of the Draft EIR/EIS, the DWR has revised basin and subbasin boundaries and names, and will continue to do so as GSAs are formed, boundary disputes are resolved, and GSAs are accepted by the DWR.

Salinas Valley Groundwater Basin and Subbasins

Under SGMA, the DWR has identified the entire SVGB (Basin 3-004) as consisting of medium to high priority subbasins. In addition, the Salinas Valley 180/400 Foot Aquifer (Basin 3-004.01), a subbasin within the SVGB where the proposed seawater intake system would be located, is listed as a high priority, critically overdrafted subbasin. The subbasin boundaries and names, and the status of the formation of GSAs within the SVGB as of July 18, 2017, are shown on **Figure 8.2.6-1** and described below. Note that the DWR uses “basin” in its formal names of the subbasins even though these are specifically considered subbasins. Also note in the discussion below, the physical footprints of the basins, the jurisdictional footprint of water provider service areas, and the footprints in the applications for GSAs do not always precisely align; some GSA applications have overlap. Consequently, some of the GSA applications are still pending because the DWR will not approve overlapping GSAs.

Salinas Valley 180/400 Foot Aquifer Basin 3-004.01

The Salinas Valley Basin Groundwater Sustainability Agency (SVBGSA) is a joint powers authority consisting of a variety of local public agencies with water supply, water management, and land use responsibilities. The agencies include Monterey County; MCWRA; the cities of Salinas, Soledad, Gonzales, and King; the Castroville Community Services District (CCSD), and the Monterey Regional Water Pollution Control Agency (MRWPCA). The SVBGSA submitted GSA formation applications for all of the subbasins within the SVGB that are within Monterey County, including the Salinas Valley 180/400 Foot Aquifer Basin 3-004.01, where the source water intake system for the MPWSP would be located. However, the GSA formation decision by



Notes: SVBGSA = Salinas Valley Basin Groundwater Sustainability Agency MCWD = Marina Coast Water District

SOURCE: DWR, 2017

http://sgma.water.ca.gov/webgis/index.jsp?appid=gasmaster&rz=true

205335.01 Monterey Peninsula Water Supply Project

Figure 8.2.6-1

DWR SGMA Basin Map

the DWR for the Salinas Valley 180/400 Foot Aquifer Basin 3-004.01 is still pending because the Marina Coast Water District (MCWD) submitted an application for Salinas Valley Monterey Basin 3-004.10, discussed below, with a footprint that overlaps a southern portion of the Salinas Valley 180/400 Foot Aquifer Basin 3-004.01 that the SVBGSA also applied to manage. MCWD may have done this because the MCWD is the water service provider in the overlapping area.

Salinas Valley Monterey Basin 3-004.10

The Salinas Valley Monterey Basin lies in between the Salinas Valley 180/400 Foot Aquifer Basin 3-004.01 to the north (discussed above) and the Seaside Basin 3-004.08 to the south (discussed below). The formation of a GSA for this basin is pending because the SVBGSA and the MCWD each submitted overlapping and conflicting GSA formation requests for most of this basin.

The MCWD is a water agency that provides water supply for: the Central Marina service area, which consists of most of the City of Marina, and; the Ord Community service area, which includes some western portions of the former Ford Ord military base. The DWR has accepted the MCWD as the exclusive GSA within the Central Marina service area, most of which is in the northwestern portion of Salinas Valley Monterey Basin 3-004.10 but extends into a small portion of the Salinas Valley Monterey Basin 3-004.10 to the north, shown as the green area on Figure 8.2.6-1.

The SVBGSA has submitted a GSA formation request to the DWR for all of the Salinas Valley Monterey Basin 3-004.10, except for the above-described MCWD Central Marina service area. However, the MCWD has also submitted a proposal to the DWR to have the MCWD be the GSA for a larger portion of the Salinas Valley Monterey Basin 3-004.10 than merely the area within the MCWD Central Marina service area. The MCWD request includes its Ord Community service area, but also extends further east into areas not served by the MCWD. The DWR GSA formation decision on the diagonal shaded area on Figure 8.2.6-1 is pending.

Seaside Basin 3-004.08

The Seaside Basin 3-004.08, where the proposed ASR wells would be installed and operated, was adjudicated in 2006 in response to overdraft of the subbasin and conflict between groundwater users (*California American Water v. City of Seaside, et al.* (Case No. M66343, California Superior Court, Monterey County). The adjudication defined the safe yield of the subbasin and allocated specific volumes of groundwater pumpage to each of the parties to the adjudication that limits the total volume of groundwater extraction to the safe yield. The implementation of the adjudication results in managing the subbasin's groundwater resources in a sustainable manner similar to the requirements of SGMA. Consequently, the Seaside Basin 3-004.08 will not have a GSA formed and will not be required to prepare and implement a GSP under SGMA.

MCWD Proposed Designation of "Marina Subarea"

MCWD, in its comment letter on the Draft EIR/EIS (see Section 8.5.2), refers to a "Marina Subarea" that includes its service area and the combined area of the Salinas Valley 180/400 Foot Aquifer Basin 3-004.01 south of the Salinas River and the northwest portion of the Salinas Valley

Monterey Basin 3-004.10. MCWD states this area would include the area affected by the proposed slant well pumping on the CEMEX property. MCWD acknowledges that this is not a DWR-recognized designation; MCWD has not formally requested such a designation from the DWR but claims, without providing documentation or published references to support the claim, that the hydrogeological conditions justify such a designation for "discussion purposes." However, the hydrogeological conditions as described in Section 4.4, Groundwater Resources, do not justify this designation because there are no known boundary conditions that would justify further subdividing the subbasin. Note that the analysis of impacts of the project are not dependent on which entity manages any particular area nor what the basins are named.

Anticipated Radius of Influence Relative to Subbasins

Based on the modeled maximum radius of influence of groundwater drawdown that could be caused by the operation of the source water intake system, as shown on EIR/EIS Figure 4.4-15 and discussed in Section 8.2.6.3 below, the majority of the affected area would be within the Salinas Valley 180/400 Foot Aquifer Basin 3-004.01. The southern boundary of this basin is a groundwater divide with the Salinas Valley Monterey Basin 3-004.10. As explained in EIR/EIS Section 4.4.1.2, the precise location of a groundwater divide changes over time in response to changes in climate, seasonal rainfall, and pumping of nearby extraction wells. Consequently, the location of the groundwater divide at any given time may not precisely align with the basin boundary as delineated by the DWR. Depending on the actual extent of the radius of influence of the proposed project pumping, the affected area may extend a short distance into the northern portion of the Salinas Valley Monterey Basin 3-004.10 and may extend into the MCWD GSA area. However, regardless of the precise extent of the radius of influence, the impact analyses concluded that there would be no adverse effects on users of groundwater in the subbasins, including in the area of MCWD's GSA, as discussed in Impacts 4.4-3 and 4.4-4 in the EIR/EIS.

8.2.6.3 Project Consistency with SGMA

As noted above, SGMA states that groundwater basins must be managed without resulting in the listed undesirable results. A summary of these analyses to address each undesirable result identified in SGMA has been added to Final EIR/EIS Section 4.4 in Impacts 4.4-3 (groundwater supplies and recharge) and 4.4-4 (groundwater quality) under the subheadings "Consistency with Regulatory Requirements." Based on those discussions, the project would not result in any of the six undesirable results cited in SGMA; therefore, MPWSP would be consistent with SGMA, and SGMA would not restrict the MPWSP's ability to pump groundwater as proposed.

Because adjudicated basins are exempt from SGMA requirements, as noted in Water Code §10720.8, impacts on groundwater resources in the Seaside Basin from operation of the proposed ASR wells are not discussed.

8.2.7 Master Response 7: The Deeper Aquifers of the Salinas Valley Groundwater Basin

COMMENTERS ADDRESSED IN MASTER RESPONSE 7

City of Marina	Just Water
Marina Coast Water District	Hebard Olsen
Monterey Regional Water Pollution Control Agency	Form Letter 2
Ag Land Trust	Public Meeting Verbal Comments
Fort Ord Rec Users	

Several comments on the Draft EIR/EIS suggested that Section 4.4, Groundwater Resources, did not adequately describe or address potential impacts on the "900-Foot (Deep)" Aquifer (see discussion of aquifer name below) and that the lack of analysis represented a flaw in the environmental evaluation of groundwater impacts. In addition, commenters asserted that the computer modeling used to evaluate the groundwater response to the proposed project did not analyze the effects on this aquifer.

Draft EIR/EIS Section 4.4.1.2 described the local and regional hydrogeology; the 400-Foot and 900-Foot Aquifers were presented on Draft EIR/EIS page 4.4-11. This Master Response addresses the inclusion of supplemental information in the Final EIR/EIS that clarifies the deeper aquifer system of the Salinas Valley Groundwater Basin (SVGB).

8.2.7.1 The Deeper Aquifers – Terms, Characteristics, and Production

In response to comments that suggested Draft EIR/EIS Section 4.4 did not adequately describe the "900-Foot (Deep)" Aquifer, this section summarizes the supplemental discussion that has been added to the Final EIR/EIS, which describes the hydrogeology of the deep aquifer zone in the SVGB, the terms used to describe it, and the current use of the aquifer for groundwater production.

Draft EIR/EIS Section 4.4.1.2 described the Pressure Area, a subbasin of the SVGB that has traditionally been recognized by the Monterey County Water Resources Agency (MCWRA) and the California Department of Water Resources (DWR). The Pressure Area is composed of aquifers and aquitards within distinct geologic formations and the characteristics of the aquifers and aquitards were described in the Draft EIR/EIS on pages 4.4-4 through 4.4-12. The Draft EIR/EIS included a discussion of the 900-Foot Aquifer in the subsection titled "400-Foot and 900-Foot Aquifers." EIR/EIS Figure 4.4-2 provides a conceptual model of the coastal aquifers, including the 900-Foot Aquifer. Because the groundwater modeling did not detect a drawdown in the 900-Foot Aquifer (as described in Section 8.2.7.2, below), the description of the 900-Foot Aquifer was minimized in the Draft EIR/EIS consistent with CEQA Guidelines Section 15125, which states, "The description of the environmental setting shall be no longer than is necessary to an understanding of the significant effects of the proposed project and its alternatives."

Increasing seawater intrusion over the past 30 years forced groundwater users in the Marina/Castroville area to drill and develop wells below the 400-Foot Aquifer. Starting in 1976,

groundwater users, including the Marina Coast Water District (MCWD), had to drill into the deeper aquifers to find a fresh groundwater supply. However, after implementation of the Castroville Seawater Intrusion Project (CSIP) in 1998, many of the groundwater users in the Castroville area who began receiving recycled water ceased using their deeper aquifer wells.

The terms "900-Foot Aquifer," "1,500-Foot Aquifer," and "Deep Zone" have been used to refer to the deeper aquifer units in the SVGB. However, these are vague definitions because the water-bearing sediments are not necessarily at these arbitrary depths. For the purposes of this EIR/EIS, and to be consistent with current findings regarding the distribution of water-bearing zones below the 400-Foot Aquifer, the term "deeper aquifers" is used to describe these units.

For informational purposes, supplemental text describing the deeper aquifers is presented in Final EIR/EIS Section 4.4.1.2 and, for the reasons just explained, the following EIR/EIS subsections have been renamed and reorganized as follows:

400-Foot ~~900-Foot~~ Aquifer; and,

Deeper Aquifers.

8.2.7.2 Computer Model Response in the Deeper Aquifer

In response to comments that suggested the Draft EIR/EIS did not adequately address potential impacts on the deeper aquifers and that the computer modeling used to evaluate the groundwater response to the proposed project did not analyze the effects on such aquifers, this section describes how the North Marina Groundwater Model, v. 2016 ($NMGWM^{2016}$) interpreted the effects of the proposed project on the deep aquifers and introduces supplemental text included in the Final EIR/EIS that presents its results.

The $NMGWM^{2016}$ is a detailed hydrologic computer model covering approximately 149 square miles and was a primary analytical tool used to evaluate impacts of the proposed project and alternatives on groundwater resources. See EIR/EIS Appendix E2. EIR/EIS Section 4.4.4.2 and Appendix E2 describe the components, model layers, and applications of the $NMGWM^{2016}$ and EIR/EIS Table 4.4-8 presents the correlation of the geologic units, aquifers, and model layers. As shown in Table 4.4-8, and discussed in detail in Appendix E2, the deeper aquifers were represented in the $NMGWM^{2016}$ as Model Layer 8.

As discussed in the EIR/EIS, the $NMGWM^{2016}$ did not indicate drawdown in Model Layer 8 from the proposed MPWSP pumping at CEMEX for either of the CEMEX site options (the proposed project and Alternative 5a with 24.1 mgd and 15.5 mgd pumping, respectively) or either of the Potrero Road options (Alternative 1 and 5b with 24.1 mgd and 15.5 mgd pumping, respectively); see Appendix E2, Figures 5.3a-b, 5.4a-b, 5.9a-b and 5.10a-b. The lack of detected response by the $NMGWM^{2016}$ in the deeper aquifers represented by Model Layer 8 prompted analysts to de-emphasize the deeper aquifers in the groundwater impacts analysis presented in the Draft EIR/EIS. Nonetheless, for informational purposes, supplemental text has been added to Final EIR/EIS Section 4.4.5.2, Impact 4.4-3, under the heading "Results of Impact Analysis – Proposed Project on Nearby Production Wells," to discuss aquifer response to the project in the deeper aquifers. Such additional clarifying text does not change the conclusions in the EIR/EIS.

8.2.8 Master Response 8: Project Source Water and Seawater Intrusion

COMMENTERS ADDRESSED IN MASTER RESPONSE 8

Fort Ord Base Realignment and Closure Field Office	Charles Cech
City of Marina	Bob Coble
Marina Coast Water District	David Gorman
Monterey County Water Resources Agency	Juli Hofmann
Monterey Peninsula Regional Water Authority	Thomas Moore
Citizens for Just Water	Hebard Olsen
Fort Ord Rec Users	Larry Parrish
Just Water	Nancy Selfridge
Salinas Valley Water Coalition and Monterey County Farm Bureau	Jan Shriner
Water Ratepayers Association of the Monterey Peninsula	Form Letter 1
David Beech	Form Letter 2
Kathy Biala	Public Meeting Verbal Comments
David Brown	

This Master Response addresses comments received on the Draft EIR/EIS regarding the origin of the slant well source water and the current seawater intrusion conditions in the Salinas Valley Groundwater Basin (SVGB), underlying the MPWSP area, including portions of the City of Marina. Several commenters maintain that the proposed project would draw fresh groundwater that could otherwise be used for potable groundwater supply from inland portions of the SVGB. Other commenters disagreed with the determination in the EIR/EIS that the groundwater underlying the project area in the Dune Sands and 180-Foot Equivalent (180-FTE) Aquifer is degraded by legacy and ongoing seawater intrusion and thus is not available for potable uses. This Master Response presents hydrogeologic and groundwater chemistry information to supplement and clarify the analyses of the groundwater resources impacts presented in EIR/EIS Section 4.4, Groundwater Resources, but does not change the impact conclusions. Where noted, EIR/EIS Section 4.4, Groundwater Resources, has been updated and refined based on information presented in this Master Response. Regarding the deeper aquifers of the SVGB (i.e., the 900-Foot Aquifer referred to in the Draft EIR/EIS and in comments), see Master Response 7.

8.2.8.1 Cone of Depression and Capture Zone

This subsection provides a brief summary of the difference between drawdown, the cone of depression, and the capture zone; this is a fundamental concept necessary to understand the response and movement of groundwater drawn to the proposed slant wells. These concepts are discussed in EIR/EIS Section 4.4.4, Approach to Analyses, and summarized and clarified in the sections below in response to comments about these concepts.

Drawdown and the Cone of Depression

Drawdown is the observed change in the aquifer water level caused by the extraction of groundwater and is calculated by subtracting the water level measured under pumping conditions from the water level measured without pumping, also referred to as the static water level. The static water level represents baseline conditions. The cone of depression, as described and shown graphically in EIR/EIS Section 4.4.4.2, Groundwater Modeling, is the zone where the drawdown caused by groundwater pumping is observed. Section 4.4.4.2 describes groundwater model terminology. The definition of the cone of depression (see Draft EIR/EIS page 4.4-44) has been revised as follows:

> As water is extracted from a well, it is pulled into the screened section of the slant wells and removed from the subsurface water-bearing unit. Groundwater elevations would decrease around the slant wells in a ~~radial~~distorted ovate fashion ~~resulting in a~~due to the ocean recharge boundary such that the cone of ~~drawdown~~ depression would not be centered at the slant wells. This cone would be the steepest and deepest closest to the well screen and rapidly become flatter and shallower away from the slant wells.

Draft EIR/EIS Figure 4.4-13 depicted this modelled cone of depression, represented by contour lines of equal drawdown, in the 180-Foot Aquifer. This figure has been renumbered 4.4-13a in the Final EIR/EIS, and Figure 4.4-13b has been added to Final EIR/EIS Section 4.4 to show the modelled cone of depression in the Dune Sand Aquifer.

The 2016 version of the North Marina Groundwater Model ($NMGWM^{2016}$) projects that this drawdown would occur as a result of a slant well extraction rate of 24.1 million gallons per day (mgd). This is considered "worst-case" because it represents the cone of depression in the Dune Sand Aquifer under 2012 sea level conditions and 0 percent return water. Final EIR/EIS Figure 4.4-13a shows the cone of depression for the 180-FTE Aquifer as projected by the $NMGWM^{2016}$. This is also considered the worst-case drawdown condition under the proposed 24.1 mgd pumping scenario. The cones of depression for both the Dune Sand Aquifer and 180-FTE Aquifer are similar: steep contours just offshore along the western extent and flatter to the east, forming a cone of depression that extends inland with drawdown amounts ranging between 1 to 5 feet. As discussed in EIR/EIS Section 4.4.4.2, Groundwater Modeling, the area or radius of pumping influence demarks the extent that water levels would decrease (or be drawn down) by the extraction of groundwater at the slant wells. For purposes of the impact analysis in the EIR/EIS, the extent of the radius of influence was marked by the one-foot drawdown contour of the cone of depression.

Capture Zone

A capture zone refers to the three-dimensional volume of aquifer that contributes the water extracted by the wells. It is a function of drawdown caused by the pumping rate and the gradient (direction and slope) of the groundwater flow. When the pumps in the slant wells are turned on, the wells would initially extract the water that is held in the surrounding sediments (ambient groundwater). As pumping continues, the modeling indicates that the wells would extract increasing proportions of infiltrating recharge from the ocean. The ocean recharge would gradually replace the

ambient groundwater within the capture zone, and move within the capture zone toward the well, but would not advance beyond the capture zone, as shown in **Figure 8.2.8-1** (Dune Sand) and **Figure 8.2.8-2** (180/180-FTE Aquifer). In the map view provided in these figures, the capture zone is a 2-dimensional surface that delineates the underlying aquifer volume where ocean water replaces ambient groundwater and ultimately becomes the primary source water to the slant wells. Figures 8.2.8-1 and Figure 8.2.8-2 show the map view of the capture zones for the proposed 24.1 mgd pumping scenario at CEMEX under a regional gradient estimated from groundwater measurements, which were developed as discussed below. The term "capture zone" has been clarified in Final EIR/EIS Section 4.4.4.2. To summarize the key differences in terms, the cone of depression is the area in which drawdown of groundwater would occur. However, the water drawn into the project supply wells would not originate from the entirety of the cone of depression, and would be drawn from the capture zone only.

Particle Tracking to Simulate Capture Zones

As described in EIR/EIS Section 4.4.4.2 and Appendix E2, groundwater capture zone boundaries were delineated using NMGWM^{2016} steady-state flow condition[1] results and particle tracking using the MODFLOW computer code post-processer MODPATH. The MODFLOW computer code post-processer MODPATH was employed to simulate groundwater flow paths. MODPATH uses the output from MODFLOW to simulate paths for "particles" of water moving through the modeled groundwater system. In addition to delineating particle paths, MODPATH computes the time-of-travel for the simulated particles to reach their ending locations. Backward tracking shows the movement of groundwater to former points of recharge (for example, the movement of ocean water recharge to a pumping well), and forward tracking shows the movement of groundwater to future points of discharge (for example, the continued inland movement of the interface between intruded saltwater and native groundwater).

NMGWM^{2016} delineated slant well ocean water capture zones under steady-state flow conditions assuming full time operation 24 hours a day, 7 days a week. Forward tracking particles placed in every cell along the coast in model layers representing the Dune Sand Aquifer and the 180-Foot/180 FTE Aquifer displayed path lines that delineate groundwater flow paths to the extraction wells. Backward tracking particles placed evenly within pumping cells provided path lines that delineate recharge that either originates at the ocean bottom or as groundwater beneath the bay bottom. In both scenarios, MODPATH demonstrated that groundwater extracted by the wells would be recharged by ocean water. EIR/EIS Appendix E2 provides additional details on the particle tracking and simulation of capture zone.

[1] Steady state refers to the condition where the magnitude and direction of groundwater flow in a groundwater model domain remains constant; the same amount of water flows into the system as flows out.

Consideration of Groundwater (Hydraulic) Gradients and Capture Zones

As explained in EIR/EIS Section 4.4.4.1, Subsurface Investigations, groundwater under unconfined conditions flows from areas of high groundwater elevation to areas of low groundwater elevation, and groundwater under confined conditions flows from areas of a higher head[2] to areas of lower head. The change in the head over distance is called the hydraulic gradient, and the groundwater flow direction is that which yields a maximum rate of decrease in head (Fetter, 1994). Hydraulic gradients, referred to hereafter as groundwater gradients, are typically shown using contour lines on 2-dimensional groundwater maps.[3] Figures 4.4-6, 4.4-7, and 4.4-8 in EIR/EIS Section 4.4.1.3 show regional groundwater gradients in the SVGB and the MPWSP area. As discussed in EIR/EIS Section 4.4.1.3, the groundwater in both the Dune Sand Aquifer and 180/180-FTE Aquifer flows inland beneath the project area (i.e., from the Monterey Bay east, toward the Salinas Valley) with measured gradients ranging from a minimum of 0.0007 to an average local gradient of 0.0011 (HWG, 2017). The inland gradient is a direct response to the extensive overpumping of the groundwater basin that has resulted in a groundwater depression located on the northeast side of the City of Salinas; see EIR/EIS Section 4.4.1.3.

As discussed in EIR/EIS Section 4.4.4.2 and in Appendix E2, the NMGWM^{2016} was converted to superposition and, as such, initial water levels are considered zero throughout the model area. Consequently, the model does not account for regional background groundwater gradients. However, these regional groundwater gradients significantly influence groundwater-flow paths from the ocean to the proposed project slant wells, and therefore are important to consider when calculating capture zone boundaries. Therefore, to incorporate the regional groundwater gradient across the CEMEX site, the gradient was calculated using the fall 2015 measured background gradient and then the approximate gradient was reproduced in the NMGWM^{2016}. The NMGWM^{2016} simulated the capture zones using the average groundwater gradients of 0.0004, 0.0007, and 0.0011, which are based on averages of measured gradients throughout the entire model domain.[4] However, the hydraulic gradients used in the modeling underestimate the local hydraulic gradients in the project area, since the steepest gradient used in the analysis (0.0011) is more representative of the average local gradient and the 0.0007 gradient better represents the minimum gradient (HWG, 2017). As shown in EIR/EIS Appendix E2, Figure 5.6, the extent of the capture zone is influenced by the groundwater gradient: the steeper the gradient, the smaller the capture zone. So, the smaller of the three capture zones (based on the gradient of 0.0011) projected by the NMGWM^{2016} would likely be more representative of actual project pumping conditions. Capture zones projected for the 15.5 mgd slant well pumping scenario would be smaller than those estimated for the 24.1 mgd scenario because less source water would be drawn to the slant wells. A graphic comparing the extent of capture zones under the 15.5 mgd and 24.1 mgd scenarios is shown in Appendix E2,

2 Head is the fluid potential for flow through an aquifer and is observed by the height of water in a groundwater well.
3 Groundwater gradients are expressed as the ratio of vertical change in head to lateral distance. For example, if groundwater levels decrease 5 feet over a horizontal distance of 10,000 feet, the gradient is expressed as 0.0005 feet per foot or ft/ft. Because it is a ratio, the units are often not included.
4 While the groundwater gradient of 0.0004 was considered for the NMGWM^{2016} in determining the extent of the capture zones, it was determined that 0.0007 was more representative of the minimum gradient based on local conditions.

Figure 5.6. EIR/EIS Appendix E2 and Appendix E3 provide additional details on particle tracking, the development of the capture zones, and the process of simulating groundwater gradients.

Relationship between Cone of Depression and Capture Zone

The cone of depression that forms from groundwater pumping and the capture zone that provides source water to the slant wells are not the same. **Figure 8.2.8-3** is a cross-sectional schematic that illustrates the relationship between the cone of depression (shown in map view on Figure 4.4-13a) and capture zone (shown in map view on Figure 8.2.8-2) under a "Pre-Project" and "Project" condition. Under the Pre-Project Condition (shown at the top of Figure 8.2.8-3), the groundwater is flowing inland from the coast at a gradient of 0.0005.[5] The Pre-Project Condition represents the groundwater condition without accounting for current well pumping or groundwater recharge. The "Project Condition" represents how the groundwater would respond to project slant well pumping in the 180/180-FTE Aquifer, assuming 2012 sea level and no return water (both conservative assumptions), and is correlative to the map view of the cone of depression shown on EIR/EIS Figure 4.4-13a. It should be noted that the vertical scale is considerably exaggerated in the "Project Condition" to clearly illustrate the relationship between the cone of depression and the capture zone; for reference, the NMGWM^{2016} projected that the maximum drawdown amount under this pumping scenario was about 29 feet at the slant wells. As illustrated in Figure 8.2.8-2, when the slant wells are pumping, water within the capture zone would be drawn into the wells from the surrounding sediments. The groundwater responds by creating a cone of depression, which would be most pronounced near the slant wells. Notice that the drawdown caused by slant well pumping decreases as the cone of depression extends eastward. The inland extent of the capture zone is shown by a vertical dashed line. This point could be described as a groundwater gradient divide: groundwater west of the divide is drawn into the capture zone by the slant wells and thus flows west, while the groundwater to the east of the boundary continues to flow inland unimpeded due to the regional gradient. The fundamental difference between the capture zone, which is supplying the water to the slant wells, and the cone of depression, which forms in response to pumping, is that the groundwater entering the slant wells originates only from within the capture zone, while the regional gradient controls the groundwater flow beyond the capture zone.

While the wells are expected to be operated 24 hours/per day every day as described in EIR/EIS Section 3.2.1.1, EIR/EIS Appendix E2 Section 5.4 examined the effects of ceasing pumping on groundwater basin recovery, in order to consider what would happen when the wells are turned off permanently. Temporary, short-term shut down for maintenance are not considered because at least some wells would be operating during servicing and repair. The effects on groundwater levels and water quality during a temporary shut-down would occur gradually and not be immediately obvious. Figure 5.5 in Appendix E2 shows the model-calculated post project recovery from drawdown due solely to 63 years of proposed project slant well pumping. Hydrographs at various locations show that drawdown would decrease and water levels would return to pre-pumped

[5] The gradient of 0.0005 was measured using groundwater contours generated from groundwater measurements in the 180/180-FTE aquifer collected in fall 2015 (Geoscience, 2017) and is used in Figure 8.2.8-3 as a representative gradient for the purposes of demonstration.

conditions within several years for all but two wells. The modeled water level recovery for monitoring wells MW-5S and MW-7S would be completed within about 20 years due to the depth and location of the wells. Considering that the recovery for surrounding wells is on the order of a few years, the longer recovery for just these two wells is the effect of the relatively low hydraulic conductivity associated with the geologic conditions of Model Layer 2 (Dune Sand Aquifer) in those areas of the model.

8.2.8.2 Groundwater Quality within the Capture Zone

This subsection clarifies the quality of the existing groundwater within the capture zone, defined above, in response to comments expressing disagreement with the finding in the EIR/EIS that the groundwater underlying the project area in the Dune Sands and 180-FTE Aquifer is degraded by legacy and ongoing seawater intrusion, and claiming that water in this location is fresher than described in the EIR/EIS. As discussed in EIR/EIS Section 4.4.1.4 and Impact 4.4-3, the proposed MPWSP pumping would draw source water from a capture zone in the Dune Sand and 180-FTE Aquifers. The groundwater in this area is degraded by seawater and therefore, unusable for potable or irrigation water supply due to its elevated total dissolved solids (TDS) and chloride concentrations. The chemistry of groundwater in this area has been analyzed by the ongoing monitoring program implemented by CalAm and peer-reviewed by the Hydrogeologic Working Group (HWG), as discussed in EIR/EIS Section 4.4.4.1, and separately by the hydrologists and hydrogeologist on the EIR/EIS team. In conjunction with the installation and pumping of the test slant well (see EIR/EIS Section 4.4.4.1 and Master Response 11, CalAm Test Slant Well), CalAm installed nine clustered monitoring wells between December 2014 and August 2015 to monitor groundwater levels and collect representative groundwater quality data from the Dune Sand Aquifer, the 180-FTE Aquifer and the 400-Foot Aquifer. Each monitoring well cluster consists of three individual, separately constructed monitoring wells completed at different depth intervals identified as S (shallow), M (middle), D (deep), where shallow wells are primarily screened in the Dune Sand Aquifer, the middle wells are screened in the 180-FTE Aquifer or 180-Foot Aquifer, and the deep wells are primarily screened in the 400-Foot Aquifer (HWG, 2017). CalAm has conducted regular water level and water quality monitoring and has, since February 2015, produced and posted on its website weekly and monthly test slant well pumping reports. As shown on Figures 4.4-13a and 4.4-13b, MW-1 and MW-3 are located within or proximate to the capture zone and best represent the conditions and quality of slant well source water.

The analysis presented in EIR/EIS Impact 4.4-3 concluded that groundwater extracted by the slant wells would be brackish and originate in the capture zone, which occupies a localized area just inland from the coast underlying the CEMEX property (illustrated by Figures 8.2.8-1 and 8.2.8-2, included in this master response to clarify the extent and direction of groundwater flow within the capture zone). There is no active groundwater pumping by other users from the Dune Sand and/or 180-FTE Aquifers within the capture zone, primarily because of the degraded water quality. **Table 8.2.8-1** summarizes the TDS and chloride concentrations in the CalAm monitoring wells collected by pumping after development of the monitoring wells and prior to the first phase of test slant well pumping (thus representing baseline conditions) and references the California Secondary Maximum Contaminant Level (MCL) (Cal. Code Regs., tit. 22, § 64449) for TDS and chloride, which is 500 mg/L and the 250 mg/L, respectively. The groundwater quality data

provided in Table 8.2.8-1 below supports the conclusion that the water in the Dune Sand Aquifer and 180-FTE aquifer that is available to the slant wells is brackish to near seawater and does not meet California drinking water standards. In addition to the groundwater sample data provided in Table 8.2.8-1, Figures 3-1 and 3-2 in the Baseline Water and Total Dissolved Solids Levels Technical Memorandum illustrates that data logger-collected TDS concentrations in MW-1 and MW-3 consistently recorded between 22,000 mg/L and 33,000 mg/L for the entire groundwater quality baseline monitoring period of 34 days (Geoscience, 2015, see Appendix E3). Long term monitoring of the slant well water quality and the MPWSP monitoring wells near CEMEX site show that the TDS in the groundwater has remained elevated since monitoring began in 2015 (Geoscience, 2018). Brackish water is defined as having a TDS concentration greater than freshwater, but not as much as seawater, which is typically about 33,500 mg/L (see Master Response 2, Source Water Components and Definitions). Therefore, for the purposes of the groundwater resources analysis in the EIR/EIS, brackish water is considered to have a TDS concentration ranging between 500 mg/L to 33,500 mg/L. Concentrations of TDS in surface and groundwater that exceed 3,000 mg/L are considered by the SWRCB (Resolution No. 88-63, Adoption of Policy Entitled "Sources of Drinking Water") as an exception to its resolution that, "[a]ll surface and groundwaters of the state are considered to be suitable, or potentially suitable, for municipal or domestic water supply and should be so designated by the Regional Boards." The groundwater in the capture zone of the MPWSP slant wells exceeds 3,000 mg/L TDS.

TABLE 8.2.8-1
TOTAL DISSOLVED SOLIDS CONCENTRATIONS IN MPWSP MONITORING WELLS LOCATED WITHIN THE SLANT WELL CAPTURE ZONE

Well Number	Sample Date	Aquifer	Total Dissolved Solids (TDS) (mg/L)	Chloride (mg/L)
			California Drinking Water Standard: 500 mg/L[a]	California Drinking Water Standard: 250 mg/L[a]
MW-1S	2/13/15	Dune Sand	26,600	14,504
MW-1M	2/14/15	180-FTE	30,900	16,037
MW-3S	2/25/15	Dune Sand	23,400	11,680
MW-3M	2/24/15	180-FTE	28,500	14,686
MW-4S	3/7/15	Dune Sand	11,900	5,497
MW-4M	3/6/15	180 FTE	17,900	9,751

NOTES:
[a] California Secondary Maximum Contaminant Level (Cal. Code Regs., tit. 22, § 64449)

SOURCE: Geoscience, 2015

Table 8.2.8-1 shows that chloride concentrations in the wells within the capture zone exceed the MCL for drinking water standard of 250 mg/L, indicating that this groundwater would be intolerable as a drinking water source unless it was desalinated. These chloride levels are also unsuitable for agricultural irrigation. With chloride concentrations over 355 mg/L, the groundwater does not meet the RWQCB Central Coast Basin Plan water quality guidelines for irrigation water. The irrigation water guidelines indicate that chloride concentrations exceeding 355 mg/L chloride could potentially result in severe effects for crops and soils (SWRCB, 2017).

8.2.8.3 Ocean Water Percentage

This subsection describes the estimated percentage of seawater in the slant well source water. The change in ocean water percentage (OWP) describes the projected water quality over time in the MPWSP slant well feedwater. An estimate of the OWP that would contribute to the slant well source water was calculated using an analytical methodology and numerical modeling (HWG, 2017) and the approach was peer reviewed by the EIR/EIS team. The OWP as it relates to return water is addressed in Master Response 4, The Agency Act and Return Water, and the methodology of the OWP calculation is provided in Appendix E3. The analytical methodology used an equation to calculate OWP based on water and salinity budgets for the capture zone volume of the proposed slant wells and the numerical modeling method utilized the CEMEX and NMGWM^{2016} groundwater models. The CEMEX and NMGWM^{2016} models provided better resolution than the analytical method in evaluating the early time interval after slant well pumping begins. Numerical modeling predicted a higher source water OWP during the early time period than the analytical method, but the long-term pumping results are consistent between the analytical and numerical predictions. Results of the analytical/numerical methods indicate that the OWP would range from 88 to 92 percent the first year, increase to 93-97 percent after two years, and exceed 94 percent over the long term. This is consistent with two years of field data from the test slant well that indicated OWP ranging from 92 to 95 percent in the first year and 90 to 92 percent in year 2.[6] These methodologies and results are discussed in Master Response 4 and are described in detail in Appendix E3.

8.2.8.4 Summary of Impact Conclusions

A clear understanding of the difference between the cone of depression and capture zone is paramount to understanding project impacts on groundwater resources presented in EIR/EIS Section 4.4.5. This section reviews the impact conclusions in the EIR/EIS, in response to comments disagreeing with the conclusions presented in Section 4.4.5, and provides further clarification based on the information discussed in the sections above.

Groundwater Supply

EIR/EIS Impact 4.4-3 concludes that the proposed project would not deplete groundwater supplies that would otherwise be available to users in the SVGB. This conclusion was reached because the proposed project would extract groundwater from a localized coastal-adjacent capture zone, which has been verified by water quality testing to contain groundwater with elevated concentration of TDS and chloride from decades of legacy seawater intrusion. The slant wells would initially extract the ambient brackish groundwater and, over time, the source water supplied by capture zone would be replaced by seawater. Given the proposed location of the slant wells, the projected configuration of the capture zone, and the inland regional gradient, groundwater originating from inland regions of the basin would not be drawn into the slant wells. This is because, to reiterate, groundwater would be drawn into the slant wells within the boundaries of a localized capture zone, which would be within the larger cone of depression.

6 The decrease in salinity in Year 2 can be explained by the infiltration of fresh rainwater during an above normal rainfall year and percolation of fresh water during sand washing operations at CEMEX.

While the cone of depression is an expression of the drawdown effects of slant well pumping, it does not demark the area that would contribute to the slant well source water supply.

Groundwater Levels in Neighboring Wells

EIR/EIS Impact 4.4-3 concludes that the project would not negatively impact groundwater levels in nearby production wells. This conclusion is based on the fact that there are no active production wells extracting groundwater from the Dune Sand or 180-FTE Aquifer within the boundaries of the capture zone or cone of depression that would be created by the MPWSP slant well pumping. While the groundwater levels within the capture zone at the CEMEX site could be drawn down by as much as 29 feet at the peak 24.1 mgd scenario, the projected groundwater drawdown elsewhere in the cone of depression would range from 1 to 5 feet, as shown in EIR/EIS Figures 4.4-14, 4.4-15, and 4.4-16. This projected amount of drawdown is not sufficient to lower groundwater in neighboring production wells in the 180-Foot and 400-Foot aquifer below the top of the screen or to expose the well pump. Currently, there are no active production wells drawing supply from the Dune Sand Aquifer. **Table 8.2.8-2** expands on information provided in EIR/EIS Table 4.4-10 to compare the screen interval and the approximate depth to water in select neighboring production wells in the 180-FTE and 400-Foot Aquifers[7]. As is evident from these data, the well screens are considerably deeper than the static water level in the well and, consistent with the conclusion in the EIR/EIS, would accommodate the 1- to 5-foot drawdown that the MPWSP slant well pumping could create without damaging the well and/or exposing well screens or pumps. This is discussed in further detail below.

TABLE 8.2.8-2
REPRESENTATIVE SCREEN INTERVALS AND WATER DEPTHS FOR PRODUCTION WELLS WITHIN VICINITY OF THE PROPOSED MPWSP SLANT WELLS

Well Owner	Well Number/ID	Aquifer	Screen Interval(s) (depth in feet from top of well)	Approximate Depth to Water (feet below ground surface) Fall 2016[a]	Approximate Distance from Groundwater Surface to Top of Well Screen (feet)

[7] These representative wells were selected because adequate well construction details were available to assess screen depth.

The MCWRA compiles annual regional groundwater level data on a quarterly basis for the SVGB including the Pressure 180-Foot Aquifer and Pressure 400-Foot Aquifer[8] and compares the data to a representative dry water year and the 30-year average (MCWRA, 2018). According to MCWRA water level data, the 30-year average (1987 to 2017) groundwater levels in the Pressure 180-Foot Aquifer fluctuate seasonally about 17 feet: from about 22 feet above mean sea level (amsl) in the winter months to 5 feet amsl in the summer. The lowest seasonal average water levels are recorded during drought years where, seasonally, the maximum seasonal fluctuation can be similar to the 30-year average (about 17 feet) but the groundwater levels drop about 7 feet overall, as was the case during the peak of the last drought in 2015 when the groundwater levels reached an annual low of about 6 feet below mean sea level. The groundwater level trends are similar in the pressure 400-Foot Aquifer where the annual seasonal fluctuation is about 20 feet between: 7 feet amsl in the winter months to 17 feet below sea level in the summer. The drought year groundwater level fluctuation was similar to the 30-year average (about 22 feet) but the groundwater levels dropped about 7 feet in the dry water year of 2015.

The MCWRA groundwater level trend data characterizes the average and drought year seasonal fluctuation of groundwater in the Pressure 180- and 400-Foot Aquifer and thus provides a benchmark for analyzing the effect of the MPWSP on the local production wells (see EIR/EIS Table 4.4-10) within the MPWSP area of pumping influence. As shown on Table 8.2.8.2, above, there is over 100 vertical feet of groundwater column between the top of the well screens and the water level in the wells. This provides ample vertical distance to accommodate the seasonal and drought condition groundwater level fluctuation considering that the 30-year average fluctuation is 17 feet in the 180-Foot Aquifer and 20 feet in the 400-Foot Aquifer and dry year groundwater levels decline about 7 feet. Modeling projects that the proposed MPWSP pumping could add between 1 and 5 feet of additional drawdown to the seasonal fluctuation resulting in a maximum effect of about 12 feet of total drawdown during a dry year. While there could be an additional 1 to 5 feet of drawdown from MPWSP pumping, that increment of change would not negatively affect well yield or expose the screens leading to damage to the production well.

However, as discussed in the EIR/EIS Impact 4.4-3, CalAm recognizes the long-term nature of the proposed project and the need to provide continued verification that the project would not adversely affect groundwater levels in nearby wells within the SVGB. Under Applicant Proposed Measure 4.4-3, CalAm proposes to fund the expansion of the existing regional groundwater monitoring program to include the area where groundwater elevations are anticipated to decrease by one foot or more in the Dune Sand Aquifer, the 180-FTE Aquifer, and the 400-Foot Aquifer. The applicant-proposed measure would monitor changes in the groundwater surface elevations caused by the proposed pumping at the slant wells through a voluntary program and use of new groundwater monitoring wells. If it is determined that the project is causing groundwater levels to decline such that neighboring groundwater production wells are damaged or otherwise negatively affected by the proposed pumping, CalAm would arrange for an interim water supply and begin developing a

[8] As discussed in EIR/EIS Chapter 4.4, SVGB Pressure Area (or Subbasin) is traditionally recognized by the MCWRA. The Pressure Area consists of a series of aquifers include the 180-Foot Aquifer and the 400-Foot Aquifer, which underlie the CEMEX site and the area of influence of the proposed MPWSP pumping.

mutually agreed upon course of action to repair or deepen the well, restore groundwater yields by improving well efficiency, provide a long term supply or construct a new well.

Violation of Water Quality Standards

EIR/EIS Impact 4.4-4 concluded that the localized change in groundwater quality in the Dune Sand and 180-FTE Aquifers due to slant well pumping is not expected to violate water quality standards or interrupt or eliminate the potable or irrigation supply available to other basin users. This conclusion is reasonable because, as discussed above, the capture zone that supplies water to the slant wells contains groundwater that was previously degraded by decades of seawater intrusion, and the TDS concentrations of this water -- ranging between brackish and saline -- makes it non-potable or suitable for irrigation supply. The proposed project would not violate water quality standards because slant well pumping would, over time, only replace the existing, highly brackish and saline ambient groundwater within the capture zone with seawater from the Monterey Bay; the project would not degrade an otherwise potable groundwater supply. Furthermore, the proposed project would not interrupt or eliminate a potable groundwater supply because the exchange of ambient brackish water with saline water would only occur within the confines of the coastal-adjacent capture zone and would not extend inland or encroach on areas of the SVGB that rely on fresher groundwater for potable or irrigation supply.

8.2.9 Master Response 9: Electrical Resistivity Tomography (ERT) and Airborne Electromagnetics (AEM)

COMMENTERS ADDRESSED IN MASTER RESPONSE 9

City of Marina	David Gorman
Marina Coast Water District	Jane Haines
Citizens for Just Water	Juli Hofmann
Fort Ord Rec Users	Carol Reeb
Public Water Now	Jan Shriner
Michael Baer	Form Letter 1
Kathy Biala	Form Letter 2
David Brown	Public Meeting Verbal Comments
Margaret-Anne Coppernoll	

Several comments received on the Draft EIR/EIS addressed Electrical Resistivity Tomography (ERT) and Airborne Electromagnetics (AEM). Commenters stated that ERT and AEM data should be used to supplement the groundwater modeling and monitoring data that was used in the Draft EIR/EIS to analyze the impacts of the MPWSP on groundwater resources and some comments suggested that ERT should be used instead of the groundwater monitoring to analyze local water quality and seawater intrusion. In addition, certain commenters took issue with how Draft EIR/EIS Section 4.4.1.4 presented, on page 4.4-28, the ERT survey results and the work by Dr. Rosemary Knight.

This master response provides supplemental information and further clarification on ERT and its use as a method to help characterize water quality and seawater intrusion along the coast of Monterey Bay. This master response also provides information and preliminary results from the SkyTEM airborne geophysical survey, also referred to as AEM, which was conducted in May 2017 near the city of Marina for Marina Coast Water District (MCWD) by the Stanford University School of Earth Energy and Environmental Sciences. Section 8.2.9.1 of this master response describes ERT technology and other previous geophysical studies conducted along the Monterey Coast and the Salinas Valley, and the application of the technology as a geophysical exploratory tool. Section 8.2.9.2 describes the limitations of ERT surveys as a method to monitor and assess seawater intrusion along the Monterey Coast and inland. Section 8.2.9.3 discusses the use of ERT data in the Draft EIR/EIS analysis of groundwater impacts and in the North Marina Groundwater Model, as well as a discussion of the preliminary results from the May 2017 AEM survey and how such results compare to the data, analysis and conclusions of the EIR/EIS. Section 8.2.9.3 concludes by explaining that CEQA and NEPA do not require a lead agency to conduct every recommended test and perform all recommended research to evaluate the impacts of a proposed project.

8.2.9.1 ERT Technology, Application, and Recent Studies

ERT is a geophysical survey method that measures electrical resistance through a material to create images of subsurface geologic and geochemical features and conditions. As discussed in

EIR/EIS Section 4.4.1.4, electrical resistivity imaging uses a series of sensors (referred to as electrodes) placed along a transect line on the ground surface. A direct electrical current is applied to the sensors and the resulting electrical field is measured along the ground using a second pair of electrodes, referred to as dipoles. The decrease in electrical current detected by the receiving dipoles is recorded and the resistivity is calculated based on the measured voltage, the distance between the electrodes, and the current flowing between electrodes. By varying the unit length, or depth of the dipoles as well as the distance between them, the horizontal and vertical distribution of the subsurface material's electrical properties can be recorded. Using computer processing, the distribution differences can represent a two-dimensional cross-sectional image of the subsurface. The high and low resistivity zones in the subsurface are displayed as a series of colors in a cross section that represent variations in electrical resistivity. In this application, variations in electrical resistivity can be interpreted as variations in the content of seawater, fresh water, or varying intermediate concentrations of brackish water (i.e., water with salinity in between seawater and fresh water). Salty water has low resistance due to the higher concentration of total dissolved solids (TDS) or salinity; fresh water has a higher resistance because of the relatively low concentration of TDS.

ERT is not a new technology and its application as a preliminary geophysical exploration method has been in use for decades. Electrical resistivity survey methods have assisted in groundwater and engineering studies to identify ground failure surfaces, bedrock quality, groundwater quality, saltwater boundaries, and areas of seawater intrusion. In addition to Stanford Professor Dr. Rosemary Knight's recent ERT work along the Monterey Bay coast, at least two other hydrogeologic studies using electrical resistivity geophysics have been conducted in the Salinas Valley. The first resistivity geophysics survey was completed in this area in 1990, and the second study was conducted in 1993 for the Monterey County Water Resources Agency (MCWRA) as part of its Salinas Valley Groundwater Basin Seawater Intrusion Delineation/Monitoring Well Construction Program using Controlled Source Audio-frequency Magnetotellurics (CSAMT), a nonintrusive, ground geophysical survey method for obtaining information about subsurface resistivity.

As mentioned in EIR/EIS Section 4.4.1.4, Dr. Knight, along with Stanford University graduate and post-graduate students and staff, completed two ERT surveys along the beaches of Monterey Bay. The two ERT surveys were conducted along a single transect and generated two-dimensional cross sections of conditions directly beneath the beach; as these surveys were a single transect on the beach, they did not capture subsurface conditions under the ocean, under CEMEX or any further inland. The first study was conducted in 2011-12 and included one 4-mile-long line along the beach from Seaside to Marina (Pidlisecky et al., 2016), ending south of the location of the proposed slant wells. This was a pilot study to: 1) demonstrate the viability of using large-offset ERT to image the distribution of subsurface freshwater and saltwater over a large spatial extent; and 2) gain insight in the distribution and geologic controls of seawater intrusion in the Monterey Bay region.

A second, more extensive ERT survey was conducted along a 25-mile transect along the coast of Monterey Bay in 2014 and 2015 (Goebel et al., 2017), extending from the Santa Cruz Mid-County Basin in the north, through a portion of the Pajaro Valley Groundwater Basin as well as a portion of

the Salinas Valley Groundwater Basin, to the Seaside Basin in the south. However, several coast line stretches, including the beach area fronting the CEMEX sand mining facility, were not surveyed due to access restrictions. The purpose of the 2014-2015 resistivity survey was to map the salinity of groundwater and further delineate the location and extent of seawater intrusion along the coastline. The resistivity sections were further interpreted by comparing the results with well logs, seismic reflection data, geologic reports, hydrologic reports, and land use maps from the region. The study determined that the electrical resistivity readings positively correlated with measured TDS concentrations to a depth of about 500 feet in the Seaside Basin Water Master (SBWM) Monitoring Wells SBWM-1 thru SBWM-4, and supported the understanding that the deeper aquifers in the Seaside Basin have not yet been affected by seawater intrusion. Although access limitations prevented placing ERT electrodes on the beach directly in front of the proposed slant well location at CEMEX, the nearby ERT survey results identified the seawater intrusion that is occurring in the 180-Foot Aquifer and 400-Foot Aquifer in the Salinas Valley Groundwater Basin.

In May 2017, Dr. Knight and graduate students conducted a third geophysical study consisting of an airborne geophysics survey of the coastal area of the Salinas Valley Groundwater Basin near Marina, extending inland from the Monterey Bay to Highway 183 and the Armstrong Ranch. A portion of the survey was also conducted off the Monterey Bay coast to capture and correlate resistivity data from the hydrogeology and water quality within the geologic units underlying the Bay. The survey employed a method known as Time Domain Electromagnetics (TEM); SkyTEM, a Denmark-based company, collected the survey data. SkyTEM introduced airborne geophysical surveys for groundwater studies around 2011 and has applied this technology in various applications throughout the world. The SkyTEM antenna, which is suspended from a helicopter at a height of about 150 feet above the ground, generates a primary magnetic field that is directed downward. This creates a secondary magnetic signal that is returned and detected by the receiver. The received signal is then converted to resistivity data and that data is inverted to produce output like that obtained from ERT. The SkyTEM survey, hereafter referred to as Airborne Electromagnetics (AEM), was conducted for MCWD and was designed to provide resistivity data that can be linked to the extent of seawater intrusion at the coast and further inland. Dr. Knight and graduate researcher Ian Gottschalk prepared a report in June 2017 (Gottschalk and Knight, 2017) with the preliminary interpretation of the AEM data acquisition and the initial results of the AEM survey were publicly presented to the Marina City Council on August 8, 2017 and provided to the Lead Agencies by MCWD in November 2017; see Section 8.5.2. The analysis of the AEM survey data relied on subsurface information provided by geophysical borehole logs from CalAm's nine monitoring well clusters installed in 2015 as part of the MPWSP Hydrogeologic Investigations Workplan. Preliminary results of the AEM study are discussed below in Section 8.2.9.2.

8.2.9.2 ERT/AEM Requires Ground-Truthing: Correlation with Actual Subsurface Data

ERT/AEM is a commonly used geophysical method; it can be used as a preliminary exploratory tool to provide data about the subsurface and is useful to identify data gaps and supplemental data needs. It is also useful for identifying preferred locations of monitoring and groundwater production wells. Dr. Knight's 2011 and 2014 ERT surveys demonstrated that there is generally a positive correlation between the ERT outputs and known subsurface geology and water

chemistry. However, as a general understanding, it should be noted that while the salinity of the groundwater in the aquifer materials can change subsurface resistivity measurements in seawater intruded areas, differences in the character of the subsurface geologic materials can also alter the measured resistivity (Goebel et al., 2017). Moreover, ERT/AEM requires correlation and ground-truthing with known data points that describe the geologic, groundwater, and water chemistry. In the case of the 2011 and 2014 ERT surveys, data from the four SBWM monitoring wells, seismic data, induction logging, and lithologic logs were critical to interpretation of ERT data. For the 2014 effort, use of downhole geophysical logs (E- logs) and drillers' reports led Goebel and others to "interpret the lowest resistivities in the inverted resistivity section as corresponding to the presence of saltwater, and the highest resistivities as corresponding to freshwater. Between these two end members, variation in lithology introduces uncertainty in the determination of fluid [groundwater] salinity" (Goebel et al., 2017)

ERT/AEM technology has the potential to augment subsurface data on seawater intrusion and subsurface groundwater conditions, but it cannot be considered a replacement for intrusive methods to evaluate the subsurface and groundwater aquifers (exploratory boreholes, groundwater monitoring wells, down-hole geophysics and modeling) because ERT/AEM has certain limitations. First, any obtained data would require verification and correlation through ground-truthing using groundwater monitoring wells and other subsurface data as control points. Without adequate ground-truthing or control points with actual subsurface lithology and water chemistry data, the ERT data could not be calibrated to actual site conditions.

Second, for each study area, there is a need for complementary data to transform the measured electrical resistivity measurements into relative salinity or TDS concentrations. As electrical resistivity depends on knowing both subsurface lithologic conditions and measured salinity or TDS concentrations of the groundwater, there is no universal salinity/TDS correlation with the specific color schemes displayed as ERT data (Knight, 2017). That correlation would have to be obtained from water testing from wells in the particular location to generate that correlation at that location. In Dr. Knight's 2011 and 2014 single-transect ERT surveys along the Monterey Coast, a review of down-hole E-log data allowed researchers to define a threshold above which resistivity corresponds to entirely freshwater-saturated materials (depicted as very blue in Dr. Knight's ERT studies), and another threshold below which resistivity corresponds to salt-water saturated materials (depicted as very red in Dr. Knight's ERT studies). As discussed in more detail below, the preliminary findings of the 2017 AEM survey show the bulk resistivity of the aquifer sediments combined with the resistivity of the water in those sediments but does not convert those resistivities to represent the actual groundwater quality. The final AEM report, which may provide that correlation, is expected in spring 2018.

Third, the ability of an ERT or AEM survey to identify the varying lithology and water chemistry in the distinct groundwater zones beneath the Salinas Valley area would depend on how the survey is designed and the desired image depth. ERT/AEM resolution decreases with depth and is less able to distinguish subtle changes in subsurface conditions as the depth increases. Therefore, if an ERT/AEM survey is not tailored for a specific shallower depth, it cannot necessarily be relied upon to accurately distinguish smaller zones of saline water from other zones producing water with lower salinity. This would be a concern for ERT/AEM surveys in the area near the city of Marina, for

example, where areal and vertical variations in lithology and, therefore, electrical properties, are numerous and widespread. However, Goebel et al. (2017) was able to show the value of using a combination of ERT data and traditional subsurface data (i.e. data from well bore logs, groundwater levels) to better understand the distribution of seawater intruded groundwater and fresher groundwater on a groundwater basin scale.

The AEM geophysical survey that was conducted in May 2017 will generate some usable data on the extent of groundwater aquifers and provide information as to the relative salinity/TDS concentrations of the water in those aquifers inland of the coast. This AEM technology makes it possible to complete numerous parallel transects efficiently and cost-effectively. It is likely, due to the recent advancements in the AEM technology, that the data will be more representative of the actual conditions than the geophysical studies conducted in the 1990s. However, as with the ERT results, the AEM data must be ground-truthed and correlated with the actual subsurface geology and water chemistry information using well logs, induction logs, and groundwater sampling results as control points. This is especially true for AEM assessments of seawater intrusion and identification of the seawater intrusion front. ERT/AEM data collected in the Monterey Bay area can be interpreted using well data. What can be extracted from the data (i.e., the extent to which lithology versus salinity/TDS can be resolved) depends on the quality of the complementary data. Locally, the verification of the recent AEM survey will include information from the monitoring wells installed by CalAm in the Marina area. The challenges with using AEM survey results to identify seawater intrusion and the seawater intrusion front could include difficulty resolving subtle changes in subsurface resistivity, identifying decreases in resistivity that do not necessarily indicate a decrease in salinity/TDS concentration, and capturing lateral resistivity changes that correlate with geologic conditions rather than water quality.

8.2.9.3 Use of ERT/AEM Results in the Analysis of Groundwater Impacts in the EIR/EIS

The Draft EIR/EIS mentioned Dr. Knight's ERT work along the Monterey Coast (EIR/EIS Section 4.4.1.4) as informational background for the Environmental Setting, and to recognize the current, notable efforts to apply geophysical methodology to the further assessment of seawater intrusion. Some comments assert that the analysis of groundwater in the EIR/EIS is incomplete or flawed because it did not incorporate findings from Dr. Knight's ERT surveys along the Monterey Coast. As explained below, the approach in the Draft EIR/EIS was appropriate, and minor clarifications and updates have been made in Final EIR/EIS Section 4.4.1.4, regarding the use of ERT/AEM data that do not change the conclusions reached in the EIR/EIS related to groundwater impacts.

Use of 2011 and 2014 ERT Survey Results in Draft EIR/EIS

The groundwater analysis did not incorporate findings from Dr. Knight's studies for three key reasons. First, the ERT survey results did not add new significant information that was not already known regarding the extent of seawater intrusion along the Monterey Coast or the hydrogeological conditions in the project area. Dr. Knight's 2011 and 2014 ERT surveys along the Monterey Coast captured only static images of subsurface conditions and water quality directly under the beach at

that time; they did not extend inland and they did not include the CEMEX property where project slant wells are proposed to be located. While they were interesting data from a scientific perspective, especially considering the resolution at depth, they did not provide additional useful information for the analysis of impacts for the MPWSP, primarily because the extent of seawater intrusion conditions at the coast have been confirmed for years through groundwater monitoring. Information regarding subsurface geology, groundwater flow and occurrence, and groundwater chemistry used in the EIR/EIS and for the 2016 version of the North Marina Groundwater Model ($NMGWM^{2016}$) development and validation were obtained from known scientific sources and included some of the same sources that Dr. Knight's team used to verify the ERT survey findings. Furthermore, the ERT results are reported as a cross-section of the groundwater system, and cannot be reliably extrapolated into the $NMGWM^{2016}$ areas that extend substantial distances west and east of the ERT section.

Use of 2011 and 2014 ERT Survey Data for $NMGWM^{2016}$

The data from the 2011 and 2014 ERT surveys did not provide useful supplemental data for input or calibration of the updated $NMGWM^{2016}$. As described in EIR/EIS Section 4.4.4.2, groundwater modeling using the $NMGWM^{2016}$ was the primary tool used to evaluate the response from pumping at the slant wells and to analyze the project impacts on groundwater resources in accordance with CEQA thresholds. The $NMGWM^{2016}$ was employed to calculate the water level decline in response to proposed MPWSP pumping, specifically, to estimate the cone of depression. MPWSP slant well pumping effects on the inland movement of the seawater intrusion front and the characteristics of the capture zone were evaluated using the $NMGWM^{2016}$ and particle tracking with the MODPATH code. The $NMGWM^{2016}$ is a detailed model, the construction of which is thoroughly documented in EIR/EIS Appendix E2. The input data for the models consists of lithologic conditions observed in drilling cores, and other field data. Given the development history, regional focus, calibration, and measured data, the $NMGWM^{2016}$ is the industry standard and best available technology to simulate the groundwater response from the proposed MPWSP pumping and to analyze the environmental impacts under CEQA and NEPA. Groundwater modeling, informed by a reasonable understanding of the local hydrogeologic conditions, which is agreed upon by experts in hydrogeology, provided sufficient information to assess impacts on groundwater in the project area. Master Response 12, The North Marina Groundwater Model (v. 2016), addresses comments about the model.

The $NMGWM^{2016}$ was not constructed or employed to calculate changes in water quality and water density due to the mixing of ocean water and groundwater. The ERT studies produced a 2-dimensional cross-sectional resistivity map of single transects along the coast that showed estimates of bulk resistivity of geologic materials and pore water at an instant in time. The estimated bulk resistivities did not represent actual groundwater quality and even if they had, the $NMGWM^{2016}$ would not benefit nor would it be improved by ERT groundwater resistivity data because the model did not project changes in groundwater quality. The resistivity estimates provided by the 2011 and 2014 surveys, therefore, would not add relevant information to the calibration or operation of the $NMGWM^{2016}$.

Use of 2017 Preliminary AEM Results in the EIR/EIS

A preliminary interpretation of the May 2017 AEM survey that was conducted for MCWD was prepared in June 2017, publicly presented at a Marina City Council meeting in August 2017, and provided to the Lead Agencies in November 2017; see Section 8.5.2. According to the preliminary report, subsurface areas of low resistivity indicate the presence of saltwater and areas of high resistivity indicate areas that contain fresh groundwater. Based on this, the preliminary interpretation concluded that there is a "sizable isolated lens of freshwater" in the Dune Sand and 180-FTE Aquifer and the presumption of saltwater intrusion in this area appears incorrect. For the purposes of the AEM study, Dr. Knight's team defined an isolated freshwater lens as a water-bearing unit with anomalously low concentrations of TDS in an area otherwise known to be intruded by saltwater (Gottschalk and Knight, 2017).

As discussed above in Section 8.2.9.2, AEM data must be validated using physical data so it provides a consistent interpretation of subsurface conditions. Like ERT, AEM is unable to distinguish between fresh water filled fine-grained sediments and saline water filled sand sediments without the presence of a control point such as a boring or monitoring well (HWG, 2017; see EIR/EIS Appendix E3). Dr. Knight's team requested, received from CalAm, and used geophysical logs of MPWSP monitoring well clusters MW-1, MW-4, and MW-7 as control points in developing its resistivity profiling.[1] These geophysical logs were created when the wells were drilled in the latter part of 2014 and spring 2015. The resistivity shown on the geophysical logs, which Dr. Knight's team relied upon and the AEM survey output represent, is the bulk resistivity of the aquifer sediments (clay, silts clays) combined with the resistivity of the water within the aquifer; this combined resistivity is not the same as the resistivity (or conductivity by inverse) of the groundwater within the aquifer.

As discussed in detail in EIR/EIS Appendix E3, the Hydrogeologic Working Group (HWG) acquired the cross-sectional profile that was developed and presented as preliminary AEM study in August 2017 and overlaid the known hydrostratigraphy on it to show the perched and regional water tables. The overlay shows dark blue areas in the Marina uplands representing the unsaturated zone above the perched water table and a seawater wedge in the 180-Foot Aquifer with lower salinity in the shallow portion and higher salinity water in the lower portion. The 400-Foot Aquifer is shown to be seawater intruded throughout this profile. The observations and interpretations associated with the AEM data profile and HWG's hydrostratigraphic overlay are consistent with the hydrogeologic conceptual model developed by the HWG, confirmed by the Lead Agencies and used in the NMGWM[2016].

As noted above, the resistivity values shown on the geophysical logs of the monitoring wells, which were used to correlate the preliminary AEM survey data, represent bulk resistivity of the aquifer sediments and groundwater and do not represent the resistivity of just the groundwater. For example, when Dr. Knight's preliminary AEM study results show areas of dark blue (high resistivity, low conductivity, indicative of a fresher water source), it represents the combined resistivity of the sediments and the groundwater but does not necessarily mean that there is potable,

[1] Other than these three control points, most of the profiles developed by Dr. Knight's team to illustrate preliminary AEM findings do not show control points such as well logs or water quality sampling points.

freshwater in a particular zone. The only way to use the preliminary AEM survey data to represent the actual quality of the groundwater is to correlate it relative to actual groundwater quality data obtained from the monitoring wells. That is what the HWG did and the results are provided in EIR/EIS Appendix E3. The HWG used the actual groundwater conductivity measurements from a data set that has been compiled from the MPWSP monitoring well network for over 2 years to modify the presentation of Dr. Knight's the preliminary AEM survey findings. The HWG chose to use conductivity measurements taken in May 2017 so they would closely correlate to the time that the Stanford team conducted the AEM survey. In Appendix E3, the HWG presents an example to illustrate the difference between correlating groundwater quality with over two-year-old down-hole geophysical logs, as Dr. Knight's team did in its preliminary AEM findings, versus using actual, current groundwater data obtained from the well to correlate the AEM data, as was done by the HWG. The example considers geophysical log of MW-7. According to the MW-7 geophysical log (see Figure 3-9 in Appendix E-3), the resistivity in monitoring well cluster MW-7 at an elevation of -20 meters (correlative to MW-7S), is 100 ohm-meters (ohm-m), which is equivalent to a conductivity of 100 microsiemens per centimeter (µs/cm) or a TDS of about 68 mg/L. This could be considered fresher water considering the recommended California Secondary Maximum Contaminant Level (MCL) (Cal. Code Regs., tit. 22, § 64449) for TDS in drinking water is only 500 mg/L. However, compared to the actual measured TDS in the monitoring well in May 2017, this estimated TDS concentration is very low and inconsistent with actual groundwater data in and around monitoring well MW-7. Water chemistry monitoring over the past two years at MW-7S has shown that the conductivity of the groundwater near MW-7 is on average 2,160 µs/cm, representing a TDS of about 1,470 mg/L, which far exceeds California's MCL for drinking water. A TDS reading of that magnitude is greater than what was predicted using geophysical log data and shows that the groundwater is far from "fresh", as reported by Dr. Knight's team. This example illustrates how the preliminary AEM results, which have been presented to the public by the MCWD and Dr. Knight's team, do not accurately depict and may exceedingly underestimate the actual TDS concentrations in the groundwater. This finding underscores the need to use caution when relying on the preliminary AEM results to determine the presence or absence of isolated lenses of freshwater in the Dune Sand or 180-Foot aquifer.

As described above, the HWG modified the preliminary AEM resistivity profile to more correctly illustrate the distribution of water quality in the aquifers using the same control points but using known groundwater conductivity measured in the monitoring wells during May 2017 rather than geophysical logs from 2015. The results of the HWG modification of the AEM resistivity profile shows a distribution of groundwater chemistry that is consistent with the findings of the HWG hydrogeologic investigation and generally consistent with the annual salinity mapping for the 180-Foot and 400-Foot Aquifers published by the Monterey County Water Resources Agency. The red and dark red colors on the profile modified by the HWG (HWG, 2017) clearly indicate a two-dimensional view of a seawater intrusion front that is present in the Marina area. The AEM survey provides data to help interpolate between control points provided by the MPWSP monitoring network and confirms the work completed for the hydrogeologic investigation regarding the distribution of water quality in the MPWSP study area (HWG, 2017).

As described in Master Response 8, Project Source Water and Seawater Intrusion, the MPWSP would capture ambient groundwater from a coastal area that is heavily intruded with seawater

and, as pumping continues in that capture zone, seawater would eventually replace the ambient, intruded groundwater. Both the preliminary AEM survey results released by Dr. Knight's team and the modification of those results by the HWG to depict actual groundwater quality, clearly show the band of highly brackish to saline groundwater along the coast where the MPSWP slant wells would be extracting water. If there are pockets or lenses of fresher groundwater inland and outside of the MPWSP capture zone, it is of minor consequence because while the water located inland from the coast may be less intruded and have lower TDS, it would not be drawn into and would not become source water for the MPWSP slant wells.

CEQA and NEPA Perspective on Use of ERT/AEM in EIR/EIS

Several comments assert the EIR/EIS is deficient since it did not incorporate the ERT survey data or the May 2017 AEM survey data, that the ERT and AEM survey data should be incorporated and the Draft EIR/EIS should be recirculated. The Lead Agencies reviewed the ERT/AEM data and, as noted above, the HWG modification of the AEM resistivity profile shows a distribution of groundwater chemistry that is consistent with the findings of the HWG hydrogeologic investigation and generally consistent with the annual salinity mapping for the 180-Foot and 400-Foot Aquifers published by the Monterey County Water Resources Agency; no changes are required to the Draft EIR/EIS. The Lead Agencies considered this additional technology and while they are required to utilize best available science to make conclusions on the potential environmental harm of a project, the use of every possible technology available to evaluate the impacts of the project is not required. As explained previously, the Lead Agencies used the NMGWM^{2016} for the analysis. This master response demonstrates that the ERT/AEM data (once ground-truthed) and the underlying parameters of the NMGWM^{2016} are consistent; thus, the NMGWM^{2016} is sufficiently credible to be used in evaluating project impacts.[2]

---

[2] "CEQA does not require a lead agency to conduct every recommended test and perform all recommended research to evaluate the impacts of a proposed project. The fact that additional studies might be helpful does not mean that they are required." (*Clover Valley Foundation v. City of Rocklin* (2011)197 Cal.App.4th 200, 245, quoting *Association of Irritated Residents v. County of Madera* (2003) 107 Cal.App.4th 1383, 1396.) "CEQA does not require a lead agency to conduct every test or perform all research, study, and experimentation recommended or demanded by commenters." (CEQA Guidelines§ 15204, subd. (a).)

The studies on which an EIR/EIS is based need not be irrefutable, nor are analyses deemed inadequate because they could have been better or because there is another study or analysis that may provide more information. (See, *State Water Resources Control Bd. Cases* (2006) 136 Cal.App.4th 674, 795; *Barthelemy v. Chino Basin Mun. Water Dist.* (1995) 38 Cal.App.4th 1609, 1620; *Laurel Heights Improvement Assn v. Regents of University of California* (1988) 47 Cal. 3d 376; *Berkeley Keep Jets Over the Bay Committee v. Board of Port Com'rs* (2001) 91 Cal.App.4th 1344, 1355 - 1356.) The only relevant issue is whether the discussion of environmental impacts relied on in the EIR/EIS reasonably sets forth sufficient information to foster informed public participation and to enable the decision makers to consider the environmental factors necessary to make a reasoned decision, regardless of whether a new methodology is available.

In *Laurel Heights Improvement Assn v. Regents of University of California*, *supra*, 47 Cal. 3d at 409, the final EIR described two environmental sampling studies conducted at the UC San Francisco Parnassus campus in 1984 and 1986, which established that research activities had not resulted in statistically significant increases in the deposition of organic chemicals or radioactive materials in the vicinity of the campus. The Court of Appeal and the project opponent found the studies lacking and concluded the EIR should not have relied on them, but the Supreme Court disagreed. It was irrelevant that the studies might be lacking in certain particulars or that the studies may not have conclusively demonstrated a lack of environmental effect; rather, the relevant issue was whether the studies were sufficiently credible to be considered as part of the total evidence to support the conclusions in the EIR.

8.2.10 Master Response 10: Environmental Baseline under CEQA and NEPA

COMMENTERS ADDRESSED IN MASTER RESPONSE 10

City of Marina	Ecological Rights Foundation, the Center for Biological Diversity, and Our Children's Earth Foundation
Marina Coast Water District	Point Blue Conservation Science
California Unions for Reliable Energy	Public Water Now
Citizens for Just Water	

This Master Response has been prepared in response to comments asking why the EIR/EIS did not include a separate baseline report and why the baseline of 2012 was selected by the Lead Agencies, as well as claims that the selection and/or characterization of the baseline conditions against which environmental impacts were measured did not comply with CEQA. As is common with most EIRs and EISs, the CEQA and NEPA baseline has been integrated into the EIR/EIS and there was no specific baseline report prepared. As CEQA Guidelines Section 15125 explains, "An EIR must include a description of the physical environmental conditions in the vicinity of the project, as they exist at the time the notice of preparation is published, or if no notice of preparation is published, at the time environmental analysis is commenced, from both a local and regional perspective. This environmental setting will normally constitute the baseline physical conditions by which a lead agency determines whether an impact is significant." NEPA (40 CFR 1502.15) requires that an "environmental impact statement shall succinctly describe the environment of the area(s) to be affected or created by the alternatives under consideration. The descriptions shall be no longer than is necessary to understand the effects of the alternatives."

Every resource section in EIR/EIS Chapter 4 (and in Section 5.5, Alternatives Impact Analysis) includes a setting/affected environment section and information on field studies conducted to develop the baseline. EIR/EIS Section 4.1.3, Baseline Conditions, explains the baseline:

> The baseline for this EIR/EIS is the existing condition on or about October 5, 2012, updated with new data as appropriate, which is when the CPUC issued a Notice of Preparation (NOP) for the proposed project to local, state, and federal agencies, Native American tribal organizations, and other interested parties. Although the Notice of Intent for the NEPA review contained within this document was issued in 2015, use of the 2012 baseline is appropriate and reasonable because (i) 2012 is a very recent point in time; (ii) the CPUC invested considerable resources amassing 2012 background/baseline data for the April 2015 Draft EIR; and (iii) environmental conditions in the study area have been relatively static such that 2012 conditions remain representative of meaningful baseline conditions. The environmental baseline reflects the pre-project environmental conditions to which the potential impacts of the proposed project and all alternatives are compared.
>
> Since the CPUC issued its NOP in 2012, the Lead Agencies have developed or received new data on some of the resource areas, so they have updated the baseline data as appropriate. This document notes those updates in its discussions of the Setting/Affected Environment for the various resource areas and applies them in the pertinent analyses. For instance, in

> Section 4.6, Terrestrial Biological Resources, updates to survey information for biological resources are described in Section 4.6.1.2, Information Sources and Survey Methodology.

As noted by the Department of Commerce, NOAA Office of National Marine Sanctuaries in its Notice of Intent to Prepare an EIS (80 FR 51787 dated Wednesday, August 26, 2015), "MBNMS has requested CPUC to re-issue the Project EIR as part of a joint draft CEQA/NEPA document." Therefore, the baseline used in this EIR/EIS represents existing conditions at the time the CEQA NOP was issued, updated as appropriate to reflect conditions since the analysis was re-initiated by the introduction of the NEPA Lead Agency.

8.2.11 Master Response 11: CalAm Test Slant Well

COMMENTERS ADDRESSED IN MASTER RESPONSE 11

City of Marina	Bob Coble
Marina Coast Water District	Margaret-Anne Coppernoll
Ag Land Trust	Myrleen Fisher
California Unions for Reliable Energy (CURE)	Jane Haines
Citizens for Just Water	Juli Hofmann
Fort Ord Rec Users	Thomas Moore
Public Water Now	Hebard Olsen
Water Ratepayers Association of the Monterey Peninsula	Nancy Selfridge
Michael Baer	Jan Shriner
David Beech	Form Letters 1 & 2
Kathy Biala	Public Meeting Verbal Comments
Charles Cech	

This Master Response addresses comments and questions about the existing CalAm test slant well, including: clarification of its background and purpose; its permitting and CEQA/NEPA review process; the monitoring wells and pump tests and how these data have been used in this EIR/EIS; and the conversion of the test slant well to a production well. This Master Response also summarizes data concerning other locations within California where slant well technology for desalination plants has been explored, but such technology has not been pursued, and explains why such evolving technology was deemed infeasible in those circumstances, in those locations, and how those conclusions don't necessarily apply to the MPWSP. Supplemental information provided in this Master Response is for clarification and does not change any of the conclusions made in the EIR/EIS.

8.2.11.1 Background

In 2013, CalAm proposed to install and operate a test slant well on the CEMEX site to gather technical data related to the feasibility of a subsurface intake system and to facilitate design and intake siting for the proposed Monterey Peninsula Water Supply Project (MPWSP), as well as to gather information about the potential effects of the proposed project on the groundwater aquifers. As described in Draft EIR/EIS Section 2.6 on page 2-30, the topic of water rights is relevant to the MPWSP in the context of project feasibility. EIR/EIS Section 2.6.1 notes that since the SWRCB is the state agency authorized to exercise adjudicatory and regulatory functions in the areas of water rights, the CPUC asked that the SWRCB issue an opinion as to whether CalAm has a credible legal claim to the supply water for the MPWSP. In response, the SWRCB prepared its *Final Review of California American Water Company's Monterey Peninsula Water Supply Project*. That July 2013 report is attached to the EIR/EIS as Appendix B2, and as described therein, the SWRCB recommended a series of test boring/wells to assess the hydrogeologic conditions at the CEMEX site, and aquifer testing to determine the pumping effects on both the Dune Sand Aquifer and the underlying 180-Foot Aquifer. As specified in EIR/EIS Appendix B2 Section 8, "Pre-project

conditions should be identified prior to aquifer testing. Aquifer tests should mimic proposed pumping rates." The installation and operation of the test slant well was in response to the SWRCB recommendation to collect the required information, and to inform CalAm's final design of the production wells.

8.2.11.2 Coastal Development Permit and CEQA Review for Test Slant Well

Several comments question the adequacy of the CEQA/NEPA review process conducted for the test slant well, challenge the EIR/EIS representation of the CEQA/NEPA review process for the test slant well, and question whether, or opine that, CEQA/NEPA was avoided completely. A test slant well, even as a temporary exploratory project, requires a Coastal Development Permit (CDP). As noted in the revised footnotes in EIR/EIS Sections 1.4.4 and 3.1, CalAm applied to the City of Marina for a CDP in July 2013, and the City oversaw the preparation of a CEQA Initial Study (IS) and Mitigated Negative Declaration (MND) for the project in 2014 (SWCA, 2014a). The IS/MND indicated that the proposed test slant well project had the potential to result in significant adverse effects on the environment, but that any such effects could be avoided or reduced to a less-than-significant level through project design modifications and development and implementation of feasible mitigation.

On July 10, 2014, the City of Marina Planning Commission declined to adopt the City-prepared IS/MND, and declined to approve or disapprove a CDP for the proposed CalAm test slant well project. CalAm appealed the Planning Commission's decisions to the Marina City Council; on September 4, 2014, the City Council also declined to adopt the IS/MND and denied CalAm's application for development of the test slant well in the coastal zone. CalAm filed a timely appeal with the California Coastal Commission (CCC), pursuant to Coastal Act Section 30603(a)(5), which allows appeals of any development that constitutes a major public works facility.

The CCC considered CalAm's application for a CDP on appeal at its November 2014 meeting, and issued Coastal Development Permit #A-3-MRA-14-0050, dated December 8, 2014, to CalAm for the test slant well.

As noted in the October 31, 2014 Staff Report (CCC, 2014), the CCC approvals of CDP applications are to be consistent with any applicable requirements of CEQA. CEQA Guidelines Section 21080.5(d)(2)(A) prohibits a proposed development from being approved if there are feasible alternatives or feasible mitigation measures available which would substantially lessen any significant adverse effect which the activity may have on the environment. The CCC identified and adopted 17 special conditions necessary to avoid, minimize, or mitigate the potential for the proposed test slant well to result in significant adverse environmental impacts and found that, within the meaning of CEQA, the proposed project, as conditioned, was adequately mitigated and consistent with CEQA.

8.2.11.3 MBNMS Authorizations and NEPA Review for Test Slant Well

On June 25, 2013, CalAm submitted a Request for Authorization to MBNMS for the issuance of two separate authorizations for the test slant well project: (1) authorization of the CDP issued by

the CCC to allow CalAm's proposed drilling into the submerged lands of MBNMS; and (2) authorization of a National Pollutant Discharge Elimination System (NPDES) permit issued by the Central Coast Regional Water Quality Control Board to allow CalAm's proposed discharge of water into MBNMS. See EIR/EIS Sections 1.4.4 and 3.1. MBNMS oversaw the preparation of an Environmental Assessment (EA) for the test slant well project, in compliance with NEPA, and a Final EA was published in September 2014 (SWCA, 2014b). MBNMS authorized the CDP on December 9, 2014 and the NPDES permit on January 6, 2015.

8.2.11.4 Monitoring Wells

One of the special conditions of the CDP, Special Condition 11 ("Protection of Nearby Wells"), required CalAm to install monitoring devices in a minimum of four wells on the CEMEX site within 2,000 feet of the test well, and one or more offsite wells, to record water and salinity levels within the wells. Between December 2014 and April 2015, CalAm constructed the test slant well and five monitoring well clusters (MW-1, MW-3, MW-4, MW-5, and MW-6) with each cluster consisting of three, 4-inch diameter monitoring wells completed at different depth intervals corresponding to the Dune Sands, 180-Foot, and 400-Foot Aquifers (Shallow – MW-4S, Medium – MW-4M, and Deep – MW-4D, respectively), meeting this Special Condition 11 requirement for monitoring wells.

Special Condition 11 also required that prior to commencement of pumping of the test slant well, the Hydrogeologic Working Group (HWG; see also Master Response 5, The Role of the Hydrogeologic Working Group and its Relationship to the EIR/EIS, Section 8.2.5) establish baseline water levels and Total Dissolved Solids (TDS) levels in those monitoring wells and provide these levels to the Executive Director of the CCC. Data monitoring began on February 19, 2015, and five monitoring reports were prepared prior to starting the pump test. An April 15, 2015 report titled *Baseline Water and Total Dissolved Solids Levels* was prepared in compliance with this provision of Special Condition 11, and included the results of Monitoring Report Nos. 1 through 5. That Baseline Report is referenced in EIR/EIS Section 4.4, Groundwater Resources, as Geoscience, 2015b. As confirmed in that report, groundwater level measurements and groundwater quality samples were collected from the test slant well and all monitoring wells, (Monitoring Reports Nos. 1 through 4) prior to the initiation of test well pumping.

8.2.11.5 The Long-Term Pump Test

Test slant well pumping was performed in two phases: a step-drawdown and 5-day constant rate pump test[1] immediately following construction and development of the test slant well, followed by the long-term pump test. The long-term[2] pump test commenced on April 22, 2015. Special Condition 11 required CalAm to stop pumping the test slant well if water levels were to drop more than 1.5 feet, or if TDS were to levels increase more than 2,000 parts per million from pre-pump test conditions. After 44 days of pumping (June 5, 2015), the test slant well was shut

1 In a step-drawdown test, the discharge rate in the pumping well is increased from an initially low constant rate to a progressively higher constant rate, whereas a 5-day constant rate test would use the same rate for 5 days.

2 The HWG Work Plan (Geoscience, 2013) makes reference to long-term as being 18 months (540 days) with the purpose of determining if there are seasonal or annual variations in source water quality due to potential changes in precipitation or upstream groundwater production.

off in compliance with Special Condition 11 because water levels were approaching the maximum allowable water level decrease. In a June 2015 memo to the CCC (HWG, 2015), the HWG provided the CCC with two analyses of groundwater elevations and TDS trends in the compliance monitoring wells, and demonstrated the influence of regional pumping.

In July 2015, the Executive Director of the CCC (Dr. Charles F. Lester) informed CalAm that the water level decrease appeared to be caused in part by the pump test and acknowledged that based on the data, several influences other than pumping of the test slant well were also responsible for the decrease in water levels (CCC, 2015). CalAm was required to submit an application for an amendment to the CDP, and the CCC recommended to CalAm that the HWG develop a proposed amendment to Special Condition 11 that better incorporated the local and regional trends in water levels and salinity.

Collection of data from the monitoring wells continued during the approximate 144-day test slant well shutdown period, and weekly reports of changes in groundwater levels and salinity during the test slant well outage continued to be prepared and posted online[3]; water levels continued to decrease in some of the monitoring wells while the test well was not pumping.

Revisions were made to Special Condition 11 of the CDP. Specifically, these revisions (CDP Amendment A-3-MRA-14-0050-A1 dated October 13, 2015) state:

- The HWG shall review weekly monitoring data and prepare a monthly report that shall be submitted to the Executive Director [of the CCC] documenting the regional/background groundwater elevation trends and TDS level trends.
- If data collected during the pump test from MW-4S or MW-4M exhibit a decrease in groundwater levels that exceed 1.5 feet ***from regional groundwater elevation trends***, or if TDS levels increase more than two thousand parts per million ***from regional TDS level trends***, the Permittee shall immediately stop the pump test and inform the Executive Director [of the CCC]. [emphasis added]

Test Well Outages

Following approval of these revisions to Special Condition 11, the long-term pumping of the test slant well resumed on October 27, 2015, and results, including a table of outages, have been made publicly available online[2]. The test slant well experienced numerous short term outages in addition to the 144-day shutdown. Comments on the Draft EIR/EIS questioned the reasons for the outages and requested the disclosure of their frequency. Over the course of the two-year test slant well operations (730 days from April 2015 to April 2017), the test slant well operated for approximately 500 days, and was idle for about 230 days. The largest blocks of idle time occurred during the voluntary shutdown between June 5 and October 27, 2015 (144 days), during the winter storm events in March/April 2016 (60 days) and in December 2016/January 2017 (18 days). All other outages (19 days total) were the result of power interruptions.

3 https://www.watersupplyproject.org/test-well

The following table summarizes the details of the pumping interruptions encountered during the test slant well long-term pump test, through April 2017[4]:

Pump Test Off		Pump Test On		Hours Off	Notes
Date	Time	Date	Time		
		4/22/2015	3:20 PM		Start of long-term pump test

SOURCE: HWG, Monthly Monitoring Report No. 25, December 2017.

Results of the Long-Term Pump Test

The *MPWSP Test Slant Well Long Term Pumping Monthly Monitoring Report No. 25* (November 1 through November 30, 2017) was published by the HWG on December 13, 2017. Rainfall events recorded from the local Marina, CA station are overlaid on the water level plots for MW-4 (see **Figure 8.2.11-1**), the compliance point for Special Condition 11. The larger precipitation events that took place between mid-October 2016 and late March 2017 likely contributed (through precipitation recharge and/or impacts of precipitation events on basin pumping) to the upward trend of groundwater levels from approximately mid-October 2016 in MW-4S through early March 2017. Overall, the seasonal trend of groundwater elevations at MW-4 from April 2015 through October 2017 are consistent regardless of the test slant well pump being on or off (see Figure 8.2.11-1).

[4] The test slant well continued to operate through November 2017 (an additional operating time of 6 months, or 180-days, or 4,320 hours) and experienced approximately 500 hours of additional outages.

Groundwater elevation and TDS changes in the compliance well (MW-4) showed no measurable impact that can be attributed to test slant well pumping throughout the monitoring record shown in Figure 8.2.11-1. The shallow aquifer (MW-4S) showed distinct seasonal trends from the start of test slant well pumping on April 22, 2015. A downward trend occurred through the summer of 2015 (even though the test slant well was not pumping), a flat trend occurred during the fall of 2015, followed by an upward trend through the winter of 2015/2016 (even though the test slant well was pumping). A downward trend began again in mid-April 2016 just prior to the May 2, 2016 re-start of the test slant well, and continued about halfway through October 2016, albeit with a slightly decreasing slope from late July through October 2016. A seasonal increase in water levels, likely due to onset of rainfall and/or a decline in regional groundwater pumping, began in mid-October 2016 and continued through the early part of March 2017.

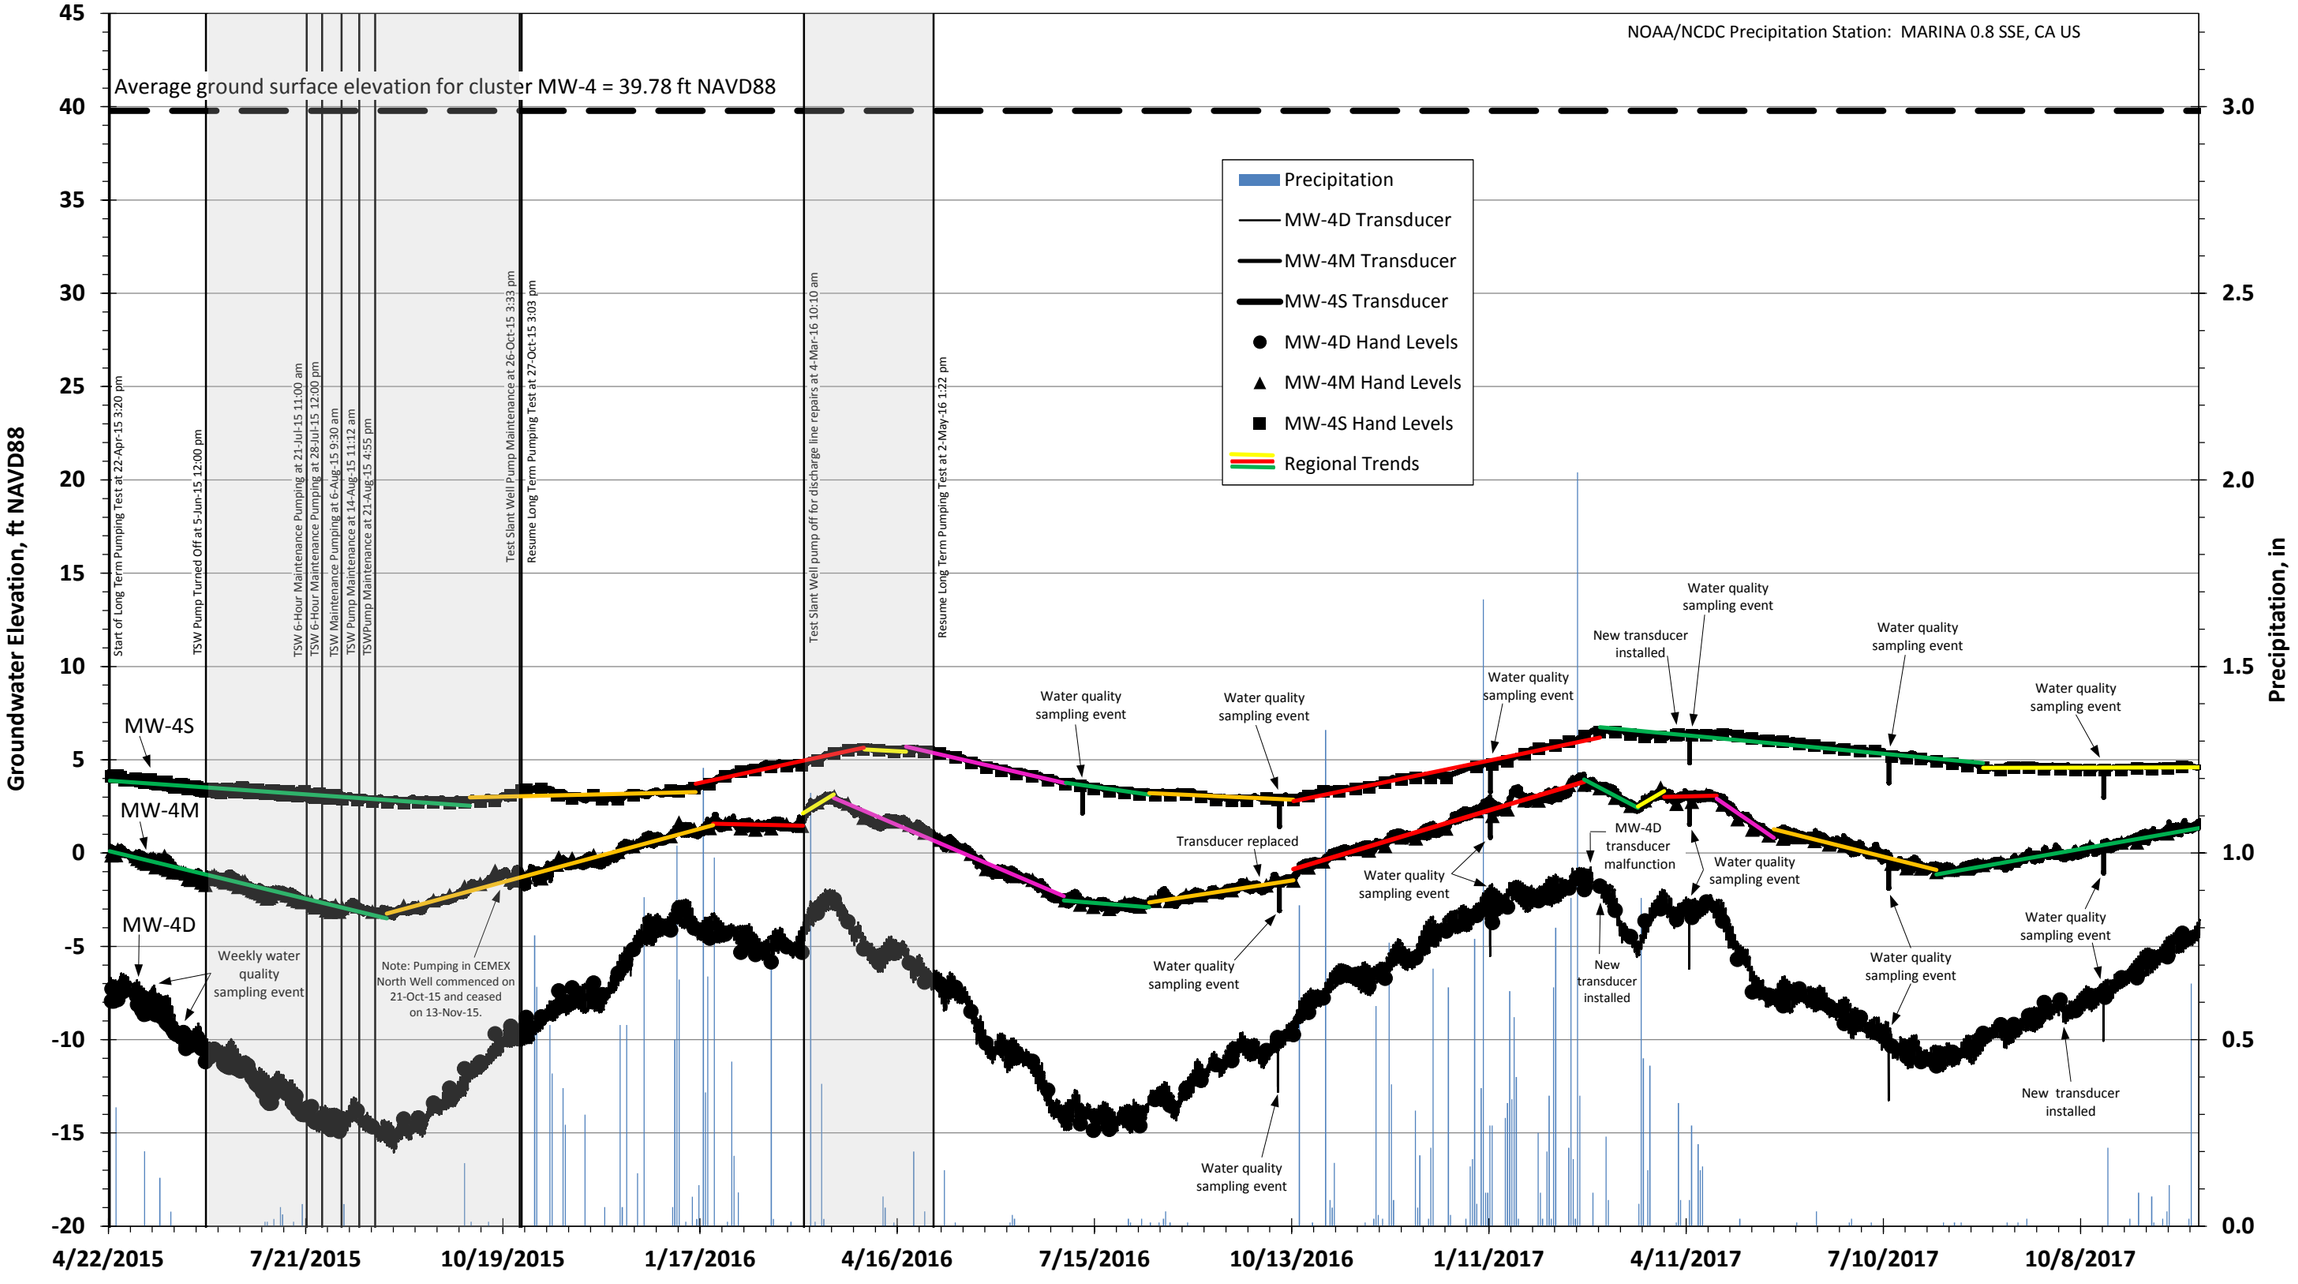
Similar to the shallow aquifer, MW-4M (at medium depth corresponding to the 180-Foot Aquifer) groundwater levels showed a distinct seasonal trend, with decreasing water levels in the spring and summer months and increasing water levels during fall and winter. There was a downward trend from mid-March through early July 2016, corresponding to a period of decreased precipitation and increased regional pumping (the start of irrigation season). The slope of the water level surface appears to have flattened in July 2016, with a slight upward slope beginning in August 2016, and a continued increasing slope through the early part of March 2017, likely as a result of decreased regional pumping (the end of the irrigation season) and the onset of the rainy season.

In summary, groundwater elevations in the Dune Sands Aquifer (MW-4S) and the 180-FTE Aquifer (MW-4M) reflected the effects of increased regional pumping in the summer months during irrigation season, and reduced irrigation pumping in the winter months, especially following rain events.

Based on data collected before and after the 144-day shutdown of test well pumping and subsequent power-related short-term test slant well outages, the HWG concluded and reported to the CCC in Monthly Monitoring Report No. 25 (HWG, 2017) that between April 2015 and November 2017:

- Groundwater levels in MW-4S and MW-4M continued to display regional trends. Therefore, groundwater levels in MW-4S and MW-4M continued to show no influences that can be attributed to test slant well pumping or non-pumping during the period (see Figure 8.2.11-1.) The groundwater elevations in MW-4S and MW-4M continued to decline when the test slant well pump was turned off between June and October 2015, and the groundwater elevations rose and then fell when the test slant well pump was turned off during March and April 2016. See Figure 8.2.11-1.
- TDS concentrations in MW-4S and MW-4M continued to display regional and/or seasonal trends, with water produced by the test slant well ranging from 25,400 mg/l[5] of TDS at start-up in April 2015 (76 percent ocean water salinity) to 31,800 mg/l in November 2016 (95 percent ocean water salinity). See HWG 2017, Table 3.

[5] Seawater generally has a TDS of 33,500 mg/l.



SOURCE: Geoscience, 2017

205335.01 Monterey Peninsula Water Supply Project

Figure 8.2.11-1

Groundwater Elevation in MPWSP MW-4

This page intentionally left blank

Groundwater level changes and TDS changes in the compliance well (MW-4S and MW-4M) continued to indicate no impact from test slant well pumping or non-pumping, and groundwater and TDS levels continued to remain within compliance with CCC permit requirements for the test slant well long-term pump test program.

8.2.11.6 Use of the Test Well Data in the EIR/EIS

The available test slant well pumping and monitoring data was used to assess the reliability of the North Marina Groundwater Model that was used in the EIR/EIS for simulating drawdown from slant well pumping (referred to as NMGWM^{2016}). The measured/observed drawdown was calculated from measured water levels in the monitoring wells during and after cessation of test slant well pumping, and was plotted against the corresponding model-calculated drawdown and recovery. There is generally good agreement between the model-calculated and measured timing of drawdown and recovery. See EIR/EIS Appendix E2, Section 4.2, and Figure 4.6.

The test slant well was also used to collect water quality data, which is shown in Table 3 in each of the Monthly Monitoring Reports, and was used in the EIR/EIS evaluation of the proposed project's conformance with Ocean Plan water quality objectives (see Draft EIR/EIS Section 4.3 on page 4.3-93, and Appendix D3). The salinity in the test slant well was also monitored and varied over time, ranging from 76 percent ocean water salinity at slant well start-up, to 95 percent ocean water salinity in November 2016, as discussed above in Section 8.2.11.5.

8.2.11.7 Conversion of Test Slant Well to Permanent Well

Some commenters on the Draft EIR/EIS question the appropriateness of converting the test slant well into a permanent well without complying with CEQA or NEPA, and because it was proposed and permitted as a "temporary" facility. The conversion of the test slant well to a permanent well is part of the proposed project and is evaluated in the EIR/EIS, as is made clear throughout the document. As stated in EIR/EIS Section 3.2.1.1, upon completion of the aquifer pump testing, CalAm proposes to convert the test slant well into a permanent well and operate it as part of the MPWSP source water intake system. Both the construction of the additional conveyance and treatment facilities needed to convert the test slant well into a permanent well and the long-term operation and maintenance of the converted test slant well are part of the proposed project, and thus evaluated in this EIR/EIS. Further, EIR/EIS Section 3.2 explains that if the MPWSP with subsurface slant wells at CEMEX is not approved and implemented, the test well would be decommissioned. However, if the proposed subsurface slant wells at CEMEX are ultimately approved as part of the proposed project, CalAm would convert the test slant well into a permanent well and operate it as part of the source water intake system. The conversion and long-term operation of the well has not been covered under previous approvals and is evaluated in this EIR/EIS as part of the proposed project.

CalAm has always proposed to convert the test slant well into a permanent well if testing at CEMEX was successful and the MPWSP is approved, and has communicated this intention in publicly available documents such as its March 2013 application for test slant well permits to the City of Marina, MBNMS, and the CCC. In those applications, CalAm pointed out that the

temporary test slant well could not be used for the MPWSP without substantial additional infrastructure and associated CEQA, NEPA, and regulatory permitting compliance, which would be addressed as part of a separate CEQA, NEPA, and permitting process for the potential future MPWSP, if and when undertaken (CalAm, 2013). Accordingly, the conversion of the test slant well to a permanent well is part of the proposed project described and analyzed in the EIR/EIS, in compliance with CEQA and NEPA requirements. If the MPWSP is not approved in any form at the CEMEX site, then the test well would be decommissioned consistent with the prior CEQA/NEPA review for, and approval of, the test slant well. The test slant well is currently permitted to operate until February 2019, per a December 2017 Coastal Development Permit amendment.

8.2.11.8 New Technology

Although the test slant well at CEMEX is not the first of its kind, to the best of the Lead Agencies' knowledge, slant well technology has not yet been used for a full-scale desalination project. Several commenters question the feasibility of relying on this new, evolving technology for the MPWSP by citing issues with the Dana Point test slant well, and by citing out of context statements made as part of the Huntington Beach and Santa Barbara subsurface intake feasibility investigations. The discussions below provide background information concerning the other potential desalination projects addressed by commenters, and places the circumstances of those endeavors into their proper context.

Dana Point Test Slant Well

The Municipal Water District of Orange County (MWDOC), in partnership with five participating agencies, investigated the feasibility of slant wells to extract ocean water and a test slant well was constructed at Doheny State Park in Dana Point, CA in 2006. A step drawdown test was performed on March 29, 2006, and a five-day constant rate test was performed from March 31 to April 5, 2006. The well was redeveloped in 2010, and equipped with a submersible pump; a long-term pump test was performed between June 2010 and February 2012. The rate of drawdown measured in the well showed an increase over time, and well efficiency dropped from 95 percent to 52 percent.

Performance issues associated with the Dana Point Test Slant Well are summarized in a technical memo that is referenced in the EIR/EIS as Geoscience 2012, and titled *Aquifer Pumping Test Analysis and Evaluation of Specific Capacity and Well Efficiency Relationships SL-1 Test Slant Well Doheny Beach, Dana Point, CA.* The loss of well efficiency was expected due to the inability to fully develop[6] the well during construction. Specifically, the Doheny test slant well was completed with a uniform 12-inch diameter casing and well screen, without a larger diameter pump house chamber due to limited funding. As described in Geoscience, 2012, the general rule of thumb for final well development is that the well must be fully developed to pump at a rate of 1.5 times the design rate. In the case of the Doheny test slant well, the well should have been developed up to a rate of approximately 3,000 gallons per minute (gpm); however, during final

6 "Developing a well" describes the act of cleaning out the clay and silt introduced during the drilling process as well as the finer part of the aquifer directly around the well screen prior to putting the well into service.

well development by pumping and surging in 2006, the well was pumped only to a maximum discharge rate of approximately 1,800 gpm because at that time, limitations of the test well pump did not allow pumping at a higher rate. As determined by Geoscience (2012), the consequence of this was that fine-grained formation material that was not properly removed from the near well zone during well development likely migrated toward the well during the long-term pump test, clogging the well screen and near well zone

Since the Doheny test slant well was the first test slant well designed for seawater intake, valuable lessons were learned regarding submersible well pump design, installation, and operation for use as a seawater intake that were applied to CalAm test slant well. For example, because of the pump house casing limitation experienced at the Doheny test slant well and the inability to fully develop the well, the CalAm test slant well at CEMEX was designed to include an 18-inch pump house casing, which can accommodate the placement of large development pumps with capacities over 3,000 gpm, and a 5-inch artificial filter pack was installed around the screens to minimize clogging. To date, the test slant well at CEMEX has not experienced the same issues as the Dana Point slant well.

Huntington Beach Independent Scientific Technical Advisory Panel

After conducting public hearings in late 2013 to determine whether to issue a CDP for the offshore portions of the Poseidon Resources LLC-proposed Huntington Beach Desalination Project (including an open water intake), the CCC and Poseidon agreed in January 2014 to collectively develop independent verification of whether any of several subsurface intake designs would be feasible for the Huntington Beach project, and convened the Huntington Beach Independent Scientific Technical Advisory Panel (HB ISTAP, or Panel). Several commenters on the MPWSP EIR/EIS suggest that since subsurface intake wells were determined to be technically infeasible at the Huntington Beach site, the technology should also be considered infeasible at the Marina site.

However, the HB ISTAP interpreted its Phase 1 charge to be the evaluation of the technical feasibility of subsurface intake technology to deliver source water for a 100 to 127 mgd desalinated water project (compared to 9.6 mgd for the proposed MPWSP), given the hydrogeologic and oceanographic site conditions at the Huntington Beach site. The HB ISTAP's Phase 1 Final Report (2014) was included as a reference to the Draft EIR/EIS on page 5.3-57. The HB ISTAP Phase 1 Final Report discussed the nine subsurface intake options considered by the Panel and noted in its discussion of well intake systems (HB ISTAP Section 3.3.6) that based on the experience at Dana Point, "the long-term performance of the [slant well] technology has yet to be confirmed." In its evaluation of subsurface intakes for Huntington Beach, the Panel acknowledged (HB ISTAP Section 5.2.5) that "slant wells completed in the Talbert aquifer would draw large volumes of water from the Orange County Groundwater Basin, which in itself is considered a fatal flaw." The Panel concluded in its Chapter 6 (Summary, Conclusions and Recommendations for Phase 2) that "slant wells tapping into the Talbert aquifer would interfere with the management of the salinity barrier and the management of the freshwater basin, and further, would likely have geochemical issues with the water produced from the aquifer."

The HB ISTAP concluded that slant wells would not be technically feasible to supply source water to support a project that would produce 100 to 127 mgd of product water at the Huntington Beach site, given the hydrogeologic and oceanographic conditions at that location. That conclusion is not directly transferable to the Marina location due to different hydrogeologic and oceanographic conditions and since the MPWSP is approximately 1/10th the size of the proposed Huntington Beach project. See also EIR/EIS Appendix E3.

Santa Barbara Subsurface Intake Feasibility Study

Some commenters on the MPWSP Draft EIR/EIS suggest that since the City of Santa Barbara found subsurface intakes to be infeasible for its project, subsurface intakes should be determined to be infeasible in Marina. On September 23, 2014, the City of Santa Barbara City Council directed staff to report back on a plan to evaluate the feasibility of using subsurface intakes as part of recommissioning that city's 10 mgd Charles E. Meyer Desalination Plant which was "mothballed" following the drought in the late 1990s. In January 2015, the Central Coast RWQCB adopted an amendment to the City's WWTP Waste Discharge Requirements that included a condition that the City should report back to the RWQCB with a work plan that would result in a completed subsurface intake feasibility study. Santa Barbara City staff accordingly explored the technical feasibility of six subsurface alternatives through an initial screening process to determine if the existing, permitted, screened open ocean intake at the existing Charles E. Meyer Desalination Plant could be replaced by a subsurface intake system.

The February 2017 Subsurface Desalination Intake Feasibility Study (Carollo, 2017) noted at page 3-19 that "slant wells have been tested for over six years at the Dana Point test site . . . [t]he overall experience with Dana Point was positive . . ." Carollo 2017 states on page 3-21 that "[o]peration of slant wells at the Dana Point and Monterey test sites in California demonstrated that this intake technology was capable of delivering 2,000 to 2,200 gpm of water." Carollo 2017 concludes on page 3-65 that "none of the subsurface intake alternatives considered in this study were determined to be potentially feasible based upon the study objectives" established by the City of Santa Barbara, and concludes specifically about slant wells on page 3-71 that "[t]o achieve the capacity required to meet this study's objectives [with slant wells], 3.5 to 6 miles of beachfront are required . . . only 1.7 miles of beach front is available . . ."

As a result, Santa Barbara chose to retain the existing open water intake, and not employ subsurface intakes because of the lack of any feasible subsurface intake alternative that could produce the full quantity of feed water required for the existing and already-permitted desalination plant within the limited City-owned beach front locations studied, and not because of the technology. Although the Santa Barbara project and the MPWSP are comparable in terms of production capacity, the conclusion that subsurface intakes are infeasible in Santa Barbara is not transferable to the MPWSP because the stratigraphy is different at CEMEX than in Santa Barbara, there is greater depth of sediment in Monterey and a larger beach within which to locate enough wells to meet the project objectives.

8.2.11.9 Slant Well Angle

Commenters have asked why the production wells are proposed to be drilled at a 14 degree angle from horizontal, when the test slant well was drilled at 19 degress from horizontal. The test slant well was planned to be drilled to 1,000 feet long at 19 degrees from horizontal, but due to snowy plover season and the USFWS requirement for construction equipment to be off the beach by the end of February 2015, the driller stopped before reaching the full length. In addition, the test slant well intentionally stopped short of penetrating the Salinas Valley Aquitard (SVA), which is the clay layer separating the 180-FTE Aquifer from the 400-Foot Aquifer. Since CalAm has committed to pumping from the shallower aquifers, the production wells are proposed to be drilled a little "flatter," at 14 degrees from horizonal, in order to gain some additional screen length in the targeted aquifers while staying above the SVA. The EIR/EIS evaluated the slant wells at 14 degrees, described in Draft EIR/EIS Section 3.2.1.1 at page 3-15, and the NMGWM^{2016} appropriately allocated slant well pumping between the Dune Sands Aquifer and the 180-FTE Aquifer, accounting for the proposed 14-degree angle of the production wells.

Regarding maintenance and cleaning of the slant wells (described in EIR/EIS Section 3.4.1), the test slant well has been cleaned using standard well cleaning procedures with no issues. The well cleaning procedures are also described in the Hydrogeologic Investigation Work Plan (Geoscience, 2013) and include swabbing and airlifting the screened interval to dislodge and remove materials collected on the well screen, and aggressively pumping and surging the well until fluids removed are effectively free of sand, sediment, and other material, and have very low turbidity values. Given the similar shallow angles, no maintenance and cleaning issues are expected for the proposed slant wells at 14 degrees. Wells constructed with well screens at 0 degrees (entirely horizontal) have been commonly used for both water supply (e.g., horizontal wells drilled into spring locations to increase the water flow) and groundwater cleanup (e.g., horizontal wells installed under structures to access and remove contaminated groundwater).

8.2.12 Master Response 12: The North Marina Groundwater Model (v. 2016)

COMMENTERS ADDRESSED IN MASTER RESPONSE 12

City of Marina	David Brown
Marina Coast Water District	Charles Cech
Ag Land Trust	Juli Hofmann
Coalition of Peninsula Businesses	Hebard Olsen
Fort Ord Rec Users	Nancy Selfridge
Water Ratepayers Association of the Monterey Peninsula	Form Letter 2
Kathy Biala	Public Meeting Verbal Comments

Numerous comments expressed concerns about the purpose of the 2016 version of the North Marina Groundwater Model (referred to herein as NMGWM^{2016}) and its construction, calibration, and reliability. Further, comments questioned the model application using the method of superposition and the relationships between model sensitivity and model reliability. These topics are clarified below in response to these comments. For further reference, see EIR/EIS Section 4.4.4.2, Groundwater Modeling, and Appendix E2, which provide a robust discussion of the NMGWM. Note that Appendix E2 is a complex, scientific technical report appropriately appended to the EIR/EIS while EIR/EIS Section 4.4, Groundwater Resources, explains the processes and assumptions and summarizes the results of the groundwater modeling effort in relatively approachable and understandable terms. Some comments concerning the modeling for the Draft EIR/EIS were submitted by members of the general public, but numerous comments were also submitted by technical consultants and, as such, are detailed and delve into the technical aspects of the groundwater modeling. Because this Master Response addresses topics raised by all such comments, some aspects of this Master Response are necessarily technical and focused on the details of the model parameters, assumptions, processes and results.

8.2.12.1 NMGWM^{2016} Purpose and Approach

Some reviewers commented on the scope of the modeling analysis, the model's results and construction, and the modeling assumptions used. Several comments cited results for individual model layers interchangeably with hydrogeologic nomenclature of Salinas Valley aquifers and aquitards, which obscures interpretation of the relationships between model performance and comparisons to observed data. Other comments questioned the validity of the selected model boundary locations, referring to them as arbitrary and not representing physical conditions, or claiming that the model boundaries were located too close to the pumping wells analyzed with the NMGWM^{2016}. These comments did not acknowledge the telescopic modeling approach, the relationships between the NMGWM^{2016} and regional Salinas Valley Integrated Groundwater Surface Water Model (SVIGSM), and the testing of boundary conditions reported as part of NMGWM^{2016} assessment. In contrast, other comments recognized the relationship between the SVIGSM and NMGWM^{2016} but concluded that discrepancies in model input and results between both models were indicative of NMGWM^{2016} limitations. Finally, there were comments about

$NMGWM^{2016}$ limitations for modeling the influence of spatial variations in groundwater salinity and density. These comments included requests to model groundwater density variations explicitly, and questioned the deployment of "equivalent freshwater head" to approximate the density contrast between "fresh water" and "sea water" in a constant density model. These topics are addressed in detail below.

HydroFocus's Assignment/Scope

HydroFocus, as a subconsultant to the consultant contracted by the Lead Agencies to prepare the EIR/EIS, was assigned to review, update, and if appropriate, re-calibrate the NMGWM for the purpose of estimating water level changes in response to proposed slant well pumping. The result of that effort is referred to as the $NMGWM^{2016}$. HydroFocus's scope of work was not related to the Lawrence Berkeley National Laboratory (LBNL) model evaluation, nor did HydroFocus receive direction from LBNL or have access to the LBNL model evaluation report prior to conducting its review and implementing its update. The LBNL recommendations (see EIR/EIS Appendix E1) and the $NMGWM^{2016}$ are the result of two independent evaluations, and their agreement provides credible evidence for the validity of the updates implemented in the $NMGWM^{2016}$.

The $NMGWM^{2016}$ was employed to calculate the water level decline in response to proposed project pumping (see "Introduction" of Appendix E2) -- specifically, to estimate the cone of depression, defined as the area where the difference between pumping and non-pumping water levels (the drawdown) are greater than or equal to 1 foot. The model also provided insight into the change in groundwater flow directions in response to pumping. The $NMGWM^{2016}$ was not constructed or employed to calculate changes in water quality and water density due to any mixing of ocean water and groundwater, and therefore model-calculated drawdown is an approximation. However, as discussed below, the influence of variable density on model-calculated drawdown is small, and aquifer property values and the modeled pumping stress have a much greater influence on the drawdown.

Model Grid and Layering

Table 2.1 of Appendix E2 describes what each model layer represents. For example, Model Layer 2 represents the shallow water-bearing sediments referred to as the Dune Sand Aquifer, A-Aquifer, Perched Aquifer, Perched 'A' Aquifer, 35-Foot Aquifer, and -2-Foot Aquifer. Similarly, Model Layer 4 represents the 180-Foot Aquifer, 180-Foot Equivalent Aquifer (180-FTE), Upper and Lower 180-Foot Aquifer, and Pressure 180-Foot Aquifer. The geographic and hydrogeologic characteristics of these water bearing units are not equivalent, and they are represented in the $NMGWM^{2016}$ by different zones, and each zone is assigned a unique value for its water transmitting and storage property values. It would therefore be erroneous to use model results for an entire model layer to make global conclusions regarding one of the property zones. For example, model-calculated water levels at all monitoring wells located in Model Layer 2 cannot effectively evaluate model reliability for the single zone that represents the Dune Sand Aquifer (the Dune Sand Aquifer is represented by one of the 16 parameter zones in Model Layer 2).

Telescopic modeling approach and boundary effects

The NMGWM^{2016} is based on the telescopic mesh refinement approach, where a relatively coarse model grid is utilized to represent the regional groundwater system defined by the physical limits of the aquifer, and a second smaller model having a relatively fine grid is utilized to represent a subregion of the aquifer (Ward, et al., 1987). Continuity between the two models is maintained using either specified water levels or specified fluxes. For example, in the NMGWM^{2016}, the simulated water levels from the SVIGSM are extrapolated and specified at the NMGWM^{2016} head-dependent flux boundaries. Using this approach, the NMGWM^{2016} boundaries have hydraulic continuity with the physical boundaries of the basin through the SVIGSM, and while there was flexibility in the locations selected for the NMGWM^{2016}, the hydraulic conditions at those boundaries are quantitatively determined by the SVIGSM and therefore are not arbitrary.

The NMGWM^{2016} was employed to calculate the cone of depression for slant well pumping at the CEMEX and Potrero Road sites. Multiple model tests confirmed that the NMGWM^{2016} results are not substantially influenced by the head-dependent flux boundaries. In one test, the cone of depression calculated with the NMGWM^{2016} (24.1 mgd) was shown to be the same as the cone of depression calculated by an extended version of the NMGWM^{2016} (see **Figure 8.2.12-1**). The "Extended Model" is described in Attachment 2 of Appendix E2 "Simple Expanded Test Model," and its northern head-dependent flux boundary is located approximately 5.5 miles north of the NMGWM^{2016} boundary. Hence, two models having different boundary configurations produced the same cone of depression, confirming that the NMGWM^{2016} boundary locations do not reduce model-calculated drawdown. As another test, HydroFocus increased the pumping rate from 24.1 mgd to 27.7 mgd (an increase of 15 percent), and results showed the expected expansion of the cone of depression within the model domain (see **Figure 8.2.12-2**). These results confirm that the NMGWM^{2016} boundaries did not reduce the extent of the cone of depression from pumping at the CEMEX site. The same comparisons for the Potrero Road Site indicated that the cone of depression is modestly influenced by the northern boundary location, but the effect is fairly insignificant for making drawdown comparisons between the CEMEX and Potrero Road Sites (see Attachment 2 of Appendix E2).

Hydrostratigraphic comparison between SVIGSM and NMGWM

The NMGWM^{2016} includes the A-Aquifer and Fort Ord Salinas Valley Aquitard (FO-SVA) in model layers 2 and 3, respectively. These units are not considered in the 2015 version of the NMGWM (referred to herein as NMGWM^{2015}) and in SVIGSM, both of which supported the analysis in the April 2015 MPWSP Draft EIR. Their inclusion in the NMGWM^{2016} is consistent with recommendations made by the LBNL based on its review of the NMGWM^{2015}, but their inclusion was also identified and was implemented independently by HydroFocus. Drawdown due solely to pumping is dependent primarily on the pumping rate and the water transmitting and storage properties of the aquifer (Driscoll, 1986; Bear, 1979). Hence, because the NMGWM^{2016} is a more accurate representation of the hydrostratigraphic framework in the Fort Ord area (because it includes the A-Aquifer and FO-SVA), it provides more reliable drawdown results than the NMGWM^{2015} and SVIGSM.

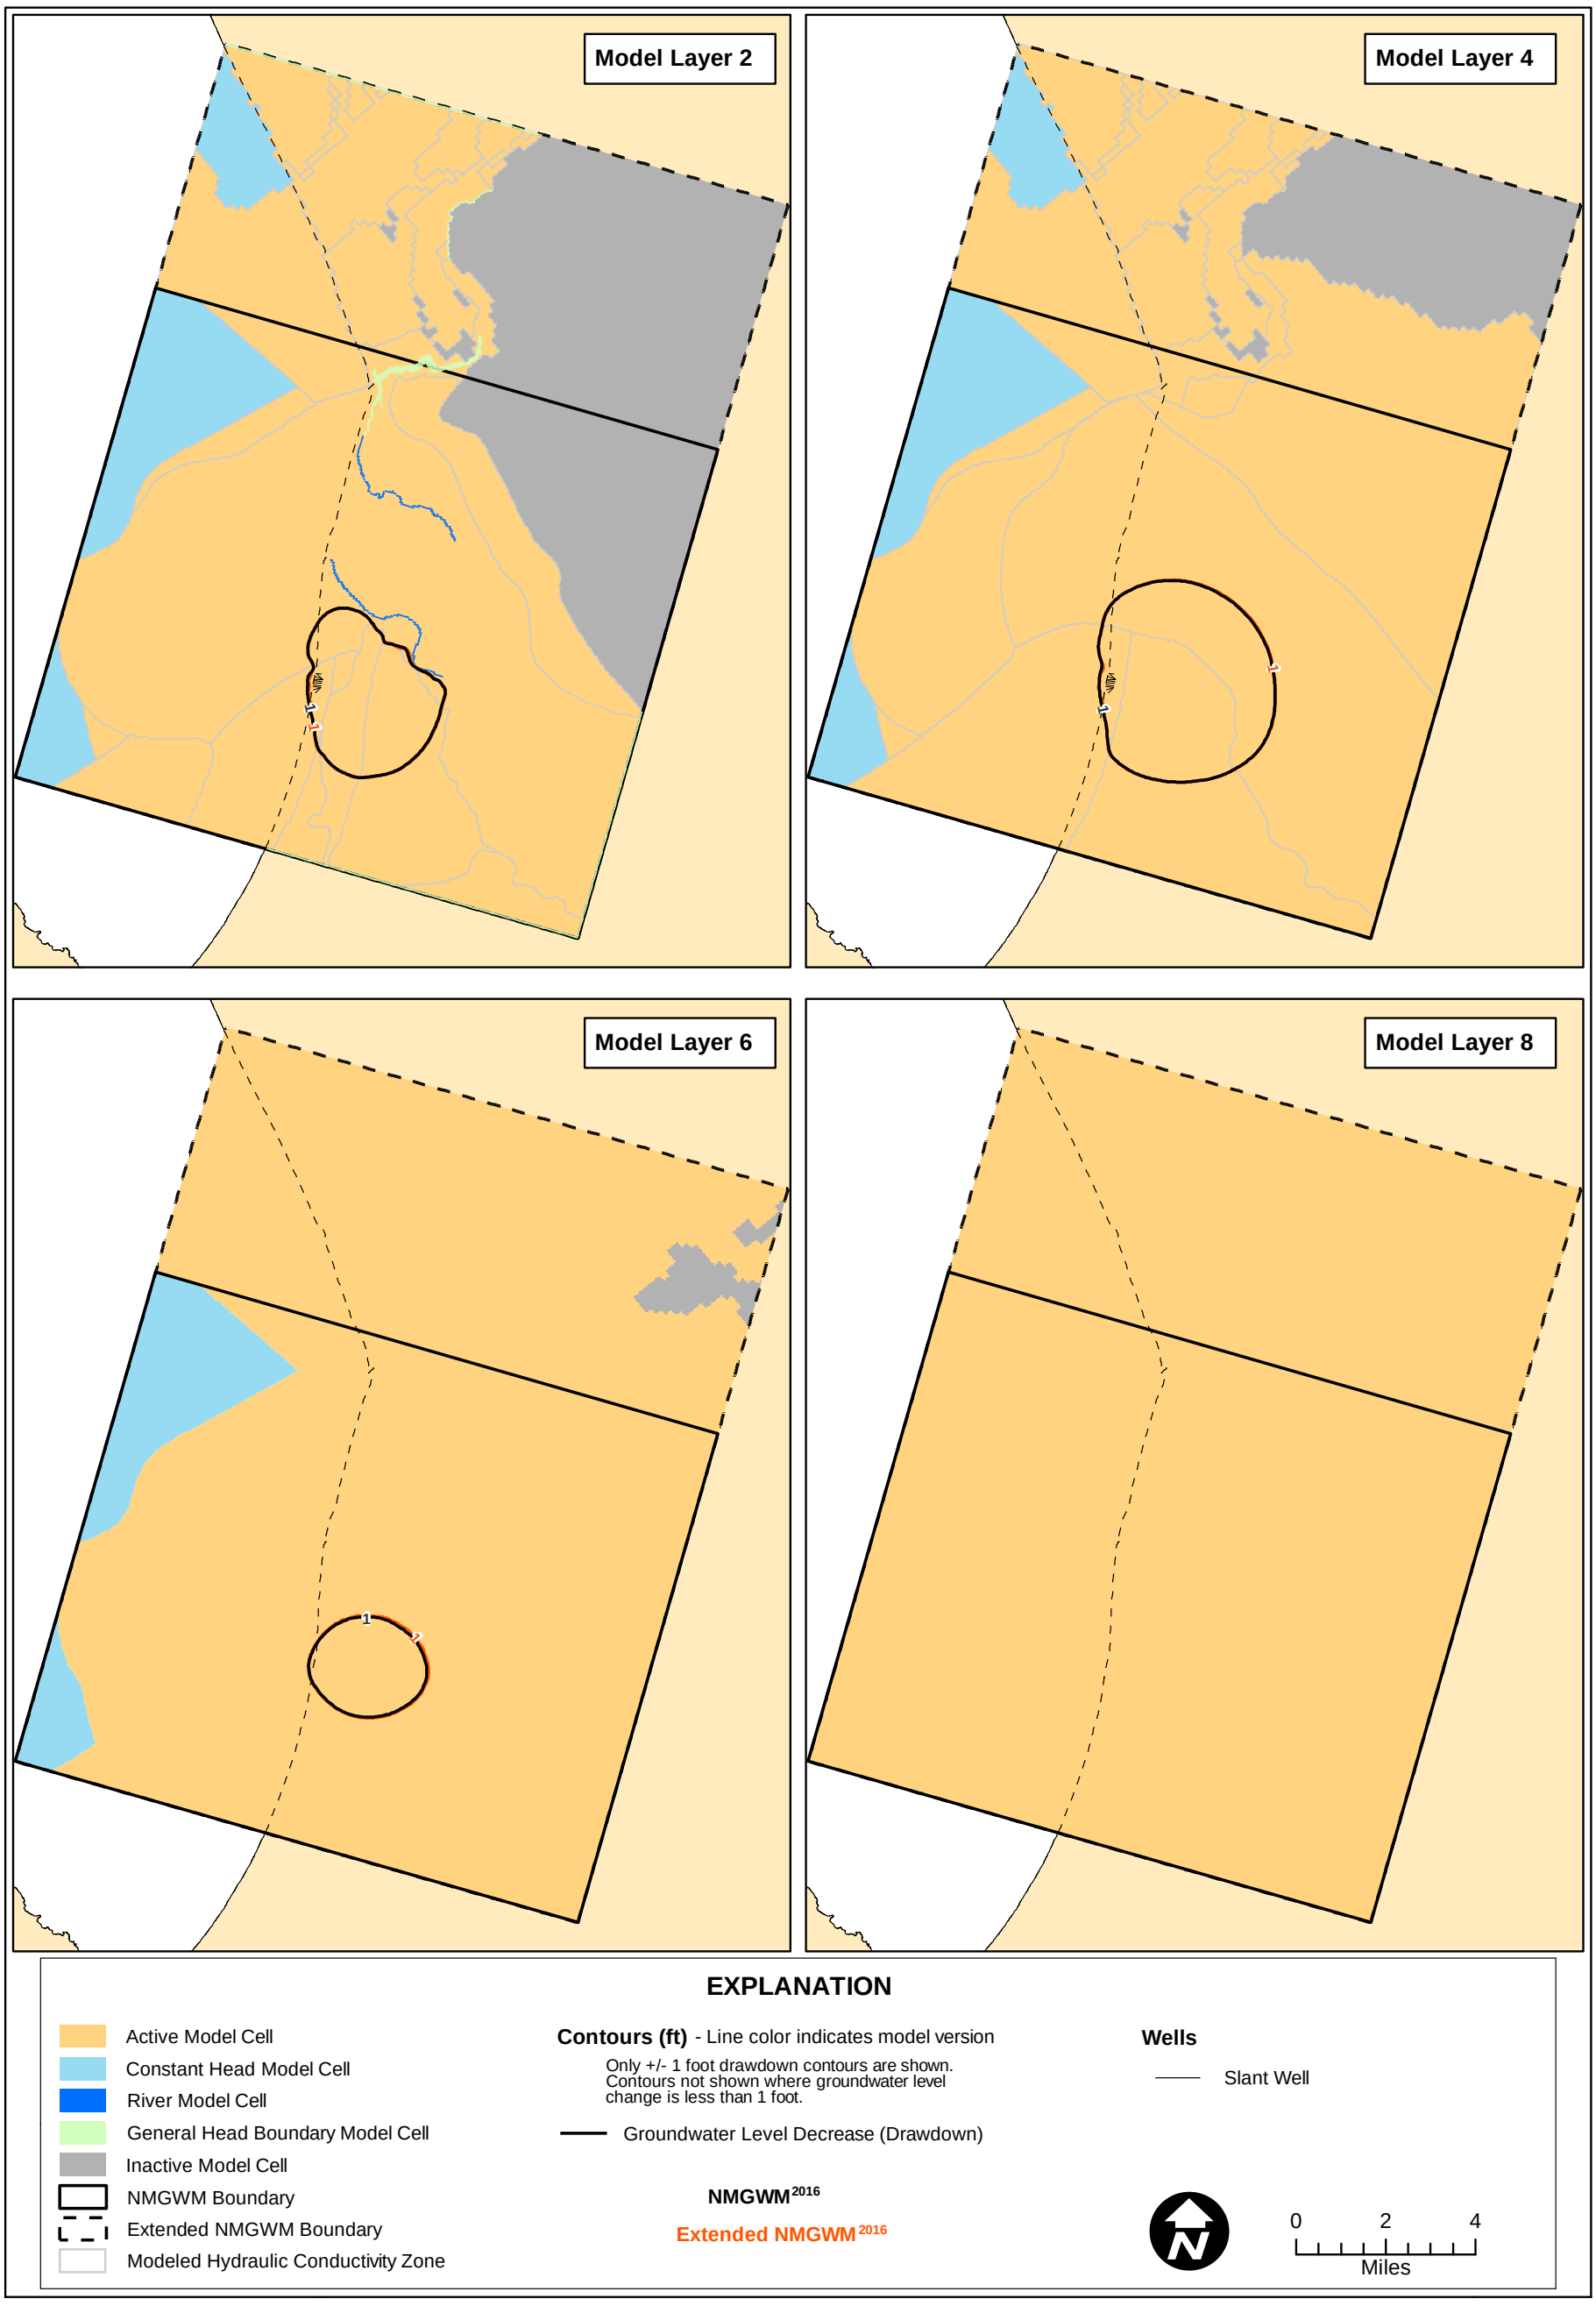
Groundwater Flow in Coastal Aquifers

In coastal aquifers, an interface can exist between groundwater with relatively low total dissolved solids ("fresh") and the saline groundwater influenced by seawater. The concentrations of dissolved constituents influence fluid density, and the resulting spatial variations in concentrations and fluid density within the transition zone can affect groundwater flow paths, the volumetric water balance, and location of the saltwater-freshwater interface. For example, the computer program SEAWAT is a modified version of MODFLOW (the computer program used for the NMGWM^{2016}), and simulates three-dimensional, variable-density, transient ground-water flow using the concept of equivalent freshwater head to solve the variable density flow equation. However, there are no guidelines to determine when it is necessary to employ a program like SEAWAT (Post et al., 2007). Therefore, HydroFocus's approach used the same concept of equivalent freshwater head to represent the density contrast between free-standing ocean water and groundwater, and then assumed that the density variations in the transition zone and resulting uncertainty in model-calculated drawdown was within the range of uncertainty quantified as part of the sensitivity assessment (see Section 8.2.12.4).

Equivalent Freshwater Head

"Equivalent freshwater head" is a common approach used to mimic the water density contrast near ocean boundaries (Senger and Fogg, 1990; Hanson et al., 2014; Payne et al., 2005). The approach increases the water level to account for the greater density of seawater within a constant density model domain. Motz (2004) examined the differences in calculated heads between SEAWAT (variable density flow model) and MODFLOW (constant density flow model) and found that the SEAWAT-calculated water levels were best matched to the MODFLOW-calculated water levels whose initial conditions had the ocean water level specified as equivalent freshwater heads over the full thickness of the aquifer. More recent work by Lu et al. (2015) suggests that submarine groundwater discharge in both confined and unconfined aquifers can be accurately simulated using constant-density flow and a coastal head correction factor. Modeling studies cited by Marina Coast Water District (MCWD) in its letter provided in Section 8.5.2 (Hydrometrics, 2008) similarly increased fresh water levels to account for the density contrast at the coast, and utilized the approach to calculate drawdown and groundwater flow paths from the ocean to coastal pumping wells.

Both the NMGWM^{2015} and NMGWM^{2016} employed equivalent freshwater heads to represent the water density contrast between ocean water and groundwater (Geoscience, 2016). The equivalent heads were assigned to the portions of Model Layer 1 that represent ocean water; the portions of Model Layer 1 that represent the inland basin areas are inactive and have no influence on model calculations. Hence, no horizontal groundwater movement occurs between Model Layer 1 cells representing the ocean and the adjacent Model Layer 1 cells that overlie the inland basin. In the NMGWM^{2015}, Model Layer 1 is 1-foot thick everywhere, whereas in the NMGWM^{2016} the thickness of Model Layer 1 is variable and equal to the thickness of the water column between the ocean surface and the bottom of Monterey Bay. While the Layer 1 thicknesses representing ocean water are different in the two models, the equivalent head values were determined by the assumed TDS concentration of ocean water and the real-world height of the water column above the seafloor. Hence, although the thicknesses of Model Layer 1 are different in the two models, the specified values of the equivalent freshwater heads for corresponding model cells are essentially the same.



SOURCE: HydroFocus, 2017

Figure 8.2.12-2

Extended NMGWM^{2016} at 27.7 MGD (15% increase)

The use of equivalent freshwater heads had negligible effect on the history matching results and model calibration, and their use, therefore, does not artificially increase the modeled potential for seawater intrusion. HydroFocus confirmed this fact by running the history matching assessment with the NMGWM^{2016} after changing the equivalent freshwater head values everywhere to be equal to mean sea level ("0"), making them equal to the initial constant density water level values in the aquifer. The comparisons between model-calculated and measured water levels for the "with" and "without" equivalent freshwater head model simulations are essentially the same, confirming that there is negligible influence from equivalent freshwater heads on model-calculated inland aquifer water levels (see **Table 8.2.12-1**). Furthermore, the projected drawdown due to proposed slant well pumping was calculated using the method of superposition, and as stated in Section 5.3 of Appendix E2 under the subsection "Initial Heads, Boundary Conditions and Stresses," superposition is implemented by setting the hydraulic gradients along all boundaries to zero. This means "the boundaries representing the ocean and the head-dependent boundaries along the edges of the model domain were set to zero." While the concept of equivalent freshwater heads was utilized during the history matching run, they were not used in any of the runs used to project drawdown and therefore had no influence on model-calculated inland movement of saltwater.

TABLE 8.2.12-1
SUMMARY STATISTICS FOR THE COMPARISON BETWEEN MEASURED AND NMGWM^{2016} CALCULATED WATER LEVELS WHEN CONSTANT HEAD VALUES ARE SET EQUAL TO MEAN SEA LEVEL OR EQUIVALENT FRESHWATER HEADS

Calibration Statistics	Mean Sea Level ("0") (feet)	Equivalent Freshwater Head (feet)
RMSE[a]	10.2	10.3
Mean Model Error[b]	1.5	0.0
Min Model Error[b]	-39.9	-40.2
Max Model Error[b]	55.0	54.9

NOTES:
[a] Root Mean Square Error, which is the standard deviation of the residuals.
[b] Model Error is the model-calculated water level minus the measured water level.

Constant Density Assumption

The NMGWM^{2016} employed equivalent freshwater heads to simulate the density contrast between seawater at the Pacific Ocean boundary of the model and the underlying fresh groundwater in the aquifer. Dissolved constituent concentrations in groundwater can change from the movement of seawater in response to slant well pumping, but the effects of these changes on drawdown were assumed negligible and not simulated by the model. The extent of the cone of depression was, therefore, approximated by assuming that the constituent concentrations and groundwater density remain constant. Because measured dissolved constituent concentrations in groundwater decrease with increasing distance inland from the coast, with or without slant well pumping, the uncertainty introduced by the constant density approximation becomes less significant with increasing distance further inland and ultimately becomes negligible. The constant density assumption was assumed reasonable for reasons summarized below.

For the conditions analyzed in Appendix E2, the pumping stress and water transmitting and storage properties of the aquifer (the "aquifer parameter" values) have a much larger effect on the model-calculated drawdown than variations in constituent concentrations and water density. In other words, the uncertainty in model-calculated drawdown attributed to the constant density assumption is negligible relative to the uncertainty in aquifer parameter values. Appendix E2 at page 26 notes that comparisons between the MODFLOW-calculated water levels (constant density) and calculations using SEAWAT (variable density) differ at most by less than 2 feet. These differences exist nearest the coast where model-calculated drawdown and associated density effects are greatest. Further inland at the extent of the model-calculated drawdown, the constituent concentrations decrease and the differences between MODFLOW- and SEAWAT-calculated water levels diminish and become insignificant. The specified pumping rates, return water volumes, projected sea level, aquifer parameter values, and the relative contributions of multiple aquifers to total slant well production all have a greater influence on the extent of model-calculated drawdown than a contrast in dissolved constituent concentrations and groundwater density. The effects of these factors on the uncertainty in the model-calculated cone of depression was rigorously tested and conservatively quantified for the NMGWM^{2016} (see Section 6.0, "Uncertainty," in Appendix E2).

8.2.12.2 Calibration Assessment

Commenters cited the lack of historical monitoring well data in the CEMEX area as limiting NMGWM^{2016} reliability to calculate drawdown in the Dune Sand Aquifer; however, such comments do not acknowledge the other CEMEX area data and associated analyses with the NMGWM^{2016} used to evaluate model performance, including data from the slant well pumping test. Additionally, commenters cited model discrepancies in the Fort Ord Area of the NMGWM^{2016} as an indication of the unreliability of the NMGWM^{2016} to calculate drawdown in the CEMEX area; however, the comparison is inappropriate because of the very different hydrogeologic conditions that exist in the two areas. For example, monitoring well data indicate perched water table conditions in the Fort Ord Area, whereas perched water table conditions do not exist in the CEMEX area. Further, part of the reported model error[1] is contributed by discrepancies with the initial water levels, and these are removed from the drawdown analysis using the method of superposition. There were also comments concerning model calibration and reliability based on reported model error, comparisons between NMGWM^{2015} and NMGWM^{2016} model output, and reported model bias. For example, some comments made conclusions on model reliability based on comparisons between NMGWM^{2015} and NMGWM^{2016} calibration statistics, even though the statistics were determined from two different data sets. One commenter concluded that their analysis and review showed that data falsification occurred ("data tampering"). These comments are all based on methods and interpretations that generally deviate from accepted modeling practice, and the additional discussion below is provided to clarify these issues.

[1] "Model error" refers to the difference between model-calculated results and the corresponding measured values (for example, the difference between model-calculated and measured water levels in monitoring wells). All models approximate real-world conditions and therefore all models include model error. Model calibration and assessment evaluate the significance of the error relative to the intended use of the model.

Absence of Historical Dune Sand Data

The Dune Sand Aquifer is present in the CEMEX area. Water level data for the Dune Sand Aquifer are absent from the October 1979 through September 2011 historical calibration because no historical monitoring well data exists within the model domain for the Dune Sand Aquifer. However, Dune Sand Aquifer monitoring well data collected during test slant well pumping was available and used to adjust aquifer parameter zones and parameter values in Model Layer 2 and Model Layer 4 (see Appendix E2, Section 3.3 "Aquifer Parameter Zones"). Figure 4.6 in Appendix E2 shows generally good agreement between the model-calculated and measured timing of water level drawdown and recovery in Dune Sand Aquifer monitoring wells, and demonstrates that the model can be employed to reliably project water level drawdown in the CEMEX area in response to proposed slant well pumping.

Monitoring well data from six cluster sites located in the "Fort Ord Area" were added to the historical model run to assess model-calculated water levels by the NMGWM^{2016} for areas south of the Salinas River. The shallowest of these monitoring wells are constructed in the A-Aquifer (not the Dune Sand Aquifer). As explained in Section 2.1 of Appendix E2, "The names and characteristics of this upper water-bearing zone are variable throughout the NMGWM. For example, *the Dune Sand Aquifer is present beneath the CEMEX* site and consists of younger and older dune sand geologic units. *The A-Aquifer located beneath the former Fort Ord Area* contains older dune sand deposits and overlies the Fort Ord-Salinas Valley Aquitard (FO-SVA) …These and other shallow aquifers are collectively represented by Model Layer 2" (emphasis added). The additional monitoring well data, therefore, represent conditions in the A-Aquifer beneath the Fort Ord Area – not the Dune Sand Aquifer at the CEMEX site. This distinction is important because the hydrogeologic conditions of the A-Aquifer and Dune Sand Aquifer are different.

The poor agreement between model-calculated and measured water levels reported in Appendix E2 for some Model Layer 2 wells located in the Fort Ord Area is due to deficiencies in prescribed initial water levels – the starting point for the historical model run – and the likelihood of "perched" groundwater conditions (in Appendix E2, see Figure 4.1 and the section "Seasonal Water-Levels and Long-Term Variations"). The discrepancy in the initial water levels is attributed solely to the input from the SVIGSM, and the method of superposition was employed to eliminate any effect these deficient initial water levels would contribute to model calculated drawdown.

Perched Conditions

As explained in Appendix E2, Section 4.1, vertical gradients between Fort Ord Area monitoring wells located in Model Layers 2 and 4 are greater than 1.0 at two sites (MW-BW-01-A and MW-OU2-29-A). Vertical gradients greater than 1.0 indicate the likely presence of an unsaturated interval between water-bearing deposits. Groundwater separated from a deeper water table by an unsaturated interval is considered "perched." The groundwater flow model assumes fully saturated conditions in all model layers, and therefore this unsaturated interval and its influence on vertical groundwater movement are not reproduced by the model. Data indicate that the perched groundwater conditions and corresponding area of poor model performance appears to be limited to the southernmost portions of the Fort Ord Area, beyond the influence of the proposed pumping capture zone, and model performance is notably more acceptable in other parts of the

Fort Ord Area where the observed vertical gradients are less steep. Relatively poor model performance in this localized area, however, does not affect model reliability in the area of interest and the calculated extent of drawdown from proposed project pumping.

Horizontal and vertical hydraulic conductivity specified for the A-Aquifer and FO-SVA in the Fort Ord Area were obtained from previous aquifer test and modeling studies (see Figure 3.3d of Appendix E2). The values selected minimized the difference between measured and model-calculated water levels, and are within the referenced range from previous studies (see Appendix E2, Figure 3.3a and 3.3b). This confirms that the water transmitting properties specified in the model are reasonable, and therefore the model errors in Model Layer 2 are attributed to other factors. Specifically, the model errors in Model Layer 2 are attributed to the large differences between measured and model-calculated water levels in the perched Model Layer 2 wells and the discrepancies in the initial water level conditions inherited from the SVIGSM. The "Model Error" discussion below explains how removing the perched well data substantially reduces the model error statistics, and Section 8.2.12.4 explains how errors due to specified initial water levels are removed from model-calculated drawdown.

Model Error Assessment

All groundwater models solve universally accepted mathematical equations to simulate subsurface water movement in porous media. The solutions are approximations because a model cannot quantify exactly the spatially variable properties that exist in the real world. A reliable groundwater-flow model is one that can produce field-measured water levels and groundwater flow within an acceptable range of error. Error exists because information on the real world system is always incomplete, and the field information that is available has associated errors (for example, measurement error or the assignment of monitoring wells to incorrect aquifers). The most likely sources of error in the $NMGWM^{2016}$ could arise from neglecting potential processes (for example, density effects on groundwater flow) and uncertainty associated with modeled boundary conditions, specified hydraulic conductivity values. Model error is therefore, evaluated to quantify model uncertainty, and the evaluation of $NMGWM^{2016}$ uncertainty is described in Section 4.1 of Appendix E2 "History Matching Assessment." That evaluation clearly states that model error was assessed using six tests widely used and accepted within the groundwater modeling community: "Ultimately the decision of model acceptability is based on the weight of one or more of the test results and their relevance to meeting modeling objectives (in this situation, concluding that the model acceptably projects the magnitude and distribution of the water level change due to coastal slant well pumping)." Several comments suggested that using only one of the six tests could delineate a "good/successful" model from a "bad/failed" model; this is not recommended groundwater modeling practice.

The use of multiple tests provides the means to identify key sources of model uncertainty that are not likely revealed relying solely on any one test. Furthermore, the acceptance or rejection of a model depends not only on the evaluation of model error but also on the intended application for which the model was created (Freyberg, 1988). For example, the model error may be high in the history matching run because recharge and pumping are poorly estimated. However, when the purpose of the model is to calculate water level changes due to a new stress, the reliability of the

model-calculated drawdown will depend primarily on the specified water transmitting and storage properties of the aquifer and not on the background recharge and pumping.

In EIR/EIS Appendix E2, multiple test results are reported that identified model deficiencies associated primarily with the prescribed initial conditions, boundary conditions, and historical recharge and pumping, all of which originated from the SVIGSM. The reliability of the specified aquifer parameters, however, was determined by comparisons between NMGWM^{2016} values and the measured or estimated values for similar materials. These comparisons indicated general agreement with values from previous hydrogeological and model studies (see Section 3.3, "Aquifer Parameter Zones," in Appendix E2). For the EIR/EIS, the "method of superposition" was employed to eliminate the deficiencies introduced by the prescribed initial conditions, boundary conditions, and recharge and pumping, whereas sensitivity tests were employed to quantify the potential uncertainty in the aquifer parameter values, boundary conditions, future project operations (see Appendix E2 Section 5.2 and EIR/EIS Section 4.4.4.2). By running the model and incorporating uncertainty related to 1) sea level rise, 2) return water volumes, 3) slant-well pumping rates, 4) model parameter values (hydraulic conductivity and storage properties), and 5) the relative volumes of groundwater flowing to the slant wells from different aquifers, HydroFocus estimated the potential range in the areal drawdown due to slant well pumping (see the discussion of uncertainty in Appendix E2, Section 6.0).

Comparison of NMGWM^{2016} and NMGWM^{2015}

NMGWM^{2016} has less model error than NMGWM^{2015}. A valid error comparison between two models must use the same wells and water level data, and when the same wells and water level data are used (see **Table 8.2.12-2**), the summary of error statistics confirm that the NMGWM^{2016} performance is superior to the NMGWM^{2015}. For example, Model Layer 2 monitoring wells located south of the Salinas River were added to the NMGWM^{2016}, and when these same wells and their corresponding water level data are added to the NMGWM^{2015} data set, the Model Layer 2 Root Mean Square Error (RMSE, which is the standard deviation of the residuals) is 40.2 feet, which is substantially higher than the RMSE calculated for the NMGWM^{2016} (10.1 feet). The comparisons between the deeper model layers have RMSE values that generally agree and are all within +/- 0.1 feet, indicating both models perform similarly in representing the deeper aquifers.

Model Bias

Bias in groundwater flow models results when model errors (the difference between model-calculated and measured water levels) do not conform to the assumptions of regression analysis (the assumptions that the model errors are independent, have zero mean, have a constant variance and follow a normal distribution) (Ward, et al., 1987). The evaluation of model error for Model Layer 4 (the 180-Foot Aquifer) provided in Appendix E2 showed that the model errors are not independent (the model errors vary with model-calculated values), the mean model error is not zero (the mean model error is equal to 1.4 feet), and visual inspection of the histogram suggests that model errors are not approximated by the normal distribution. These results indicate model bias in Model Layer 4. Further analysis of model errors was conducted by HydroFocus and revealed the cause of this bias, and the modeling approach employed to assess the proposed project was developed to eliminate the effect of this bias on the model results. The results of the model error analyses are discussed below.

TABLE 8.2.12-2
SUMMARY OF ERROR STATISTICS
BETWEEN NMGWM^{2015} AND NMGWM^{2016} USING IDENTICAL WATER LEVEL DATA

	NMGWM^{2015}* (feet) (using NMGWM^{2016} calibration data)					NMGWM^{2016}* (feet)				
	Layer 2	**Layer 4**	**Layer 6**	**Layer 8**	**Entire Model**	**Layer 2**	**Layer 4**	**Layer 6**	**Layer 8**	**Entire Model**
RMSE[a]	40.2	7.3	10.7	11.4	12.8	10.1	7.2	10.7	11.3	10.2
Minimum Error	-63.2	-16.4	-40.2	-38.6	-63.2	-35.2	-15.8	-39.9	-35.4	-39.9
Mean Error	-30.1	1.2	1.7	-1.9	-0.3	-4.9	1.4	2.1	0.4	1.5
Maximum Error	-1.2	32.7	54.9	39.2	54.9	9.2	32.2	55.0	41.2	55.0
Relative Error	62.8%	14.7%	10.2%	14.5%	7.9%	15.7%	14.4%	10.3%	14.4%	6.3%

NOTES:
* Statistics exclude two perched wells MW-BW-01-A and MW-OU2-29-A.
Root Mean Square Error (expressed in feet)

In Appendix E2, Figure 4.3d "Relationships between measured water levels, model-calculated water levels, and water level residuals, Well 02J01, Model Layer 4" shows two graphs. The upper graph shows model-calculated and measured water levels during the time period October 1979 through September 1991 for Well 02J01, which is screened in Model Layer 4 (180-Foot Aquifer). The upper graph also shows the residual (model error) for the same time period. The values and distances (scale) for both vertical axes (y-axes) are the same. Measured water levels are reported relative to mean sea level, which by convention is assigned a value of zero. The model error is also plotted relative to zero, and positive errors indicate model-calculated water levels are greater than measured, and negative errors indicate that model-calculated water levels are lower than measured. The lower graph shows the relationship between model error and model-calculated water level. Close inspection of these two graphs shows the following:

1. The upper graph shows that measured and model-calculated water levels decrease and become more negative over time. The shift from positive to negative water levels indicates that the water levels have decreased from above mean sea level to below mean sea level.

2. The lower graph shows that the model errors are generally large in magnitude and positive when model-calculated water levels are relatively high and above mean sea level. Conversely, the model errors are generally smaller in magnitude and more negative when model-calculated water levels are relatively low and below mean sea levels.

The water level and error plots indicate that model error is not random (the model results for Model Layer 4 are biased). The bias is consistent with the positive correlations shown for Model Layer 4 in Appendix E2 Figure 4.3b and Figure 4.3d (calculated correlation of 0.2). The positive correlation is consistent with the observation that the greatest water levels (the water levels that are the highest above mean sea level) have the greatest model errors and the errors tend to be positive, whereas the lowest water levels (the water levels that tend to be below mean sea level) have relatively smaller model errors that tend to be negative. In other words, the model error is positive (increases) when the water levels are positive, and the error is negative when the water

levels are negative. Hence, the slope of the line in the lower graph of Appendix E2 Figure 4.3d is positive, and shows an increasing relationship between model error and model-calculated water levels.

The model-calculated and measured water levels in Appendix E2 Figure 4.3d rise and fall each year as a result of seasonal changes in recharge and pumping. The seasonal trends in Figure 4.3d are superimposed on the longer, multi-year trends that show water levels generally decline from above sea level to below sea level. Comparisons between the model-calculated and measured water levels reveal that in the early years of the plotted data set, the seasonal model-calculated water level decline begins sooner than the measured seasonal water level decline, and this shift in timing causes relatively large differences between model-calculated and measured water levels (relatively large model error). In the later years of the plotted data set, there is better agreement between the timing of the seasonal water level decline, and as a result the model error is relatively smaller. The net effect of these time-shifts is the cause of the model bias described above.

Appendix E2 Figure 4.3c shows that the same relationship between seasonal model-calculated and measured water levels shown in Figure 4.3c exists in the SVIGSM – the greatest water levels have model errors that tend to be positive, and the lowest water levels have model errors that tend to be negative. The magnitude and timing of groundwater recharge and pumping utilized by the $NMGWM^{2016}$ was obtained from the SVIGSM, and therefore the model bias in the $NMGWM^{2016}$ produced by the seasonal changes in recharge and pumping is inherited from the SVIGSM.

Data Tampering

The documented correlation between model-calibrated water levels and model error described above under “Model Bias” has been erroneously cited in some comments as evidence of data tampering. However, the facts indicate that data tampering has not occurred, and this can be clarified with a discussion about what a groundwater-flow model is, how a groundwater model is constructed, and how a groundwater model is ultimately used.

As described in EIR/EIS Section 4.4.4.2, groundwater models are computer simulations that represent water flow in the environment using mathematical equations. The “model” is a mathematical model, meaning that groundwater flow is simulated by solving a governing mathematical equation that represents the physical processes that occur in a groundwater system. That governing equation is commonly referred to as the three-dimensional partial differential equation of groundwater flow.

MODFLOW is one of many computer codes that numerically solve the governing groundwater flow equation. As noted in EIR/EIS Section 4.4.4.2, since MODFLOW's release, the USGS has released numerous updated versions, and MODFLOW is now the de facto standard code for aquifer simulation. The MODFLOW computer source code is written in FORTRAN programming language, which is compiled to create an executable, which is the engine that actually performs the numerical calculations. The $NMGWM^{2016}$ is an application of MODFLOW, where the MODFLOW executable performs the calculations on the input data sets constructed specifically for the North Marina Area. The output from the MODFLOW executable is model-calculated water levels and groundwater fluxes for the North Marina Area.

Input data to MODFLOW includes the three-dimensional distribution of water storage and transmitting properties of the site-specific aquifers and aquitards in the North Marina Area. The input data also includes site-specific values for groundwater recharge and extractions by pumping wells. Lastly, input data includes specified conditions at the boundaries of the model domain (for example, boundary conditions specified to represent the Pacific Ocean). The water levels measured in wells (observations) are not input data, but rather are utilized to compare against their corresponding model output (model-calculated water levels) for the same time and spatial location. Similar to a "ruler" utilized to quantify the error in the estimated length of an object, measured water levels are compared to model-calculated water levels to quantify model error (the difference between model-calculated and measured water levels). Hence, model input (water storage properties, water transmitting properties, recharge, pumping, and boundary conditions) can be altered to change model output, but changes to measured water levels (observations) have no effect on model output. With this in mind, three facts indicate that data tampering – in this case, modification of the measured or model-calculated water levels employed to calculate model error – has not occurred. They are as follows:

1. The measured data were not altered before running the model. Measured water levels were provided by Monterey County Water Resources Agency (MCWRA), and Section 2.3 of Appendix E2, "Assessment of Model Inputs and Outputs," reports that measured water levels used by the model and reported by MCWRA are the same. Measurement dates used in the model for one well were off and another well was assigned to a different aquifer. Specifically, the water level measurement dates reported by MCWRA for well 14S/3E-6R1 were 11 days off in the $NMGWM^{2015}$ input data set, and well 14S/2E-14L01 was designated as representing Model Layer 6 but identified by MCWRA as representing the 180-Foot Aquifer (Model Layer 4). Neither of these exceptions had any effect on the measured water level values reported.

2. Three independent runs using different MODFLOW executables produced the same output (model-calculated water levels) and confirm that the model-calculated water levels were not modified during the model run. As noted in Table 3.1 of Appendix E2, Geoscience and HydroFocus utilized two different MODFLOW executables. Geoscience employed MODFLOW using the proprietary software "Groundwater Vistas," whereas HydroFocus employed the MODFLOW executable "freely available from the USGS." Section 2 of Appendix E2, "Assessment of Model Inputs and Outputs," states, "We ran the model ($NMGWM^{2015}$) and confirmed the model results [model-calculated water levels] were the same as reported." Furthermore, Appendix E-1, "Lawrence Berkeley National Laboratories Peer Review," describes similar testing and reported "computer simulations carried out by the modeling team can be replicated using the input and executable codes provided to us." This confirms that the FORTRAN computer code for the numerical groundwater-flow model (MODFLOW) was not altered prior to running the executable as a means to "tamper" with the data.

3. Model-calculated water levels were not altered after running MODFLOW. There is no processing of model output after running MODFLOW other than plotting the results using Excel software. The model-calculated water levels in the Excel files match the output from MODFLOW obtained from three independent runs using three different MODFLOW executables.

8.2.12.3 Superposition

The analysis using the NMGWM^{2016} employed the method of superposition. Some commenters interpreted this to mean a new model was developed rather than an application of the model. Other commenters utilized results from their own application of the NMGWM^{2016} and superposition method, and their results were different from those reported in Appendix E2. However, the analysis undertaken by the commenters was flawed, and conclusions based on those results were both unreliable and appeared to demonstrate misunderstanding about the method of superposition. The additional discussion below is provided to clarify the issues.

The NMGWM^{2016} was employed to calculate drawdown in response to pumping. Drawdown due solely to proposed project pumping is dependent primarily on the pumping rate, the water transmitting and storage properties of the aquifer (Driscoll, 1986; Bear, 1979), and any change in groundwater recharge or discharge that would occur solely as a result of that drawdown. For example, if pumping were to cause coastal water levels to decline below sea level, ocean water would percolate into the underlying aquifer and move inland to replace the extracted water. This increase in ocean-water recharge induced by the new pumping would reduce the drawdown relative to that which would have occurred in the absence of the ocean-water recharge.

For the EIR/EIS, the method of superposition was employed to remove the discrepancies introduced by the SVIGSM (initial water levels, boundary conditions, and bias attributed to specified recharge and pumping). Superposition is routinely employed for solving complex problems. It is a modeling approach that is useful in saving time and effort and eliminating uncertainty. The principal advantages and constraints of using superposition are described by Reilly et al. (1987) and summarized below:

1. The effects of a specified stress on the groundwater system can be evaluated even if other stresses in the basin are unknown.
2. The effects of a change in stress on the system can be evaluated even if the original conditions or subsequent period of equilibrium conditions are unknown.
3. The effect of one stress on the system can be isolated from the effects of all other stresses.

The superposition approach does not employ a “new” model; rather, the initial water levels and background recharge and pumping are all set to zero. These inputs are not “predictive variables” in the model, and they have no influence on the projected future drawdown calculated by the model. The approach therefore effectively removes the deficiencies introduced by the SVIGSM (see Section 5.2 of Appendix E2).

In the application of the NMGWM^{2016}, the complex problem is quantifying groundwater level changes and fluxes due to geographically and temporally varying recharge and discharge processes occurring within the Salinas Valley Groundwater Basin. The question asked is “what change in these groundwater levels and fluxes are expected as a result of a new stress – groundwater extraction by the proposed slant wells?” Rather than employ a model to simulate the complex problem (i.e., to quantify the effects of all recharge and discharge processes occurring within the basin), superposition is employed to determine the incremental drawdown due solely to

the proposed groundwater extraction by the slant wells. In other words, superposition is employed to isolate the expected change in groundwater levels and fluxes due solely to the project. These changes would be additive to future changes that occur as the net result of all other factors such as climate, background pumping, background recharge, and land use changes, which cannot be predicted with certainty. Accordingly, validating the future drawdown calculated by the superposition modeling approach, which corresponds to validating the change in future water levels due solely to proposed project pumping, is in practical terms less difficult than validating model projections that include the additional complexity of assumed climate, water use, and land use changes, none of which are known with certainty. See Appendix E2, Section 4.2, "Test Slant Well Pumping," for an example where real-world monitoring data is used to compare measured drawdown with the drawdown calculated with the superposition model.

Water Levels

The drawdown from proposed slant well pumping can be isolated using one of two approaches: (1) subtracting the results from two model runs, one run with the new stress and a second run without the stress, or (2) directly using superposition. For example, in its report attached to the MCWD comments, GeoHydros employed the superposition method to isolate the model-calculated drawdown due to slant well pumping from the proposed project (GeoHydros, 2017). To do this, GeoHydros added the proposed slant well pumping to the recharge, pumping, constant head, and head-dependent flow boundary input data from the "History Matching Assessment" described in Appendix E2. The approach is identical to the one described in Attachment 1 to Appendix E2 ("Example Superposition Model"). In Attachment 1, a model of a hypothetical groundwater basin is used to show that drawdown from a new pumping well calculated directly by superposition is identical to the drawdown calculated indirectly by subtracting the results from two model runs (one model run with the new well pumping stress and the second model run without the new well pumping stress). Both approaches employ the theory of superposition, but GeoHydros chose to use the latter approach of subtracting two model runs to isolate the drawdown rather than calculate it directly. If correctly implemented, the results from the two approaches must be identical, as was shown by the example problem in Attachment 1 to Appendix E2. However, the GeoHydros analysis was not conducted correctly, and the flawed GeoHydros results are therefore different from the results reported in Appendix E2. As explained below, the GeoHydros analysis was flawed because it did not consider changes in the hydraulic interaction between groundwater, the Salinas River, and Tembladero Slough, and the GeoHydros report and results have therefore not been incorporated into the EIR/EIS analysis.

The recharge and pumping model input files from the History Matching Assessment include the historical river losses and gains due to the hydraulic interactions between groundwater, the Salinas River, and Tembladero Slough. GeoHydros used the same recharge and pumping input files for both of its simulations: one simulation that was identical to the History Matching Assessment and an identical simulation but with the addition of proposed slant well pumping. The GeoHydros approach failed to account for the changes in Salinas River and Tembladero Slough gains and losses that occur in response to the new pumping stress introduced by the slant wells, and the drawdown calculated by the GeoHydros approach is therefore greater than reported in Appendix E2. In order to account for the changes in river gains and losses, the NMGWM^{2016}

was modified as explained in Section 5.3 of Appendix E2 ("Modifications to the NMGWM^{2016}"). Hence, the GeoHydros results are not credible for assessing the adequacy of the NMGWM^{2016} and the superposition approach.

Water Budget

The method of superposition, whether employed directly using a superposition model as described in Appendix E2, or indirectly by subtracting two model runs as employed by GeoHydros, also provides the change in the volumetric groundwater budget. GeoHydros calculated the change in fluxes between model layers by subtracting the water budgets from the two model runs. Based on the GeoHydros calculations using flawed model results, GeoHydros reported that 756 afy of the water removed by the slant wells would come from "upward flow into the overlying 180-Foot and Dune Sand Aquifers" from the 400-Foot and deeper aquifers. They concluded that the model-calculated gain in the 180-Foot Aquifer represents harm to the deeper aquifers. However, this conclusion comes from an inappropriate interpretation of superposition results that ignore the real-world groundwater conditions beneath the CEMEX site. Further, the conclusion does not consider the poor water quality conditions measured in the 180-Foot Aquifer and existing groundwater overdraft of the deeper aquifers caused by inland pumping.

Superposition calculates the change in the volumetric water budget relative to the real-world groundwater system. A positive water budget change indicates "gain," whereas a negative water budget change indicates "loss." However, a gain is not necessarily indicative of greater "inflow" but can also indicate reduced outflow. Similarly, a loss is not necessarily indicative of greater "outflow" but can also indicate reduced inflow. The volumetric budget changes calculated by superposition and reported by GeoHydros must therefore be applied to real-world groundwater conditions to determine slant well pumping effects on groundwater-flow.

The real-world groundwater conditions beneath the CEMEX site as reported by Geoscience (2016) is illustrated in **Figure 8.2.12-3**, which is a modified cross-section that includes groundwater elevations determined from measured water levels in monitoring wells (corrected to equivalent freshwater heads based on measured TDS concentrations). Groundwater flow directions are inferred from the equivalent freshwater heads, whereby groundwater moves from areas of high equivalent freshwater head to areas of relatively low equivalent freshwater head. The inferred vertical flow directions in Figure 8.2.12-3 indicate that groundwater moves downward from the 180-Foot Aquifer to the 400-Foot Aquifer. Hence, the model-calculated gain in the "180-Foot Aquifer" is actually a reduction of the existing downward flow from the 180-Foot Aquifer to the 400-Foot Aquifer. The water quality data posted on the cross-sections indicate that near the coast and where project pumping induced drawdowns would be the greatest, the measured TDS concentrations in the 180-Foot Aquifer can exceed 28,000 mg/L. Hence, the 756 afy reported by GeoHydros as being removed from the deeper aquifers would actually be a reduction in downward flow of high-TDS groundwater. Reducing the inflow of high-TDS groundwater into the deeper aquifers would provide a water quality benefit. Because the GeoHydros analysis is conceptually consistent with that found in the EIR/EIS, but flawed and therefore quantitatively different from the EIR/EIS analysis as described above under "Water Levels," no revision to the EIR/EIS analysis is warranted in response to the GeoHydros analysis.

8.2.12.4 Sensitivity Analysis

Some comments interpreted model sensitivity as a model limitation, and require clarification about the difference between model calibration and model prediction, as each relate to model sensitivity. In model calibration, the parameter sensitivity analysis identified the hydraulic conductivity and storativity[2] values that most influence the comparison between model-calculated and measured results in the history-matching assessment (parameter calibration sensitivity). The most sensitive calibrated values are usually the most reliable when it can be shown they are comparable to reported values from previous studies. When employing a model to predict future conditions, the parameter sensitivity analysis identifies the hydraulic conductivity and storativity values that have the most influence on the predicted water level changes (parameter prediction sensitivity). Because the proposed pumping is an entirely new stress, the most sensitive prediction parameters are not necessarily the same as the most sensitive calibration parameters (often they are not). The prediction parameter sensitivity results provide little to no information about the reliability of the calibrated parameter values.

Appendix E2 Section 6.0, "Uncertainty," explains that both the predictive sensitivity to assumed project operations and the predictive sensitivity to modeled aquifer parameters were considered. In the case of modeled aquifer parameters, the sensitivity assessment used "…extreme values relative to the calibrated values and values reported by other sources, and therefore using these values essentially bracket the range in possible drawdowns." Extreme values were employed to provide a conservative answer to the question "would the model predictions change so as to change the conclusions regarding proposed slant well operation." Extreme values were employed to rigorously test and conservatively quantify the drawdown calculated by the $NMGWM^{2016}$ as part of a planning assessment, and the results have limited application for assessing the adequacy of the model calibration conducted in the history-matching assessment.

8.2.13 Master Response 13: Demand (Project Need) and Growth

COMMENTERS ADDRESSED IN MASTER RESPONSE 13

City of Marina	Public Trust Alliance
Monterey Peninsula Water Management District	Public Water Now
California Unions for Reliable Energy	Surfrider Foundation
Carmel River Steelhead Association	Margaret-Anne Coppernoll
Coalition of Peninsula Businesses	Juli Hofmann
Ecological Rights Foundation, the Center for Biological Diversity, and Our Children's Earth Foundation	Carol Reeb
Land Watch Monterey County	Roy Thomas
Pebble Beach Company	

This Master Response addresses comments concerning customer water demand, available water supplies, and growth that could be induced by the proposed MPWSP water supply. Given the wide variety of comments related to water supply and demand, and for clarity: Section 8.2.13.2 addresses comments on demand, Section 8.2.13.3 addresses comments on supplies, and Section 8.2.13.4 addresses comments on growth that would be induced by project water supply and the impacts of that growth. Appendix L: Alternative Supply - Demand Scenarios was prepared in conjunction with this master response to test the possibility of whether the project could be smaller if one considered different supply and demand numbers as suggested in some comments; Section 8.2.13.5 summarizes the results of that inquiry.

EIR/EIS Sections 2.3 through 2.5 provide information on estimated water customer demand, supplies, the basis for those estimates, and supplemental information about water supply and demand and factors affecting them in the area that would be served by the MPWSP. Use of these supply and demand assumptions in the EIR/EIS does not mean that these assumptions will for certain prove true. Forecasting future demand and supply is not an exact science. As stated in EIR/EIS Section 2.5.4, "estimating future water demand necessarily entails the use of assumptions about demand factors that cannot be predicted with absolute certainty." The demand and supply estimates presented in EIR/EIS Sections 2.3 through 2.5 are planning and environmental evaluation tools that are based upon the evidence available from multiple (sometimes conflicting) sources and reasonable assumptions stemming from that evidence. Future supply and/or demand could, in reality, turn out to be higher or lower than estimated. Commenters have expressed that more or less supply is needed and more or less demand should be assumed, and any one of those commenters could end up being correct. The lead agencies do not control demand of service area residents and businesses, which is affected by such things as the economy, trends in use habits, drought, water cost, and more; nor do they control supplies, which are dramatically affected by weather and climate. While the estimates assumed in the EIR/EIS are reasonable based on available data, they are inherently uncertain and cannot be guaranteed. Section 8.2.13.1, below, provides additional discussion of supply and demand in the context of the proposed project and the EIR/EIS analysis.

Note also that evidence concerning supply and demand is being gathered by the CPUC in a process that is separate from, but parallel to, the CEQA and NEPA process. Such evidence will be considered, along with all of the data within the EIR/EIS, to inform and shape the decision on the size of project and the possibility of phasing in the project or alternatives. The Lead Agencies have endeavored to consider and reflect in the EIR/EIS evidence that has been presented in the general CPUC proceeding. It will be up to the decisionmakers to weigh all of the evidence in the record, determine which, if any, option best suits the project purpose and need/satisfies the project objectives, and take appropriate actions based upon findings. This means that the CPUC could decide (for example only) that it is most likely that there will be no further hospitality industry economic recovery such that water need not be supplied for that purpose. So long as substantial evidence supports that ultimate decision, the state permitting agencies may judge the evidence as they see fit.

8.2.13.1 Purpose of the EIR/EIS Demand and Supply Information

NEPA and CEQA analyses typically address potable water demand and supply in the context of evaluating a project's impact on available supply (typically in the utilities section of the impact analysis). In this case, the MPWSP has been proposed to *provide* water supply to the CalAm service area. Given that the MPWSP project objectives and purpose and need are primarily related to supplying water to meet existing and some future water customer needs, supply and demand are fundamentally tied to the ability of the project to satisfy the project need and objectives. Supply and demand are therefore, important to fashioning the requisite range of feasible and reasonable project alternatives. In addition, to the degree that evidence indicates that the project may provide water in an amount that exceeds current demand, the project would be growth-inducing. EIR/EIS Sections 2.3 through 2.5, and Appendix L, provide the Lead Agencies and members of the public with data on water demand and supply in the CalAm service area with which to assess the likelihood that the MPWSP will provide adequate water supply to replace existing Carmel River and Seaside Groundwater Basin (SGB) supplies that were reduced by State Water Board orders and the SGB adjudication. This will allow the provision of an appropriate, acceptable level of supply for the identified additional future customer needs that CalAm proposes to serve.

8.2.13.2 Demand Assumptions

Existing Annual Service Area Demand

Many comments objected to CalAm's estimate of existing annual demand, which is based on service area demand in 2010, stating that the estimate overstates existing demand and ignores the trend of decreasing demand since 2010. The use of 2010 service area demand data to represent existing annual demand is consistent with the California Department of Public Health's California Waterworks Standards,[1] discussed in EIR/EIS Section 2.3.2, Peak Demands. As described in Section 2.3.2, this regulation – and CPUC General Order 103-4 – requires that the water sources of public water systems of the size of CalAm's Monterey District service area have the capacity

1 California Code of Regulations Title 22, Division 4, Chapter 16, Section 64554.

to meet peak demands. Specifically, the regulations require that systems have the capacity to meet maximum (max) day demand and peak hour demand, and specifies that max day demand and peak hour demand are to be determined *based on the most recent ten years of operation* (emphasis added). Peak month demand represents the Monterey District's most critical challenge in meeting peak demand, as elevated demand in the peak month is more sustained, over multiple days, and needs to be considered as a factor in plant sizing (Svindland, 2013b). The trend that shows declining water use is considered. The 2010 service area demand data was used because it provides a higher, more conservative estimate of the local water use to better plan for potential future peak demands and for consistency with California Waterworks Standards and CPUC General Order 103-A. CalAm selected year 2010 to represent peak month demand of existing customers with the explicit expectation that demand would continue to decline, as stated in Draft EIR/EIS Section 2.3.2, and that by 2020, when the desalination plant was expected to be on line, 2010 demand would represent the maximum demand year for this 10-year period, and July 2010 would represent max month demand (Svindland, 2016, as cited in Section 2.3.2).

Comments Urge Lower Demand Number

Some commenters stated that service area demand in 2015 or 2016 was lower than in 2010 and various commenters recommend that demand in one of these years be used to represent service area demand for MPWSP planning; some pointed to the downward trend in water demand shown in EIR/EIS Table 2-2 as evidence that a downward trend in demand would continue. While a generally downward trend in water demand is expected to continue as permanent conservation measures continue to be implemented, demand in recent years has been influenced by two uncommon events: the deepest recession since the Great Depression, recovery from which has been unusually protracted (Federal Reserve Bank of Dallas, 2013); and a severe five-year drought. These events complicate the task of estimating service area demands under more "typical" conditions when the influence of these events is expected to subside.

As described in EIR/EIS Section 2.3, the economic recession that began in late 2007-early 2008 affected the Monterey Peninsula hospitality industry, reducing occupancy levels and visitation rates, and, consequently, reducing water demand at local visitor-serving businesses. The recession was global in scope and commonly recognized as the deepest since the Great Depression, with an unusually weak and prolonged recovery period (Federal Reserve Bank of Dallas, 2013; Fischer, 2014; Russell Sage Foundation et al., 2017). High unemployment and low consumer confidence lingered for years after it was officially declared to be over in mid-2009, with different geographic areas experiencing different rates and degrees of recovery. If lingering effects of the recession continued to depress water demand to some extent in recent years, demand in a fully recovered, robust economy could rebound above 2015 or 2016 demand. The drought was in progress during the last four years shown in Table 2-2 and the governor's declared statewide drought emergency was in effect in the last two years shown. Permanent measures to reduce water use, such as plumbing retrofits and landscaping changes, were implemented during this period. However, it is also likely that many people on the Monterey Peninsula, as throughout the state, made voluntary behavioral changes to reduce their water use during the drought – changes that a water manager cannot count on to be sustained at the same level of commitment in normal rainfall years or when restrictions imposed by the CDO are lifted. Under normal rainfall

conditions and without the CDO restrictions, year-to-year declines cannot be expected to be as dramatic as were achieved during the drought, and service area demand could increase to some degree compared to the later years of the drought. For example, urban water production statewide in May 2017[2] (following a wet winter after five years of severe drought) was somewhat higher than in May 2016 and residential per capita water use in May 2017 was somewhat higher in all hydrologic regions than in May 2016 (SWRCB, 2017). For this reason, it may be unwise to assume that the final years of a severe drought, such as 2015 or 2016, provide a reliable estimate of customer demand in non-drought years. In addition, as discussed above, use of 2010 to estimate peak month demand of existing customers ensures capacity to meet the peak need consistent with state waterworks regulations. The general downward trend in demand is expected to continue for some time and this expectation underlies the assumption that using 2010 demand would be consistent with state waterworks regulations regarding capacity to meet peak demands discussed above. That said, the incremental water use reductions achieved each year by conservation measures and programs cannot be expected to continue at the same rate indefinitely as programs and measures reach market saturation in a given service area, barring currently unforeseen technological breakthroughs. The rate of continuing reductions in water use can, therefore, be expected to slow over time and eventually level off.

Comments Urge Higher Demand Number

Some comments state that the demand estimates in the Draft EIR/EIS were too low, that demand estimates reflect current constraints on water use, and that the project should be sized to allow more "relaxed" conservation. Related comments stated that demand estimates need to reflect non-revenue water use and the need for Salinas Valley Groundwater Basin (SVGB) return water; that it was short-sighted not to size the plant to meet general plan buildout; and that minor changes to the EIR/EIS could address a plant sized to meet general plan buildout demand. While some relaxation in the behavioral changes people made during the drought can be expected, as noted in the discussion of 2015 and 2016 demand above, such changes are not expected to warrant a larger-capacity project. The experience of drought, changing weather patterns, and concern about effects of climate change have increased the recognition of the need for ongoing conservation efforts. For example, Governor Brown's April 2017 Executive Order B-40-17 terminating the January 2014 Drought State of Emergency also calls for "Making Conservation a Way of Life" and retains prohibitions on wasteful water use. MPWMD and CalAm are not expected to abandon or weaken water conservation programs that have been put in place since 1995 or the MPWMD's prohibition on water waste if the MPWSP were implemented. Demand described in the EIR/EIS is system demand (not water customer consumption) and, therefore, accounts for non-revenue water loss. Regarding SVGB return water, see the discussion under "Supply available for other use" below in Section 8.2.13.3 and Master Response 4. Regarding one commenter's opinion that the project should be sized to address general plan buildout, EIR/EIS Chapter 2, Section 2.3, describes the demand the project is proposed to meet, which would include some development under adopted general plans: development of legal lots of record represents development that would be anticipated in general plans. EIR/EIS Table 2.5 (Section 2.5) shows the amount of water

[2] The most recent month reported as of July 2017.

needed to meet future water demand associated with general plan buildout and in Table 6.3-8 (Section 6.3), the EIR/EIS growth inducement analysis compares the amount of project water that could be available for growth with the amount needed for general plan buildout. The amount of water that would be available to serve growth depends on the project's SVGB return water obligation. Note also that CalAm, the Monterey Peninsula Regional Water Authority representing Monterey Peninsula jurisdictions, the Coalition of Peninsula Businesses, and others agreed to the size of the MPWSP desalination plant in a proposed settlement agreement on plant sizing in 2013 (CalAm, et al. 2013).

Other Demands

Pebble Beach Entitlements

Several comments stated that the Draft EIR/EIS failed to adequately scrutinize the amount of water CalAm assumed for the Pebble Beach water entitlements and that existing customer demand does not include water to serve the Pebble Beach water entitlements. Other comments stated that the recycled water project that was the basis for these entitlements enabled the conservation of far more potable water than the amount represented by the entitlements, that CalAm has an obligation to serve the entitlements from whatever sources are currently available, and that the full entitlement amount represents an existing "irrevocable, divisible, binding entitlement to potable water, as a vested property right and interest" for use on and by the benefitted properties and should, therefore, be classified as existing demand. Related comments stated that because the Pebble Beach entitlements must be honored from existing supplies whether or not a new water project is built, water for the entitlements would not be growth inducing. Comments noted that this obligation has been recognized by the State Water Board and in written agreement between CalAm, the Pebble Beach Company and MPWMD, and that the proposed MPWSP would not change the effect of the Pebble Beach entitlements.

Draft EIR/EIS Section 2.3.3.1 explained that the MPWMD granted the Pebble Beach water entitlements to the Pebble Beach Company and two other fiscal sponsors for underwriting the development of a wastewater reclamation project that MPWMD estimates saves approximately 1,000 acre-feet per year (afy) of potable water. The Pebble Beach Company was granted a 380 afy entitlement. Draft EIR/EIS Section 2.3.3.1 also discussed how much of the original 380 afy entitlement had been used and the basis for concluding that 325 afy was a reasonable estimate of the remaining entitlements not reflected in recent system demand. The State Water Board recognizes that the wastewater project reduced demand on the Carmel River by more than the amount of the water entitlements, as some comments noted, and has stated that the 380 afy represented by the water entitlements is available to serve the Del Monte Forest properties when they are developed. The State Water Board also recognizes that during the CDO extension period (extended by Order 2016-0016 to December 31, 2021), increased diversions from the Carmel River by CalAm to satisfy the Pebble Beach entitlements would not be counted as part of CalAm's diversion limit but instead added to the adjusted base against which CalAm's compliance was measured. The properties developed using these entitlements also are not subject to the prohibition on new service connections contained in the State Water Board CDOs (Anton, 1998; SWRCB, 2009; SWRCB 2016). The commenters who questioned the inclusion of the

Pebble Beach entitlements as part of CalAm's service area demand provided no evidence or reason for excluding this legal obligation to serve water. The water entitlements constitute an existing commitment by MPWMD and obligation to serve by CalAm when the properties are developed, and therefore, are considered part of CalAm's existing demand. Therefore, EIR/EIS Section 2.3.1, Existing Service Area Demand, includes a new section, 2.3.1.3, Pebble Beach Entitlements. Compared to the Draft EIR/EIS, the Pebble Beach entitlements have been moved in the Final EIR/EIS from being part of the project water to a baseline condition because these entitlements represent demand that CalAm is obligated to serve whether or not the project is implemented. As such, the project would not remove an obstacle to growth of the properties served by this water entitlement and the project would not be considered to induce the growth of those lands.

Economic Recovery

Some comments asserted that the Draft EIR/EIS failed to adequately scrutinize the amount of water assumed within the proposed project to serve tourism rebound, that this CalAm estimate was inflated and unsupported, and that tourism has rebounded although water demand remains low, while another comment cited previous MPWMD testimony that CalAm's 500 afy estimate was reasonable. CalAm estimated that water demand at local hospitality-related businesses, which had been depressed due to the lingering effects of the recession that began in late 2007-early 2008, could increase by about 500 afy under a more robust, recovered economy. This estimate was included as part of future service area demand that the MPWSP (with other service area supplies) would need to serve. The Draft EIR/EIS growth inducement analysis (Section 6.3) conducted additional review of available commercial sector water consumption data and concluded that some degree of economic recovery had likely occurred and that additional demand at existing businesses under a fully recovered economy may be less than CalAm had estimated – closer to 250 afy than 500 afy. The Draft EIR/EIS described the 2016 economic study of travel impacts mentioned in some comments, which showed that transient occupancy tax receipts in Monterey County declined for several years following 2008, but by 2012 were greater than before the recession. While this study provides evidence that the hospitality industry in the county has recovered to some extent, the study does not support a direct comparison of tax receipts in different years because the tax receipt data were not adjusted for inflation; therefore, increased tax receipts in recent years likely reflect, to some extent, increases in lodging prices that have occurred since 2008, in addition to increased occupancy rates due to a recovering economy. Thus, that single study does not establish that the county's economy has fully recovered.

In response to a comment stating that economic rebound would affect demand in all commercial, industrial, and institutional sectors – not just restaurants and lodging – CalAm water consumption data for the industrial and public authority sectors were reviewed in addition to the commercial sector consumption data discussed in Draft EIR/EIS Section 6.3.5.1 and shown in Table 6.3-2. The data show that demand for the three sectors combined in years after the recession commenced is lower than pre-recession demand by a greater margin than a comparison of the commercial sector alone for the same time periods. For example, a comparison of demand in the four years before the recession started (2004 through 2007) with the four years after (2008 through 2011) shows that average annual commercial sector demand was 230 acre-feet (af) lower

than average annual demand in the four years before the recession started, whereas average annual demand for the three sectors combined was 600 af lower. Non-residential demand since 2012 has continued to decrease, thereby increasing the difference in demand compared to 2007 or other years before 2008, even though the economic study discussed above suggests that the economy had begun to recover, to some extent, by 2012. The lower demand in recent years is assumed to reflect responses to the drought at least as much – likely more – than lingering effects of the recession. Some post-drought rebound in demand is expected to occur, as discussed above under "Comments Urge Lower Demand Numbers," and available evidence has not established that the economy in CalAm's service area has fully recovered. However, non-residential demand in a fully recovered economy is not expected to return to pre-recession demand levels given permanent reductions in water consumption achieved by ongoing conservation programs since 2007. If somewhat more supply were needed for economic recovery than was assumed in the Draft EIR/EIS growth inducement analysis, taking into account economic rebound in the industrial and public authority sectors in addition to the commercial sector, this would not change the Draft EIR/EIS conclusions regarding the project's growth-inducing impact but could reduce somewhat the amount of water assumed to be available for growth.

Legal Lots of Record

Comments stated that the Draft EIR/EIS failed to adequately scrutinize the amount of water that CalAm has assumed is needed as part of the project to serve legal lots that do not now use water; that development has occurred since MPMWD's preliminary reports were prepared in the early 2000s estimating the water needed for these lots; and that some vacant lots on improved parcels that were included in MPWMD's vacant lot study may never be split from the main property and developed. Draft EIR/EIS Section 6.3.5.1 described the basis for CalAm's estimate of demand associated with vacant legal lots of record and summarized available information about this estimate. This included information on the preliminary studies that had been prepared for MPWMD and MPWMD's testimony during MPWSP proceedings that, based on MPWMD's assessment of available data, CalAm may have underestimated demand associated with lots of record. As the EIR/EIS states, one objection MPWMD had with one of the vacant lot studies (which it had commissioned but did not adopt) was that the demand estimate did not include demand associated with vacant lots on improved parcels in unincorporated areas. EIR/EIS Section 6.3.5.1 has been revised to include updated information from MPWMD (in Draft EIR/EIS comments, summarized above) that some lots have been developed and some vacant lots on improved parcels may never be developed. Due in part to the limited data on this component of project demand, Draft EIR/EIS Section 6.3.5.3 and Table 6.3-8 compared the water supply that would be provided by the project to serve legal lots of record and other new development with the estimate of water supply needed to serve development under adopted general plans in CalAm's service territory, and concluded that the amount of water supply provided by the project was consistent with (and less than) the estimate of water supply that would be needed to support general plan buildout.

Other Approaches to Estimating Future Water Demands

Some comments stated that the Draft EIR/EIS failed to conduct a per capita demand analysis or similar analysis based on water use per dwelling unit to determine the level of growth that would be supported by the proposed project. Estimating demand based on per capita water use is one of

several methods to estimate future water demand. The EIR/EIS compared the water that would be provided for additional development with the estimate of future water needs prepared by MPWMD, as described in Section 6.3.5.3 and shown in Table 6.3-8. The approach MPWMD took in 2006 to estimate future demand involved close consultation with service area jurisdictions and was based on anticipated land use development in the jurisdictions consistent with the respective adopted general plans. The analysis factored in water use based on different types of non-residential land uses, and recognized differences in water use in unincorporated county residences compared to city residences due to larger lot sizes, among other factors. One could reason this approach is no less valid than one based on estimated per capita or per dwelling unit water use, and arguably provides a more nuanced assessment of future water needs accounting for different land use types. The updates to the MPWMD estimates discussed in EIR/EIS Section 2.5.3.4 and shown in detail in EIR/EIS Table 2-5 were provided after the moratorium on new water connections was established in 2009. Therefore, little if any of this projected future demand will have been realized (became actual water use that would be reflected in existing demand) and the MPWMD estimates as revised are assumed to continue to reasonably reflect future water supply needs in CalAm's service area. The estimate of future water demand used in the EIR/EIS is appropriate and adequate because it is based on existing demand (for the substantial portion of the MPWSP that would replace water supplies no longer available to CalAm due to legal decisions discussed in EIR/EIS Section 2.2) and was evaluated with reference to the analysis of future water needs that was prepared by MPWMD.

Summary of Demand Assumption Revisions

For the reasons discussed above, the overall demand of 14,275 afy shown in Draft EIR/EIS Tables 2-3, 6.3-1, and 6.3-3 has not changed. However, the breakdown of identified existing and anticipated future demands shown in Table 6.3-3 has been revised: existing demand has been revised to include the 325 afy associated with existing Pebble Beach water entitlements, thereby increasing the estimate of existing demand from the 12,520 afy shown in the Draft EIR/EIS to 12,845 afy in the Final EIR/EIS. Correspondingly, because demand associated with anticipated future development shown in Table 6.3-3 no longer includes the Pebble Beach entitlements, it has been reduced by 325 afy, from 1,755 afy in the Draft EIR/EIS to 1,430 afy in the Final EIR/EIS.

8.2.13.3 Supply Assumptions

This section responds to comments concerning Draft EIR/EIS assumptions regarding available water supply. As discussed in the EIR/EIS and below, data concerning supply (as with data regarding demand) were derived primarily from estimates provided by CalAm and MPWMD.

ASR System

Several comments stated that the amount of water supply provided by the Aquifer Storage and Recovery (ASR) project assumed in the EIR/EIS was too low – that MPWMD assumed a higher yield from the ASR project and that a yield of 1,920 afy should be assumed rather than 1,300 afy assumed in the EIR/EIS. MPWMD commented that it has recently revised its estimate of the average annual yield from the ASR project. Draft EIR/EIS Section 2.4.3 explained that although the EIR prepared for the Phase I and Phase II ASR projects estimated the combined yield of the two phases would be 1,920 afy, diversions to the ASR system are contingent on maintaining

minimum daily instream flows in the Carmel River. Precipitation and streamflow can vary substantially from year to year; due to these uncertainties and constraints on potential diversions, the estimated long-term average annual ASR system yield of 1,300 afy assumed for the purpose of MPWSP water supply planning was considered reasonable to account for these fluctuations. MPWMD's updated estimate of the ASR project yield indicated that the weighted average yield (accounting for the statistical frequency of different water year types) of the Phase 1 and 2 ASR projects with the recently approved Monterey Pipeline is about 1,600 afy (see response to comment MPWMD-14). While CalAm's 1,300 afy estimate of long term average yield of the ASR project is more conservative than MPWMD's 1,600 afy estimate, CalAm's estimate is not unreasonable given the low yields during drier years – which many expect to be more frequent in the future due to climate change. Draft EIR/EIS Section 2.4.3 reported the substantial variation of Carmel River water available for ASR storage in recent years: "In water year 2011, which was wetter than average, 1,117 af of Carmel River water was injected into the groundwater basin. In water year 2012, 132 af was injected; in 2013, 295 af was injected, in 2014, no Carmel River water was injected, and in 2015, 215 af was injected."

Table 13 Water Rights

One commenter stated that the EIR/EIS should include water supply available under CalAm's Table 13 water rights, that Table 13 water supply should not be excluded on the basis that it is only available in wet years, and that it is not limited to wet years because it can be stored through the ASR system. As discussed in Draft EIR/EIS Section 2.4.6.1, CalAm's Table 13 water rights are subject to river flow criteria and other conditions, and Table 13 water must be used in the Carmel River watershed. That is, water available under this right cannot be diverted to storage in the ASR system, which is outside the Carmel River watershed. While Table 13 water is a useful supplement to CalAm supplies when it is available, it is less reliable than supply available via CalAm's other Carmel River rights because Table 13 water would not be available in dry years. Due to the variability of this supply, it is not appropriate to include it as a reliable element in CalAm's yearly supply portfolio. For example, as stated in Draft EIR/EIS Section 2.4.6.1, CalAm's combined diversions of Carmel River water under CalAm's Table 13 and ASR water rights were less than 300 afy in water year 2015. Regarding the effect of Table 13 water on desalination plant operations, in the proposed sizing settlement agreement signed by CalAm, the Monterey Peninsula Regional Water Authority, MPWMD, and others in 2013, CalAm agreed that if Table 13 water is available, "CalAm shall be able to lower the operating level of the desalination plant or use the Table 13 rights first in the year to allow other existing rights to be used later in the year for emergencies" (CalAm et al., 2013).

Sand City Desalination Plant

One commenter stated that more water is available to CalAm from the Sand City desalination plant than the 94 afy assumed for the project and noted that the description of the No Project Alternative in Draft EIR/EIS Section 5.4.2.3 assumed that 230 afy would be available from the Sand City plant. As discussed in EIR/EIS Section 2.4.4, CalAm's long term supply from the Sand City desalination plant water is 94 afy, and is the amount assumed in EIR/EIS Chapter 2 and Section 6.3. More is available in the near term – until Sand City needs the full 206 afy balance of

the plant's 300 afy production for development in Sand City. The timing and amount of availability of water for CalAm in excess of 94 afy is not under the control of CalAm, but is solely a function of growth in Sand City. To characterize CalAm's supply portfolio under the No Project Alternative when CalAm's unlawful Carmel River diversions end, pursuant to the 2016 CDO, 230 afy was assumed to be available from the Sand City plant. This is a near-term estimate of supply based on the amount assumed in the State Water Board's 2009 CDO for year 2016-2017, the last year for which the 2009 CDO provided a quantified estimate of supply available to CalAm from the Sand City plant.[3] The Final EIR/EIS Section 5.4.3.2 discussion under "Supply Shortages" has been revised to clarify that supply available to CalAm from the Sand City desalination plant under the No Project Alternative would eventually be reduced to 94 afy, as assumed for the MPWSP. Alternative supply and scenarios presented in Appendix L and summarized below in Section 8.2.13.5 include scenarios that assume 230 afy would be provided by the Sand City desalination plant.

GWR Supply

One commenter stated that the Draft EIR/EIS analysis underestimated the supply that would be available to CalAm from the GWR project and that 3,700 afy would be available to CalAm rather than the 3,500 afy assumed in the EIR/EIS. The amount of GWR supply that the EIR/EIS assumes would be available to CalAm is based on GWR project information. MRWPCA staff confirmed in September 2017 that an average of 3,500 afy of GWR water would be provided to CalAm. The GWR project also includes a drought component, which entails banking 200 afy in the groundwater basin for agricultural use during drought periods. That is, of a total of 3,700 acre-feet that would be injected into the groundwater basin each year, on average, 200 afy would be banked and withdrawn when needed during drought periods to provide additional supply to Salinas Valley growers (Imamura, 2017).

At the request of the CPUC, MRWPCA submitted three hypothetical scenarios to expand the GWR Project and produce more than 3,500 acre feet of purified recycled water annually for (CalAm's) Monterey District service area. In its testimony, MRWPCA emphasized that these scenarios are speculative; at this time, MRWPCA has no plans or proposals to expand the PWM Project beyond the current plans for expansion to 5 mgd (million gallons per day). As such, these scenarios are not assessed in this Final EIR/EIS. See Testimony at ohttp://docs.cpuc.ca.gov/PublishedDocs/SupDoc/A1204019/990/197582477.pdf.

Supply for Peak Demands

One commenter suggested that, similar to electric utilities, CalAm's Monterey District would require a "reserve margin," which the commenter defined as "a measure of the amount of electricity imports and in-state generation capacity available over average peak demand conditions" and asserted that the MPWSP project objective "to develop a reliable water supply for the CalAm Monterey District service area, accounting for peak month demand of existing

[3] The 2016 CDO does not quantify an estimate of near term supply available to CalAm from the Sand City plant. The 2016 CDO states that the Sand City desalination plant provides CalAm a minimum of 94 afy and the balance of the plant's capacity not needed for expanded use in Sand City.

customers" is a type of "planning or month-ahead reserve margin requirement" to meet demand of existing customers. Related comments suggested that a reserve margin of 10 percent applied to 2016 annual demand would be adequate to meet system capacity needs. Like any water supplier, CalAm needs adequate capacity to meet peak demands, as a practical matter and as required by state Waterworks Standards discussed above in Section 8.2.13.2 and EIR/EIS Section 2.3.2. Thus, the size of the MPWSP is logically tied to these peak demands. As noted above under "Existing Annual Service Area Demand," peak month demand is the peak demand that challenges system capacity in CalAm's Monterey District, and state Waterworks Standards require the system to have the capacity to meet peak demands considering the most recent ten years of operation. While a commenter suggested that a 10 percent margin should be adequate to meet CalAm's capacity requirements, monthly demand varies by much more than 10 percent. **Table 8.2.13-1** shows the variation in average monthly production demand anticipated for the project in a typical year. "System production demand" includes CalAm service area demand assumed for the proposed project and SVGB return water. The production demand shown is based on a 9.6 mgd desalination plant with an assumed 6 percent SVGB return water obligation. As shown, demand in the peak month, July, is roughly 35 percent greater than average monthly demand for the year overall, and demand in December is roughly 30 percent lower than the average monthly demand for the year. The comments raising the topic of a reserve margin defined it as being an amount "over average peak demand" but did not indicate what the "average peak demand" was assumed to be for the CalAm system. Comments subsequently implied that the reserve margin was an amount above average demand, and failed to demonstrate how the assumed 10 percent reserve margin could meet CalAm's peak demand capacity requirements. Regarding the assumption that 2016 demand accurately represents existing average annual demand, see the discussion of "Comments Urge Lower Demand Numbers" above in Section 8.2.13.2.

"Supply available for other use"

Several comments stated that water supply shown in Draft EIR/EIS Table 2-4 as "available for other uses" is surplus, should be subtracted from the asserted demand for this project, and shows that a smaller desalination plant would be feasible. The water shown in EIR/EIS Table 2-4 as "supply available for other use" is the volume of water available for other uses after service area demand is subtracted from anticipated supplies. Much of this water would be used to meet CalAm's SVGB return water obligation. SVGB return water is discussed in Section 2.5.1 and Section 2.6. See also Table 6.3-4 in Chapter 6, which shows supplies, demands, and two estimates of SVGB return water. Thus, supply shown as available for other use after service area demand is met is not necessarily surplus that would allow for a reduction in the size of the proposed project. Refer to Master Response 4, The Agency Act and Return Water. As discussed under "Conclusion: MPWSP Water Service Capacity" in EIR/EIS Section 6.3.5.1, there could be surplus supply after meeting the return water obligation – or a deficit – depending on the actual amount of the return water obligation. As that discussion states, supply not needed for other uses would be available to support new development. In addition, as indicated in the notes in Draft EIR/EIS Table 2-4, the estimates of annual water supply provided by desalination plant production show a direct unit conversion of the rated capacity of a 9.6 mgd and a 6.4 mgd plant, and thus reflect operation at 100 percent capacity. This is greater than industrial facilities are typically recommended to operate. If operating the plant at or near full production capacity

TABLE 8.2.13-1
TYPICAL MONTHLY SYSTEM PRODUCTION DEMAND - PROPOSED MPWSP

	January	February	March	April	May	June	July	August	September	October	November	December	Monthly Average
MPWSP System Production Demand (mgd)[a]	10.0	10.2	10.9	11.6	16.4	18.6	19.1	18.8	18.6	14.7	11.7	9.6	14.2
Percent of Average Monthly Demand[b]	70%	72%	77%	82%	116%	131%	134%	132%	131%	103%	83%	68%	100%

NOTES:
mgd = million gallons per day

[a] System production demand includes existing annual service area demand and additional demands the project is proposed to meet (Pebble Beach water entitlements, demand associated with hospitality industry economic recovery, and legal lots of record, shown in Draft EIR/EIS Chapter 2 Table 2-3), and Salinas Valley Groundwater Basin return water assuming a 6 percent return water obligation for a 9.6 mgd desalination plant.

[b] This row compares the typical demand for the month with annual average monthly demand to show the month-to-month variation in system production demand over the course of a year. For example, in July, demand is about 35 percent higher than the annual average (134%-100%), and in December, demand is about 30 percent lower than the annual average (100%-68%).

SOURCE: CalAm, 2016; ESA, 2017.

provided more water than needed to meet service area demand and the return water obligation, the plant could be operated at a lower capacity. As discussed above, the plant is sized to provide the flexibility needed to meet peak month demands.

Supply Provided by the Desalination Plant

One commenter asserted that the Draft EIR/EIS provided insufficient information on how CalAm's multiple water supply sources will be operated together to ensure supplies were optimized and another commenter expressed concern about high operating capacity assumed for the plant. As shown in EIR/EIS Table 3-7, the proposed desalination plant is expected to operate at a relatively constant rate throughout the year. As described in EIR/EIS Section 3.4.2, during wet periods, CalAm would store desalinated water supply in the SGB via the ASR system, and the stored desalinated product water as well as stored Carmel River supplies would typically be extracted during summer months and periods of peak demand. To illustrate how the plant would be operated in conjunction with CalAm's other supplies, **Table 8.2.13-2** shows an example of typical monthly operations for the proposed 9.6 mgd desalination plant assuming a 6 percent SVGB return water obligation.[4] The EIR/EIS assumption that the plant would operate primarily at or near full production capacity (e.g., at 95 to 100 percent most months in the monthly operations table below and at 100 percent capacity in EIR/EIS Tables 2-4 and 6.3-4) is conservative from the perspective of evaluating the environmental impacts of plant operations and indirect effects of water supply the project would provide, but operating at 95 to 100 percent capacity is a higher operating capacity than would likely be considered practical. Most industrial facilities do not operate this close to 100 percent capacity.[5] Should supplies be somewhat greater than demand, or longer-term demand decline due to conservation programs, the plant could be operated at a somewhat lower capacity. Indeed, although MPWMD has not determined the allocation of water that would be provided by the project, MPWMD stated in a comment on the Draft EIR/EIS that it may not allocate all of the water produced by the project. One reason MPWMD may choose not to allocate the full amount that could be produced would be to allow the plant to operate at a lower capacity (see comment MPWMD-21). Absent assurance that the plant would be operated at a lower level, the EIR/EIS analysis assumed that the plant would operate at or near full capacity. The monthly operations shown in Table 8.2.13-2 assume normal rainfall conditions. In dry years, less water may be available from the Carmel River, e.g., for diversion to the ASR system. In extended dry periods, such as the recent drought, even water that may have previously been injected into the ASR system over a period years[6] could be depleted. In such periods, supplies provided by the desalination plant would be even more critical.

4 This table is based on a monthly operations table showing a 7 percent SVGB return water obligation that was prepared by CalAm. The table was revised for this example to show a 6% return obligation, for consistency with the mid-range return obligation percentage considered in EIR/EIS groundwater modeling, by reducing the amount of return water delivered from May to October to CSIP.

5 For example, according to the U.S. Census Bureau's quarterly surveys of plant capacity utilization rate, U.S. domestic manufacturing plants on average used 71 to 73 percent of their full production capacity in 2016, although a few industries operated above 90 to 95 percent in some or all quarters. Reverse osmosis desalination was not listed as a category of industrial facilities in the survey (U.S. Census Bureau, 2017).

6 As noted in the ASR discussion above, it is assumed when CalAm has a replacement supply that enables it to cease unlawful diversions that it will not be required to use stored ASR water in the same year it is injected.

NOTES: MGD = million gallons per day
Components may not sum to the totals shown due to rounding.

[a] Based on MPWSP supply and demand assumptions: average demand of 14,275 afy, 94 afy supply from the Sand City desalination plant, and 1,300 afy from the ASR system.
[b] Annual totals in acre-feet/year are calculated by converting the estimated monthly averages in mgd shown here, provided for information purposes. 1 mgd = 1,120 afy
[c] Assumes a 6 percent Salinas Valley Groundwater Basin return water obligation.

SOURCE: CalAm, 2016; ESA, 2017.

Water Available after Seaside Groundwater Basin Replenishment

For the first 25 years of operations, CalAm would pump 700 afy less than its adjudicated right from the SGB to provide "in-lieu" replenishment of water it has pumped in excess of its adjudicated rights since that basin was adjudicated. At the end of the 25-year period, CalAm would have access to its full 1,474 afy adjudicated right. The additional 700 afy that would then be available to CalAm could be used to offset loss of capacity at Los Padres Reservoir, as stated in comment MPWMD-17; to reduce the operating level of the desalination plant; or to serve additional growth within the CalAm service area, as stated in "Conclusion: MPWSP Water Service Capacity" in EIR/EIS Section 6.3.5.1. Added to the supply available for future development assuming either 6 or 12 percent SVGB return obligation, shown in Draft EIR/EIS Table 6.3-8, this would still be less than the revised MPWMD estimate of future supply needs. If no water is needed to be returned to the SVGB, supplies with the additional 700 afy from the SGB that would be available for future development would total 4,149 afy. This **would exceed the amount of water needed for growth** under adopted general plans based on the revised MPWMD estimate of future supply needs (3,526 afy) shown in Draft EIR/EIS Table 6.3-8. Supply available for future development would exceed this estimate of future supply needs by 623 afy, which represents 2.3 percent of the source water needed for a 9.6 mgd plant (assumed to be 24.1 mgd, or 26,990 afy). Therefore, if the SVGB return water obligation turned out to be an amount less than 2.3 percent, the amount of water available after the Seaside Basin replenishment period would change the Draft EIR/EIS conclusion regarding the consistency of the project with planned growth and thus the project's growth inducing impact. However, as explained in Master Response 4, Section 8.2.4.3 (see also EIR/EIS Appendix E3), the actual annual volume of return water could be 10 percent in the first few months of project pumping and would be no more than 5 percent within 5 years of project pumping. Therefore, based on current available information, the Draft EIR/EIS conclusion – that the supply provided by the project would be consistent with growth anticipated in jurisdictions' adopted general plans – remains valid.

Summary of Supply Assumptions

For the reasons discussed above, the amount of water supply provided by the project and CalAm's other supply sources shown in Draft EIR/EIS Table 2-4 has not changed. Based on current groundwater investigations, the SVGB return water obligation would be about 5 percent within 5 years and therefore, Draft EIR/EIS conclusion about the consistency of water supply provided by the project with water needed for growth under adopted general plans would not change.

8.2.13.4 Growth Inducement

Water Available for Growth

Comments claimed that demand is overestimated and available supply underestimated, and therefore, the project would provide more water than needed, inducing more growth than identified in the Draft EIR/EIS. Some comments asserted that because demand has been decreasing, the project would result in more water than the analysis assumed for new development, and that the amount of water available for growth would exceed water needed for general plan buildout in the

service area. Related comments asserted that the EIR/EIS approach of looking at growth projections and buildout in general plan EIRs is not appropriate because the general plans and their environmental documents are outdated and baseline conditions have changed. Sections 8.2.13.2 and 8.2.13.3, above, address comments concerning the EIR/EIS demand and supply assumptions and document why they remain reasonable – and, consequently, why the quantity of water assumed to be available to serve additional growth is also reasonable. As discussed in EIR/EIS Section 6.3.2.1, a jurisdiction's general plan is its comprehensive, long-term plan for physical development, including the general distribution, location, and extent of land uses, and recommended standards of population density and building intensity. Consequently, service area jurisdictions' adopted general plans provide an appropriate indication of the development anticipated in CalAm's service area. The comparison in EIR/EIS Table 6.3-8 of water supply available for future development provided by the project and CalAm's other supply sources with future water supply needs is based on the estimate of future water needs prepared by MPWMD in 2006, in consultation with representatives of service area jurisdictions. As described in Section 6.3.5.3, the jurisdictions provided estimates of anticipated development at the time, consistent with their adopted plans. All of the subsequent updates of the 2006 estimates, which are shown in Draft EIR/EIS Table 2-5, were provided since 2009, when the moratorium on new water connections was in effect. Therefore, the MPWMD estimate of future water supply needs, as revised, remains a reasonable point of comparison for growth that would be supported by project water supply. The Draft EIR/EIS analysis confirmed that the project water supply available to support new development would be consistent with that estimate of future water needs and no change has been made to the EIR/EIS.

One commenter asserted that the EIR/EIS assumption that project water not needed to meet existing demand potentially could be used for any purpose was inconsistent with stated project objectives and could lead to the need for another water supply project in the future with the same objectives – serving lots of record, Pebble Beach entitlements, and tourism demand – if the MPWSP water supply was not reserved for the stated project objectives. The commenter stated that the EIR/EIS should include mitigation to limit use of project water to the stated purposes, and if the CPUC does not have authority to impose such mitigation, the EIR/EIS should be revised to identify this as a potentially significant impact. CalAm is responsible for providing water within its service territory. The MPWMD – not CalAm, the CPUC or MBNMS – is responsible for allocating water supply within CalAm's service territory (see EIR/EIS Section 2.5.4), but has not yet prepared an allocation for the proposed MPWSP supply. Note that comment MPWMD-21 presents some options that the MPWMD would consider in the allocation process, including reserving some water for lots of record, economic recovery, and Pebble Beach entitlements. The "impact" suggested by this commenter would flow from the inability of all parties to make water available per the project objectives. This is speculative and also not reasonably foreseeable given that water for Pebble Beach is based on established entitlements, and especially given the MPWMD's comments about allocation. In the absence of definitive information about how MPWMD would allocate the proposed water supply, and given that CalAm and the Lead Agencies cannot dictate how project water is used, the EIR/EIS properly discloses the potential that jurisdictions that are allocated project water would be able to use it for purposes other than those underlying CalAm's project objectives. EIR/EIS Section 6.3.6 identifies the project's growth inducing impact as significant and unavoidable.

Impacts of Growth

Comments regarding growth impacts stated that the Draft EIR/EIS analysis cannot avoid or ignore the impacts of growth induced by the project on the theory that the growth may have been included in the analysis of various general plans; that induced growth would contribute to cumulative GHG emissions and global climate change; and that the impacts of growth induced by cumulative water supply projects were not adequately described or analyzed. Draft EIR/EIS Section 6.3 acknowledges that the project would remove an obstacle to growth by removing, to a degree, water supply limitations in CalAm's service area. The analysis identifies the impacts of growth that the project would support. The impacts of planned growth that would be supported, in part, by the project have been identified in the general plan CEQA documents of service area jurisdictions; as discussed in EIR/EIS Section 6.3.6, some of the identified indirect impacts of growth are significant and unavoidable; others are significant but can be mitigated. These are the impacts to which the project would indirectly contribute by providing water supply, and are the basis for the determination that the project's growth inducing impact would be significant and unavoidable. Section 6.3.6 and Table 6.3-9 summarized the impacts of this growth. Draft EIR/EIS Appendix J2 provided a more detailed summary of the impacts and the mitigation measures identified in the general plan CEQA documents to mitigate the effects of that growth. Table 6.3-9 identified 'contribution to cumulative greenhouse gas emissions and global climate change' as one of the significant unavoidable impacts associated with growth supported by the project. In addition, the EIR/EIS growth inducement analysis states that although some of the general plan CEQA documents of service area jurisdictions were prepared before passage of the California Global Warming Solutions Act of 2006, the project was indeed expected to indirectly contribute to a significant and unavoidable increase in greenhouse gas emissions as a result of growth supported by project water supply; see EIR/EIS Section 6.3.6. The general plans and their respective CEQA documents are not unrelated to the project water supply, as one comment suggested. Project water not needed as Carmel River and SGB replacement supply to meet existing demand would be allocated to jurisdictions or reserved by MPWMD. Decisions relating to project water that is allocated to jurisdictions would be the responsibility of the respective jurisdictions and subject to their land use plans, policies and regulations, chief among which typically is the general plan. Comments to the effect that the analysis "wrote-off" growth-related impacts as an obligation of the municipal planning process may misunderstand Section 6.3.6.2, Authority to Mitigate Effects of Growth. As discussed above, the Draft EIR/EIS identified growth inducement as a significant and unavoidable impact of the proposed project. However, as stated in section 6.3.6.2, the CPUC, MBNMS, and CalAm do not have the authority to approve, deny, or impose mitigation measures upon land uses that may rely on project water for their development. Urban growth typically results in many common impacts – those impacts are described and disclosed for the MPWSP in Section 6.3.6. Multiple water projects in the region would increase growth in the region, as discussed in Draft EIR/EIS Section 6.3.7. The cumulative analysis accurately concludes that the effect of growth induced by cumulative water projects would be to increase the severity of the impacts and expand the area that would be affected by these impacts.

8.2.13.5 Alternative Supply and Demand Assumptions

Questions have been raised as to whether the project may or may not be necessary or could be smaller if one considered different supply and demand numbers that some commenters believe are more reasonable than those used in the Draft EIR/EIS. In order to test out that possibility, Appendix L was prepared for informational purposes only (i.e., without change to the assumptions in the EIR/EIS, as addressed above throughout this Master Response) to consider the results of using different supply and demand numbers. The primary consideration is whether facts exist to support a smaller desalination plant (e.g., having one less reverse osmosis [RO] unit) such that either a smaller plant or a phased plant could be approved for the 9.6 mgd project or the 6.4 mgd Alternative 5a. The results of that sensitivity analysis could inform and affect the ultimate project decision.

The first scenario considered in Appendix L is based on the following demand assumptions:

- Demand in 2013 (rather than 2010), the year before the drought emergency was declared, represented existing annual demand of 11,360 afy rather than 12,270 afy
- The same amount of water would be needed to serve Pebble Beach entitlements as assumed in the EIR/EIS (325 afy)
- Economic recovery of the tourism industry would require half the supply shown in EIR/EIS Table 2-3 for this demand component (250 afy rather than 500 afy)
- Development of lots of record would require half the supply shown in EIR/EIS Table 2-3 for this demand component (590 afy rather than 1,180 afy)

Together these assumptions would thus reduce overall service area demand to 12,521 afy, compared to the 14,275 afy assumed for the project.

These demand assumptions were paired with three different ASR supply assumptions and two different Sand City desalination supply assumptions, shown below, to create six variations of Scenario 1, Scenarios 1a through 1f.

- ASR supply of 0 (during a drought), 1300 afy (as assumed in the EIR/EIS), or 1,600 afy (as currently estimated by MPWMD)
- Sand City desalination plant supply of 94 afy (CalAm's long term supply assumed for the MPWSP) or 230 afy (CalAm's near-term supply assumed for the No Project Alternative)

Under Scenario 1, assuming that the ASR system provided at least as much supply as assumed in the Draft EIR/EIS (i.e., 1,300 or 1,600 afy), the plant size could be reduced by one 1.6 mgd RO unit. This would reduce the plant size from 9.6 to 8.0 mgd for the proposed project or from 6.4 to 4.8 mgd for Alternative 5a. However, in a drought when little or no supply was available from the ASR system, there would be insufficient supply to meet assumed demands if the plants were one RO unit smaller. Based on the above demand and supply assumptions that would allow for elimination of an RO unit, if a unit were *not* eliminated, the amount of supply that could be provided in excess of demand would still be within the amount of water needed for growth under adopted general plans discussed in the Draft EIR/EIS. Therefore, these assumptions would not change the Draft EIR/EIS conclusions about the project's growth inducing impact. Moreover, the

recent severe, five-year drought demonstrated that it is not reasonable to assume that there would never be drought conditions that could deplete ASR reserves and prevent new ASR supplies being diverted from the Carmel River for storage and use. Consequently, changes in plant sizing based on scenarios that assume the availability of adequate ASR supplies would need to be considered carefully.

Scenario 2 considered in Appendix L is based on the following assumptions:

- Demand in 2015 (rather than 2010), well into the recent drought, represented existing annual demand of 9,545 afy rather than 12,270 afy
- The same assumptions regarding the other demand components described above for Scenario 1 (Pebble Beach entitlements = 325 afy, economic recovery demand = 250 afy, and lots of record demand = 250 afy)
- The same assumptions regarding ASR and Sand City supply described above for Scenario 1 (ASR supply = 0, 1,300 afy, or 1,600 afy; Sand City supply = 94 or 230 afy)

These demand and supply assumptions were combined to create six variations, Scenarios 2a through 2f.

Under Scenario 2, the plant size could be reduced by one RO unit even in drought conditions when no water was available from the ASR system. Assuming the availability of ASR system supplies, i.e., non-drought conditions, plant size could be reduced by two RO units – from 9.6 to 6.4 mgd for the proposed project or from 6.4 to 3.2 mgd for Alternative 5a. However, in a drought when little or no supply was available from the ASR system, there would be insufficient supply to meet assumed demands if the plant was two RO units smaller. If the 2015 demand and supply assumptions that include 1,300 or 1,600 afy from the ASR system (i.e., those that allow for elimination of two units) were assumed to be correct, but the proposed plant size was *not* reduced by at least one unit, the amount of supply that could be provided above demand **would exceed the amount of water needed for growth under adopted general plans described in the Draft EIR/EIS. This would change the Draft EIR/EIS conclusion regarding the consistency of the project with planned growth and thus the project's growth inducing impact.** However, as noted above regarding Scenario 1, the recent drought has shown that it is not reasonable to assume there will never be drought conditions that could deplete ASR reserves and eliminate this as a supply source in some years. Given that development under general plan buildout would require adequate supply in all water year types, including droughts, the amount of supply available for additional development when no water was available from the ASR system is therefore, a more reasonable volume with which to compare with the amount of water needed for general plan buildout. When ASR supply is not available, the amount of water that would be provided in excess of demand under Scenario 2 is within the amount of water needed for growth under adopted general plans discussed in the Draft EIR/EIS.

Refer to Appendix L for more information on the alternative supply and demand scenarios that were explored.

8.2.14 Master Response 14: CEMEX Settlement Agreement

COMMENTERS ADDRESSED IN MASTER RESPONSE 14

City of Marina	CEMEX
Marina Coast Water District	

This Master Response provides an update to the status of the CEMEX sand mining facility, also known as the Lapis #110 Pit, the Lapis Sand Pit, and the Lapis Sand Plant. As explained in EIR/EIS Section 4.17.1.2, the California Coastal Commission (CCC) on March 17, 2016, issued a Notice of Intent (NOI) to Commence a Cease and Desist Order to CEMEX property owners (CCC, 2016). The NOI described past discussions between the CCC and CEMEX regarding CCC staff's allegations of the lack of proper coastal development permits and several other violations of the Coastal Act related to sensitive dune habitat in the vicinity of the active mining operations and coastal access. CEMEX has disputed and continues to dispute the CCC's allegations set forth in the NOI and asserts that it conducts the Lapis sand plant operations lawfully, and between March 2016 and July 2017, engaged in discussions with CCC regarding the cease and desist order proceedings.

Further, following publication of the Draft EIR/EIS, on May 16, 2017, the California State Lands Commission (CLSC) issued a letter to CEMEX concluding that the Lapis Sand Mine engaged in unlawful conversion of state public trust resources and indicated that CEMEX must either immediately submit a lease application or cease dredge pond (mining) operations. On June 6, 2017, the City of Marina passed Resolution No. 2017-57 that authorized the City Attorney to pursue the possibility of a civil action against CEMEX to declare and abate the Lapis Sand Mine as a public nuisance under sections 3479 and 3480 of the California Civil Code pursuant to California Code of Civil Procedure section 731, and to pursue the possibility of commencing action or proceedings for abatement under section 17.60.040 and section 17.25.030 of the Marina Municipal Code.

The following subsections describe the settlement agreement ultimately reached among CEMEX, the CCC, the CSLC, and the City of Marina, the Removal Plan required by that agreement, and the effects of the agreement on the proposed project and the EIR/EIS analysis. Because the settlement agreement was reached after the close of the Draft EIR/EIS comment period, no comments have been received that pertain specifically to this agreement. However, some comments (e.g., MCWD, City of Marina) pertain to ongoing CEMEX mining operations described in the Draft EIR/EIS that now are expected to cease, such as references to the active or retired portions of the mining operation, the availability of on-site habitat mitigation opportunities, or CalAm's access to its permanent easement, or how the mining operation affects coastal erosion. This Master Response therefore provides a consolidated explanation of reasonably foreseeable changes relevant to the proposed project and EIR/EIS associated with the expected change in mining activities.

8.2.14.1 CEMEX and CCC Settlement Agreement

Subsequent to the publication of the Draft EIR/EIS, in July 2017, the CCC, the CSLC, and the City of Marina reached an agreement with CEMEX to end the sand mining operations at the CEMEX site. Among other things, the Consent Settlement Agreement and Cease and Desist Order CCC-17-CD-02 (Settlement Agreement; CCC, 2017) requires that CEMEX stop sand mining on the CEMEX property by December 31, 2020, pursuant to a cessation plan; put a cap on the amount of sand that can be mined until that time; remove dredges, equipment associated with dredges, a pump station, and other facilities from the CEMEX property pursuant to a removal plan; abstain from causing any further changes in intensity of use of the property; undertake reclamation of the property and protect sensitive species on site; and transfer the property to an approved non-profit or governmental entity for conservation at a reduced price, with a deed restriction to protect the access and the habitat at the site in perpetuity. The deed restriction must preserve the open space and habitat values of the property, and must reflect that improvements to provide low-impact passive recreation, public access, and public education; removal activities; and activities to restore native habitat will be consistent with existing easements or other rights of record.

Removal Plan

Section 5.0 of the Settlement Agreement requires CEMEX to prepare and submit to the CCC Executive Director, no later than 90 days following the December 31, 2020 end of the sand mining phase-out period, a Removal Plan that summarizes all measures to be taken in connection with the removal of the physical structures and materials from the site, including erosion control measures to be used during removal activities. The Removal Plan shall describe the equipment to be used, and the schedule to complete removal, consistent with a schedule provided in the Settlement Agreement, with all CEMEX buildings and facilities to be removed by December 31, 2024 and final grading and seeding to occur by December 31, 2025.

CalAm Easement at CEMEX

Section 23.2 of the Settlement Agreement states that, “Notwithstanding anything in this Agreement to the contrary, this Agreement . . . shall not . . . interfere with any existing rights or obligations of California-American Water Company . . . related to the Property, including, but not limited, to the recorded easement and related option in favor of CalAm and does not require the removal of such easement and related option.”

In November 2014, CalAm and CEMEX entered into an “Agreement for Temporary Investigatory Easement, Option for Permanent Easements and Joint Escrow Instructions” (CalAm-CEMEX Agreement). In that easement agreement, CEMEX granted to CalAm an option to purchase permanent easements on, across, and under the property, solely for the purpose of accessing, constructing, installing, operating, and maintaining slant wells and related pipelines and utilities for the desalination facility proposed to be constructed as part of the MPWSP. The permanent easement granted to CalAm would occupy approximately 30 acres of the CEMEX property, situated south of the existing access road. Starting at the point where the existing access road intersects the beach, the trapezoidal-shaped easement area would run south along the front

(ocean-side) of the dunes for about 1,800 feet before turning inland (east) for about 700 feet, then turning north for about 1,500 feet where it would intersect with the existing access road about 800 feet inland from the beach. CalAm would also maintain an additional 30-foot-wide easement along approximately 4,000 feet of the Source Water Pipeline alignment for another approximately 3 acres. See **Figure 8.2.14-1**.

8.2.14.2 Final EIR/EIS Considerations

Impacts of Settlement Agreement on MPWSP Access

As described in EIR/EIS Section 3.4.1, the analysis assumes that CalAm maintenance workers would access the slant wells via the existing CEMEX access road. Access to the CalAm easement across the CEMEX property is provided for in the CalAm-CEMEX Agreement. Section 3(h) of that agreement specifies that CalAm and CEMEX will determine a route for a vehicular access easement across the greater CEMEX property to the CalAm easement (see Figure 8.2.14-1), although CEMEX retained the right to relocate the vehicular access easement at any time so long as CalAm is provided with equivalent access to its easement. If the vehicular access easement is relocated such that the existing access road is no longer used, the new route would still be within the area analyzed as the extent of project disturbance and shown on EIR/EIS Figure 3-3a. Since the Settlement Agreement allows for public access and low-impact passive recreation on the property (Settlement Agreement Sections 6.1, 6.2(D)(3)), the new owners of the property will likely prepare a public access plan. Pursuant to Section 23.2 of the Settlement Agreement and the terms of the CalAm-CEMEX Agreement, the new owners and any public access plan would necessarily respect the access provision of the CalAm-CEMEX Agreement. Therefore, the assumptions regarding ongoing access to the slant well sites for project maintenance have not been changed in the Final EIR/EIS.

Impacts of Settlement Agreement on Coastal Erosion

As explained in the EIR/EIS Coastal Erosion Study (see Appendix C2, and EIR/EIS Section 4.2.4.5), one of the most important variables in the coastal erosion model is the historic erosion trend. Shoreline change data were compiled from a variety of sources and were combined with the Thornton et al., 2006 dune erosion rates, where available (see Appendix C2, Section 2.2) since estimated erosion based on dune crest recession is a more robust estimate of erosion than shoreline change. In this region where beaches have been controlled in part by sand mining, the coastal retreat study assumed there would be no changes to existing sand mining practices. With the closure of the Lapis Sand Plant in 2020 as a result of the Settlement Agreement, ongoing coastal erosion at this location is expected to slow compared to erosion rates that have occurred with sand mining. Therefore, the erosion profiles in the EIR/EIS likely overestimate the rate of future shoreline change. The analyses and conclusions related to coastal erosion in the EIR/EIS have not been revised, and instead have been retained as conservative estimates of potential erosion-related impacts. From a practical standpoint, a slower rate of erosion would mean that the slant wells would be unimpaired and not exposed by coastal erosion for a longer period of time (such that they would not need to be relocated until a later time).

Consideration of Removal Plan and Reclamation Plan Implementation in Cumulative Scenario

EIR/EIS Section 4.17, Mineral Resources, describes the existing mining operations at CEMEX, as well as the Lapis Plant Reclamation Plan that was approved by the State Mining and Geology Board on June 15, 1992. As noted in Section 4.17.1.2, Mining Operations, Phase I revegetation and recontouring measures have been carried out along the slopes of the southern portion of the CEMEX property, while Phase II reclamation plans call for revegetation of the northeastern slope once mining operations have ceased. At the time of publication of the Draft EIR/EIS, the Reclamation Plan anticipated that sand mining could continue until or beyond 2039; therefore, a timeframe for the required reclamation under Phase II was not known. However, as noted in Section 3.4 of the Settlement Agreement, the initiation of reclamation activities consistent with the Reclamation Plan, including restorative grading, revegetation and monitoring, shall begin no later than December 2023.

Additionally, the Removal Plan described in Section 8.2.14.1, above, will require the removal of CEMEX structures and facilities by no later than December 2024.

Given this increased certainty regarding the implementation schedule for the Reclamation Plan and the nature and timing of the Removal Plan, both have been added to the list of projects to be analyzed in the EIR/EIS for potential cumulative effects along with the proposed project impacts (see Project No. 63 in Final EIR/EIS Table 4.1-2), and have been incorporated into the analysis of cumulative impacts as appropriate throughout Chapter 4 and Section 5.5 of the Final EIR/EIS. No new significant impacts or substantial changes to previously-identified significant impacts were identified as a result of this addition of the Removal Plan and Reclamation Plan to the cumulative scenario.

8.2.15 Master Response 15: Alternative Desalination Projects – Status, Information Sources, and Cumulative Scenario

COMMENTERS ADDRESSED BY MASTER RESPONSE 15

Marina Coast Water District	David Beech
California Unions for Reliable Energy (CURE)	Margaret-Anne Coppernoll
Deep Water Desal, LLC	Myrleen Fisher
Ecological Rights Foundation, the Center for Biological Diversity, and Our Children's Earth Foundation	Juli Hofmann
Public Water Now	Nancy Selfridge
Surfrider Foundation	

The currently proposed Monterey Bay Regional Water Project (MBRWP or DeepWater Desal Project) and People's Moss Landing Water Desalination Project (People's Project) are considered in the EIR/EIS as alternatives to the proposed MPWSP. This Master Response provides clarification on these two projects and their status, and also addresses questions (further explained below) on the assumptions used for considering cumulative impacts of these projects. The DeepWater Desal Project (Alternative 3) is described in EIR/EIS Section 5.4.5 and the People's Project (Alternative 4) is described in Section 5.4.6.

8.2.15.1 Monterey Bay Regional Water Project (MBRWP or DeepWater Desal) Status

The status of this project is as follows:

- An NOP/NOI was issued on June 1, 2015, by the California State Lands Commission and the Monterey Bay National Marine Sanctuary (MBNMS), explaining that a joint EIR/EIS would be prepared.
- The joint CEQA/NEPA document has been initiated, and some studies completed, yet it is currently unknown when the Draft EIR/EIS will be published due to outstanding information needs.
- The Applicant is in the process of completing additional studies necessary for the Draft EIR/EIS impact analysis.

8.2.15.2 People's Project Status and Basis for Analysis

Project Status

Several comments indicated that the People's Project appeared to be more feasible than other desalination projects due to the timeline for its approval since it would be utilizing existing infrastructure. The Moss Landing Harbor District is the CEQA lead agency for the People's Project; however, the project has been on hold since 2016 due to outstanding information needed to complete the CEQA analysis. MBNMS is the federal NEPA lead agency for the proposed

People's Project, and since 2015 the project's application to MBNMS has been deemed incomplete. The initial application was filed on October 7, 2015, and was determined by MBNMS to be incomplete on October 27, 2015. At that time, MBNMS notified the applicant of additional information required to complete the application and start the environmental review process. MBNMS also advised the applicant it would be most efficient to move forward with a joint CEQA/NEPA document.

On March 25, 2016, the applicant submitted additional information, including an administrative draft project description for the People's Project. MBNMS notified the applicant in writing on April 25, 2016 that the application was still incomplete. MBNMS provided specific details on what additional information was needed for a complete application and to start the environmental analysis. As of March, 2018, MBNMS has received a revised project description from the applicant and will review the submittal for completeness. Since the application to MBNMS is still incomplete, a Notice of Intent (NOI) to prepare an EIS has not been published, and cannot be published until MBNMS determines the application is complete. If MBNMS determines that sufficient information has been submitted to initiate the NEPA process, it will issue a Notice of Intent to start the EIS scoping process. Additional studies will be required to complete the NEPA document or joint CEQA/NEPA document. Given the current status of the application to MBNMS, no date has been established for completion of a NEPA document.

The People's Project applicant submitted an Administrative Draft EIR to the Moss Landing Harbor District, the CEQA lead agency. After thorough review, the Harbor District determined that the Administrative Draft EIR was not adequate under CEQA; the Harbor District informed the applicant of the document deficiencies and provided details on additional studies and data needed to complete the CEQA process. At this time, (March 2018), the applicant has developed additional project description information for consideration by the Harbor District. However, no date has been established for the completion and publication of the CEQA environmental document.

Basis for Impact Analysis of People's Project and Applicant Contact

Comments suggested that neither the CEQA lead agency for the People's Project (Moss Landing Harbor District) nor the People's Project applicant and counsel were contacted to obtain information for the MPWSP alternatives analysis and that available information was not utilized in the EIR/EIS alternatives analysis. On the contrary, MBNMS contacted the People's Project applicant, the consultant, and legal counsel verbally and in writing in February and March 2016, to request project description information. The MPWSP EIR/EIS preparers worked with MBNMS to obtain this project information from the People's Project applicant since MBNMS is the federal lead agency for the People's Project, DeepWater Desal project, and MPWSP. The EIR/EIS includes the same project description information that was submitted to the Moss Landing Harbor District in 2016. MBNMS requested permission to share project information submitted by the People's Project applicant on March 25, 2016 with the MPWSP EIR/EIS preparers. The People's Project's counsel granted MBNMS permission to share the project description information with the MPWSP EIR/EIS preparers on June 6, 2016. However, the applicant did not grant permission to share the remainder of the Administrative Draft EIR or any supporting studies. The analysis in

the MPWSP Draft EIR/EIS was based on project description information that was shared by the People's Project applicant in June 2016.

One comment noted that solar panels are part of the People's Project. The 2016 Project description information received from the applicant stated that the primary source of electricity for the project would be either direct service from the Moss Landing Power Plant through an agreement with Dynegy, or from Pacific Gas and Electric Company (PG&E) from the existing local electrical grid. Circuits feeding the desalination plant would be provided from an existing 12 kV electrical system through a 460-volt circuit. In the future, the Moss Landing Commercial Park also intends to install a solar photovoltaic (PV) facility of 3.5 MW at the existing site to serve a portion of the project's energy requirements in order to provide a "green and clean" energy source to the project. The project site has sufficient available space outside wetland areas to install such a facility. The solar PV facility would be constructed as a separate project in the future once sufficient details are known, and therefore it is not an integral part of the proposed project at this point in time.

The EIR/EIS analysis did not assume installation/operation of the solar panels as part of the People's Project since: 1) sufficient details were not available for the solar project; 2) the timing of this future project was uncertain; and 3) the applicant stated that the main source of power would not be from the solar field. The applicant was fully informed of the data that was being shared with the EIR/EIS preparers and did not amend or update the project description regarding the solar panel project.

Regarding comments related to the Draft EIR/EIS's lack of cultural resources information at the People's Project plant site, the applicant did not provide information on available cultural resources surveys or studies at the time that MBNMS requested project information from the applicant, and MBNMS has no knowledge of site-specific cultural resource surveys conducted by a qualified cultural resource professional. Given the limited information that was provided to the EIR/EIS preparers, the impact conclusions assumed no cultural resources studies had been conducted, impacts on currently unknown cultural resources would be a potentially significant impact, and mitigation measures were necessary.

8.2.15.3 Cumulative Impact Scenario Related to DeepWater Desal Project and People's Project

Several comments suggested that all three proposed desalination projects in the Monterey area – CalAm's MPWSP, the DeepWater Desal Project, and the People's Project – should be considered in the cumulative impact analysis since commenters suggested that all three might ultimately be built. The Lead Agencies have not implemented this suggestion for the reasons described below.

EIR/EIS Section 4.1.7.2 explains in detail the assumptions used to determine which projects would be considered in conjunction with the proposed project and with each of the alternatives in the cumulative impacts scenario. Projects included in the cumulative impact scenario are listed in EIR/EIS Table 4.1-2.

As stated in EIR/EIS Section 4.1.7, the cumulative impact analysis focuses on the impacts on the environment that result from the incremental impact of the proposed project (or alternative under consideration) when added to other past, present, and reasonably foreseeable future actions. As explained in EIR/EIS Section 5.1.1, under CEQA and NEPA, the EIR/EIS must identify and analyze the impacts of reasonable alternatives that would also meet the purpose and need, and would avoid or minimize adverse environmental impacts of the proposed project. The DeepWater Desal Project and the People's Project are considered in the EIR/EIS as alternatives to the MPWSP because they each are desalination plants being separately proposed to meet, in part, the objectives of the MPWSP (and sometimes other objectives as well). However, as explained below, the DeepWater Desal Project is also considered in the cumulative impacts analysis for the MPWSP because the DeepWater Desal project proponent has indicated that it intends to proceed even if another desalination plant (e.g., the proposed project) is selected to serve CalAm's Monterey Service District. Conversely, the People's Project is not considered in the cumulative analysis with the MPWSP because the MPWSP and People's Project share the same objectives to provide water to CalAm's Monterey District, thus, it is not reasonably foreseeable that the People's Project would proceed if the MPWSP is approved.

Reasonably Foreseeable Projects

The Surfrider Foundation, in its comment letter on the Draft EIR/EIS, claims that unless there is a "binding restriction" prohibiting the development of all three desalination projects, then the EIR/EIS must include all three in the cumulative analysis. There is no "binding restriction," as all three projects must be reviewed on their own merits by the numerous agencies with permit jurisdiction. However, as described in EIR/EIS Section 4.1.7, CEQA and NEPA cumulative impact analysis requirements are based on projects that are reasonably foreseeable or probable to occur. Further, CEQA Guidelines Section 15130(b) specifies that one of two methods must be used to analyze cumulative impacts. For the first method (used for the majority of the analyses in the EIR/EIS), Section 15130(b)(1) defines the list of projects that must be considered as "A list of past, present, and probable future projects producing related or cumulative impacts…" Similarly, NEPA refers to cumulative effects as the "impact on the environment which results from the incremental impact of the action when added to other past, present and reasonably foreseeable future actions…" (40 CFR 1508.7, NAO 216-6A). The key words here are "probable," or "reasonably foreseeable," which limits the analysis to those projects that are likely to occur. The EIR/EIS analysis is consistent with these provisions, as described in more detail below. See also Master Response 13, Demand (Project Need) and Growth, for a discussion of current and projected water demand in the region.

DeepWater Desal Project

As noted in EIR/EIS Table 4.1-2, the DeepWater Desal Project would provide up to 25,000 afy of potable water supply to participating communities in the Monterey Bay region, potentially including the Monterey Peninsula, Castroville, Salinas, and parts of Santa Cruz County. DeepWater Desal's project business model includes a co-located data center. As proposed by DeepWater Desal, the project would develop supplemental water supplies to serve the customers in CalAm's Monterey District service area. However, if the proposed MPWSP is built,

DeepWater Desal indicates that it can provide water to other areas, as described above. Therefore, the EIR/EIS considers two reasonably foreseeable scenarios that include development of the DeepWater Desal Project:

1. Development of the DeepWater Desal Project as an alternative to the MPWSP, as described in Chapter 5 (serving CalAm's Monterey District service area, as well as other areas). This is Alternative 3 described and analyzed in Chapter 5.

2. Development as a separate project *in addition* to the MPWSP or another alternative that would serve CalAm's Monterey District service area. In this case, the impacts of the DeepWater Desal Project are considered in the cumulative scenario as they relate to the provision of water to Santa Cruz County and the City of Salinas. The DeepWater Desal Project with provision of water to Santa Cruz County and the City of Salinas is a reasonably foreseeable project in the cumulative scenario relevant to the proposed project and Alternatives 1 (slant wells at Potrero Road), 2 (open water intake), 4 (People's Project), and 5a and 5b (reduced-scale projects).

People's Project

As proposed by its applicant, the primary purpose of the People's Project is to develop 12 mgd (13,400 afy) of desalinated water to serve customers in CalAm's Monterey District service area. The NOP for the project states that a small portion (3.3 mgd) of the water may serve north Monterey County: "These demands have not yet been fully verified, but there has been strong interest for the Proposed Project to serve demands in the North Monterey County Area. Through the EIR process these demands will be evaluated in order that the Proposed Project can serve these potential North County demands" (Moss Landing Harbor District, 2015). However, subsequent information received from the applicant indicates that the northern Monterey County service is uncertain.

Since the People's Project and the MPWSP would both serve the same customers in the CalAm Monterey District Service Area, this EIR/EIS assumes the People's Moss Landing Project is an *alternative* to the MPWSP (see Chapter 5). Unlike the DeepWater Desal Project proponent, who has publicly stated its intent to proceed even if the MPWSP is built and whose business model would allow the project to serve its entire output to customers in Santa Cruz County and the City of Salinas, there is no other available information that indicates that the People's Project would be built *in addition* to the proposed MPWSP, based on the People's Project's stated purpose and objectives to meet the exact same demand that is proposed to be met by the MPWSP. Therefore, it is not a reasonably foreseeable project in the cumulative scenario relevant to the MPWSP. Similarly, if the DeepWater Desal Project were developed as an alternative to the MPWSP (i.e., Alternative 3), the People's Project would not be a reasonably foreseeable project in the cumulative scenario, because Alternative 3 assumes that all of the Monterey Peninsula's needs would be met by the DeepWater Desal Project and no demand (and therefore, no market) would remain in the Monterey Peninsula for the People's Project to serve. As noted above, however, if the People's Project were approved to serve the water needs of the Monterey Peninsula, the EIR/EIS cumulative analysis does assume that the DeepWater Desal project would be a cumulative project in that scenario. Furthermore, the California Ocean Plan requires that desalination project applicants document the need for water. The Ocean Plan states that the

regional water board shall require the owner to: "Consider whether the identified need for desalinated water is consistent with an applicable adopted urban water management plan prepared in accordance with California Water Code Section 10631, or if no urban water management plan is available, other water planning documents such as a county general plan or integrated regional water management plan." If any project is approved to serve demand in the Monterey Peninsula, it is unlikely that another project with the intent to serve this same population would be able to provide the necessary documentation of the need for water. Despite this, and in light of DeepWater Desal's stated intention to serve other areas, this EIR/EIS takes a conservative approach and considers DeepWater Desal in the cumulative scenarios as described above.

Therefore, although acknowledged as an alternative to the proposed project (as described in Chapter 5), the People's Project contributions to cumulative impacts are not considered as part of the cumulative scenario relevant to the proposed project or another alternative. If, in the future, the People's Project objectives change, the cumulative impact analysis in the CEQA and/or NEPA documents prepared for the People's Project would be required to assess cumulative effects based on the changed intent of that project.

San Francisco, CA 94108

To Whom It May Concern,

The Draft Environmental Impact Report/Environmental Impact Statement for the Monterey Peninsula Water Supply Project State Clearinghouse No. 2006101004 identifies the potential for the proposed project to impact the Army's existing groundwater remediation system at Fort Ord Operable Unit Carbon Tetrachloride Plume (OUCTP) (Section 4.4.5.2, page 4.4-77). It identifies mitigation measure 4.4-4 (page 4.4-86) which proposes to conduct groundwater monitoring incorporating the Army's groundwater monitoring data, and if an analysis by CalAm concludes that slant well pumping could affect the OUCTP plumes, then "the project applicant will reimburse the U.S. Army for the necessary additional costs to address changes in the plume flow direction, arrest mitigation of the plumes, and/or to remediate areas of new contamination created by slant well pumping." This mitigation measure is later described as requiring CalAm to prevent expansion of the OUCTP plumes.

FOBRAC-1

The Army's groundwater remediation projects at the former Fort Ord is being conducted under CERCLA. If the proposed project will in any way adversely affect the Army's implementation of CERCLA remedial actions, the project proponent will be considered a potentially responsible party under CERCLA, and its responsibilities would need to be properly identified in consultation with U.S. Environmental Protection Agency. The proposed mitigation measure does not sufficiently address the identified impact.

Portions of the proposed project occurs within the former Fort Ord, over or near the Army's environmental remediation sites under CERCLA. The Army encourages the project proponent to avoid any adverse impacts to the CERCLA actions. We suggest this be noted in Section 4.7.2.1 where CERCLA is described under Regulatory Framework (page 4.7-13).

The draft EIR/EIS also describes that the project would comply with the excavation permit program of the City of Seaside that would address the potential for encountering unexploded ordnance (UXO) while engaging in ground-disturbing activities within the Seaside Munitions Response Area (MRA). The proposed project also involves ground-disturbing activities in other areas of the former Fort Ord, outside of the Seaside MRA. Because of the former Fort Ord's history as a military installation, there is a potential for munitions and

FOBRAC-2

explosives of concern (MEC) (including UXO) to be present. Should any munitions or suspected MEC item be encountered during ground-disturbing or intrusive activity, people engaging in the activity should immediately stop the activity; should not attempt to disturb remove or destroy it; but should immediately notify the local law enforcement agency having jurisdiction on the property so that appropriate explosive ordnance disposal personnel can be dispatched to address the item. This notice of the potential presence of MEC is provided in federal deeds for transferred former Fort Ord properties. In addition, the Army offers munitions recognition and safety training to anyone who requests it. The training is intended to increase the ability to recognize suspicious items and participants will learn the proper procedures when a suspicious item is encountered. The training is available by contacting the U.S. Army Base Realignment and Closure office at 831-393-1284.

MBNMS Desalination Project Lead
99 Pacific Ave., Bldg. 455a
Monterey, CA 93940

Dear Ms. Grimmer,

Thank you for the opportunity to comment on the Draft Environmental Impact Report/Environmental Impact Statement (EIR/EIS) for California American Water's (CalAm's) Monterey Peninsula Water Supply Project (MPWSP).

While the Monterey Bay National Marine Sanctuary (MBNMS) is the lead Federal agency ensuring National Environmental Policy Act (NEPA) compliance for the proposed action, the U.S. Army's (Army's) NEPA implementing regulations under 32 Code of Federal Regulations (CFR) 651.14.h, require the Army to coordinate with the lead agency to ensure all proposed actions which would affect the Army are thoroughly analyzed. Thus, the Army became a cooperating agency on this Draft document as portions of the MPWSP are proposed to be installed and operated on Army property, including portions of the 36-inch new Transfer Main pipeline, the Aquifer Storage and Recovery (ASR) Wells #5 and #6, and associated ASR pipelines, in the Ord Military Community in Seaside, CA. The Army has discretionary approval authority over proposed projects on Army lands and will use the NEPA analysis during decision-making with regard to the proposed action.

This letter provides the Army's enclosed comments on the Draft EIR/EIS under Federal NEPA implementing regulations 40 CFR 1500 et seq. and 32 CFR 651. These comments provide clarifications to the Draft EIR/EIS that the Army believes are necessary to ensure compliance under NEPA.

The POC for this letter is Joelle Lobo at 831-242-7829 or joelle.l.lobo.civ@mail.mil.

Sincerely,

Lawrence T. Brown
Colonel, US Army
Commanding

Chapter 1. Introduction and Background

Section 1.3.1 CalAm's Project Objectives, page 1-5.
Appears that a main objective of the MPWSP is to minimize the take of marine biological matter based on the proposed use of subterranean slant wells as included in the proposed project. Consider including this objective along with the list of primary objects of the project as given in Section 1.3.1. USARMY-1

Section 1.5.4.3 Other Agencies' Consideration of the EIR/EIS and Proposed Project, page 1-17:
The Draft EIR/EIS does not present an option (other than the No Action Alternative) where the proposed project or alternatives would not involve use Army land. Therefore, the Army should be listed as an organization which, due to their discretionary approval authority over land use for some components of CalAm's proposed project, will use the EIR/EIS to make decisions, not merely as an agency with "potential" permitting authority. USARMY-2

Chapter 3. Description of the Proposed Project

Section 3.2.3.5 Terminal Reservoir, page 3-30
The Draft EIR/EIS states the proposed Terminal Reservoir would be located in an undeveloped portion of the former Fort Ord. Please provide clarification as to who has jurisdiction over this portion of land. USARMY-3

Section 3.2.4.1 ASR Injection/Extraction Wells (ASR-5 and ASR-6 Wells), page 3-43.
Please include in the Draft EIR/EIS information regarding siting studies and how the proposed ASR #5 and #6 sites were selected.

The following information was provided by CalAm:
"The open areas south of the SM ASR wells is unfavorable for ASR wells compared to the Fitch Park site, due primarily to the geologic structure of the basin. The bedrock and the Santa Margarita Sandstone ([Tsm] the target aquifer for ASR) are rising in elevation in this area due to the Laguna Seca Anticline, which results in a lack of sufficient saturated Tsm thickness to support the planned well injection rates. Also, the area to the east of the SM ASR wells is now within the area of influence of the Pure Water Monterey recycled water injection wells, which precludes this area for potable supply wells due to aquifer residence times required for the recycled water." Additional conversations indicated that the area on the north side of General Jim Moore, across from the proposed ASR wells, encountered land use conflicts when investigated for potential ASR siting.

In addition to including the above please include in the Draft EIR/EIS any other information pertaining to siting and examining alternatives for the proposed ASR wells, i.e. what were the criteria used to determine a successful ASR Well site, what tests were done to determine suitability of the proposed site and what were the results (from USARMY-4

the Fitch Park Monitoring Well No. 1 Summary of Operations Report), and what other sites were considered/examined and what were the results? USARMY-4 cont.

Figure 3-14 Site Plans: ASR-6 and ASR-6 Well, page 3-45.
Please include figures with clearer resolution. Text in the existing figures is difficult to read. USARMY-5

Section 3.3.2.2 ASR Injection/Extraction Wells, page 3-48.
Please include a discussion on the requirement for 24 hour per day construction for the proposed ASR wells, including the reason continuous drilling is required (i.e. based on technology for this type of drilling, based on schedule, etc.). If technology for other-than-24 hour drilling is available, please describe. Please also indicate if permanent access road(s) would be installed to the ASR Wells from General Jim Moore Blvd. USARMY-6

Section 3.3.4.3 Disinfection of Existing and Newly Installed Pipelines, page 3-53.
Use of Army owned stormwater outfall for discharges associated with pipeline construction generated effluent requires explicit permission by the Army. Effluent generated on Army land will generally be discharged to a percolation pond. USARMY-7

Section 3.3.9 Construction Schedule, page 3-55.
Paragraph 3 of this section states, “Installation of pipelines within the city of Seaside, including all or portions of the three ASR pipelines (ASR Conveyance Pipeline, ASR Recirculation Pipeline, and ASR Pump-to-Waste Pipeline) and the sections of the new Transmission Main would occur only during the day.” The terms of the Army issued permit will require daytime only pipeline construction on Army owned property. USARMY-8

Section 3.4.1 Operation of the Seawater Intake System, MPWSP Desalination Plant, and Brine Discharges, page 3-56.
Section 3.4.1 states that the MPWSP Desalination Plant would operate 24 hours a day, 365 days per week. Please include a discussion on operational adjustments should demand, available water supply, or overall precipitation change, such that water needs are lowered, recognizing that desalinated water is environmentally and economically costly. Please also include any adjustments to operations in response to future regional power shortages. USARMY-9

Table 3-8 Anticipated Permits and Approvals, page 3-63.
In the second row (labeled, ‘U.S. Army’), please change the second column to the following: "Real property outgrants for construction and operation to CalAm or other entities involved in water augmentation projects (Army Regulation (AR) 405-80, 200-1)". USARMY-10

Chapter 4.3 Surface Water Hydrology and Water Quality

Section 4.3.2.2 State Regulations, NPDES Municipal Stormwater Permit, page 4.3-40
The Presidio of Monterey is a Phase II MS4 – Non-traditional permitee with requirements applicable within the Ord Military Community in Seaside, CA. Stormwater outfall for discharges associated with the pipeline or ASR well construction generated effluent requires explicit permission by the Army. Effluent generated on Army land will generally be discharged to a percolation pond. USARMY-11

Section 4.3.5.1 Construction Impacts
Impact 4.3-2: Degradation of water quality from construction-related discharges of dewatering effluent from open excavations and water produced during well drilling and development, Dewatering Discharges (All Other Project Facilities), page 4.3-63.
Request MS4 Permittees receive analytics for any discharges. USARMY-12

Chapter 4.4 Groundwater

Figure 4.4-7 Groundwater Flow – Seaside Basin Shallow Zone, July/August 2015 and Figure 4.4-8 Groundwater Flow – Seaside Basin Deep Zone, July/August 2015, pages 4.4-17-4.4-18
Please provide a legend to describe the features on these figures. USARMY-13

Section 4.4.1.4 Groundwater Quality, Disinfection Byproducts, page 4.4-27 and Section 4.4.5.2 Operations Impacts and Mitigation Measures, Impact 4.4-4 Violate any groundwater quality standards or otherwise degrade groundwater quality during operations, Addition of Treated Water to the Santa Margarita Aquifer, page 4.4-82

Section 4.4.1.4 states, "The Disinfection Byproducts (DBP) data collected during the 2015 water year indicated that trihalomethanes (THMs) peaked approximately 30 to 90 days after injection and storage, followed by a gradual decline. After approximately 150 to 210 days of storage, THMs had degraded to below the initial injection levels." However, per the "*Draft Summary of Operations Report for the Monterey Peninsula ASR Project, Water Year 2015*", dated June 2016, prepared by Pueblo Water Resources for the Monterey Peninsula Water Management District, Figure 22, it appears that THMs exceed the initial injection level after 210 days for the ASR-3 site. Please include a discussion that considers this data. USARMY-14

Section 4.4.1.4 states, "More importantly, throughout the 2015 water year, THMs were below the MCL of 80 micrograms per liter and haloacetic acids (HAAs) were below the MCL of 60 micrograms per liter." However, per the "*Draft Summary of Operations Report for the Monterey Peninsula ASR Project, Water Year 2015*", dated June 2016, prepared by Pueblo Water Resources for the Monterey Peninsula Water Management District, Figures 21, 22, and 24, it appears that the THMs reached or exceeded the MCL of 80 micrograms per liter. Please include a discussion that considers this data. USARMY-15

In order to better understand fate of DPBs and the resulting chemistry of the groundwater, recommend including a table or graph in the Draft EIR/EIS that shows the relative levels of DPBs in the cited 2015 study (and other studies with available data) as compared to the regulatory limits, including pH levels, and including the rate of decline in concentration of DPBs over the given timeframes and the resulting concentrations, to show if the decline in concentration returns to below injection levels or if elevated concentration conditions exist. The proposed amount of yearly injected desalinated water may be higher than the injected 2015 Carmel River water. Please also include details of the study such as the reason for decline in DPB concentration over time and if this pattern of initial increase and decline in DBP concentration is expected to be consistent for larger amounts of injected DBPs. USARMY-16

Three separate sources of water: desalinated, purified, and river water, are proposed to be injected into the Seaside aquifer, likely at higher than historic volumes. To more clearly understand the cumulative impacts of DBPs and/or other constituents associated with proposed project or alternatives, due to volume and/or source of injected water, please include an estimated (maximum) injection volume from the combined Carmel River, desalinated, and purified waters into the aquifer and associated DBP concentrations. Please include a discussion or information on the expected fate of DBPs for the combined Carmel River, desalinated, and purified water volumes. USARMY-17

Please include a discussion on whether the Seaside aquifer is confined or if aquifer waters have potential to intermix with other waters or emerge into the environment. Please cite any relevant chemical or toxicological studies regarding effect of DBPs on other organisms in the environment. USARMY-18

Additionally, please include a discussion on adaptive management strategies should DBPs in the aquifer or in extracted waters exceed regulated drinking water concentrations. USARMY-19

Chapter 4.6 Terrestrial Biological Resources

Table 4.6-4 Applicable Regional and Local Land use Plans and Policies relevant to Terrestrial Biological Resources, page 4.6-107.
Please include the “Integrated Natural Resource Management Plan (INRMP) Presidio of Monterey and Ord Military Community, November 2008” to table 4.6-4. The 2008 INRMP, or most current version, would apply to the project components proposed on Army property including portions of the new Transmission Main, ASR wells, and ASR wells pipeline. USARMY-20

Section 4.6.5 Direct and Indirect Effects of the Proposed Project, Impact 4.6-4: Be inconsistent with any local policies or ordinances protecting biological resources, such as a tree preservation policy or local tree ordinances, page 4.6-222.
Landscape in the work areas should be restored after work is completed, including the planting of shrubs and trees as additional screening, using the Presidio of Monterey INRMP approved plants. All trees schedule for removal or preservation on Army property, including mitigation for tree removal and protection for tree preservation, shall be done in accordance with the Presidio of Monterey INRMP. USARMY-21

Chapter 4.9 Traffic and Transportation

Section 4.9.5.1 Construction Impacts, Mitigation Measure 4.9-1: Traffic Control and Safety Assurance Plan, page 4.9-24.
Any proposed work on Army owned property will required a real property outgrant as prescribed by Army Regulation (AR) 405-80. Prior to issuance of an outgrant, the Army will required a detailed briefing by CalAm to ensure all of the Army's interests are addressed in the Traffic Control and Safety Assurance Plan, including POM Fire Station, POM Police Station, housing office, community and youth centers, as well as public works, commercial, safety and other related interests. USARMY-22

Section 4.9.5.1 Construction Impacts, Mitigation Measure 4.9-1: Traffic Control and Safety Assurance Plan, page 4.9-24.
Terms of the Army issued permit would likely require that access to Army services along General Jim Moore Blvd. are maintained during construction including the POM Fire Station, the Army Air Force Exchange Service (AAFES) Service Station and Mini-Mart, Army Community Services offices and facilities, the Ord Military Community Chapel, and Porter Youth Center. USARMY-23

Section 4.9.5.1 Construction Impacts, Mitigation Measure 4.9-1: Traffic Control and Safety Assurance Plan, page 4.9-26.
Unreasonable delays in the establish bus schedule as agreed upon with Monterey-Salinas Transit will have a direct impact on the military mission. Prior to commencement of construction, coordination with the Army will be required to ensure bus routes maintain timeliness such that Department of Defense (DoD) personnel traveling from the Ord Military Community family housing arrive on time to their duty stations. USARMY-24

Section 4.9.5.1 Construction Impacts, Impact 4.9-3 Increased traffic safety hazards for vehicles, bicyclists, and pedestrians on public roadways, and area trails, sidewalks and other pathways, during construction, page 4.9-28.
Significant traffic congestion persists at the intersection of General Jim Moore Boulevard and Normandy Road during the peak traffic hours associated with Marshall Elementary School, the Dual Language Academy of the Monterey Peninsula, and the Army's Porter Youth Center. The cumulative pedestrian and vehicular traffic associated with these schools and youth center, converge on the Army owned intersection of USARMY-25

General Jim Moore Boulevard and Normandy Road. To ameliorate potential safety related issues regarding young children and families crossing the intersection during construction, recommend mitigation to construct the New Transmission Main in this area during summer months while schools are in recess, or after school and common business hours. USARMY-25 cont.

Section 4.9.5.1 Construction Impacts, Impact 4.9-4 Impaired emergency access during construction, page 4.9-29.
Presidio of Monterey Emergency Services will require the specific traffic control measures for proposed construction along General Jim Moore Blvd. and the resulting impact to emergency services response times. Terms of the Army issued permit will require a briefing by CalAm to the Army Directorate of Emergency Services on these measures to determine impact on response times and the level of risk to the Ord Military Community and federal employees. USARMY-26

Section 4.9.5.1 Construction Impacts, Impact 4.9-6 Increased wear-and-tear on the designated haul routes, page 4.9-31.
The terms of the Army issued permit will require CalAm coordination with the Army during the development of the Roadway Rehabilitation Program in order to ensure roadway wear and tear, damages, and restoration of Army owned roads are properly addressed. The terms of the Army issued permit will require that roadway wear and tear, damages, and required restoration of Army owned roads associated with the proposed action will be the responsibility of CalAm. USARMY-27

Section 4.9.5.1 Construction Impacts, Impact 4.9-7 Parking interference during construction, staging areas, page 4.9-33.
The Draft EIR/EIS proposes a staging area on Army property at the AAFES Service Station at the north-west corner of General Jim Moore Blvd. and Gigling Rd. Use of a staging area in this location would require a permit from the Army which is unlikely due tenant request and potential for additional traffic hazards. USARMY-28

Chapter 4.12 Noise and Vibration

Section 4.12.5.1 Temporary or Periodic Increases in Ambient Noise Levels, Speech Interference, page 4.12-18.
Please clarify how the threshold “substantial construction noise where the duration of construction noise exceeds two weeks” was derived. It is unclear how the two week timeframe was obtained. USARMY-29

Section 4.12.6.1 Construction Impacts, Impact 4.12-1: Result in a substantial temporary or periodic increase in ambient noise levels in the project vicinity during construction, page 4.12-21.

The second paragraph of this Section states, "The proposed pipelines and pump station would be constructed during daytime hours to the extent feasible. This analysis assumes that the ASR Recirculation Pipeline, ASR Conveyance Pipeline, ASR Pump-to-Waste Pipeline, Terminal Reservoir, and some portions of the new Desalinated Water Pipeline and the new Transmission Main within the City of Marina would be constructed only during daytime hours (see Mitigation Measure 12.4-4 (Nighttime Construction Restrictions in Marina); however, nighttime construction could be required for all other pipelines to meet the project schedule." This is in contradiction to Section 3.3.9 where it is stated that, "Installation of pipelines within the city of Seaside, including all or portions of the three ASR pipelines (ASR Conveyance Pipeline, ASR Recirculation Pipeline, and ASR Pump-to-Waste Pipeline) and the sections of the new Transmission Main would occur only during the day."

The terms of the Army issued permit will require daytime only pipeline construction on Army owned property.

USARMY-30

Section 4.12.6.1 Construction Impacts, Impact 4.12-1: Result in a substantial temporary or periodic increase in ambient noise levels in the project vicinity during construction, page 4-12.29.

Please include a figure showing decibel level impacts associated with ASR wells construction. Please show expected noise levels at increasing distances from the construction sites for both proposed 24 hour drilling and for daytime only construction.

USARMY-31

Section 4.12.6.1 Construction Impacts, Impact 4.12-1: Result in a substantial temporary or periodic increase in ambient noise levels in the project vicinity during construction, page 4-12.29.

Construction noise is assumed to be attenuated by closed windows. However, the proposed construction for the ASR Wells is estimated to last for approximately 1 year, during which time ambient temperature may significantly vary. The housing in this area does not have central air conditioning. The terms of the Army issued permit will require that CalAm ensure all possible noise controls are implemented and monitored for effectiveness and provide adaptive management strategies should noise exceed threshold values, with residence opening windows as climate dictates.

USARMY-32

Section 4.12.6.1 Construction Impacts, Mitigation Measures 4.12-1e: Offsite Accommodations for Substantially Affected Nighttime Receptors, page 4.12-34.

The terms of the Army issued permit will require that noise mitigation is based on actual noise levels at the residence (receptor), not based on geographical distance from the construction.

USARMY-33

Section 4.12.6.1 Construction Impacts, Mitigation Measures 4.12-1e: Offsite Accommodations for Substantially Affected Nighttime Receptors, page 4.12-34.
Terms of the Army issued permit would require the impacted residents have a choice of off-site accommodations to fit their needs.

USARMY-34

Section 4.12.6.1 Construction Impacts, Mitigation Measures 4.12-1e: Offsite Accommodations for Substantially Affected Nighttime Receptors, page 4.12-34.
The Army's military family housing partner under the Residential Communities Initiative (RCI) recommends that in additional to Mitigation 4.12-1e, individuals displaced from their homes during the 24 hour ASR well construction should be afforded a meal per diem to offset the disruption in daily activities such as access to kitchen for cooking meals. Terms of the Army issued permit would require this stipend with a recommended per diem amount at least equivalent to the General Services Administration (GSA) per diem for the current fiscal year for Monterey County (https://gsa.gov/portal/content/104877)

USARMY-35

Section 4.12.6.2 Operational Impacts and Mitigation Measures, Impact 4.12-5 Substantial permanent increases in ambient noise levels in the project vicinity above levels existing without the project during operations, page 4.12-51.
The terms of the Army issued permit will require operational noise adjacent to ASR Wells #5 and #6 to remain consistent with the City of Seaside noise standards under Seaside Municipal Code Chapter 17.30.

USARMY-36

Chapter 4.13 Public Services and Utilities

Table 4.13-1 Local utility and public service providers, by jurisdiction, page 4.13-2.
Please add Presidio of Monterey Fire Department and Presidio of Monterey Police Department to the list of service providers in this table. Presidio of Monterey Fire and Police Departments are located on the Ord Military Community in Seaside, CA.

Please change row #4 of the table from "Federal Lands" to "U.S. Army". Pls. change "Note a" to the following: "Project components are proposed for the U.S. Army owned property at the Ord Military Community (OMC) in Seaside, CA."

Please add project components "New Transmission Main" and "ASR Pipelines" to row #4 of the table.

In the table, please indicate the Presidio of Monterey Fire Department responds to U.S. Army lands, City of Monterey, City of Seaside, the California State University of Monterey Bay, and City of Marina. Please indicate that Presidio of Monterey Police Department responds to U.S. Army lands only.

USARMY-37

Section 4.13.1.1 Fire Protection, Law Enforcement, and Emergency Services, page 4.13-3

Under "Fire Protection", please add the following paragraph:
"U.S. Army
The Presidio of Monterey Fire Department serves all Army property on the Ord Military Community and Presidio of Monterey, as well as holding mutual aid agreements with Seaside, Marina, the California State University of Monterey Bay, and the Monterey County Regional Fire District."

Under "Police", please add the following paragraph:
"U.S. Army
The Presidio of Monterey Police Department serves all Army property on the Ord Military Community and Presidio of Monterey"

USARMY-38

Section 4.13.5.1 Construction Impacts, Impact 4.13-1 Disrupt or relocate regional or local utilities during construction, page 4.13-16.

Water Well Construction Permit #09-11644 obtained for the monitoring well drilling near the proposed ASR #5 site included a condition that the well shall be at least 50 feet from any sewer main, line, or lateral. Please be informed that sewer laterals may exist in the direct vicinity of the proposed ASR wells #5 and #6.

USARMY-39

Chapter 4.15 Cultural and Paleontological Resources

Section 4.15.6.1 Construction Impacts, Mitigation Measure 4.15-2b: Inadvertent Discovery of Cultural Resources, page 4.15-49.

Since this mitigation measure applies to all project components, including those proposed on Army land, it must reference compliance actions in accordance with federal law under the National Historic Preservation Act and implementing regulations under 36 Code of Federal Regulations § 800. Please include the following as part of Mitigation Measure 4.15-2b:

"If cultural resources are inadvertently discovered during construction on Army owned property, work shall immediately cease within a 100- foot radius of the find and the Army, Presidio of Monterey, Cultural Resources Manager (CRM) will be contacted to assess the discovery. The CRM will implement procedures set forth in the Presidio's Integrated Cultural Resources Management Plan (ICRMP) and Army Regulation (AR 200-1), which may include completion of consultation under Section 106 of the National Historic Preservation Act (NHPA)(16 USC. 470f; 36 CFR Part 800) prior to resuming construction in the vicinity of the find. CalAm will be responsible for completing any additional archaeological work required to comply with federal regulations."

USARMY-40

Section 4.15.6.1 Construction Impacts, Mitigation Measure 4.15-4: Inadvertent Discovery of Human Remains, page 4.15-51.
Since this mitigation measure applies to all project components, including those proposed on Army land, it must reference compliance actions in accordance with federal law under the Native American Graves Protection and Repatriation Act, Section 3. Please include the following as part of Mitigation Measure 4.15-2b:

"If human remains are encountered during construction on Army owned property, work shall cease within a 100-foot radius of the discovery and immediate notification will be made to the CRM. The CRM will initially evaluate the site to determine if the remains are either Native American in origin or associated with a recent crime scene (i.e., 50 years old or less). If the remains appear recent, the CRM will notify the Army's Criminal Investigation Command who will assume control of the crime scene and custody of the remains. If the remains appear to be Native American in origin, the CRM will notify the Presidio Garrison Commander and the Monterey County Coroner. Upon verification of the CRM's initial assessment, the Coroner will notify the Native American Heritage Commission within 24 hours. If the find includes human remains, the County Coroner and Army point of contact (POC) must be notified. If the remains are determined to be Native American remains, the Native American Heritage Commission shall be notified. The Native American Heritage Commission will appoint a Most Likely Descendant, who will provide recommendations for the disposition of the remains. All activities with regard to the discovery and handling of human remains and cultural resources will comply with applicable requirements of the Integrated Cultural Resource Management Plan (ICRMP)." USARMY-41

Chapter 5 Alternatives Screening and Analysis

Section 5.1.2 Project Objectives and Significant Impacts, page 5.1-3 and Section 5.3.6 Evaluation of Intake, Outfall, and Desalination Plant Options, page 5.3-29
Please include a discussion on why no alternatives to the new Transmission Main, particularly the portions on Army land, were deemed reasonable for further analysis. Please also include a discussion on why the proposed ASR Wells 5 and 6 are only proposed for location in Fitch Park neighborhood. USARMY-42

8.3.3 Monterey Bay National Marine Sanctuary Advisory Council, Research Activity Panel (MBNMS RAP)

John Hunt, Chair
Monterey Bay National Marine Sanctuary
Research Activity Panel

March 28, 2017

MBNMS Desal Project Lead
99 Pacific Ave, Building 455a, Monterey, CA 93940
(Electronic public comment submission via the Federal e-Rulemaking Portal)

Re: Docket #NOAA-NOS-2016-0156
California-American Water Company Monterey Peninsula Water Supply Project (MPWSP)
Public Comment

Dear MBNMS Desal Project Lead,

The Research Activity Panel (RAP) is a working group of the Monterey Bay National Marine Sanctuary Advisory Council. Among the RAP's key objectives is to advise Sanctuary staff on conservation science issues that will influence policy. The RAP has received presentations on the CalAm MPWSP Draft Environmental Impact Statement (DEIS), and members of the RAP have submitted comments to the chair for submission on behalf of the RAP. Please consider our comments on the following topics:

1. The effects of ocean currents in the brine mixing zone (BMZ) model analyses.

2. Impacts to freshwater and brackish water habitats from decreased freshwater flows related to Alternative 5a reliance on the Pure Water Monterey GWR Project.

3. RAP offer to review and participate in the design of monitoring programs developed as part of mitigation measures cited in the DEIS.

4. Documents that should be considered when characterizing habitat in the area affected by brine discharge.

1. Ocean Currents

We wish to express concern over the decision not to include the effects of ocean currents in the brine mixing zone (BMZ) model analyses. As stated in the Appendix D1 Executive Summary, "Zero current speed was assumed for all dilution calculations." Water column currents are mentioned as a mechanism by which the physical mixing of the outfall water will be enhanced (see 4.3-10), but currents can also act as an advective process. In fact, it is likely that the predominant effect of a strong alongshore current would be to coherently transport the brine plume away from the vent sites faster than it would through dispersion and mixing alone. There are several sources that provide information on the water column current velocity patterns in this region of the Monterey Bay shelf. Measurements of water column currents were collected in the southern shelf region of Monterey Bay in 2011 and 2012 by researchers involved in the NSF Benthic Exchange project (grant OCE0961810; cf. Cheriton et al., 2014; Sevadjian et al., 2015). At shelf depths of 55-60 m, near-bed currents of 10 cm/s were common and could reach up to 20 cm/s. Near-bed currents of similar magnitude (~ 5-10 cm/s) have been measured closer to shore, at 20-m sites off of the Pajaro River (Nickols et al., 2012) and the north side of the Monterey Peninsula

MBNMS-RAP-1

(Walters et al., 2012). Currents on the order of 10-20 cm/s could transport water 3 m (~ 10 ft) in approximately 15 to 30 seconds. We also note that the outer shelf current measurements mentioned above were collected during the fall season ('Oceanic' climate, see 4.3-10), and thus likely represent the least energetic seasonal currents. The degree to which these advection dynamics would change the BMZ around the vent sites is unclear, but without currents taken into account, the calculations run by these models do not represent the most conservative or "worst-case" estimates, as argued in the draft (see 5.5-48). Therefore, we recommend that these water column current patterns be taken into consideration in the BMZ calculations and analyses.

MBNMS-RAP-1 cont.

2. Freshwater and Brackish Water Habitats

Coastal estuarine habitat of the lower Salinas Valley (including Elkhorn Slough) is reliant on freshwater inputs from local watersheds to maintain fresh and brackish water conditions. The extraction of additional summer surface water by the Pure Water Monterey GWR Project, used to offset reductions in desalination production of Preferred Alternative 5a, will lead to changes in salinity dynamics (including saltwater intrusion within surface waters) of the Salinas River, Old Salinas River, Moro Cojo, Tembladero and Elkhorn Slough estuaries. A full analysis should be done to compare the incremental benefits achieved from reducing the scale of the desalination project with the potential environmental impacts of extracting approximately 3,500 AFY of Salinas Valley surface water before Alternative 5a is recommended as the "preferable alternative."

See below for Tables 2-12 and 2-13 from DEIS Appendix H: Pure Water Monterey GWR Project, Consolidated Final EIR.

MBNMS-RAP-2

3. Monitoring Design

The DEIS contains a number of statements such as: "The Lead Agencies will prepare a Mitigation, Monitoring, Reporting, and Compliance Program (MMRCP)/ Environmental and Construction Compliance Monitoring Plan (ECCMP) if they approve the proposed project or an alternative analyzed in Chapter 5." The RAP offers to review and/or participate in the design of programs developed to monitor and assess social, physical, chemical or biological effects of the CalAm MPWSP.

MBNMS-RAP-3

4. Additional References for Consideration

Members of the RAP are aware of and have participated in additional studies characterizing the physical, chemical and biological conditions of the marine areas near the brine discharge site. The following documents should be considered when characterizing habitat of the impacted area.

Eittreim, S.L., A.J. Stevenson, L.A. Mayer, J. Oakden, C. Malzone, and R. Kvitek (1997). Multibeam Bathymetry and Acoustic Backscatter Imagery of the Southern Monterey Bay Shelf. http://montereybay.noaa.gov/research/techreports/treittreim1997b.html

Edwards, B.D., J.V. Gardner, and M.D. Medrano (1997). Grain Size, Organic Carbon, and CaCO3 of Surface Sediments from the Southern Monterey Bay Continental Shelf Seafloor. http://montereybay.noaa.gov/research/techreports/tredwards1997.html

MBNMS-RAP-4

Eittreim, S.L., editor (1997). Southern Monterey Bay Continental Shelf Investigations: Former Fort Ord Restricted Zone http://montereybay.noaa.gov/research/techreports/treittreim1997a.html

Eittreim, Stephen L., Kaye Kinoshita, George B. Tate and David A. Cacchione (1997). Rippled Scour Depressions of the Southern Monterey Bay Shelf [abstract]. In: MBNMS (editor). 1997. Facets of Biodiversity. Monterey Bay National Marine Sanctuary Currents Symposium; 1997 March 15; Santa Cruz, CA. p. 24. Abstract text:

> Similar to many other continental shelves of the world, the southeast Monterey Bay inner shelf contains distinct depressions floored with rippled sand in which the dominantly coarse material of the depressed floor moves as bedload. These 1-m-deep features occur in the offshore former Fort Ord region, the site of impingement of very large storm waves from the northwest, and have been ascribed to rip-current and alongshore flow associated with these large waves. Recently-acquired EM-1000 multibeam bathymetric data now show that two types of these features exist on the southeast Monterey Bay shelf: the dominantly shore-parallel type in 10-30m water-depth and the shore-normal type at greater water depths, to 60m. Both types tend to have thin pinch-outs that point offshore. The shore-normal, deep-water type is concentrated in one area that has been called a nodal zone for alongshore sediment transport separating the consistently southerly flow off northern Fort Ord from the variable and northerly flow off southern Fort Ord. The inter-trough areas of the shore-normal troughs are flat featureless plains with small ripples populated with abundant short seapens. No large crecentic dunes exist in the inter-trough areas as is the case on the shelf off north-central California. Repeated measurements show that, whereas the shallow shore parallel troughs are extremely dynamic, with major changes in shape over periods of months, the deep shore-normal trough system shows no change whatsoever, within the accuracies of differential GPS navigation.

MBNMS-RAP-4 cont.

Table 2-12
Source Waters Flows: Existing and Assumed Available for Proposed Project (in AFY)

Type of Source Water:	Definitions of "Existing" Flows (in AFY)							Projected future flows in 2017 (AFY)	Proposed Project Maximum Use of Source Water Flows, (AFY) (Note 2)
	2012 (actual)	2013 (actual)	Historical Average Flows (averaging period)						
			2012-13 *(2-yr average)*	2009-13 *(5-yr average)*	2007-13 *(7-yr average)*	2004-13 *(10-yr average)*	All data (see below)		
Excess/Unused Regional Treatment Plant Municipal Effluent (MRWPCA, Regional Treatment Plant flow monitoring data, January 2014)	9,714	4,621	7,183	8,225	8,704	9,457	10,300 (1999-2013)	6,242 (Note 1)	3,000 to more than 5,000
Agricultural Wash Water Flows (Source: City of Salinas and MRWPCA, 2014)	3,058	3,228	3,143	2,676	2,579	NA (Note 3)	2,579 (2007-13)	3,732 (Note 1)	2,579
City of Salinas Urban Runoff to Salinas River (Source: Schaaf & Wheeler, 2015a)	229	19	124	196	165	176	225 (1932-2013)	225	
Reclamation Ditch at Davis Road (Source: Schaaf & Wheeler, 2015b)	6,759	1,965	4,362	7,034	6,374	7,482	7,159 (2003-13)	7,159	1,522
Tembladero Slough at Castroville (Source: Schaaf & Wheeler, 2015b)	9,190	2,610	5,900	9,536	8,531	10,030	9,593 (2003-13)	9,593	1,135
Blanco Drain Diversions (Source: Schaaf & Wheeler, 2014b)	NA (Note 5)	NA (Note 5)	NA (Note 5)	NA	NA	NA	2,620 (2010-12)	2,620 (Note 5)	2,620
Lake El Estero Storage Management Water (Source: Schaaf & Wheeler, 2014a)	65	0	33	66	55	60	87 (1952-2013)	87	87
TOTALS (Note 6)	**22,256**	**10,478**	**16,383**	**21,557**	**20,034**	**NA (Note 4)**	**25,404**	**NA**	**9,311 (Note 6)**

Notes:
1. Projection of flows available in first year of Proposed Project operation 2017 (See **Appendix B rev**).
2. Source: Schaaf & Wheeler/Monterey Peninsula Water Management District, 2015 (see **Appendix B rev**).
3. Flows not available for years prior to 2007.
4. Due to lack of data regarding agricultural wash water prior to 2007 and recent trends, these numbers could not be summed to provide a total of source water flows for this averaging period.
5. Blanco Drain flows calculated based on seasonal pumping records (April to November)
6. The total use of source water would be less than the sum of all source waters due to seasonal nature of the demands and losses due to Salinas Treatment Facility Storage and Recovery. The analysis assumes that new source water that exceeds the amount used by the Proposed Project for recycling would be disposed via the MRWPCA existing ocean outfall. The amount of effluent to be disposed to the MRWPCA ocean outfall would be less with Proposed Project than current conditions as shown in **Appendix B rev**.
NA = Not available.

Table 2-13

Source Water Use Scenarios, including Priority, Seasonality, and Use by Project Phase and Drought Reserve Status

Priority	Source	Seasonal Availability	Usage Period	Projected Use Scenarios by Type of Operational Year (AFY)		
				While Building Drought Reserve	Drought Reserve is Full at 1,000 AFY	During Years when CSIP Uses Drought Reserve
1	Unused Treated Municipal Wastewater	October through March	When available	1,992	1,787	1,503
2	Agricultural Wash Water (See Note 1)	Year-round	Store at Salinas Treatment Facility for summer	2,579	2,579	2,362
3	Salinas Urban Stormwater Runoff (See Note 1)	October through April				
4	Reclamation Ditch at Davis Road	Year-round, higher in October through April	When available	721	721	1,071
5	Blanco Drain Pump Station	Year-round, higher in April through September	When available	1,268	1,020	2,003
6	Tembladero Slough At Castroville	Year-round, higher in October through April	When available	0	0	478
7	Monterey Stormwater at Lake El Estero (See Note 2)	October through April	When available	0	0	0

Notes:
1. The amount of Agricultural Wash Water and Salinas Urban Stormwater Runoff source water use shown in this table are combined because they will be mixed, stored, and diverted to the Regional Treatment Plant together. The ability of the Proposed Project to recycle the full amount available (shown in Table 2-12) would be reduced due to the storage and recovery of these waters at the Salinas Treatment Facility and the associated percolation and evaporation during storage. The storage and recovery component does, however, shift the availability of the supplies to the dry season when there is a greater demand for irrigation water within the CSIP area.
2. Wet season supply from Lake El Estero is not required in these typical scenarios shown; however, there may be conditions during which diversions may occur.
See **Appendix B rev** for detailed monthly source water use projections based on water year type, drought reserve status, and project phase.

We thank the project proponents, lead agencies and consultants for their thorough evaluation of the many facets of this project, and for considering these comments.

Sincerely,

John Hunt

SAN FRANCISCO, CALIFORNIA 94103-1398

APR 10 2017

Regulatory Division

SUBJECT: File Number 2013-00111S

Ms. Bridget Hoover
Water Quality Protection Program Director
Monterey Bay National Marine Sanctuary
99 Pacific Street Bldg 455
Monterey, California, 93940

Dear Ms. Hoover:

This letter is written in response to a request for comments on the Draft Environmental Impact Report/Environmental Impact Statement concerning the Monterey Peninsula Water Supply Project. The project would include construction of a desalinization plant with related facilities for seawater intake, water treatment, and desalinated water conveyance and storage. The proposed project area extends approximately 18 miles along the Monterey Bay coast, from the town of Castroville in the north, to the City of Carmel in the south, Monterey County, California. Since the activities included in the project may impact waters of the U.S. (Monterey Bay and its tributaries and adjacent wetlands), the Corps of Engineers will need to review those portions of the project.

All proposed work and/or structures extending bayward or seaward of the line on shore reached by: mean high water (MHW) in tidal waters, or ordinary high water in non-tidal waters designated as navigable waters of the United States, must be authorized by the Corps of Engineers pursuant to Section 10 of the Rivers and Harbors Act of 1899 (33 U.S.C. Section 403). Additionally, all work and structures proposed in unfilled portions of the interior of diked areas below former MHW must be authorized under Section 10 of the same statute. USACE-1

All proposed discharges of dredged or fill material into waters of the United States must be authorized by the Corps of Engineers pursuant to Section 404 of the Clean Water Act (CWA) (33 U.S.C. Section 1344). Waters of the United States generally include tidal waters, lakes, ponds, rivers, streams (including intermittent streams), and wetlands.

Depending on the nature and extent of project impacts within the Corps of Engineer's jurisdiction, the proposed project may require a standard individual 404 permit from the Corps and would need to comply with the 404(b)(1) Guidelines, which include the following prerequisites:

1) there are no practicable alternatives to the proposed discharge that would have a less adverse effect on the aquatic environment;
2) the proposed discharge would not cause or contribute to a violation of state water quality standards;

3) the proposed discharge would not contribute to significant degradation of waters of the U.S., and
4) the project would implement all appropriate and practicable measures to minimize potential adverse impacts of the discharge on the aquatic ecosystem.

During the process of the 404(b)(1) analysis, the Corps would want the basic project purpose stated clearly to help determine whether the project, to achieve its basic purpose, is water dependent. In this context, a project would be water dependent if it requires access or proximity to or siting within a special aquatic site to fulfill its basic purpose. For reference, see 40 CFR Sec 230.10 -Restrictions on discharge, and in particular, Sec 230.10(a)(3). The alternative analysis presented in Chapter 5 of the EIS does not present enough information about impacts to waters of the U.S. to determine whether the proposed preferred project alternative is the LEDPA. Table 5.3-4 presents several alternatives and it appears that for the intake options, several may have decreased impacts compared with the preferred alternative. The 404(b)(1) alternatives analysis will determine the LEDPA, and when that is provided to the Corps, the applicant will need to demonstrate why some of the other options that may have less fill discharge to waters of the U.S. are either not practicable, would not achieve the basic project purpose, or would have other environmental impacts.

USACE-1 cont.

The Corps of Engineers regulatory program supports the national goal of "no overall net loss" of wetlands. For permitted activities that result in unavoidable losses, the Corps requires replacement wetlands to offset those losses. The U.S. Army Corps of Engineers and U.S. Environmental Protection Agency released a new Compensatory Mitigation Rule on April 10, 2008, to clarify how to provide compensatory mitigation for unavoidable impacts to the nation's wetlands and streams. A copy of this rule can be found on our Headquarters website: http://www.usace.army.mil/Missions/CivilWorks/RegulatoryProgramandPermits/mitig_info.aspx The new rule changes where and how mitigation is to be completed, but maintains existing requirements on when mitigation is required. The rule also preserves the requirement for applicants to avoid or minimize impacts to aquatic resources before proposing compensatory mitigation projects to offset permitted impacts.

USACE-2

A jurisdictional survey (delineation) should be provided by the applicant on a scaled topographic map or site plan. When this document is forwarded with the application, the Corps staff will validate and authenticate the limits of Corps jurisdiction. While it is not necessary to confirm all boundary points, the Corps will verify the jurisdictional boundary along one or more transects and may visit random intermediate points. All delineations of wetlands must be conducted in accordance with the *1987 Corps of Engineers Wetlands Delineation Manual*, or appropriate Regional Supplement, and submitted to the District for review and verification. Two Regional Supplements have been approved for use within the boundaries of the San Francisco District: the *Arid West Supplement*, and the *Western Mountains, Valleys and Coast Supplement*. Copies of these documents are available to download on our website: http://www.spn.usace.army.mil/Missions/Regulatory/JurisdictionDeterminations.aspx.

The Corps of Engineers receives thousands of requests each year to perform wetland delineations for potential applicants for permits under Section 404 of the Clean Water Act. Due to limited staff and resources, response time can be several months or longer. To expedite this process, the San Francisco District encourages applicants to use consultants to conduct wetland delineations, especially for large and/or complex areas. The San Francisco District is not authorized to recommend any private consulting services and advises applicants to check references and referrals of prospective consultants before contracting services.

USACE-2 cont.

You may refer any questions on this matter to Frances Malamud-Roam of my Regulatory staff by telephone at 415-503-6792 or by e-mail at Frances.P.Malamud-Roam@usace.army.mil. All correspondence should be addressed to the Regulatory Division, South Branch, referencing the file number at the head of this letter.

Sincerely,

for Rick M. Bottoms, Ph.D.
Chief, Regulatory Division

MAR 2 9 2017

Mr. Paul Michel, Superintendent
National Oceanic and Atmospheric Administration
Monterey Bay National Marine Sanctuary
99 Pacific Avenue, Building 455A
Monterey, California 93940

Subject: Draft Environmental Impact Statement/Report for the Monterey Peninsula Water Supply Project, Monterey, California (EIS No. 20170000)

Dear Mr. Michel:

The U.S. Environmental Protection Agency has reviewed the above-referenced document pursuant to the National Environmental Policy Act (NEPA), Council on Environmental Quality regulations (40 CFR Parts 1500-1508), and our NEPA review authority under Section 309 of the Clean Air Act.

EPA recognizes the water supply challenges that result from the Monterey Bay area's geography and climate. In order to provide a reliable, long-term, and drought-resistant water supply to its customers, California American Water Company has applied to the Monterey National Marine Sanctuary for authorization to operate a seawater intake system, a reverse osmosis desalination plant, and ancillary facilities to serve Monterey county residents and businesses. We commend the Sanctuary for evaluating, in the Draft EIS, several project site locations, sizes, and technologies as alternatives to the Applicant's Proposed Action. The document's evaluation of a reasonable range of alternatives will aid the public and decision-makers in understanding and comparing the environmental impacts of various approaches to meeting the area's water supply needs. We also note that the North Marina Groundwater Model, presented in the Draft EIS, appears conceptually sound and well parametrized. USEPA-1

The Draft EIS identifies Alternative 5a as the Sanctuary's Preferred Alternative. Alternative 5a would authorize the drilling of seven subsurface slant wells, a brine discharge into Sanctuary waters, and a desalination facility and pipelines that would process a maximum of 6.4 million gallons per day. EPA has reviewed the Draft EIS and rated the Preferred Alternative *Lack of Objections (LO)* (see attached "Summary of EPA Rating Definitions"). The remainder of this letter provides EPA's suggestions to assist the Sanctuary in the development of the Final EIS. USEPA-2

Fort Ord Superfund Site

The Department of the Army's groundwater remediation projects at the former Fort Ord are being conducted under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA). Contamination at the site includes the Operable Unit Carbon Tetrachloride Plume (OUCTP), located two miles from the proposed subsurface seawater intake wells. According to the Draft EIS, if the radius of influence of the proposed slant wells does reach the western portion of the OUCTP A-Aquifer Plume, then the decrease in groundwater elevations could alter the existing groundwater flow direction. This change in flow direction could pull the OUCTP Plume further northwest, spreading the contamination to areas that are not now contaminated above action levels. USEPA-3

Printed on 100% Postconsumer Recycled Paper. Process Chlorine Free.

Mitigation Measure 4.4-4 states that "the project applicant will reimburse the U.S. Army for the necessary additional costs to address changes in the plume flow direction, arrest mitigation of the plumes, and/or to remediate areas of new contamination created by slant well pumping." It is unclear exactly what would trigger implementation of Mitigation Measure 4.4-4. EPA suggests that the Sanctuary continue to work with the Army's Fort Ord Base Realignment and Closure office to refine Mitigation Measure 4.4-4 to include appropriate thresholds for action. In addition, it would be helpful to include, with input from the Army, a description of the possible mechanisms through which reimbursement of the Army could be provided, if necessary. EPA also suggests that the Final EIS and Record of Decision include a requirement that the Army be notified, in advance, of any operational changes to the project.

USEPA-3 cont.

The Draft EIS also includes Mitigation Measure 4.4-3, under which groundwater monitoring that incorporates the Army's groundwater monitoring data would be conducted. Specifically, CalAm proposes to expand the existing regional groundwater monitoring program to include the area where groundwater elevations are anticipated to decrease by one foot, plus one mile (p.4.4-68). We encourage CalAm to continue to coordinate with the Army to ensure that placement of future groundwater monitoring wells would be complementary to any groundwater cleanup activities in the Fort Ord Superfund Site.

Energy Conservation

Proposed Mitigation Measure 4.11-1 states that:

> "CalAm shall make good faith efforts to ensure that at least 20 percent of the approved project's operational energy use requirements are achieved with "clean" renewable energy, including but not necessarily limited to: the use of methane gas from the existing Monterey Regional Waste Management District (MRWMD) landfill-gas-to-energy (LFGTE) facility located adjacent to the MPWSP Desalination Plant site; and installation of solar photovoltaic (PV) panels at or adjacent to the desalination plant."

EPA supports the use of renewable energy; however, we note that neither expansion of the LFGTE facility nor the installation of solar PV panels is included as part of the proposed project. The Draft EIS explains how the CalAm project could connect to the LFGTE facility, but provides no further discussion of PV.

USEPA-4

We suggest that the Sanctuary evaluate the feasibility of incorporating solar PV panels into the project design. If PV panels are found to be feasible, include them in the Description of the Proposed Project in the Final EIS, and include an analysis of the operational energy savings that would result from incorporating solar energy into the project. Alternatively, consider evaluating solar panels separately as a mitigated alternative, consistent with 40 CFR 1502.14(f). One design option would be to install solar panels on buildings and on carports over parking lots, the latter which would also reduce evaporative emissions from vehicles and provide shade in addition to generating electricity.

Wetlands Impacts

The Draft EIS does not distinguish between permanent and temporary impacts. The U.S. Army Corps of Engineers generally states that temporary is no longer than one year and one growing season. In the Draft EIS, all construction impacts are categorized as temporary, even if they may be longer than a year. EPA suggests that the Final EIS clarify the definition of "temporary" relied upon for characterizing

USEPA-5

impacts of the proposed project, and discuss temporary and any permanent impacts to waters of the US accordingly. USEPA-5 cont.

In closing, EPA appreciates the opportunity to review this Draft EIS. When the Final EIS is released for public review, please send one copy to the address above (mail code: ENF-4-2). If you have any questions, please contact me at (415) 972-3521, or contact Stephanie Gordon, the lead reviewer for this project, at 415-972-3098 or gordon.stephanies@epa.gov.

Sincerely,

Kathleen Martyn Goforth, Manager
Environmental Review Section

Enclosure: Summary of EPA Rating Definitions

cc: Bridget Hoover, Water Quality Protection Program Director, Monterey Bay National Marine Sanctuary
William Collins, Fort Ord Base Realignment and Closure Office, Department of the Army
Frances Malamud-Roam, U.S. Army Corps of Engineers
Grant Himebaugh, Central Coast Regional Water Quality Control Board

SUMMARY OF EPA RATING DEFINITIONS*

This rating system was developed as a means to summarize the U.S. Environmental Protection Agency's (EPA) level of concern with a proposed action. The ratings are a combination of alphabetical categories for evaluation of the environmental impacts of the proposal and numerical categories for evaluation of the adequacy of the Environmental Impact Statement (EIS).

ENVIRONMENTAL IMPACT OF THE ACTION

"LO" (Lack of Objections)

The EPA review has not identified any potential environmental impacts requiring substantive changes to the proposal. The review may have disclosed opportunities for application of mitigation measures that could be accomplished with no more than minor changes to the proposal.

"EC" (Environmental Concerns)

The EPA review has identified environmental impacts that should be avoided in order to fully protect the environment. Corrective measures may require changes to the preferred alternative or application of mitigation measures that can reduce the environmental impact. EPA would like to work with the lead agency to reduce these impacts.

"EO" (Environmental Objections)

The EPA review has identified significant environmental impacts that should be avoided in order to provide adequate protection for the environment. Corrective measures may require substantial changes to the preferred alternative or consideration of some other project alternative (including the no action alternative or a new alternative). EPA intends to work with the lead agency to reduce these impacts.

"EU" (Environmentally Unsatisfactory)

The EPA review has identified adverse environmental impacts that are of sufficient magnitude that they are unsatisfactory from the standpoint of public health or welfare or environmental quality. EPA intends to work with the lead agency to reduce these impacts. If the potentially unsatisfactory impacts are not corrected at the final EIS stage, this proposal will be recommended for referral to the Council on Environmental Quality (CEQ).

ADEQUACY OF THE IMPACT STATEMENT

"Category 1" (Adequate)

EPA believes the draft EIS adequately sets forth the environmental impact(s) of the preferred alternative and those of the alternatives reasonably available to the project or action. No further analysis or data collection is necessary, but the reviewer may suggest the addition of clarifying language or information.

"Category 2" (Insufficient Information)

The draft EIS does not contain sufficient information for EPA to fully assess environmental impacts that should be avoided in order to fully protect the environment, or the EPA reviewer has identified new reasonably available alternatives that are within the spectrum of alternatives analysed in the draft EIS, which could reduce the environmental impacts of the action. The identified additional information, data, analyses, or discussion should be included in the final EIS.

"Category 3" (Inadequate)

EPA does not believe that the draft EIS adequately assesses potentially significant environmental impacts of the action, or the EPA reviewer has identified new, reasonably available alternatives that are outside of the spectrum of alternatives analysed in the draft EIS, which should be analysed in order to reduce the potentially significant environmental impacts. EPA believes that the identified additional information, data, analyses, or discussions are of such a magnitude that they should have full public review at a draft stage. EPA does not believe that the draft EIS is adequate for the purposes of the NEPA and/or Section 309 review, and thus should be formally revised and made available for public comment in a supplemental or revised draft EIS. On the basis of the potential significant impacts involved, this proposal could be a candidate for referral to the CEQ.

*From EPA Manual 1640, Policy and Procedures for the Review of Federal Actions Impacting the Environment

8.3.1 Responses to Comments from Department of the Army, Fort Ord Base Realignment and Closure Field Office

FOBRAC-1 Mitigation Measure 4.4-4 applies to the proposed MPWSP at 9.6 million gallons per day (mgd) as described in Chapter 3, Project Description. As discussed in Impact 4.4-4 in Section 4.4, Groundwater Resources, the operation of the proposed MPWSP is not anticipated to adversely affect the Fort Ord Operable Unit Carbon Tetrachloride Plumes (OUCTP) plumes. Nonetheless, in an abundance of caution, Mitigation Measure 4.4-4 is proposed to address the possibility that the capture zone of the seawater intake system could extend to and affect the OUCTP plumes. Changes to Mitigation Measure 4.4-4 in response to this comment are discussed further below.

However, it is important to note that Alternative 5a, described in Section 5.4.7, may be selected by the Lead Agencies as the environmentally superior/agency preferred alternative. Under Alternative 5a, the seawater intake system would be operated at a reduced volume of 6.4 mgd, which in turn would result in a reduced capture zone that would not approach the OUCTP plumes, avoiding the potential (though not anticipated) impact of the proposed project.

Mitigation Measure 4.4-4 specifically includes the requirement that CalAm monitor the development of the radius of influence, defined as 1 foot of drawdown. In the event that the radius of influence approaches the OUCTP plumes, the monitoring would enable (and Mitigation Measure 4.4-4 would require) CalAm to respond prior to adverse effects on the OUCTP plumes. As discussed in Impact 4.4-4 in Section 4.4, the operation of the seawater intake system may result in a drawdown of 1 foot close to the northwestern edge of the OUCTP plumes. As explained in Master Response 8, Project Source Water and Seawater Intrusion, this would not necessarily change the flow direction at those locations. More importantly, the capture zone[1] would have a much smaller extent than the radius of influence, defined above. This means that the proposed project would be unlikely to capture any groundwater being treated at the OUCTP plumes. As previously noted, Mitigation Measure 4.4-4 is proposed as a conservative measure in the event that the capture zone extends further than anticipated.

In response to this comment, the following text has been added to the end of the CERCLA subsection in Section 4.7.2.1, Regulatory Framework:

> <u>The cleanup projects being conducted at the former Fort Ord, described above in Section 4.7.1 Setting/Affected Environment, are being conducted under CERCLA. If the MPWSP were to adversely affect the ongoing cleanup</u>

[1] A capture zone is the three-dimensional volume of aquifer that contributes the water extracted by the wells. See Master Response 8, Project Source Water and Seawater Intrusion.

activities, CalAm may be considered a potentially responsible party as defined in CERCLA.

In addition, Mitigation Measure 4.4-4 has been revised as follows:

Mitigation Measure 4.4-4: (Groundwater Monitoring and Avoidance of Impacts on Groundwater Remediation Plumes).

Prior to the start of MPWSP construction, CalAm ~~the project applicant~~ shall incorporate the future quarterly groundwater elevation monitoring results for the two OUCTP plumes into the well monitoring program described above in **Applicant Proposed Measure 4.4-3** until the two OUCTP plumes have been appropriately remediated and the RWQCB no longer requires remediation activities. Groundwater elevation data shall be obtained from the periodic monitoring reports developed by the U.S. Army and its contractors. The elements of the additions to the groundwater monitoring program proposed under this mitigation measure are described below.

- Using the most recent monitoring reports available through the U.S. Army and its contractors, the groundwater elevations in the A-Aquifer and the Upper 180-Foot Aquifer for wells at and downgradient of the westernmost edge of the two OUCTP plumes shall be incorporated into the well monitoring program described above for **Applicant Proposed Measure 4.4-3**.

- The groundwater elevation results shall be evaluated by CalAm and its consultants on a quarterly basis to assess whether the ~~cone of depression~~ -1 foot drawdown contour from the proposed seawater intake system is approaching ~~or has reached~~ the edge of the two OUCTP plumes. If the analysis concludes that the slant well pumping could intersect or could influence the flow direction of two OUCTP plumes, then CalAm ~~the project applicant~~ shall contact the U.S. Army, the Regional Water Quality Control Board – Central Coast Region, the California Department of Toxic Substance Control, and the USEPA to initiate communications and develop and implement a plan to either stop or decrease the pumping to prevent any impact on the OUCTP plumes. In the unlikely event that an impact does occur, CalAm shall bear ~~reimburse the U.S. Army for~~ the necessary additional costs to address changes in the plume flow direction, arrest migration of the plumes, and/or to remediate areas of new contamination created by slant well pumping. CalAm shall consider using existing groundwater remediation and monitoring wells that remain on the site to expand the existing treatment systems.

- When the ongoing remediation of the two OUCTP plumes has been completed and the RWQCB authorizes closure of the two OUCTP plumes remediation activities, this mitigation measure shall no longer apply.

FOBRAC-2 The commenter stated that unexploded ordinance (UXO) from the previous military use of the former Fort Ord may be present outside of the City of Seaside,

which administers an excavation permit program that includes the potential to encounter UXO. In Section 4.7.5.1, Impact 4.7-3 includes analysis for encountering UXO and requires compliance with the City of Seaside's Ordnance Remediation District regulations and the environmental protection provisions of the Findings of Suitability for Early Transfer (FOSET) agreement described in Section 4.7.1.1. The components of the proposed MPWSP that are located within the former Fort Ord are all located within the City of Seaside. As discussed in Impact 4.7-3, the only project component within the Seaside Munitions Response Area (MRA) is about 700 feet of the southernmost portion of the new Transmission Main, and construction within this area would therefore be required to comply with the permit. In addition, as explained on Draft EIR/EIS pages 4.7-7 to 4.7-8, investigations for and cleanup of UXO have been completed along General Jim Moore Boulevard where the project components would be located and the construction of the road would also have exposed UXO, if any. The commenter notes that the U.S. Army offers munitions recognition and safety training to anyone who requests it. As discussed in Impact 4.7-3, UXO recognition training is part of the permit requirements. No revisions were made in response to this comment.

8.3.2 Responses to Comments from Department of the Army, U.S. Army Installation Management Command

USARMY-1 The design and operation of the proposed MPWSP subsurface intakes is constrained by policies intended to avoid or minimize adverse environmental impacts outlined in the State Water Resources Control Board's (SWRCB) California Ocean Plan, California Coastal Commission (CCC) policies, and National Oceanic and Atmospheric Administration (NOAA) policy guidelines for desalination facilities. See EIR/EIS Section 5.3.1. The primary objectives of the MPWSP include developing supplies to replace Carmel River and Seaside Basin supplies that are constrained by regulatory and legal decisions. A secondary objective includes locating key project facilities in areas that minimize environmental impacts. See EIR/EIS Section 1.3.1. No change to the EIR/EIS has been made in response to this comment.

USARMY-2 In response to this comment, Section 1.5.4.3, Other Agencies' Consideration of the EIR/EIS and Proposed Project, has been revised as follows:

> On the federal level, agencies with ~~potential~~ reviewing or permitting authority include NOAA Fisheries, the U.S. Army, the U.S. Army Corps of Engineers, and the U.S. Fish and Wildlife Service (USFWS).

USARMY-3 The Terminal Reservoir is no longer a proposed project component. Therefore, the description of Terminal Reservoir in Draft EIR/EIS Section 3.2.3.5, and all references and analysis related to the component, have been removed from the EIR/EIS.

USARMY-4 The comment cites information provided by CalAm that describes the constraints on locating the proposed ASR wells in a location other than as proposed because of land use (i.e., Fort Ord ordinance cleanup areas and residential), biological resources in the area, and limitations on the geologic formation. The Lead Agencies reviewed and concur with these limitations. Therefore, the Lead Agencies did not consider other sites for the proposed ASR-5 and ASR-6 wells in the preparation of the Draft EIR/EIS.

Note that the proposed ASR-5 and ASR-6 wells previously were analyzed by the U.S. Army Garrison, Presidio of Monterey, in a Final Environmental Assessment (EA) and Finding of No Significant Impact (FONSI) (U.S. Army, 2010), after CalAm requested a right-of-entry and 50-year land lease with an option for renewals on the two parcels located within the Fitch Park Housing Area that are the current proposed locations of the ASR-5 and ASR-6 wells.[1] As explained in

[1] In the 2010 EA/FONSI, these wells are referred to as "ASR-3 and ASR-4;" however, as shown on Exhibit 2B in U.S. Army, 2010, these are the same sites currently proposed for the ASR-5 and ASR-6 wells as a component of the MPWSP.

the FONSI, that action was then determined to have no adverse impacts (after implementation of avoidance, minimization, and mitigation measures). The EA describes the process of evaluating alternatives to that project, and that CalAm considered several other locations for the ASR wells along the General Jim Moore Boulevard corridor (where existing ASR facilities are located), but did not pursue other locations. No additional discussion of evaluation of alternative sites was provided in the EA.

Final EIR/EIS Section 5.2, Alternatives Not Evaluated in Detail, has been revised to include the information provided in this response. See Section 5.2.7, Siting Alternatives for ASR-5 and ASR-6 Wells.

USARMY-5 Figure 3-14 has been replaced with higher-resolution graphics in the Final EIR/EIS.

USARMY-6 Draft EIR/EIS Section 3.3.2.2 describes the continuous 24-hour drilling of the ASR wells to be necessary until final depth is reached and the borehole is stabilized. The EIR/EIS text has been revised to include the explanation that this would prevent the borehole from potentially collapsing in on itself, filling the borehole with the surrounding geologic materials, and/or binding up the drill bit and trapping it in the borehole, as could occur if drilling were paused. The access driveways from General Jim Moore Boulevard are shown in Final EIR/EIS Figure 3-14 and described in Section 3.2.4.1.

USARMY-7 In response to this comment, text in Section 3.3.4.3 has been revised as follows:

> Before connecting existing and new pipelines, CalAm would drain and disinfect the existing pipe segments before putting them into service. Similarly, upon completing construction activities, facility operators would disinfect the newly installed pipelines and pipeline connections before bringing the pipes into service. Effluent produced during the pipeline disinfection process would be discharged to the local stormwater drainage system in accordance with the Central Coast RWQCB *General Waste Discharge Requirements for Discharges with Low Threat to Water Quality* (Order No. R3-2011-0223, NPDES Permit No. CAG993001) (RWQCB, 2011), or discharged in compliance with stormwater control requirements in the respective local jurisdictions (e.g., as directed by U.S. Army approvals on Army-owned property). See Impact 4.3-3 in Section 4.3, Surface Water Hydrology and Water Quality, for additional information.

The management of discharges of treated water and disinfectant from existing and newly installed pipelines during construction is discussed in Section 4.3.5.1 under Impact 4.3-3. In response to this comment, text in the first paragraph of this impact has been revised as follows:

> … The treated water generated from the draining of existing pipelines and the effluent generated from disinfection of newly installed pipelines would be discharged to the local storm drainage system or discharged in compliance with stormwater control requirements in the respective local jurisdictions (e.g., to percolation ponds as may be directed by U.S. Army approvals on Army-owned property). …

USARMY-8 Section 3.3.9, Construction Schedule, has been revised to clearly state that any pipelines constructed within U.S. Army-owned property would require daytime construction only.

USARMY-9 See Master Response 13, Demand (Project Need) and Growth, for a detailed discussion of reasonably foreseeable demand scenarios. Should demand, available water supply, or overall precipitation change, such that water needs are lowered, the desalination plant could be operated at a lower level. Indeed, although the Monterey Peninsula Water Management District (MPWMD) has not determined the allocation of water that could be provided by the proposed project, MPWMD stated in a comment on the Draft EIR/EIS (see comment MPWMD-21) that it may not allocate all the water produced by the project; one reason it may choose not to allocate the full amount would be to allow the plant to operate at less than full capacity, depending on the level of customer demand.

While the seawater intake system and desalination plant typically would operate year round, as discussed in EIR/EIS Section 3.4.1, there would be periods over the life of the project when CalAm would need to shut down the MPWSP Desalination Plant for a host of reasons (e.g., mechanical or electrical problems, water quality issues, loss of power, etc.). CalAm would be able to serve customer demand using other sources, including water stored in the ASR system, during such outages. Typical annual variation in rainfall is unlikely to affect the proposed operation of the desalination plant because, as shown in EIR/EIS Table 3-6, during the wet season when surface water is available to serve the Monterey District, desalinated product water would be injected into ASR and stored for later use. The quantity of desalinated product water that could be injected would be determined by the amount of desalinated water not being delivered to customers, and is estimated to be about 2,100 afy, but could vary in any given year. Further, as explained in Section 3.4.4, CalAm is obligated to replenish the Seaside Groundwater Basin on an approximately 25-year schedule, with the actual volume of water replenished during any given year varying but being equal to or greater than 700 afy based on a running 5-year average. Therefore, in the event that increased rainfall and/or decreased demand occur prior to completion of the Seaside Groundwater Basin payback period, CalAm could continue to operate the desalination plant as proposed in order to fulfill this obligation. In the event of a short-term power outage, CalAm would rely on other supply sources and then resume desalination plant operations; see EIR/EIS Section 3.4.1 and Table 3-7.

USARMY-10 The second column (U.S. Army) of the second row (Permit or Approval) of Table 3-8, Anticipated Permits and Approvals, has been revised to read:

> Real property outgrants for construction and operation for non-Army users (Army Regulation (AR) 405-80, 200-1) ~~Land Use (Army Regulation (AR) 405-80, 200-1)~~

USARMY-11 See response to comment USARMY-7.

USARMY-12 As discussed in Draft EIR/EIS Section 4.3.5.1 under Impact 4.3-2, all dewatering discharges related to excavations, well drilling, and well development would occur in compliance with regulatory requirements that are protective of the receiving waters; impacts associated with such discharges were found to be less than significant. To obtain NPDES coverage for construction related discharges, CalAm would be required to test dewatering effluent for possible pollutants and provide results of the water quality analysis to the Central Coast Regional Water Quality Control Board. The Construction General Permit requires all dischargers to electronically file all Permit Registration Documents (PRDs), Notices of Termination (NOT), changes of information, annual reporting, and other compliance documents required by permit through the State Water Board's Stormwater Multi-Application and Report Tracking System (SMARTS) website where this information is publicly accessible (https://smarts.waterboards.ca.gov/smarts/faces/SwSmartsLogin.xhtml); no change has been made to the Draft EIR/EIS in response to this comment.

USARMY-13 The legend has been expanded to describe the features on Figures 4.7-7 and 4.4-8.

USARMY-14 The discussion of Disinfection Byproducts in Section 4.4.1.4 has been revised to reflect the cited information about past operation of existing ASR-3:

> After approximately 150 to 210 days of storage, THMs in four out of the five wells monitored had degraded to below the initial injection levels. Although the concentration of THMs in the ASR-3 well had not yet reached the initial injection level as of 210 days, the concentration was exhibiting a continuing downward trend suggesting the initial injection concentration would be reached within about 240 days. HAAs degraded to below reporting limits by 90 to 100 days. More importantly, throughout the 2015 water year, after the initial increase following injection, THMs were below the MCL of 80 micrograms per liter and HAAs were below the MCL of 60 micrograms per liter in all five wells monitored.

Pueblo Water Resources describes the rates and trends as "approximate" and "typical" because the actual rates and trends for an individual well during any one of the monitoring events vary and may be slightly outside of the typical trends observed since the evaluations began in 2001. Considering that the

concentrations are below MCLs and the trends are always downward back to the initial injection levels, this one outlier is not considered to be significant.

USARMY-15 As explained in the subsection titled Disinfection Byproducts in Section 4.4.1.4 Groundwater Quality, the concentrations of THMs in ASR-3 did initially increase and then decrease over time to below the Maximum Contaminant Level (MCL) or 80 micrograms per liter (mg/L). See the revision in response to comment USARMY-14 for clarification that THMs were below the MCL after the initial increase following injection.

USARMY-16 As discussed in the subsection titled Disinfection Byproducts in Section 4.4.1.4 Groundwater Quality, the concentrations of disinfection byproducts (DBPs) declined over time to below the regulatory action level of their respective MCLs in all wells monitored. Graphs of the concentrations of disinfection byproducts showing the rate of decline compared to the regulatory action level of their respective MCLs are shown on Figures 20 through 24 in Pueblo Water Resources, 2016, cited in Section 4.4. As requested, Figures 20 through 24 from Pueblo Water Resources, 2016, are provided in this Section 8.2.3. The graphs also show that with time, the concentrations of disinfection byproducts continued to decrease to below the initial injectate levels, indicating that elevated concentration conditions do not persist. The Pueblo 2016 report did not present pH values on the listed figures. However, Table 11 of the Pueblo 2016 report states that the 2014 and 2015 injectates had pH measurements of 7.2 and 7.6, both within the MCL for pH of 6.5 to 8.5. As listed in Table 4.4-2 in the Draft EIR/EIS, the injected volumes have varied from 2 to 1,117 acre-feet per year, but the concentrations of disinfection byproducts have always returned to below injectate levels. This pattern of initial increase followed by a decline in DBP concentration is expected independent of the injected volume.

As stated in Pueblo Water Resources, 2016 and Padre Associates, Inc., 2004, cited in Section 4.4, the formation and degradation of DBPs are consistent with other ASR sites with reduced (anaerobic) subsurface conditions. The DBPs are formed when naturally occurring organic and inorganic materials in the water and subsurface materials react with the disinfectants. The DBPs are then degraded through biometabolism by microorganisms indigenous to the groundwater aquifers or adsorbed to the materials of the aquifer matrix. Under the proposed project, the maximum volume of water that could be supplied to the ASR system from the MPWSP desalination plant would be 2,100 acre-feet per year. Given the limitations of Water Rights Permits 20808A and C, the maximum volume of water that could be diverted from the Carmel River system could be 5,326 acre-feet per year (Water Rights Permits 20808A and 20808C) that are subject to instream flow requirements; as noted above, the actual volume has been between 2 and 1,117 acre-feet per year due to the seasonal rainfall limitations and instream flow requirements. Thus, the volume of water that CalAm could inject into the ASR system in a given year could be a maximum of

Figure 8.3.2-5

SMS Deep Disinfection Byproducts Parameters

about 7,426 acre-feet. However, the water from the desalination plant would be advanced treated and would contain less organic material than the water injected from the Carmel River, which in turn would generate a lower concentration of DBPs. As stated above, an initial increase followed by a decline in DBP concentration is expected, independent of the injected volume.

USARMY-17 As explained in response to comment USARMY-16, the volume of water that CalAm could inject into the ASR system in a given year could be a combined maximum of about 7,426 acre-feet from all sources. As explained in Impact 4.4-3 on Draft EIR/EIS page 4.4-68, the volume of treated desalinated water that would be routed to the ASR system for storage would depend on precipitation and the water demands in any given year, but is expected to be about 2,100 acre-feet per year. The MPWMD's 2006 ASR EIR analyzed the impacts on groundwater storage and water levels in the Seaside Groundwater Basin (MPWMD, 2006). The analysis presented a pilot study and a groundwater model to evaluate the impacts on groundwater storage in the SGB through operation of the ASR program. The analysis assumed up to 2,426 acre-feet per year could be injected through the implementation of the ASR program, of which up to 2,003 acre-feet per year would be extracted, consistent with the terms of the water rights permits. The findings of the analysis concluded that injecting excess treated water into the ASR injection/extraction wells was beneficial to groundwater storage within the Seaside Groundwater Basin, so long as extraction did not exceed injection on an annual basis. In addition, as discussed above in response to comment USARMY-16, the fate of the disinfection byproducts would be the same as described in the subsection titled Disinfection Byproducts in Section 4.4.1.4, Groundwater Quality, and the decline in DBP concentrations would be independent of the injected volumes of supply.

USARMY-18 As discussed in Section 4.4.1.2, Local and Regional Hydrogeology, the Santa Margarita Sandstone, the aquifer into which treated water would be injected, is a confined aquifer. At this depth and under these conditions, water would not be able to intermix with groundwater in other aquifers. There would be no organisms within the Santa Margarita Sandstone that could be affected by the disinfection byproducts.

USARMY-19 As discussed in the subsection titled Disinfection Byproducts in Section 4.4.1.4, Groundwater Quality, water injected into the ASR system is monitored to track the degradation rate of the disinfection byproducts. This monitoring program is required by the State Water Resources Control Board under the Division of Water Rights Permit 20808C – Amended Permit for Diversion and Use of Water, which includes rules for the recovery of the stored water (see Section 4.4.2, Regulatory Framework). The Permit requires quantifying the amount of time needed to ensure that, prior to extraction, the concentration of the disinfection byproducts has decreased to below MCLs. As an adaptive management strategy,

the residency time of the treated water in the aquifer is dictated by the degradation rate of the disinfection byproducts and can vary accordingly.

USARMY-20 The Integrated Natural Resource Management Plan (INRMP), Presidio of Monterey and Ord Military Community, has been reviewed and a brief summary added in Final EIR/EIS Section 4.6.2.1, Federal Regulations, in Section 4.6, Terrestrial Biological Resources. Additionally, provisions have been added to mitigation measures where appropriate to acknowledge the applicability of the INRMP to project components within U.S. Army-owned land within the Ord Military Community area. In Mitigation Measure 4.6-1p (Control Measures for Spread of Invasive Plants), item number 7 has been added as follows:

> Within U.S. Army-owned land, control measures for invasive species also shall conform to guidelines in the Integrated Natural Resource Management Plan (INRMP) Presidio of Monterey and Ord Military Community (e.g., Section 9.2.4, Undesirable Plant Pests).

See also response to comment USARMY-21, below. The Lead Agencies also anticipate that the U.S. Army will require compliance with applicable INRMP policies and guidelines in permits and/or other agreements obtained by CalAm for facilities within U.S. Army-owned land.

Table 4.6-4 in Section 4.6.2.3, Regional and Local Regulations, summarizes the regional and local (i.e., not federal or state) land use plans, policies, and regulations pertaining to inland biological resources that are relevant to the MPWSP and that were adopted for the purpose of avoiding or minimizing an adverse environmental effect, and has not been revised to include the INRMP (a federal land management plan).

USARMY-21 The Draft EIR/EIS includes measures for site restoration and tree replacement in accordance with local policies and ordinances. Mitigation Measure 4.6-1c, which applies to all project components, specifies that all temporarily disturbed areas shall be returned to pre-project conditions or better. Through implementation of Mitigation Measure 4.6-1c, any landscaped areas would be restored after work is complete. Through implementation of Mitigation Measure 4.6-4, CalAm would be required to comply with any local tree policies or ordinances, which may require the replacement of a protected tree depending on the applicable policy or ordinance.

In response to this comment, item 4 has been added to Mitigation Measure 4.6-4 (Compliance with Local Tree Ordinances) as follows:

> Tree removal, preservation, or mitigation on Army property shall be in accordance with the Integrated Natural Resource Management Plan Presidio of Monterey and Ord Military Community (November, 2008).

USARMY-22 See response to comment USARMY-10 regarding how Army Regulation 405-80 is now presented in Table 3-8, Anticipated Permits and Approvals. The comment is acknowledged, and it will be the responsibility of CalAm and/or its contractors to secure the necessary permits and comply with the conditions imposed at that time by permitting agencies.

USARMY-23 As described on Draft EIR/EIS page 4.9-27, where feasible and appropriate, project pipelines would be installed so as to avoid construction within vehicle travel lanes and to minimize impacts on roadway capacity and function. For the proposed pipeline along General Jim Moore Boulevard, the impact analysis conservatively assumed that construction could require temporary lane closures, and that the impact related to pipeline installation is considered to be potentially significant. However, the Traffic Control and Safety Assurance Plan (Mitigation Measure 4.9-1) would include measures to minimize the adverse effects of temporary lanes closures. Regarding access for emergency service providers (such as the POM Fire Station on General Jim Moore Boulevard), as stated on page 4.9-25, the Traffic Control and Safety Assurance Plan would stipulate that access for emergency vehicles would be maintained at all times. Access for the other uses cited in the comment would be maintained, but could be temporarily impeded by project construction. See response to comment USARMY-22 regarding CalAm's responsibility for obtaining permits.

USARMY-24 Temporary disruption to public transit during construction is discussed under Impact 4.9-5. As stated there, pipeline installation activities could temporarily affect public transportation along affected roadways in the project area. However, implementation of Mitigation Measure 4.9-1 (Traffic Control and Safety Assurance Plan), which includes measures that would minimize impacts on public transportation during construction, would reduce the impact to a less-than-significant level. Relevant to the comment's concern about DoD personnel commuting by Monterey-Salinas Transit buses, the Traffic Control and Safety Assurance Plan would stipulate that construction truck trips and lane closures would be scheduled to occur outside of peak morning and evening commute hours to minimize adverse impacts on traffic flow (which includes traffic flow by buses).

USARMY-25 See response to comment USARMY-24 regarding the Traffic Control and Safety Assurance Plan (Mitigation Measure 4.9-1) and its stipulation that construction truck trips and lane closures would be scheduled to occur outside of peak traffic hours to minimize adverse impacts on traffic flow (if agencies with jurisdiction over the affected roads identify highly congested roadway segments during their review of the encroachment permit applications). As stated on Draft EIR/EIS page 4.9-24, the traffic control and safety assurance plan shall be developed on the basis of detailed design plans for the approved project, and shall include, but not necessarily be limited to the elements listed on Draft EIR/EIS pages 4.9-24 to 4.9-26. The following additional element has been added to the list of measures

that could be included in the traffic control and safety assurance plan required by Mitigation Measure 4.9-1:

- Develop a school traffic and pedestrian safety plan to minimize adverse impacts associated with truck trips and lane closures (e.g., in the vicinity of the Marshall Elementary School east of the General Jim Moore Boulevard / Normandy Road intersection).

USARMY-26 See response to comment USARMY-23 regarding emergency access during project construction. Mitigation Measure 4.9-1, Traffic Control and Safety Assurance Plan, requires CalAm and/or its contractors to obtain any necessary road encroachment permits prior to constructing each project component and to comply with the conditions of approval attached to all project permits. This measure has been revised to clarify that a permit from the U.S. Army is among those potentially necessary permits with which CalAm and its contractors must comply. The statement about the process the U.S. Army would undertake during its review of a request by CalAm to work on Army-owned property is acknowledged. See response to comment USARMY-22 regarding CalAm's responsibility for obtaining permits.

USARMY-27 Potential increased wear-and-tear on the designated haul routes used by project construction vehicles is discussed under Impact 4.9-6. As stated there, the degree to which this impact would occur depends on the roadway design (pavement type and thickness) and the existing condition of the roadway. It is acknowledged that some roadways may not have been constructed to support use by heavy construction trucks and vehicles, and project-related increases in construction truck trips could cause excessive wear-and-tear on these roadways, a potentially significant impact. However, implementation of Mitigation Measure 4.9-6 (Roadway Rehabilitation Program), which requires rehabilitation of any roadways damaged following construction, would reduce this impact to a less-than-significant level. See response to comment USARMY-22 regarding CalAm's responsibility for obtaining permits.

USARMY-28 The concern about the proposed use of a portion of the AAFES Service Station parking lot as a construction staging area is noted. The Draft EIR/EIS concluded that project-generated traffic would result in less-than-significant impacts, and it is unclear from the comment what the potential for additional traffic hazards would be. Regardless, the Lead Agencies acknowledge that CalAm's proposed use of staging areas is subject to agreements with property owners and that the U.S. Army may decline to permit the use of this location as a temporary construction staging area. As shown on EIR/EIS Figure 3-8, there are several other proposed staging areas in the vicinity that may be used if the location at the northwest corner of General Jim Moore Boulevard and Gigling Road cannot be permitted.

USARMY-29 The two-week (10 working days) duration is used as a threshold by some local noise ordinances, based upon the premise that construction noise exposure for less than two weeks is more tolerable (e.g., City of Oakland, Noise Ordinance No. 11895; Ventura County, Construction Noise Threshold Criteria and Control Plan). Text has been added to Section 4.12.2.1 to clarify the basis of this threshold. The purpose of this threshold in the EIR/EIS is to assess the significance of temporary or periodic increases over ambient noise levels that may not be found significant if judged solely in comparison to applicable local noise regulations (i.e., those described in Table 4.12-3 in Section 4.12.3.3). CEQA requires that impacts be assessed using both of these criteria (i.e., temporary and permanent noise increases).

USARMY-30 Both discussions cited by the commenter in Chapter 3 and Section 4.12 confirm that construction of the ASR Recirculation Pipeline, ASR Conveyance Pipeline, and ASR Pump-to-Waste Pipeline would occur during daytime hours. However, the discussion on Draft EIR/EIS pages 4.12-21 and 4.12-28 with regard to construction of the New Transmission Main incorrectly identified only those portions of the New Transmission Main within the City of Marina as assumed to occur during daytime hours. The second paragraph on Draft EIR/EIS page 4.12-21 and the last paragraph on page 4.12-28 of the Draft EIR/EIS have been revised to indicate that construction of the New Transmission Main within areas under U.S. Army jurisdiction (i.e., locations within the City of Seaside) also would occur during daytime hours only.

USARMY-31 New figures 4.12-2 through 4.12-5 have been added to Section 4.12 of the Final EIR/EIS. These figures depict the estimated noise contours associated with proposed 24-hour drilling associated with ASR well construction, consistent with those presented for the nearest receptor on page 4.12-29 of the Draft EIR/EIS.

EIR/EIS Table 4.12-8 presents the construction-related noise associated with construction of the New Transmission Main at the closest sensitive receptors. The data provided in that table are sufficient to draw significance conclusions for New Transmission Main construction for the purposes of CEQA and NEPA, and to require mitigation as described in Impact 4.12-1. In addition, as requested in the comment, the table below presents the construction-related noise associated with daytime-only open trench construction of the New Transmission Main at multiple distances, consistent with those presented for the nearest receptor in Table 4.12-8. As shown below, noise levels at residences greater than 180 feet would not exceed the 70 dBA Leq daytime threshold.

Pipeline (Construction Method)	Closest Sensitive Receptor(s)	Distance to Receptor (feet)[a]	Attenuated Construction Equipment Noise Level at Receptor(s) (dBA L_{eq})[a]
New Transmission Main (Open Trench Construction)	Residences (various)	100	74.0
		150	70.5
		180	68.9
		250	66.0
		400	62.0
		500	60.0
		750	56.5

USARMY-32 The predominant noisy activity associated with the construction of the ASR-5 and ASR-6 wells would be the 24-hour drilling for approximately four weeks. Sound-attenuating curtains can be installed surrounding this activity. Given the nighttime drilling activity and the understandable need to occasionally have windows open, Mitigation Measure 4.12-1e: Offsite Accommodations for Substantially Affected Nighttime Receptors is identified on page 4.12-34 of the Draft EIR/EIS to address this impact to the extent feasible. However, acknowledging the inconvenience associated with temporary re-location, this impact is identified as significant and unavoidable.

Once drilling is complete, other construction activities would occur only during the daytime and would include concrete work, piping, mechanical and electrical work and installation of a control building. These later activities would involve occasional operation of off-road equipment (e.g., forklift or crane) and intensity would be similar to that of construction of a single family home. See response to comment USARMY-22 regarding CalAm's responsibility for obtaining permits.

USARMY-33 Mitigation Measure 4.12-1e, Offsite Accommodations for Substantially Affected Nighttime Receptors, is revised as indicated below to establish an application mechanism based on sound level as opposed to distance:

Mitigation Measure 4.12-1e: Offsite Accommodations for Substantially Affected Nighttime Receptors.

CalAm shall provide temporary hotel accommodations for all residences and any other nighttime sensitive receptors ~~located within 100 feet of a designated construction work area that would~~:

1. <u>That would be</u> exposed to 24-hour <u>project</u> construction activities and
2. Where nighttime construction noise would exceed 60 dBA with windows closed or 35 dBA with windows open, even with implementation of acoustic barriers and/or shielding measures.

The accommodations shall be provided for the duration of 24-hour construction activities. CalAm shall provide accommodations reasonably similar to those of the impacted residents in terms of number of beds and amenities. If identified accommodations do not include typical residential kitchen facilities (e.g., cooktop, oven, full size refrigerator), then CalAm shall provide displaced individuals with a per diem allowance to offset costs of meals for the period of relocation.

See response to comment USARMY-22 regarding CalAm's responsibility for obtaining permits.

USARMY-34 See text revision identified in response to comment USARMY-33 for additional discussion of appropriate accommodations.

USARMY-35 See text revision identified in response to comment USARMY-33 for additional discussion of proportionate accommodations.

USARMY-36 Mitigation Measure 4.12-5, Stationary-Source Noise Controls, provides a performance standard of 60 CNEL at the property lines of nearby residences and other noise-sensitive receptors. This standard is 5 dBA lower than that codified in Section 17.30.060 of the City of Seaside municipal code so as to address impacts related to permanent increases above those existing without the project (Impact 4.12-5). See response to comment USARMY-22 regarding CalAm's responsibility for obtaining permits.

USARMY-37 Table 4.13-1 in Section 4.13, Public Services and Utilities, has been revised to incorporate the requests of this comment. Specifically, columns have been added to address the Presidio of Monterey Fire Department and Presidio of Monterey Police Department. Check marks indicate that the Presidio of Monterey Fire Department serves U.S. Army Lands (including the locations of the proposed New Transmission Main and ASR Pipelines), City of Monterey, City of Seaside, and City of Marina. A check mark also has been added to indicate that the Presidio of Monterey Police Department serves U.S. Army Lands. The requested change to table note "a" has been made.

USARMY-38 The following text has been added to Section 4.13.1.1, Fire Protection, Law Enforcement, and Emergency:

Fire Protection

U.S. Army

The Presidio of Monterey Fire Department serves all Army property on the Ord Military Community and Presidio of Monterey, as well as holding mutual aid agreements with Seaside, Marina, the California State University of Monterey Bay, and the Monterey County Regional Fire District.

Police

U.S. Army

The Presidio of Monterey Police Department serves all Army property on the Ord Military Community and Presidio of Monterey.

USARMY-39 The comment's indication that sewer laterals may exist in the vicinity of the proposed ASR-5 Well is noted. Mitigation Measure 4.13-1a in Section 4.13, Public Services and Utilities, requires CalAm or its contractors to locate all underground utility lines, including sewage, prior to excavation and to highlight these lines on construction drawings. Mitigation Measure 4.13-1b requires that CalAm or its contractors coordinate final construction plans, schedule, and specifications with affected utilities. Exhibit 3 in the U.S. Army's Final Environmental Assessment (EA) and Finding of No Significant Impact (FONSI) (2010) for these ASR well sites depicts an existing sewer line that is located more than 50 feet from the proposed locations of the ASR wells. Nonetheless, if additional utilities are present in this vicinity, the proposed mitigation measures will require that CalAm coordinate with the Army and/or any utility provider in this area prior to construction.

USARMY-40 In response to this comment the following text has been added to the end of Mitigation Measure 4.15-2b, Inadvertent Discovery of Cultural Resources:

> If cultural resources are inadvertently discovered during construction on Army-owned property, work shall immediately cease within a 100-foot radius of the find and the Army, Presidio of Monterey, Cultural Resources Manager (CRM) shall be contacted to assess the discovery. For discoveries on Army lands, the CRM will implement procedures set forth in the Presidio's Integrated Cultural Resources Management Plant (ICRMP) and Army Regulation (AR 200-1), which may include completion of consultation under Section 106 of the National Historic Preservation Act (NHPA) prior to resuming construction in the vicinity of the find. CalAm shall be responsible for completing any additional archaeological work required to comply with federal regulations.

USARMY-41 In response to this comment the following text has been added to the end of Mitigation Measure 4.15-4, Inadvertent Discovery of Human Remains:

> If human remains are encountered during construction on Army-owned property, work shall cease within a 100-foot radius of the discovery and the CRM shall be notified immediately. The CRM shall initially evaluate the site to determine if the remains are either Native American in origin or associated with a recent crime scene (i.e., 50 years old or less). If the remains appear recent, the CRM shall notify the Army's Criminal Investigation Command who shall assume control of the crime scene and custody of the remains. If the remains appear to be Native American in origin, the CRM shall notify the Presidio Garrison Commander and

implement procedures set forth in Section 3 of the Native American Graves Protection and Repatriation Act.

USARMY-42 The alignment for the "new" Transmission Main (see EIR/EIS Section 3.2.3.4) was chosen based on the connection point with existing and proposed ASR wells located in the Santa Margarita sandstone aquifer of the Seaside Groundwater Basin and other factors. The location of the Transmission Main was designed based on the most direct route, avoiding sensitive land uses while also meeting engineering standards for flow requirements based on pressure differences due to elevation changes between the ASR wells and the City of Monterey. This alignment was an alternative to the proposed Transmission Main alignment that was evaluated in the April 2015 Draft MPWSP EIR; the current alignment was determined in the April 2015 Draft EIR to be the environmentally preferred alternative; see also EIR/EIS Section 1.4.4, specifically, Item 2(a) and 2(b). Regarding ASR well location alternatives, see response to comment USARMY-4.

8.3.3 Responses to Comments from Monterey Bay National Marine Sanctuary Advisory Council, Research Activity Panel

MBNMS-RAP-1 Consistent with the requirements of the California Ocean Plan, the dilution analyses completed in support of the EIR/EIS impact assessment assumed zero current speed, representing the worst-case condition in terms of dilution. As described in EIR/EIS Section 4.3, the main environmental parameter relevant for dilution and mixing is the receiving water density structure. The comment presents data demonstrating currents in the vicinity of the diffuser to commonly be 5 to 10 centimeters per second (cm/s) and up to 20 cm/s (by citing: grant OCE0961810; cf. Cheriton et al., 2014; Sevadjian et.al., 2015; Nickols et al., 2012; Walters et al, 2012), and claims such currents could act to transport the brine plume away from the discharge structure more rapidly than occurs through dispersion and mixing alone. The comment urges further analysis in order to determine the effects of fast currents, i.e., whether such transport could result in salinities exceeding the Ocean Plan salinity requirement by causing incremental salinities to exceed 2 parts per thousand (ppt) above ambient conditions within or beyond the Brine Mixing Zone (BMZ) boundary.

Additional dilution analyses have been completed since the publication of the Draft EIR/EIS at the request of the Monterey Regional Water Pollution Control Agency (MRWPCA), in part to support NPDES permitting efforts of the Pure Water Monterey Groundwater Replenishment (GWR) Project. The additional dilution modeling was not required for the EIR/EIS analysis, is consistent with the analysis conducted for the Draft EIR/EIS, and does not change the conclusions of the EIR/EIS with respect to dilution-related impacts. A supplemental dilution analysis report was completed by Dr. Phil Roberts and is presented in Appendix D1 of the Final EIR/EIS. As part of the supplemental analyses and as a result of this comment, Roberts assessed the effect of currents on the dilution dynamics of dense, negatively buoyant discharges.

In the supplemental dilution analysis, Roberts simulated the pure brine discharge scenario (worst case condition due to highest density) at current speeds of 0, 5, 10, and 20 cm/s. Because of the orientation of the MRWPCA diffuser, the predominant current direction is expected to be perpendicular to the diffuser axis. The nozzles are perpendicular to the diffuser, so the current direction relative to the individual jets is either counter-flow (jets directly opposing the current), or co-flow (jets in the same direction as the currents). Simulations were run for both conditions and results were presented for the distance from the diffuser that plumes contact the ocean floor (representing the edge of the Zone of Initial Dilution (ZID)), as well as minimum dilution achieved at the edge of the BMZ. All results were compared to the analyses where current speed was assumed to be zero.

Overall, the effect of the currents is to increase dilution compared to the zero current results. The maximum impact distance (edge of the ZID) from the diffuser would occur with co-flowing currents and increase as the current speed increases. In this case, the maximum impact distance, or edge of the ZID, for currents of 20 cm/s is 27 feet (8.2 meters) with a minimum dilution of 78:1 as compared to 10 feet if zero current is assumed with a minimum dilution of 16:1. Clearly, even with the maximum current assumed, the edge of the ZID (27 feet or 8.2 meters) is much less than the distance to the edge of the BMZ (328 feet or 100 meters). Additionally, although the edge of the ZID is farther from the diffuser compared to the zero current case, the resulting salinities are substantially lower as greater dilution is achieved. It is therefore concluded that assuming zero current is indeed conservative and represents a "worst-case" scenario, and the Ocean Plan regulations would, therefore, be met for all anticipated currents. For a more detailed description of assessment methodology, model assumptions, and detailed results, see the Roberts report presented in Final EIR/EIS Appendix D1.

MBNMS-RAP-2 An EIR for the Pure Water Monterey GWR Project has been prepared and certified, and the project has been approved (see EIR/EIS Section 1.1, and Project No. 59 in Table 4.1-2) by the Monterey Regional Water Pollution Control Agency. That project is independent from the MPWSP, not the subject of this EIR/EIS, and not subject to modification or other decisions based on this EIR/EIS.

The cumulative impact analysis of Alternative 5a presented in each resource section of EIR/EIS Chapter 5.5 includes consideration of the GWR Project (see summary below and Section 5.5 for discussion of cumulative impacts associated with Alternative 5a). Also, the analysis has been structured to facilitate a comparison of impacts – direct, indirect, and cumulative – across the proposed alternatives. As noted in Section 5.6, Environmentally Superior Alternative/ NOAA-Preferred Alternative, because the GWR Project already has been approved and is not subject to any decisions based on this EIR/EIS, "the methodology of choosing the environmentally superior, or agency-preferred alternative, includes … Identifying two environmentally superior/agency-preferred alternatives; one without, and one with the GWR Project" (Draft EIR/EIS pages 5.6-2 and 5.6-3).

The GWR Final EIR concludes that the GWR Project would not result in a significant impact relating to altered salinity dynamics in local lagoon/estuary systems. The GWR Project diversions, including all proposed surface water, urban runoff, and wastewater diversions, were found to not have a significant adverse impact on brackish tidal and wetland habitat in the downstream portions of the watershed. This includes the Salinas River estuary, Old Salinas River channel, Tembladero Slough, Elkhorn Slough, and Moro Cojo Slough

during project operations (as documented on pages 4.5-97 through 4.5-105 and 4.11-71 through 4.11-73 of the Draft GWR EIR, as modified in the Final GWR EIR). Further, the combined GWR diversions from both Salinas River and Tembladero Slough/Reclamation Ditch were determined to result in a less-than significant impact on fisheries and aquatic habitat from the reduction in flows to the downstream coastal sloughs in the area (e.g., Elkhorn Slough), and Moro Cojo Slough.

Changes in salinity dynamics of the Salinas River, Tembladero Slough, Old Salinas River, and Elkhorn Slough estuaries were quantified as part of the environmental assessment presented in the GWR Final EIR. The GWR Project would not divert any flows from the Moro Cojo Slough and would not change the amount of flow into or out of the Moro Cojo Slough (MRWPCA and MPWMD, 2016, page 4.5-107); therefore, Moro Cojo Slough was not assessed and no cumulative impacts on Moro Cojo slough related to salinity dynamics could result from implementation of Alternative 5a.

As stated in the GWR Final EIR with respect to impacts on the Salinas River estuary, "Due to the very small percentage change in total [Salinas River] Lagoon inflows due to the Proposed Project (less than 1%), no measurable salinity changes to the [Salinas River] Lagoon would occur." (MRWPCA and MPWMD, 2016, page 4.5-104)

With respect to GWR project-specific impacts on Tembladero Slough and the Old Salinas River, the GWR Final EIR states:

> There is a potential for increases in salinity near the water surface, and/or longer periods of salinity accumulation in the Tembladero Slough and the OSR [Old Salinas River] Channel before seasonal flushing by winter runoff. …the Proposed [GWR] Project would have a less-than-significant impact on the water quality because the salinity changes would be within the range of salinities that are currently found in these water bodies every year. Species and habitats relying upon the OSR and Tembladero Slough waters have demonstrated their tolerance for high salinity waters. In particular much higher salinity levels (above 15 ppt) are seen during prolonged dry periods, such as late summer and fall of 2013 through 2015. (MRWPCA and MPWMD, 2016, page 4.5-105)

Finally, with respect to GWR project-specific impacts on Elkhorn Slough, the GWR Final EIR states:

> The analysis . . . shows that the Proposed Project would cause less than 0.8% salinity increase at Elkhorn Slough and 0.8% would occur only in a peak event using conservative assumptions such as drought conditions with low tidal influence. On a daily, weekly and monthly average, the Proposed [GWR] Project would cause changes of even less than that amount (i.e., an undetectable change given the wide variations of salinity

> in the slough caused by the tidal cycle each day). Salinity levels (including measurements of electroconductivity and total dissolved solids concentrations), are used as the primary indicator of the relative amounts of freshwater versus saline ocean water in a water body. Thus, the Proposed Project would not result in an adverse impact on the biological resources or other beneficial uses within the Elkhorn Slough. (MRWPCA and MPWMD, 2016, page 4.5-107)

With respect to potential cumulative impacts on salinity dynamics from reduced surface water flow volumes resulting from operation of Alternative 5a in combination with the GWR Project, the MPWSP EIR/EIS acknowledges that Alternative 5a slant well pumping could remove brackish groundwater from the Salinas River recharge system. As discussed in detail in Section 4.4.5 (see Draft EIR/EIS page 4.4-70), when a river gains groundwater from an aquifer, it is called a gaining stream; when it loses groundwater to the aquifer, it is called a losing stream. In the case of the MPWSP, the portion of the Salinas River within the area of influence from the slant well pumping is a gaining stream. Consequently, the slant well pumping could draw in groundwater that would otherwise discharge to the river. In this manner, Alternative 5a would remove groundwater from the Salinas River recharge system and reduce annual river flow volume by 0.11 percent (as compared to 0.16 percent for the MPWSP). However, Alternative 5a (or the proposed project) would not directly pull surface water from the Salinas River; it would intercept groundwater from the seawater-intruded Dune Sands Aquifer that would otherwise have flowed to the River. This magnitude of groundwater diversion from the Salinas River would be a minor, if not unmeasurable, reduction in surface water flows. As described in EIR/EIS Section 5.5.6.8, under the heading "Combined Impacts with GWR Project," the combined reduction in Salinas River flows resulting from Alternative 5a (0.11 percent) and the GWR Project (1 percent) would be a combined cumulative reduction of 1.11 percent of average annual flow.[1] Consistent with the findings of the GWR Final EIR, presented above, this reduction in annual flow would not result in any measurable salinity changes. The same conclusion is applied to Tembladero Slough, where the removal of 47 afy (as compared to 65 afy for the proposed project) of brackish groundwater discharge would not constitute a recognizable loss in surface flow, nor any measurable salinity change, for that system (see Draft EIR/EIS pages 4.6-236 and 5.5-161). Overall, the reduction of surface water attributable to slant well pumping under Alternative 5a would not result in a substantial reduction of surface flows in the Salinas River or Tembladero Slough and, due to the brackish quality, would not measurably

[1] The Draft EIR/EIS stated that the GWR Project would result in a 2 percent reduction in Salinas River Flows (page 5.5-162). The GWR Final EIR states that a 1 percent reduction would occur (MRWPCA and MPWMD, 2016, page 4.5-98). Section 5.5.6.8 in the Final EIR/EIS has been revised to reflect a combined cumulative reduction of 1.11 percent, rather than 2.11 percent.

alter the salinity dynamics of these estuary systems, even when considered in combination with diversions under the GWR Project. Alternative 5a would not affect surface flows in Elkhorn Slough and thus would not contribute to, or combine with, potential effects of GWR on the hydrology or water quality (relevant to salinity dynamics) of Elkhorn Slough.

A full analysis comparing the environmental advantages and benefits of implementing Alternative 5a is presented in detail in EIR/EIS Section 5.6.2 (summarized here). Alternative 5a (in combination with the already approved GWR project) would result in numerous environmental advantages as compared to other alternatives. The EIR/EIS acknowledges in Section 5.6.2 that, as a standalone project, Alternative 5a would not meet the project objectives or purpose and need in terms of providing adequate water supply to the CalAm Service District, but that the combination of Alternative 5a and with the approved GWR would meet project objectives. The cumulative effects of Alternative 5a and GWR may be greater for some of the construction-related impacts (such as air quality, traffic, and noise), and some of the footprint-related impacts (all of the GWR facility footprints plus the footprint of Alternative 5a). However, some of the operational impacts would be reduced compared to the proposed project because the 3,500 afy provided by the GWR Project would require less energy than producing it by desalination, resulting in reduced impacts on GHG and air quality. The reduced capacity desalination plant would require less source water from the slant wells, resulting in a reduction in the severity of the less than significant impacts on groundwater levels, and the GWR project would provide additional irrigation supplies to CSIP that would benefit the groundwater basin. Further, the GWR project would result in benefits relating to water quality, including reducing overall pollutants discharged to Monterey Bay (such as nitrogen), reducing pollutant loads in Clean Water Act 303(d)-listed impaired waters (Salinas River and Monterey Bay), and improving dry season flows and lagoon/estuary system water quality (Monterey One Water, 2017). For these reasons, Alternative 5a was determined to be the environmentally superior/NOAA-preferred alternative.

MBNMS-RAP-3 The Lead Agencies acknowledge and appreciate the Research Activity Panel's offer to review the Mitigation Monitoring, Reporting, and Compliance Plan (MMRCP) and/or Environmental and Construction Compliance Monitoring Plan (ECCMP) (see EIR/EIS Section 4.1.6). These plans will be prepared prior to Lead Agency decisions on the project or an alternative.

MBNMS-RAP-4 The recommendation to consider the scientific information contained in a series of additional scientific studies in the project area that were conducted in 1997 as part of the Fort Ord decommissioning effort is acknowledged. The Lead Agencies have considered these documents, and although the information on marine habitats, their composition, chemistry, and associated marine biota

contained in these studies does not alter the Lead Agencies' understanding or characterization of the Marine Biological Resources baseline in the EIR/EIS, the text describing Benthic (seafloor) Habitats on Draft EIR/EIS page 4.5-8 has been clarified as follows:

> The soft substrate habitat in the study area has been characterized as a flat featureless plain with a gently sloping sandy seafloor (Eittreim et al., 1997). This soft substrate habitat consists primarily of deltaic deposits from the Salinas River and other unclassified soft substrate. Physical processes, such as waves and currents, sort the sediment particles roughly by grain size so that there are onshore-offshore gradients in the fineness of sediments, with coarser sand deposits closer to shore grading to muddy areas farther offshore (Edwards et al., 1997). The sea floor habitat located within the high-energy surf zone is characterized by coarse, mobile sands and contains a limited range and abundance of species commonly including flatfish, rays, shrimp, crabs, sand dollars, amphipods, clams, and large polychaete worms (Edwards et al., 1997). […]

8.3.4 Responses to Comments from United States Army Corps of Engineers

USACE-1 In Section 4.6.2, Regulatory Framework, the Draft EIR/EIS described that wetlands and other waters receive protection under Section 404 of the Clean Water Act and that Section 10 of the Rivers and Harbors Act governs certain activities in navigable waters. The Draft EIR/EIS also specified that the U.S. Army Corps of Engineers (USACE) has primary federal responsibility for administering regulations that concern waters of the U.S. Certain activities that could interfere with navigation may require a Section 10 permit and the discharge of dredge or fill into waters of the U.S. may require a Section 404 permit. Potential project construction and operational impacts on wetlands or waters regulated by the USACE are described in Impact 4.6-3 and Impact 4.6-8, respectively. Several project components have potential to impact waters of the U.S., including potential direct impacts from the new Desalinated Water Pipeline, Castroville Pipeline, and Ryan Ranch-Bishop Interconnection Improvements. Some other project components, including the subsurface slant wells and Source Water Pipeline, would have potential for indirect impacts resulting from construction, such as soil erosion or the inadvertent discharge of toxic construction chemicals resulting in polluted runoff to waters of the U.S. Mitigation measures are proposed under Impacts 4.6-3 and 4.6-8 to address these potential impacts. The type of USACE permit (Nationwide, Individual, or other) would be determined during the permitting process, which is separate from the CEQA/NEPA analysis, and is dependent upon the extent of impacts within USACE jurisdiction. A wetland delineation report has been prepared since publication of the Draft EIR/EIS. It is referenced in Section 4.6 of the Final EIR/EIS as AECOM, 2017, and it was transmitted by CalAm to the USACE on November 7, 2017, with a request for a Preliminary Jurisdictional Determination, but it has not yet been verified by the USACE or other permitting agencies. Since the wetland delineation report concludes that the proposed project could impact less than 0.5 acre of jurisdictional waters of the U.S., it is anticipated the proposed project would qualify for a Nationwide Permit 12 (Utility Line Activity), and an individual permit would not be necessary. If that is the case, a 404(b)(1) alternatives analysis to identify the Least Environmentally Damaging Practicable Alternative (LEDPA) would not be required.

The EIR/EIS analyzes impacts on waters of the U.S. consistent with the requirements of CEQA and NEPA, as described in Section 5.1.1, Alternatives Analysis – CEQA/NEPA Requirements. The alternatives analysis in the Draft EIR/EIS provides adequate information for compliance with CEQA and NEPA guidelines. Table 5.3-4, which is referenced in the comment, presents a preliminary evaluation of intake options for purposes of screening alternatives; this table is not intended to provide detailed impact analysis but provides documentation of the full range of alternatives initially considered. Alternatives carried forward for full analysis are described in Section 5.4 and evaluated, in detail, in Section 5.5. Sections 5.5.6.3 through 5.5.6.8 provide detailed discussions of the impacts of alternatives carried forward for

analysis on biological resources, including waters of the U.S. Please note that the level of detail required for permitting under Clean Water Act Section 404(b)(1) will be developed as part of the permitting process. If an Individual Permit is required, then CalAm would submit an application that complies with the 404(b)(1) Guidelines.

USACE-2 Mitigation Measure 4.6-3 requires that the project be designed to avoid and/or minimize impacts on jurisdictional waters. Where disturbance to jurisdictional waters cannot be avoided, then compensation shall be provided. See response to comment Marina-79, in Section 8.5.1, which describes revisions to this mitigation measure. The revised measure requires that any temporarily impacted jurisdictional waters be returned to pre-construction conditions or better and that compensation for permanent impacts shall be provided at a 2:1 or greater ratio. Providing compensatory mitigation for loss of jurisdictional waters at a ratio of at least 2:1 would ensure consistency with the USACE's program, which supports the national goal of "no overall net loss" of wetlands, and with the USACE's requirement to replace wetlands to offset unavoidable losses.

As described on page 4.6-35 of the Draft EIR/EIS, wetlands or waters potentially regulated by the USACE, RWQCB, and/or CCC were mapped in the project's study area during field surveys conducted in support of the project. As described in response to comment USACE-1, a wetland delineation report, based on some of these field surveys and conducted in accordance with USACE guidance, has been prepared since publication of the Draft EIR/EIS. It was transmitted by CalAm to the USACE on November 7, 2017, with a request for a Preliminary Jurisdictional Determination, but it has not yet been verified by the USACE or other permitting agencies.

8.3.5 Responses to Comments from United States Environmental Protection Agency

USEPA-1 The Lead Agencies acknowledge the USEPA's opinion regarding the adequacy of the evaluation of alternatives and of the North Marina Groundwater Model presented in the Draft EIR/EIS.

USEPA-2 The Lead Agencies acknowledge the USEPA's rating of the preferred alternative as "Lack of Objections."

USEPA-3 Mitigation Measure 4.4-4 has been revised to clarify that CalAm would contact the U.S. Army, USEPA, and other agencies in the event that the extent of 1 foot of drawdown approaches the Fort Ord plumes. The corrective actions would be discussed with these agencies and may include changing the operations of the MPWSP and/or reactivating and/or expanding the existing wells and treatment systems in the former Fort Ord area. A drawdown of 1 foot or less would be unlikely to significantly affect groundwater flow directions again because of the much larger seasonal fluctuations in the Salinas Valley.

Please see clarifications made to Mitigation Measure 4.4-4 regarding CalAm's actions if slant well pumping could intersect or could influence the flow direction of two OUCTP plumes, in response to comment FOBRAC-1 in Section 8.3.1.

USEPA-4 In response to this and other comments on the Draft EIR/EIS, the quoted text in the comment has been deleted from Mitigation Measure 4.11-1 and the measure has been revised as shown below. The proposed Monterey Regional Waste Management District landfill-gas-to-energy (LFGTE) facility Phased Capacity Improvements Project is not part of the proposed project, but is analyzed as a project in the cumulative scenario (see project No. 58 in EIR/EIS Table 4.1-2, Cumulative Projects).

The revised Mitigation Measure 4.11-1 continues to provide that on-site solar photovoltaic (PV) panels may be used to satisfy the net zero operational GHG emissions requirement. In response to this comment, a subsection entitled "Secondary Impacts of Mitigation Measure 4.11-1" has been added to Final EIR/EIS Section 4.11 to address the potential impacts of on-site PV panels. Because it is not yet known which option or options would be implemented (e.g., because the feasibility of the LFGTE project, being evaluated independent of the proposed project, has not yet been determined but may make the use of on-site PV unnecessary or not cost-effective), this option is evaluated at a programmatic level based on a conceptual description of a potential on-site PV installation.

Mitigation Measure 4.11-1: GHG Emissions Reductions Plan.

(a) ***Energy Conservation Technologies.*** CalAm shall have a qualified professional <u>(a licensed mechanical engineer or other appropriately</u>

certified professional approved by the CPUC) prepare and submit a GHG Emissions Reduction Plan (Plan) to the CPUC ~~and the Sanctuary~~ for approval prior to the start of project construction activities. Once approved by the CPUC ~~and the Sanctuary~~, the Plan shall be implemented. The Plan shall include a detailed description of the carbon footprint for all operational components of the approved project (e.g., slant well pumping, the MPWSP Desalination Plant, transmission of source and product water, ASR system) based on manufacturer energy usage specification data for each piece of equipment and the most current ~~PG&E~~ power system emissions factor for GHG emissions based on the energy portfolio of PG&E, the applicable Electric Service Provider under Direct Access service, or Monterey Bay Community Power and its successors and assigns, as applicable.

The Plan shall include a summary of state-of-the-art energy recovery and conservation technologies available for utility scale desalination facilities and shall include a commitment by CalAm to incorporate all available feasible energy recovery and conservation technologies; or, if CalAm finds that any of the technologies will not be feasible for the project, the Plan shall clearly explain why such technology is considered to be infeasible. The carbon footprint estimate for the project shall include consideration of all proposed energy recovery and conservation technologies that will be employed by the project, and shall describe the approximate GHG emissions reductions that will be associated with each technology.

(b) ***Renewable Energy.*** CalAm shall ~~make good faith efforts to ensure that at least 20 percent of the approved project's operational energy use requirements are achieved with "clean" renewable energy, including but not necessarily limited to: the use of methane gas from the existing Monterey Regional Waste Management District (MRWMD) landfill-gas-to-energy (LFGTE) facility located adjacent to the MPWSP Desalination Plant site; and installation of solar photovoltaic (PV) panels at or adjacent to the desalination plant. The carbon footprint estimate for the project shall include consideration of all renewable energy that would directly be available and used by the project in the form of kilowatt hours per year, and shall describe the approximate GHG emissions reductions that will be associated with the use of the renewable energy.~~ ensure that the approved project's operational electricity use results in net zero GHG emissions. In meeting this net zero GHG emissions requirement, subject to the procedures below, CalAm shall adhere to the following loading order:

(1) Obtain renewable energy from on-site solar photovoltaic (PV) panels and/or the adjacent Monterey Regional Waste Management District (MRWMD) landfill-gas-to-energy (LFGTE) facility. If renewable energy from the LFGTE facility is secured, CalAm must demonstrate that the associated criteria pollutant emissions, when combined with the other operational criteria pollutant emissions disclosed in EIR/EIS Table 4.10-7, would not exceed the Monterey Bay Air Resources District significance thresholds.

(2) Procure renewable energy from off-site sources within California via purchases from one or more of the following: (a) PG&E, (b) an Electric Service Provider under Direct Access service, or (c) Monterey Bay Community Power and its successors and assigns.

(3) Procure and retire Renewable Energy Certificates (also known as RECs, green tags, Renewable Energy Credits, Renewable Electricity Certificates, or Tradable Renewable Certificates) for projects or activities in California.

(4) Procure and retire Carbon Offsets, in a quantity equal to the GHG emissions attributable to the project's operational electricity use. "Carbon Offset" means an instrument issued by an Approved Registry and shall represent the past reduction or sequestration of one metric ton of CO_2e achieved by any GHG emission reduction project or activity within California. "Approved Registry" means: (i) the Climate Action Reserve, the American Carbon Registry, the Verified Carbon Standard, or the Clean Development Mechanism; or (ii) any other entity approved by the California Air Resources Board to act as an "offset project registry" under the state's Cap-and-Trade Program.

CalAm may meet this net zero GHG emissions requirement via any of the options, or their future equivalents, or any combination of options, or their future equivalents, included in the aforementioned loading order.

Further, CalAm shall progress through the loading order on the basis of the options' physical and economic feasibility, as reasonably determined by CalAm, with low-cost options preferred over high-cost options. In the event that options have equivalent costs, options enumerated earlier in the loading order shall be selected by CalAm over options enumerated later in the loading order. On or before June 1 of each year the approved project is in operation, CalAm shall submit documentation to the CPUC demonstrating that the project's operational electricity use in the immediately preceding calendar year resulted in net zero GHG emissions. Calculation of the GHG emissions attributable to the project's operational electricity use (if any) shall be calculated by CalAm on an annual basis using the most up-to-date emissions coefficient for purchased electricity (if any), as compiled or published by PG&E, the applicable Electric Service Provider under Direct Access service, or Monterey Bay Community Power and its successors and assigns, as applicable. If the CPUC determines that CalAm failed to achieve net zero GHG emissions for the approved project's operational electricity use for a particular year, then the CPUC shall notify CalAm in writing of the exceedance within 45 days of receipt of the documentation submitted by CalAm under this mitigation measure. The notice shall specify the metric tons of GHG emissions that exceeded the net zero obligation. Within 45 days of receipt of this notice, CalAm shall procure and retire Carbon Offsets in an amount at least equivalent to the exceedance, and will submit documentation to the CPUC demonstrating this procurement and retirement.

USEPA-5 For the purposes of the Draft EIR/EIS analysis, temporarily impacted areas include those areas that would be returned to pre-project conditions following construction and permanently impacted areas include those areas that would be permanently lost following construction. The discussion in Impact 4.6-3 describes any temporary or permanent impacts on wetlands or waters. For example, in the discussion for the New Desalinated Water Pipeline on Draft EIR/EIS page 4.6-212 states, "Riparian woodland and scrub at Locke-Paddon Park and near the intersection of Marina Green Drive and Del Monte Boulevard are potential waters of the U.S./waters of the state. Pipeline installation activities could temporarily impact 0.42 acre of riparian woodland and scrub." As part of the permitting process, CalAm would apply for a Clean Water Act Section 404 permit and/or a Rivers and Harbors Act Section 10 permit from the U.S. Army Corps of Engineers (USACE). The evaluation of impacts as defined by the USACE would be determined during that permitting process, which is separate from this CEQA/NEPA analysis.

In response to this comment, the following change has been made to Impact 4.6-3 on Draft EIR/EIS page 4.6-209:

> Direct impacts on those wetlands could include removal of vegetation, soil, or structures and/or the placement of fill in the wetland/other water, or hydrological modifications (i.e., altering the flow of water in or out of the wetland or water). Temporarily impacted areas include those areas that would be returned to pre-project conditions following construction. Permanently impacted areas include those areas that would be permanently lost following construction.

RE: Comments on Draft Environmental Impact Report ("DEIR") / Draft Environmental Impact Statement ("DEIS") for proposed Monterey Peninsula Water Supply Project

Dear Ms. Borak and Ms. Grimmer:

Thank you for the opportunity to provide comments on the above-referenced document regarding the proposed Monterey Peninsula Water Supply Project. The proposed project would provide a water supply for the California-American Water Company's ("Cal-Am's") service area in the Monterey Bay area. It would produce drinking water using a seawater desalination facility obtaining source water from slant wells to be constructed along the Monterey Bay shoreline in the City of Marina and would discharge a high-salinity effluent through an existing wastewater outfall being used by the Monterey Regional Water Pollution Control Authority. The produced water would be transported through a distribution system of pipelines and associated infrastructure to be built within several jurisdictions in the Monterey Bay area.

The proposed project will require several permits and approvals, including coastal development permits ("CDPs") from several nearby local jurisdictions and from the Coastal Commission for proposed development within the Commission's retained jurisdiction. Coastal Commission staff is currently coordinating its project review with other state agencies, and we expect to conduct a full review of the project's conformity to relevant Coastal Act policies and requirements upon Cal-Am's submission of its CDP application to the Commission.

We reviewed key sections of this DEIR/DEIS related to issues of conformity to Coastal Act policies and we have just a few brief comments:

- Use of subsurface intakes: We concur with the use of subsurface intakes where feasible as a means to avoid and minimize adverse effects on marine life. We commend the project applicant for selecting a subsurface method for its proposed project. CCC-1

- Environmentally sensitive habitat areas: The document's *Section 4.6 – Terrestrial Biological Resources* identifies the upland area proposed for the project's slant wells as "primary habitat" under the City of Marina's Local Coastal Program designation. This designation applies to areas that provide habitat for rare, endangered, or threatened plant and animal species or habitat that is necessary for the survival of an endangered species. Allowable CCC-2

types of development allowed within these areas are extremely limited and must be designed and sited to minimize habitat impacts. We recommend the Final EIR thoroughly evaluate and consider alternatives that would fully avoid or minimize habitat impacts within areas designated as primary habitat.

CCC-2 cont.

Again, thank you for the opportunity to comment, and please let me know if you have any questions.

Sincerely,

Tom Luster

Subject: Draft Environmental Impact Report /Environmental Impact Statement (DEIR/EIS) for the CalAm Monterey Peninsula Water Supply Project (MPWSP), State Clearinghouse No. 2006101004

Dear Ms. Borak and Ms. Grimmer:

The Department of Fish and Wildlife (CDFW) is in receipt of the Draft Environmental Impact Report/Environmental Impact Statement (DEIR/EIS) for the California-American Water Company (CalAm) Monterey Peninsula Water Supply Project (Project). A past Draft EIR for the Project was issued on April 30, 2015 by the California Public Utilities Commission (CPUC), for which CDFW submitted a comment letter dated June 30, 2015.

The purpose of the proposed Project is to develop up to 9,752 acre-feet per year (afy) of water supplies to meet, in conjunction with other existing sources of supply, a future average annual demand of 15,296 afy in CalAm's Monterey District service area (Monterey District). The Project would be constructed to replace those portions of CalAm's existing supplies that have been constrained by legal decisions regarding CalAm's diversions from the Carmel River and pumping from the Seaside Groundwater Basin. The proposed Project would produce desalinated water, convey it to the existing CalAm distribution system, and increase the system's use of storage capacity in the Seaside Groundwater Basin. The Project would consist of several components: a seawater intake system; a desalination plant; a brine discharge system; product water conveyance pipelines and storage facilities; and an aquifer storage and recovery (ASR) system. CalAm also proposed a variant to the proposed Project that would combine a

reduced-capacity desalination plant and all other facilities included in the proposed Project, with a water purchase agreement from the Monterey Regional Water Pollution Control Agency's (MRWPCA) proposed Pure Water Monterey Groundwater Replenishment (GWR) project. The Project area extends approximately 14 miles, from the MPWSP Desalination Plant site located in unincorporated Monterey County in the north to the western terminus of the proposed Monterey Pipeline in the City of Pacific Grove, and east approximately eight miles to the unincorporated community of Hidden Hills along Highway 68.

The Project area includes habitat for State and federally listed species, State fully protected species, and State species of special concern including, but not limited to, the following: Federally threatened and State species of special concern Western snowy plover (*Charadrius alexandrines nivosus*), State and federally threatened California tiger salamander (*Ambystoma californiense*), federally threatened and State species of species of special concern California red-legged frog (*Rana draytonii*); the State endangered seaside bird's-beak (*Cordylanthus rigidus var. littoralis*), beach layia (*Layia carnosa*), Tidestrom's lupine (*Lupinus tidestomii*), and Menzies' wallflower (*Erysimum menziesii*); the State threatened Monterey gilia (*Gilia tenuiflora ssp. arenaria*); and the State rare Pacific Grove clover (*Trifolium polyodon*) and Dudley's lousewort (*Pedicularis dudleyi*). Several other State and federally listed species, State fully protected species, and State species of special concern have the potential to occur within the Project as well including sensitive plants, amphibians, marine mammals, and nesting bird species. Additionally, the Project area supports sensitive habitat types such as coastal wetlands, dune scrub, maritime chaparral, Monterey pine forest, and potentially other habitat types which are considered sensitive by CDFW. CDFW-1

As stated in its prior comments regarding the Draft EIR, CDFW has concerns about the Project-related impacts to the sensitive habitats that are adjacent to or within the Project alignment, as well as the associated impacts to species that utilize habitats found in the Project area. Project-related impacts to these special status biological resources should be evaluated and addressed prior to Project implementation, in order to comply with State laws described below.

Department Jurisdiction

Trustee Agency Role: CDFW is a Trustee Agency with the responsibility under the California Environmental Quality Act (CEQA) for commenting on projects that could impact plant and wildlife resources. Pursuant to Fish and Game Code Section 1802, CDFW has jurisdiction over the conservation, protection, and management of fish, wildlife, native plants, and habitat necessary for biologically sustainable populations of those species. As a Trustee Agency for fish and wildlife resources, CDFW is responsible for providing, as available, biological expertise to review and comment on environmental documents and impacts arising from project activities, as those terms are used under CEQA.

Responsible Agency Role: CDFW is a Responsible Agency when a subsequent permit or other type of discretionary approval is required from CDFW, such as an Incidental Take Permit (ITP), pursuant to the California Endangered Species Act (CESA), or a Lake and Streambed Alteration Agreement (LSAA) issued pursuant to Fish and Game Code Sections 1600 *et seq*.

CDFW has regulatory authority over projects that could result in the "take" of any species listed by the State as threatened or endangered, or designated as a candidate for listing, pursuant to Fish and Game Code Section 2081. If the Project could result in the take of any species pursuant to CESA, CDFW may need to issue an ITP for the Project. CEQA requires a Mandatory Finding of Significance if a project is likely to substantially impact threatened or endangered species (Sections 21001(c), 21083, Guidelines Sections 15380, 15064, 15065). Impacts must be avoided or mitigated to less than significant levels unless the CEQA Lead Agency makes and supports Statement of Overriding Consideration (SOC).

The CEQA Lead Agency's SOC does not eliminate the Project proponent's obligation to comply with CESA. In other words, compliance with CESA does not automatically occur based on local agency project approvals or CEQA compliance; consultation with CDFW is warranted to ensure that Project implementation does not result in unauthorized take of a State-listed species.

Incidental take authority is required prior to engaging in lawful take of any plant or animal species listed under CESA. Plants listed as threatened or endangered under CESA cannot be addressed by methods described in the Native Plant Protection Act. No direct or indirect disturbance, including translocation, may legally occur to State-listed species prior to the applicant obtaining incidental take authority in the form of an ITP.

Permit Streamlining: Issuance of an LSAA or an ITP by CDFW is considered a "project" (CEQA Guidelines Section15378) and is subject to CEQA. CDFW typically relies on the Lead Agency's CEQA compliance to make its own findings. For the Lead Agency's CEQA document to suffice for permit/agreement issuance, it must commit to fully describing the potential Project-related impacts to stream/riparian resources and listed species, as well as measures to avoid, minimize, and mitigate impacts to these resources. Take of State-listed species must be "fully mitigated" in order to comply with CESA (California Fish and Game Code Section 2081(b)(2)). If the CEQA document issued by the California Public Utilities Commission (CPUC) for this Project does not adequately analyze impacts to resources that require permits issued by CDFW, CDFW may need to act as a Lead CEQA Agency and complete a subsequent CEQA document. This could significantly delay permit issuance and, subsequently, Project implementation. For that reason, it is very important that the EIR reflect suitable and feasible avoidance, minimization, and compensatory mitigation, such that CDFW is able to make findings per CEQA necessary for ITP issuance. In addition, CEQA grants Responsible Agencies authority to require changes in a Project to lessen or avoid

effects of that part of the Project which the Responsible Agency will be called on to approve (CEQA Guidelines Section 15041).

Bird Protection: CDFW has jurisdiction over actions that may result in the disturbance or destruction of active nest sites or the unauthorized take of birds. Sections of the Fish and Game Code that protect birds, their eggs and nests include sections 3503 (regarding unlawful take, possession or needless destruction of the nest or eggs of any bird), 3503.5 (regarding the take, possession or destruction of any birds-of-prey or their nests or eggs), and 3513 (regarding unlawful take of any migratory nongame bird).

Biological Information: As required by CEQA, the DEIR/EIS should clearly identify resources on the Project site and their potential to be impacted by the proposed Project; analyze potential impacts as to their significance; and identify measures to reduce all potentially significant impacts to a level of less-than-significant. Impact analysis should be predicated on complete biological surveys. Measures and alternatives that would avoid and minimize potential impacts to resources of concern, as well as on-site conservation measures, should be considered prior to measures and alternatives that would provide for compensatory resources on or off-site.

Specific Biological Resources Comments and Recommendations

Botanical Inventory: There is the potential for sensitive plant species to occur within the Project area. Botanical surveys are recommended to be conducted prior to Project activities and be performed in accordance with guidelines developed by CDFW (DFG, 2009; https://nrm.dfg.ca.gov/FileHandler.ashx?DocumentID=18959&inline) and the United States Fish and Wildlife Service (USFWS) (USFWS, 2000; https://www.fws.gov/sacramento/es/Survey-Protocols-Guidelines/Documents/Listed_plant_survey_guidelines.PDF)
. Botanical surveys are floristic in nature and must be timed appropriately and cover the entire Project area and may require multiple surveys in order to detect all species which could potentially be present on the property before impact analysis occurs. The above referenced guidelines instruct the use of reference sites to confirm appropriate survey timing, particularly for seasonably variable, often difficult to detect species. CDFW is aware that extensive botanical surveys have been conducted including analysis of reference populations, but would like to reiterate that environmental conditions have not been favorable towards plant species in the last few years during the unprecedented drought, and as a result sensitive plant populations may have not expressed themselves adequately for detection and identification during surveys. CDFW-2

Special Status Plants: As previously mentioned, State-listed plant species that are known to occur within the Project area and may occur within the Project alignment include seaside bird's-beak, Menzies' wallflower, Monterey gilia, beach layia, Pacific Grove clover. and Tidestrom's lupine. Based on botanical surveys, the DEIR/EIS discloses the potential impacts that the Project may have on listed plants and provides measures to mitigate for potential impacts to those plants. Due to the potential for CDFW-3

State-listed plants to occur within the Project alignment, consultation with CDFW is strongly recommended to determine if the Project can avoid take. If take cannot be avoided, acquisition of a State ITP from CDFW prior to Project implementation is warranted to comply with CESA.

For information regarding ITPs please see the following link: http://www.dfg.ca.gov/habcon/cesa/. Included in the ITP would be measures required to avoid and/or minimize direct take of State listed plants on the Project site, as well as measures to fully mitigate the impact of the take. CDFW would like to work with the CPUC, CalAm, and USFWS to identify measures which could be included as conditions of approval prior to CEQA certification.

CDFW-3 cont.

As noted in CDFW's June 30, 2015 letter for the Draft EIR, Mitigation Measure 4.6-1(e) in the DEIR/EIS discusses the restoration and reintroduction of sensitive plants as a result of Project impacts including the development of a Habitat Mitigation and Monitoring Plan (Mitigation Measure 4.6-1n). The reintroduction of sensitive plant species that may be impacted by the Project is typically not recommended for species associated with the sensitive habitats found in the Project area. Rare plants are restricted to a specific micro habitat that is suitable for their establishment and persistence. Reintroducing sensitive plant species outside of their existing habitat may not be successful, and relocation into habitat that is already occupied by these species could ultimately be detrimental to the existing population. No evidence is provided that such measures would be successful. Studies that followed the success or failure of permits issued by CDFW for various plant species have shown that success (including partial success) is less than 15% overall, for all species. Success for annual plant species is even less over the long term. With no information regarding the potential for success of reintroduction and relocation of these sensitive plants, reliance on reintroduction and relocation as the primary measure to mitigate for the impact of the take of the populations on the Project site would not meet ITP issuance criteria to fully mitigate the take of these species and may not be sufficient to reduce the impact to less than significant if the restoration and reintroduction fails. CDFW recommends that the Project be designed to substantially avoid impacts to sensitive plant species, and any residual impacts mitigated by conservation of occupied habitat at a rate of at least 2 to 1 in addition to habitat restoration. CDFW recommends Restoration success criteria include the restored population having greater than the number of individuals of the impacted population(s), in an area greater than or equal to the size of the impacted population(s), for at least 3 consecutive years without irrigation, weeding, or other manipulation of the restoration site.

CDFW-4

State Listed Rare Plants: Section 4.6.2.2 State Regulations of the DEIR/EIS discusses information regarding State rare plants. Previously, State rare plants were similar to fully protected species because CDFW had no method to authorize take. Recent legislation has included take of State rare plant species under the incidental take authority of CDFW, and CDFW now has the mechanism to permit take of State rare plants under CCR Title 14, Section 786.9(b) using the same procedures and under

CDFW-5

the same conditions as take authorizations issued pursuant to Section 2081 of Fish & Game Code (please see CCR Title 14, Section 786.9), effective January 1, 2015 (http://www.fgc.ca.gov/regulations/2014/index.aspx#786_9). If take of the State rare species Pacific Grove clover is proposed as a result of the Project, an ITP from CDFW to authorize take is warranted. In the DEIR/EIS, CDFW also recommends that Pacific Clover be moved from the sub-heading of Other Special-Status Species to the sub-heading Federal or State Listed Species due to its State rare listing.

CDFW-5 cont.

Nesting Birds: The trees, shrubs, and grasses within and in the vicinity of the Project site likely provide nesting habitat for songbirds and raptors. CDFW encourages Project implementation to occur during the non-nesting bird season; however, if ground-disturbing activities must occur during the breeding season (February through mid-September), the Project applicant is responsible for ensuring that implementation of the Project does not result in any violation of the Migratory Bird Treaty Act or relevant Fish and Game Codes as referenced above. Prior to work commencing, including staging, clearing, and grubbing, CDFW recommends that surveys for active nests be conducted by a qualified wildlife biologist no more than 10 days prior to the start of the Project commencing and that the surveys be conducted in a sufficient area around the work site to identify any nests that are present and to determine their status. A sufficient area means any nest within an area that could potentially be affected by the Project. In addition to direct impacts, such as nest destruction, nests might be affected by noise, vibration, odors, and movement of workers or equipment. CDFW recommends that identified nests be continuously surveyed for the first 24 hours prior to any construction related activities to establish a behavioral baseline, and once work commences, for all nests to be continuously monitored to detect any behavioral changes as a result of the Project. If behavioral changes are observed, CDFW recommends that the work causing that change cease and CDFW consulted for additional avoidance and minimization measures.

CDFW-6

If continuous monitoring of identified nests by a qualified wildlife biologist is not feasible, CDFW recommends a minimum no-disturbance buffer of 250 feet around active nests of non-listed bird species and a 500 foot no-disturbance buffer around the nests of unlisted raptors until the breeding season has ended, or until a qualified biologist has determined that the birds have fledged and are no longer reliant upon the nest or parental care for survival. Variance from these no disturbance buffers may be implemented when there is compelling biological or ecological reason to do so, such as when the Project area would be concealed from a nest site by topography. Any variance from these buffers is advised to be supported by a qualified wildlife biologist and it is recommended CDFW be notified in advance of implementation of a no-disturbance buffer variance.

Burrowing Owl: The Project site may be occupied by burrowing owls. CDFW recommends following the preconstruction survey methodology developed by the California Burrowing Owl Consortium (CBOC, 1993;

CDFW-7

https://nrm.dfg.ca.gov/FileHandler.ashx?DocumentID=83842) if the site contains burrows that could be used by burrowing owls. CDFW recommends that impacts to occupied burrows be avoided in accordance with the following table unless a qualified biologist approved by CDFW verifies through non-invasive methods that either: 1) the birds have not begun egg laying and incubation; or 2) that juveniles from the occupied burrows are foraging independently and are capable of independent survival. The below table can be found from the Burrowing Owl Staff Report (CDFG 2012; https://nrm.dfg.ca.gov/FileHandler.ashx?DocumentID=83843&inline).

Location	Time of Year	Level of Disturbance		
		Low	Med	High
Nesting sites	April 1-Aug 15	200 m*	500 m	500 m
Nesting sites	Aug 16-Oct 15	200 m	200 m	500 m
Nesting sites	Oct 16-Mar 31	50 m	100 m	500 m

* meters (m)

The Staff Report recommends that foraging habitat be acquired and permanently protected to offset the loss of foraging and burrow habitat. CDFW also recommends replacement of occupied burrows with artificial burrows at a ratio of one burrow collapsed to one artificial burrow constructed (1:1) as mitigation for the potentially significant impact of evicting a burrowing owl if a biologist knowledgeable with the biology and natural history of the species determines that suitable burrows are a potential limiting factor for burrowing owl. If the Project proposes to evict burrowing owls that may be present, CDFW recommends passive relocation during the non-breeding season. CDFW recommends that the CEQA document prepared for this Project describe methods that would be used to evict owls from burrows, including a monitoring program to ensure that evicted individuals are using a relocation site.

CDFW-7 cont.

California Tiger Salamander (CTS): CTS are known to occur within the Planning Area and may occur within the Project alignment. The DEIR/EIS is advised to clearly disclose the potential impacts that the Project may have on CTS and provide measures to mitigate for all potential impacts to CTS. CDFW recommends that a site assessment and protocol level surveys be conducted for CTS because of known occurrences of CTS in the Project vicinity and aquatic features that may be CTS breeding habitat, identified adjacent to the Project site. CDFW recommends that surveys for this species follow current United States Fish and Wildlife Service (USFWS) protocol methods. Survey guidance can be found at: https://nrm.dfg.ca.gov/FileHandler.ashx?DocumentID=83915.

CDFW-8

The results of the site assessment and protocol level surveys for CTS can then be utilized to evaluate the potential for impacts to the species which would be analyzed by the CPUC in the CEQA document, as well as to determine the potential for take to occur. If the Project has the potential to result in take of this species, take authorization from CDFW in the form of an ITP, pursuant to Fish and Game Code Section 2081(b),

would be required prior to Project implementation, to comply with Fish and Game Code. In the absence of protocol surveys, the applicant can assume presence of CTS within the Project area and obtain an ITP. Impacts related to the permitted taking of CTS must be minimized and fully mitigated in order for CDFW to issue an ITP.

DEIR/EIS Mitigation Measure 4.6-1o provides avoidance and minimization measures for CTS and California red-legged frog (CRLF). The mitigation measure discusses options to relocate CTS and CRLF if identified during preconstruction surveys or ground disturbing activities. It also discusses installation of exclusion fencing where there is a moderate to high potential for CTS and CRLF to occur as specified in Mitigation Measure 4.6-1c. Please be advised that preconstruction surveys are not an appropriate time to detect presence/absence of CTS for which an ITP may be warranted. Also, handling and relocating CTS and installation of exclusion fencing in occupied CTS habitat without an ITP would be a violation of Fish and Game Code and CESA. If the Project does not complete the above recommended CTS surveys and chooses not to acquire an ITP, CDFW recommends that all small mammal burrows within dispersal distance of a known or potential breeding pond be avoided by a minimum buffer of 50 feet to avoid take of CTS. CDFW-8 cont.

Avoidable Wildlife Impacts from Erosion Control Mesh Products: Due to this Project site's extensive wildlife habitat interface, CDFW requests that erosion control and landscaping specifications allow only natural-fiber, biodegradable meshes and coir rolls. "Photodegradable" and other plastic mesh products have been found to persist in the environment, ensnaring and killing terrestrial wildlife. Reptile and amphibian deaths resulting from the use of plastic mesh products are well-documented. Plastic mesh erosion control products would likely cause unanticipated, avoidable impacts, including the potential take of special status species. CDFW believes requiring the use of biodegradable products would be a feasible mitigation measure to reduce impacts to wildlife species. CDFW-9

USFWS & NOAA Consultation: As stated previously, CDFW recommends consultation with the USFWS prior to any ground disturbance related to this Project due to potential impacts to federally listed species. Take under the Federal Endangered Species Act (FESA) is more stringently defined than under CESA; take under FESA may also include significant habitat modification or degradation that could result in death or injury to a listed species, by interfering with essential behavioral patterns such as breeding, foraging, or nesting. Consultation with the USFWS and NOAA in order to comply with FESA is advised well in advance of Project implementation. CDFW-10

Thank you for the opportunity to comment on the DEIR/EIS. CDFW is available to consult with the CPUC regarding potential effects to fish and wildlife resources, as well as specific measures that would mitigate potential effects of the Project. Depending upon the results of the actual Project site configuration, and other details which should be disclosed in the DEIR/EIS, CDFW may have additional comments and recommendations regarding avoidance, minimization, and mitigation of Project impacts

to habitat and special status species. If you have any questions regarding these comments, please contact Annette Tenneboe, Senior Environmental Scientist (Specialist), at (559) 243-4014, extension 227 or by e-mail at annette.tenneboe@wildlife.ca.gov. If you have specific questions in regards to marine biological resources, please contact Marine Region staff Steve Rienecke, Environmental Scientist, by telephone at (805) 594-6174 or by email at Steven.Rienecke@wildlife.ca.gov.

Sincerely,

Julie A. Vance

Subject: Monterey Peninsula Water Supply Project EIR Comments

In response to the request for comments on the Draft Environmental Impact Report/Environmental Impact Statement for the Monterey Peninsula Water Supply Project, California State Parks has prepared the following comments.

1. PRC 5001.65 states commercial exploitation of resources in units of the State Park system is prohibited. Taking of the State Park land for a municipal water system is not appropriate and is not conducive to our mission statement, which is to provide for the health, inspiration and education of the people of California by helping to preserve the state's extraordinary biological diversity, protecting its most valued natural and cultural resources, and creating opportunities for high-quality outdoor recreation. CA Parks-1

2. Regarding the construction of Transmission Main Pipeline, the EIR states on page 4.8-16 that it will "traverse an approximately .25 band of Fort Ord Dunes State Park lands between Divarty Street/1st Street and the alignments' Highway 1 undercrossing near Lightfighter Drive". Please clarify what a .25 band is and provide more information and detailed maps of these areas that depict the limits of State Park land needed. CA Parks-2

3. Any easements needed will require approval and close coordination with California State Parks. Impacts to park resources shall be repaired and replaced in-kind and any vegetation removed shall be replaced with native plants sourced from the area. CA Parks-3

4. Regarding construction and placement of Transmission Main Pipeline near First Street in Fort Ord, work shall be coordinated with California State Parks as the utilities for the planned Fort Ord Dunes State Park campground will be installed in this area. Construction may also conflict with campground construction and public access at 1st Street construction site. The acquisition of utility easements from our office regarding these activities will be required. Please coordinate well in advance as the easement process can take up to two years to process. Parking lot maintenance and or road agreements may also need to be negotiated. CA Parks-4

5. In the event any Desal appurtenances were to be built within State Park ownership, easement, rights-of-entry (ROE) and lease negotiations shall be prepared and approved well in advance of any work commencing on State Park property. Easements and leases may take up to two years to negotiate and execute. Leases, ROEs and/ or easements may include reimbursements to State Parks for processing these requests, including staff time processing any CEQA compliance or coastal development permits. Lease negotiations, if approved, may include, but not be limited to, assessing revenue fee structures for Desal facilities placed on public lands. Easements, if granted, will need to be appraised using the Department of General Services Appraisal Guidelines and be accompanied by legal descriptions approved by our survey staff. CA Parks-5

6. The following comments pertain to Options in the EIR that occur on State Park property (Intake Option 3 – Subsurface Slant Wells at Potrero Road, Intake Option 4 – Open-Water Intake at Potrero Road, Outfall Option 3 – New Outfall at Potrero Road, Alternative 1 – Slant Wells at Potrero Road, Alternative 5b – Reduced Project 6.4-mgd, Desalination Plant (Intake Slant Wells at Potrero Road).

a. The construction and placement of these facilities in a state beach is not in compliance with the State's Public Resources Code or compatible with our mission statement. If natural resource and recreational public land is condemned for private purposes, approvals, easements and fees shall be negotiated with California State Parks for the use of state lands for the installation of permanent desalinization facilities and associated appurtenances located within State Park lands. CA Parks-6

b. Operation and maintenance of facilities shall not degrade or otherwise compromise coastal sand dune habitat, snowy plover habitat or inhibit public beach access or recreation. Subterranean intake pump vaults and resulting vibrations through the sand column within snowy plover habitat should be studied prior to FEIR certification and project approval to understand what impacts may occur. This activity may trigger a need for an incidental take permit from the US Fish and Wildlife Service. Impacts to Western Snowy Plovers during the construction, operation and maintenance, including impacts from noise and vibration, need to be thoroughly observed and analyzed and the results of any studies made available to State Parks. California State Parks may require compensation for plover monitoring each year during the breeding season for at least 5 years and mitigation of any lost native vegetation at a replacement ratio of 3:1. Improvements such as paving and maintenance to the impacted parking lots may also be required by State Parks. Any utility lines proposed for installation would need to be installed underground so as not to become perches for avian predators. CA Parks-7

c. The proposed alternatives will include municipal scale infrastructure improvements which are not specifically identified. Construction of municipal water processing facilities in the proposed State Park land is not compatible with the local coastal plan CA Parks-8

that protects coastal values or the mission of State Parks. Items such as pumps, electrical service, maintenance facilities, discharge drains for maintenance, equipment housing, underground vaults, vehicle parking, control panels, access manholes, and any above ground features are in conflict with the natural and rural setting in the park. Currently there are no permanent facilities of the type proposed in the park. The parking lot is unpaved and there are no utilities (water, sewer, electrical, or communication) to the site. There are no flush toilets at the site.

CA Parks-8 cont.

d. Another issue is the use of the parking lot for anything other than coastal access. This site is only one of the few coastal access points for the public in this segment of the Monterey coast and State Parks is unlikely to be able to build additional parking due to the sensitive nature of the surrounding lands. Any Desal related appurtenances shall not interfere with public access parking and shall not impinge upon or take coastal dune habitat.

CA Parks-9

e. Visual impacts are also another concern, where the proposed use may involve the need for security fences and lights around fixtures. All areas that are fenced will require landscaping and all lighting will require light shields that do not illuminate adjacent coastal sand dune habitat.

CA Parks-10

f. Water production, noise and vibration impacts, and discharges of any kind are prohibited.

CA Parks-11

If you have any questions regarding these comments, please do not hesitate to contact me at (831) 649-2862 or Stephen.bachman@parks.ca.gov

Sincerely,

Stephen Bachman

Subject: Draft Environmental Impact Report/Environmental Impact Statement (EIR/EIS) for the Monterey Peninsula Water Supply Project, Monterey County

Dear Ms. Borak:

The California State Lands Commission (CSLC) staff has reviewed the subject Draft EIR/EIS for the Monterey Peninsula Water Supply Project (Project), which is being prepared by the California Public Utilities Commission (CPUC) and the Monterey Bay National Marine Sanctuary (MBNMS). The CPUC is the lead agency under the California Environmental Quality Act (CEQA) (Pub. Resources Code, § 21000 et seq.), because it is considering issuance of a Certificate of Public Convenience and Necessity to the California American Water Company (CalAm) pursuant to Public Utilities Code section 100. MBNMS is the lead agency under the National Environmental Policy Act (NEPA) (42 U.S.C. § 4321 et seq.) as portions of the Project fall within its jurisdiction. The CSLC is a trustee agency for projects that could directly or indirectly affect sovereign lands and their accompanying Public Trust resources or uses. Additionally, because the Project involves work on sovereign lands, the CSLC will act as a responsible agency.

CSLC staff previously commented on the Notice of Preparation for the Project in a letter dated November 8, 2012, and the previous Draft EIR, in a letter dated September 30, 2015 (enclosed). In September 2015, the CPUC announced that the Draft EIR would be modified and recirculated as a joint EIR/EIS in coordination with MBNMS.

CSLC Jurisdiction and Public Trust Lands

The CSLC has jurisdiction and management authority over all ungranted tidelands, submerged lands, and the beds of navigable lakes and waterways. The CSLC also has

certain residual and review authority for tidelands and submerged lands legislatively granted in trust to local jurisdictions (Pub. Resources Code, §§ 6009, subd. (c); 6009.1; 6301; 6306). All tidelands and submerged lands, granted or ungranted, as well as navigable lakes and waterways, are subject to the protections of the common law Public Trust.

As general background, the State of California acquired sovereign ownership of all tidelands and submerged lands and beds of navigable lakes and waterways upon its admission to the United States in 1850. The State holds these lands for the benefit of all people of the State for statewide Public Trust purposes, which include but are not limited to waterborne commerce, navigation, fisheries, water-related recreation, habitat preservation, and open space. On tidal waterways, the State's sovereign fee ownership extends landward to the mean high tide line, except for areas of fill or artificial accretion or where the boundary has been fixed by agreement or a court. Such boundaries may not be readily apparent from present day site inspections.

On December 17, 2014, the CSLC authorized a General Lease – Right-of-Way Use to CalAm for the construction and operation of a temporary exploratory test slant well in Monterey Bay. In order to operate the existing test well as a permanent well, CalAm must obtain a new lease. In addition, the Project includes nine new proposed slant wells which appear to be located on sovereign land within Monterey Bay; construction and operation of these wells would also require a lease. The existing Monterey Regional Water Pollution Control Agency's ocean outfall and diffusers proposed for use as part of this Project are currently authorized under CSLC Lease No. PRC 6091.9. A lease amendment or new lease may be required for CalAm to use the existing outfall. Questions regarding CSLC jurisdiction or leasing requirements should be directed to Cheryl Hudson with the Land Management Division (see contact information below). CSLC-1

Project Description

The Project as proposed by CalAm would be located near the Salinas River along the coast in the southern portion of Monterey Bay, Monterey County. The Draft EIR/EIS identifies Alternative 5a – "Reduced Project 6.4 Million Gallons Per Day Desalination Plant (Intake Slant Wells at CEMEX)" as the Environmentally Superior Alternative. This Alternative would include an agreement to purchase 3,500 acre feet/year of recycled water from the proposed Pure Water Monterey Groundwater Replenishment project, to replace those portions of CalAm's supplies that have been constrained by legal decisions regarding CalAm's diversions from the Carmel River and pumping from the Seaside Groundwater Basin. The Alternative would achieve the Project's goals and objectives through reduced operational energy use, reduced GHG emissions, and reduced effects on groundwater levels influenced by fewer slant wells and less volume of pumping, compared to the proposed Project.

CSLC staff understands the Project would include the following components:

- A subsurface seawater intake system;
- A desalination plant;

- A brine discharge system;
- Product water conveyance pipelines, one pump station, storage facilities; and
- Improvements to the existing Seaside Groundwater Basin's aquifer storage and recovery system.

Environmental Review

As a responsible agency, the CSLC's exercise of discretion is limited to the portions of the Project that are under the CSLC's jurisdiction (State CEQA Guidelines, § 15096, subd. (d)). As a result, the comments below focus on the construction and operation of the discharge pipeline and slant wells, which are the components of the Project that would be subject to the CSLC's leasing authority. CSLC staff requests that the CPUC consider the following comments on the Project's Draft EIR/EIS.

Greenhouse Gas (GHG)

The portions of the Project under the jurisdiction of the CSLC have not substantially changed since the release of the 2015 EIR. CSLC staff acknowledge that the current EIR/EIS has sufficiently responded to all of staff's previous comments with one exception. Although it is understood that the impacts associated with GHG emissions would remain significant and unavoidable, that impact conclusion is "based on the information currently available." Mitigation Measure (MM) 4.11-1 indicates that the proposed GHG Emissions Reduction Plan would provide feasible measures when completed. For that reason, CSLC staff believes that the lead agencies have not gone far enough to explore feasible mitigation, or to demonstrate that feasible measures are not available. In addition, MM 4.11-1 itself does not contain specific, feasible, enforceable obligations, or formulas containing performance standards that would further mitigate the significant effect of the Project (State CEQA Guidelines, § 15126.4, subd. (a)(2)). Although the assumption is that the preparation of the plan would reduce the carbon footprint of the Project, the measure, as written, does not guarantee this result and may constitute deferred mitigation impermissible under CEQA (State CEQA Guidelines, § 15126.4, subd. (a)(1)(B)). CSLC-2

For example, MM 4.11-1 states in part:

> The Plan shall include a summary of state-of-the-art energy recovery and conservation technologies available for utility scale desalination facilities and shall include a commitment by CalAm to incorporate all available feasible energy recovery and conservation technologies; or, if CalAm finds that any of the technologies will not be feasible for the project, the Plan shall clearly explain why such technology is considered to be infeasible. (Emphasis added.)

Therefore, if no technologies are found to be feasible, they are not required to be implemented. In addition, the measure states "CalAm shall make good faith efforts to ensure that at least 20 percent of the approved project's operational energy use requirements are achieved with "clean" renewable energy...." (Emphasis added.)

However, there is no definition of what a "good faith effort" would entail. Additionally, the mitigation measure fails to identify potential impacts of the measure itself, such as the possible "installation of solar photovoltaic panels at or adjacent to the desalination plant," which would also need to be discussed, albeit in less detail than the effects of the Project (State CEQA Guidelines, § 15126.4, subd. (a)(1)(D)). CSLC-2 cont.

CSLC staff requests that MM 4.11-1 be reworded to improve enforceability. The MM should identify specific, feasible energy recovery and conservation technologies that could be used individually, or in combination to reduce net GHG emissions and require the lead agencies to meet targeted reductions.

As noted above, a lease (or leases) would be required from the CSLC for the construction and operation of the proposed slant wells and use of the existing outfall. A more concise and enforceable measure would assist staff in determining whether additional analysis would be required prior to lease approval.

Thank you for the opportunity to comment on the Draft EIR/EIS for the Project. As a responsible and trustee agency, the CSLC will need to rely on the Final EIR/EIS for the issuance of any amended or new lease as specified above, and therefore, we request that you consider our comments prior to certifying the EIR/EIS.

Please send copies of future Project-related documents, including electronic copies of the Approving Resolution, Final EIR/EIS, Mitigation Monitoring and Reporting Program, Notice of Determination, CEQA Findings and, if applicable, Statement of Overriding Considerations when they become available. Please refer questions concerning environmental review to Cynthia Herzog, Senior Environmental Scientist, at (916) 574-1310 or via e-mail at Cynthia.Herzog@slc.ca.gov. For questions concerning CSLC leasing jurisdiction, please contact Cheryl Hudson, Public Land Management Specialist, at (916) 574-0732 or via e-mail at Cheryl.Hudson@slc.ca.gov.

Sincerely,

Cy R. Oggins, Chief
Division of Environmental Planning
and Management

COMMENTS ON THE DRAFT ENVIRONMENTAL IMPACT REPORT/ ENVIRONMENTAL IMPACT STATEMENT FOR THE CALIFORNIA AMERICAN WATER COMPANY PROPOSED MONTEREY PENINSULA WATER SUPPLY PROJECT (Docket ID: NOAA-NOS-2016-0156)

Dear Ms. Borak and Ms. Grimmer:

The Central Coast Regional Water Quality Control Board (Central Coast Water Board) and State Water Resources Control Board (State Water Board) (collectively Water Boards) have reviewed the Draft Environmental Impact Report/Environmental Impact Statement (DEIR/EIS) for the Monterey Peninsula Water Supply Project (MPWSP) proposed by California American Water Company (CalAm). CalAm proposes to construct a facility capable of producing 10,750 acre-feet (9.6 MGD) of potable water per year. The seawater intake system for the MPWSP would consist of 10 subsurface slant wells at the CEMEX sand mining site in the City of Marina and would extract 24.1 million gallons per day of source water through the seafloor. The MPWSP would transport brine from the desalination facility to commingle with wastewater from the Monterey Regional Water Pollution Control Agency, when available, prior to being discharged through the existing Monterey Regional Water Pollution Control Authority's ocean outfall pipeline. The pipeline discharges into the Monterey Bay National Marine Sanctuary and is equipped with multiport diffusers that are oriented horizontally to the seafloor. The diffuser has 171 two-inch-diameter ports: 65 in the 60-inch section and 106 in the 48-inch section. The ports discharge horizontally alternately from both sides of the diffuser at a spacing of 16 feet on each side. The 42 ports closest to shore are presently closed, so there are 129 open ports distributed over a length of approximately 1024 ft. The ports are approximately six inches above the rock ballast and nominally 54 inches above the sea bed.

The Central Coast Water Board is the agency responsible for issuing the National Pollutant Discharge Elimination System (NPDES) permit for the discharge of brine and other wastes from the MPWSP to the Pacific Ocean and for making a determination regarding the MPWSP's consistency with California Water Code section 13142.5, subdivision (b) (Water Code section 13142.5(b)). CalAm submitted a request for a Water Code section 13142.5(b) determination to the Central Coast Water Board on February 10, 2017. The Central Coast Water Board, in consultation with the State Water Board, is currently reviewing this information to determine if it

FRANCIA MARCUS, CHAIR | THOMAS HOWARD, EXECUTIVE DIRECTOR

RECYCLED PAPER

is sufficient for performing the analyses required by Chapter III.M of the Water Quality Control Plan for the Ocean Waters of California (Ocean Plan), which provides direction for the regional water boards on how to conduct a Water Code section 13142.5(b) analysis for a seawater desalination facility. Water Boards staff will prepare a recommendation regarding the best available site, design, technology, and mitigation measures feasible for the MPWSP, considering the requirements in Chapter III.M of the Ocean Plan for the Central Coast Water Board to consider in conjunction with the NPDES permit.

Water Boards staff acknowledges that the analysis required in Chapter III.M of the Ocean Plan, including determining consistency with Water Code section 13142.5(b), is separate and distinct from the DEIR/EIS and California Environmental Quality Act (CEQA) process. However, Water Boards staff will rely on analyses and information conducted as part the CEQA process for the Water Code section 13142.5(b) determination to the extent possible. Therefore, Water Boards staff offers the following comments on the DEIR/EIS.

General Comments

CalAm is proposing to use slant wells to withdraw seawater for the MPWSP. Slant wells are a type of subsurface intakes which are the preferred intake technology in the Ocean Plan[1] because they minimize or eliminate intake and mortality of marine life over the operational lifetime of the facility. CalAm's construction and maintenance plan for the slant wells appears to avoid impacts to marine life. Slant wells, constructed from an onshore well-head, will have no mortality to marine life caused by construction of the intake. Additionally, it appears that there would be no construction-related mortality associated with the discharge as the brine will be disposed through the existing Monterey Regional Water Pollution Control Agency ocean outfall pipeline. If it is determined that adjustments to the duckbill nozzles on the existing diffuser are necessary, an estimate of any marine life mortality caused by this construction should be included. SWRCB-1

Brine from the MPWSP would be commingled with wastewater from the MRWPCA when available. During the dry season, when wastewater is unavailable, brine only will be discharged through the MRWPCA multiport diffusers, which is the preferred brine disposal technology if wastewater for commingling is unavailable. The proposed MPWSP appears to comport with the preferred intake and discharge technologies in the Ocean Plan.[2] SWRCB-2

Overall, it appears that the MPWSP has been sited and designed in a manner that would result in minimal impacts to marine life and is consistent with the intent of the Ocean Plan to protect marine life and water quality. This is especially important because the facility's intake and discharge would be within the Monterey Bay National Marine Sanctuary, which contains extensive kelp forests, is a diverse ecosystem, is home to sensitive species, and provides habitats to over 500 species of fish.

Additional Comment on Surface Water Hydrology and Water Quality (Section 4.3 of the DEIR/EIS)

1. Although the MPWSP would use the preferred brine discharge technology of commingling brine with wastewater, the DEIR/EIS should assess any potential discharge-related mortality of all forms of marine life,[2] including any incremental SWRCB-3

[1] Ocean Plan Chapter III.M.2.d.(1)

[2] Ocean Plan Chapter III.M.2.d.(2)

shearing- or salinity-related mortality for both the commingled and brine-only discharge scenarios. The DEIR/EIS should also describe proposed mitigation for any discharge-related mortality for each discharge scenario. SWRCB-3 cont.

2. The DEIR/EIS describes using potential operational measures, including flow augmentation, to ensure that the MPWSP operational discharges meet water quality requirements in the NPDES permit. The Ocean Plan defines flow augmentation as when a facility withdraws additional source water for the specific purpose of diluting brine prior to discharge. Water Boards staff is unclear how Cal Am defines flow augmentation and the potential operational scenarios that are being defined as flow augmentation in the DEIR/EIS. Since CalAm proposes to use subsurface intakes for the MPWSP, it would be exempt from the Ocean Plan's prohibition on flow augmentation as an alternative brine discharge technology.[3] However, the DEIR/EIS should clarify the possible sources of water that may be used for the potential operational measure of flow augmentation as defined in the Ocean Plan. SWRCB-4

Thank you for the opportunity to comment on this draft environmental document. If you have any questions or would like to discuss our comments further, please contact me at Claire.Waggoner@waterboards.ca.gov (916) 341-5582 or Peter von Langen at (805) 549-3688.

Sincerely,

Claire Waggoner and John Robertson

8.4.1 Responses to Comments from California Coastal Commission

CCC-1 The Lead Agencies acknowledge the California Coastal Commission's commendation of the project applicant's selection of subsurface intakes in order to avoid and minimize adverse effects on marine life.

CCC-2 Alternatives that would avoid impacts on primary and/or secondary habitats were evaluated in the EIR/EIS. Although Alternative 1 is considered to result in a significant and unavoidable impact with respect to conflict with the North County LCP/LUP, as described on Draft EIR/EIS page 5.5-140, "It is noted that the Alternative 1 subsurface slant well construction would occur within the disturbed parking lot area and would not significantly disrupt habitat in this location; nonetheless, because the subsurface slant wells are not a resource-dependent use, they would conflict with this policy." Thus, Alternative 1 (and for similar reasons, Alternative 5b) would avoid the impacts on primary and/or secondary habitat described for the slant wells under the proposed project since the intake system and source water pipeline would not be located in primary and/or secondary habitat. Additionally, each of the alternatives that include an open-water intake (Alternatives 2, 3, and 4) would avoid the impact on primary and/or secondary habitat associated with the slant wells at CEMEX. However, these alternatives have different and more severe impacts on marine habitats; therefore, there are impact tradeoffs associated with the alternatives.

Impacts on primary habitat would be common to some or all alternatives. Under Alternatives 1, 2, 3, 4, and 5b, the Source Water Pipeline would not impact primary habitat. Under Alternative 5a, the Source Water Pipeline would impact primary habitat similar to the proposed project. The new Desalinated Water Pipeline and new Transmission Main, which are components of all alternatives, would have similar impacts on primary habitat as the proposed project. Therefore, while none of the action alternatives would fully avoid impacts on primary habitat, the Final EIR/EIS does thoroughly evaluate several alternatives that would minimize impacts within primary habitat.

8.4.2 Responses to Comments from California Department of Fish and Wildlife

CDFW-1 The Draft EIR/EIS does not evaluate Dudley's lousewort (*Pedicularis dudleyi*). According to the best available information from the California Natural Diversity Database (CNDDB) and California Native Plant Society (CNPS) as of publication of the Final EIR/EIS, there are no extant or historical populations within approximately 20 miles of the project area (the nearest population is in Big Sur), and therefore no compelling reason to include it as potentially occurring within the project area. Further, the species was not detected during multiple survey dates (see EIR/EIS Section 4.6.1.2, Information Sources and Survey Methodology, for a list of survey dates).

CDFW-2 The Lead Agencies acknowledge CDFW's comment regarding the environmental conditions in the project area in recent years. The Draft EIR/EIS acknowledges that sensitive plant species have potential to occur at the project site, but does not base its impact analysis solely on the results of surveys, but also relies on an evaluation of habitat conditions to determine whether there is potential for a special-status plant to occur within the project boundary. For example, for Hickman's onion, described in Section 4.6.1.8 on page 4.6-51, the Draft EIR/EIS states, "This species has not been observed during project-related botanical surveys, but has potential to occur in grassland or grassland understory of coast live oak woodlands alongside the Ryan Ranch-Bishop and Main System-Hidden Hills Interconnection Improvements sites." Additionally, as described in Mitigation Measures 4.6-1e, focused surveys for special-status plants would be conducted in accordance with guidelines established by CDFW prior to commencement of ground disturbing activities to determine the location of any special-status plant species within the project area.

CDFW-3 As described in Table F-1 in Appendix F, beach layia and Tidestrom's lupine have a low potential to occur in the project area. The Draft EIR/EIS analyzes potential impacts on Seaside bird's-beak, Menzies' wallflower, Monterey gilia (described as sand gilia in the Draft EIR/EIS), and Pacific Grove clover as these species have a moderate or higher potential to occur in the project area. The Lead Agencies acknowledge that if take of any of these state-listed species cannot be avoided, CalAm would apply for an Incidental Take Permit (ITP) from CDFW prior to project implementation during the permitting process (see Table 3-8, Anticipated Permits and Approvals). CDFW's specific comments on mitigation measures (which would be adopted at the time of approval of the project or an alternative) are addressed in responses to the following comments.

CDFW-4 Mitigation Measure 4.6-1e does not require reintroduction of sensitive plant species, nor recommend it as the primary measure to mitigate for take of such plants, but states that it may be one option to compensate for temporary or permanent loss of special-status plant occurrences and specifies that "Compensatory measures shall be

determined on a case-by-case basis in consultation with the resource agencies with jurisdiction over those species." The Lead Agencies acknowledge that CDFW, as a resource agency that may have jurisdiction (depending on the species and location of compensatory habitat), would not recommend reintroduction. Subparts 1 and 2 of Mitigation Measure 4.6-1e require the siting of project facilities to avoid permanent and temporary impacts on special-status plants and their required constituent habitat elements to the extent feasible, and to implement measures during construction to avoid take of special-status plants, as requested in the comment.

As recommended in the comment, Mitigation Measure 4.6-1e has been revised to require a minimum 2:1 compensation ratio for permanent impacts and to clarify the options for compensation. The measure has also been revised to clarify the applicable performance standards as recommended in this comment (i.e., that the restored population must have greater than the number of individuals of the impacted population(s), in an area greater than or equal to the size of the impacted population(s), for at least three consecutive years without irrigation, weeding, or other manipulation of the restored site).

See response to comment CDFW-3 regarding the potential need for an ITP.

CDFW-5 In response to this comment, the following text has been added to the discussion of the California Fish and Game Code in Final EIR/EIS Section 4.6.2.2, State Regulations:

> Additionally, as described in CCR Title 14, Section 786.9, CDFW may also permit take of state rare plants under the same conditions as take authorizations issued pursuant to Section 2081 of the Fish and Game Code.

Also in response to this comment, text regarding listed and non-listed species on Draft EIR/EIS page 4.6-4 in Section 4.6.1.1, Definitions, has been revised to acknowledged that listed special-status species refers to those species that are listed as threatened or endangered under FESA and/or CESA or as rare by the California Fish and Game Commission.

Finally, the discussion of Pacific Clover has been moved from the heading "Other Special-Status Species" to "Federal or State Listed Species" in Table 4.6-2 and in Table F-1 in Appendix F in the Final EIR/EIS as recommended in this comment. See response to comment CDFW-3 regarding the potential need for an ITP.

CDFW-6 As encouraged in this comment, Mitigation Measure 4.6-1i describes that if ground-disturbing activities must occur during the breeding season, then CalAm would implement measures to avoid impacts on nesting birds protected under the Migratory Bird Treaty Act or Section 3503 of the Fish and Game Code. Additionally, Mitigation Measure 4.6-1i has been revised to incorporate CDFW's recommendations in this comment, which include behavior monitoring for the first 24 hours prior to any construction related activities and during the project,

consultation with CDFW, and using a 250-foot no disturbance buffer around active nests of non-listed bird species and a 500-foot no disturbance buffer around the nests of non-listed raptors.

CDFW-7 Consistent with this comment, Mitigation Measure 4.6-1h requires that impacts on occupied burrowing owl burrows be avoided by establishing a no ground-disturbing work buffer using buffer distances described in CDFW Staff Report on Burrowing Owl Mitigation. The measure also requires that CalAm implement preconstruction surveys described in the Staff Report on Burrowing Owl, which is more detailed and specific than that required in the California Burrowing Owl Consortium's Burrowing Owl Survey Protocol and Mitigation Guidelines. Also consistent with this comment, regarding compensation, the measure requires that "if burrowing owls are found on-site, compensatory mitigation for loss of breeding and/or wintering habitat shall be implemented onsite or offsite in accordance with Staff Report on Burrowing Owl Mitigation guidance and in consultation with CDFW." The measure addresses the requirements for relocation of owls in subparts 6 through 8, including through the development and implementation of a Burrowing Owl Exclusion Plan that must be approved by CDFW. Mitigation Measure 4.6-1h specifies that the plan must include relocation measures consistent with this comment (i.e., replacement of occupied burrows with artificial burrows at a ratio of 1:1, with passive relocation occurring only during non-breeding season).

CDFW-8 As described in EIR/EIS Section 4.6.1.2, reconnaissance-level field surveys were conducted to determine the potential for special-status species, including the California tiger salamander, to occur within the project area. The EIR/EIS acknowledges that California tiger salamander have potential to occur in the project area in Section 4.6.1.8 and provides a detailed assessment of where this species has potential to occur. The EIR/EIS identifies potential habitat for California tiger salamander as non-native grassland within 1.2 miles of potential breeding ponds and assumes that this species may occur in these areas in the absence of protocol-level surveys. The EIR/EIS provides a comprehensive analysis of the potential direct and indirect (i.e., take) project impacts on California tiger salamander in Section 4.6.5 based on where they have potential to occur. Construction-related impacts and mitigation measures to reduce those impacts to less than significant are described in Impact 4.6-1. There are no potential operational impacts on California tiger salamander. See response to comment CDFW-3 regarding the need for an ITP for construction activities. Because the project, as well as avoidance measures such as installation of exclusion fencing, has potential for take of California tiger salamander, the Lead Agencies anticipate that CalAm would need to obtain an ITP from CDFW prior to project implementation. Take authorization will also be sought from the USFWS.

As described in Mitigation Measure 4.6-1o, California tiger salamander would only be relocated with authorization from USFWS and CDFW (i.e., through Federal and California Endangered Species Act consultation or permits, respectively).

Additionally, Mitigation Measure 4.6-1o has been revised to clarify that installation of exclusion fencing for California tiger salamander also would be subject to such authorization. The measure has also been revised to specify that if take authorization for California tiger salamander is not obtained from CDFW and USFWS, then all small mammal burrows within dispersal distance of a known or potential breeding pond shall be avoided by a minimum buffer of 50 feet.

CDFW-9 In response to this comment, Mitigation Measure 4.6-1c has been revised to incorporate CDFW's recommendations regarding the use of natural-fiber, biodegradable meshes and coir rolls, and to prohibit the use of photodegradable and other plastic mesh erosion control products (see subpart 22).

CDFW-10 As described in 4.6.2.1, Federal Regulations, a federal agency is required to consult with USFWS and NMFS if the proposed project may affect a federal listed species. ONMS has consulted with USFWS and NMFS through Section 7 of the Federal Endangered Species Act, as required.

In response to this comment, the following text from Draft EIR/EIS page 4.6-122 has been revised in Section 4.6.5:

> The following impact analysis evaluates impacts of the proposed project as required by CEQA and NEPA. A Biological Assessment, which would evaluate the project's impacts on federally listed species, would be prepared in support of FESA Section 7 consultation between the ONMS and USFWS <u>and between the ONMS and NMFS</u>.

8.4.3 Responses to Comments from California Department of Parks and Recreation

CA Parks-1 The proposed project does not include the taking of any state park land. However, CalAm would need to seek an easement, right-of-entry, and/or a lease agreement with State Parks for any facility that would encroach upon State Parks property. A sentence has been added in Final EIR/EIS Section 5.4.3.1 to acknowledge this. Accordingly, CalAm would be required to comply with any conditions required as part of the easement, right-of-entry, and/or lease agreement with State Parks for such facility, including conditions described in this letter, such as repaving and maintaining parking lots following disturbance.

CA Parks-2 The text in Draft EIR/EIS Section 4.8.2.2 that describes state regulations, including the Fort Ord Dunes State Parks General Plan on page 4.8-16, has been revised to read:

> "The new Transmission Main . . . would traverse an approximately 0.25-mile-long band . . ."

Draft EIR/EIS Section 3.3.4 explains the width of the disturbance corridor for pipeline construction would vary typically from 50 to 100 feet and trenchless technologies could require wider corridors at entry and exit pits. See Figures 3-6, 3-7, and particularly Figure 3-8.

CA Parks-3 CalAm will need to apply to State Parks for an easement, right-of-entry, and/or a lease agreement. As noted in Draft EIR/EIS Table 4.6-4, the installation of the new Transmission Main in the Fort Ord Dunes State Park would occur within central dune scrub. The potential impacts are addressed in Impact 4.6-2. In response to this and other comments, Mitigation Measure 4.6-2b has been revised to ensure that impacts on central dune scrub (among other plant communities and habitat types) will be restored to previous conditions or better at the end of construction, so that by the fifth year following restoration, native vegetation covers at least 70 percent of the baseline/impact area native vegetation cover, and so that there is no more cover by invasives than the baseline/impact area. Additionally, the Lead Agencies anticipate that conditions of approval of the State Parks easement, right-of-entry, and/or lease agreement may further define specific planting requirements within State Parks lands.

CA Parks-4 The Fort Ord Dunes State Park Campground is recognized as a potential project in Draft EIR/EIS Table 4.1-2 as Project No. 46 that may contribute to cumulative impacts. The cumulative impacts on land use and recreation if the campground and MPWSP are constructed at the same time or sequentially are addressed in Impact 4.8-C in EIR/EIS Section 4.8, Land Use, Land Use Planning, and Recreation.

CalAm will need to apply for an easement from State Parks and is willing to negotiate maintenance and/or road agreements.

CA Parks-5 See response to comment CA Parks-1. Table 3-8 has been revised to include State Parks, as follows.

Agency or Department	Permit or Approval	Discussion
California Department of Parks and Recreation	Easement, right-of-entry (ROE), and/or lease negotiations for 0.25-mile portion of the new Transmission Main that would encroach on Fort Ord Dunes State Park	• State Parks has jurisdiction and management authority over Fort Ord Dunes State Park and any easement, ROE, and/or lease if granted, will need to be appraised using DGS guidelines and be accompanied by State Parks-approved legal descriptions.

CA Parks-6 As discussed on page 5.3-30 of the Draft EIR/EIS, only Intake Option 9 was carried forward into the development of whole alternatives. Likewise, as noted on page 5.3-51 of the Draft EIR/EIS, only the proposed use of the existing (MRWPCA] outfall was carried forward in the development of Alternatives 1 and 5b; therefore, Intake Option 4 and Outfall Option 3 were screened out from further consideration in the EIR/EIS.

Intake Option 3, described in Draft EIR/EIS Section 5.3.3 and evaluated in Section 5.3.6 that may occur on State Parks property, would be located in the parking lot at the end of Potrero Road. Table 5.3-4 considers the impact of this intake option on the Potrero Road parking lot. The alternatives evaluated in the Draft EIR/EIS that include Intake Option 3 are described in Section 5.4.3 (Alternative 1, Slant Wells at Potrero Road) and Section 5.4.8 (Alternative 5b, Reduced Project Slant Wells at Potrero Road). All onshore construction activities and disturbance would occur in the parking lot at the western terminus of Potrero Road, and would not disturb the dunes or active beach area; the electrical control building would be located at the edge of the parking lot. The setting/affected environment at the Potrero Road parking lot is described in Section 5.5.8.1 and impacts of the alternatives on the parking lot and recreational resources are discussed in Sections 5.5.8.4 (Alternative 1), and 5.5.8.8 (Alternative 5b). See response to comment CA Parks-1 regarding the need for an easement, right-of-entry, and/or lease agreement.

CA Parks-7 With respect to coastal dune habitat and snowy plover habitat, the impacts of Alternatives 1 and 5b facilities on these and other sensitive terrestrial biological resources are described in EIR/EIS Section 5.5.6.4 (Direct and Indirect Effects of Project Alternative 1 – Slant Wells at Potrero Road), and Section 5.5.6.8 (Direct and Indirect Effects of Alternative 5 – Reduced Desal Project 5a [CEMEX] and 5b [Potrero Road]). The Alternatives 1 and 5b facilities that would be located within State Parks land would be constructed in a parking lot behind the sand dunes and would not directly impact sensitive natural communities or wetlands. Indirect

impacts on coastal sand dune habitat and snowy plover habitat would be reduced to a less-than-significant level with implementation of mitigation measures listed in EIR/EIS Sections 5.5.6.4 and 5.5.6.8 (see Section 4.6, Terrestrial Biological Resources, for the full text of these measures). With regard to impacts from pump vibration, impacts from Alternatives 1 and 5b would be the same as described for the proposed project. Sections 4.6, 5.5.6.4, and 5.5.6.8 of the Final EIR/EIS have been revised to cross-reference the analysis in Section 4.12, Noise and Vibration, which concludes that operation of the slant wells under the proposed project would not produce groundborne vibration. Since there would be no groundborne vibration, there would be no impact from groundborne vibration on western snowy plover. This determination would be the same for Alternative 1 and Alternative 5b.

Although groundborne vibration would not result in incidental take of the western snowy plover, the USFWS will be consulted with reagrding potential impacts from construction and maintenance activities. As part of that permitting process, ONMS is consulting with USFWS through the Section 7 consultation process as necessary for potential impacts on snowy plover. In response to comments on the Draft EIR/EIS and to this ongoing consultation process, Mitigation Measure 4.6-1d (Protective Measures for Western Snowy Plover) has been revised to specify performance standards for the fifth year following restoration of temporarily impacted snowy plover habitat and to require a minimum 3:1 ratio of permanent compensation for permanent loss of western snowy plover habitat (see Final EIR/EIS Section 4.6). These revisions are consistent with the comment's requests.

With respect to paving and maintenance of parking lots and installation of utility lines, see response to comment CA Parks-1.

CA Parks-8 See response to comment CA Parks-6.

CA Parks-9 Impacts of Alternatives 1 and 5b on public coastal access and parking at Potrero Road are discussed in Draft EIR/EIS Sections 5.5.8.4 and 5.5.8.8. Existing access and parking at the Potrero Road parking lot would temporarily be precluded during construction, and parking options for Salinas River State Beach visitors would be limited to two of three existing options (Sandholdt Road lot or Monterey Dunes Way lot). The EIR/EIS includes Mitigation Measures REC-1a and REC-1b, which would require public notice regarding closure and implementation of a plan for maintaining safe beach access during construction. Mitigation Measure REC-1b has been revised to require that CalAm submit the Beach Access Management Plan to State Parks for review and approval prior to construction. Potrero Road parking access would be fully restored following construction.

Impacts of Alternatives 1 and 5b on coastal dune habitat are discussed in Sections 5.5.6.4 and 5.5.6.8. Mitigation Measure 4.6-2b described in response to comment CA Parks-3 would apply to these alternatives.

CA Parks-10 Draft EIR/EIS Section 5.5.14.1 describes the aesthetic setting/affected environment at the Potrero Road parking lot. Impacts of Alternatives 1 and 5b on the visual resources at Potrero Road are discussed in Sections 5.5.14.4 and 5.5.14.8. Permanent structures would not require security fencing and would not be visible from the beach or block coastal views. See Draft EIR/EIS pages 5.5-279 and 5.5-292 for a discussion of nighttime light and glare. Mitigation Measure 4.14-2 (Site-Specific Nighttime Lighting Measures), which would require lighting fixtures to be cast downward and shielded to prevent light from spilling onto adjacent offsite uses (including into adjacent offsite habitat) would apply to these alternatives.

CA Parks-11 See responses to comments CA Parks-5 through CA Parks-10. EIR/EIS Section 5.5.12 addresses impacts from noise and vibration and Section 5.5.3 addresses surface water runoff and discharges.

8.4.4 Responses to Comments from California State Lands Commission

CSLC-1 As described in Draft EIR/EIS Section 3.4, the proposed project, including the conversion of the test slant well to a permanent well and use of the existing outfall, could require discretionary permits from federal, state, and local jurisdictions. Table 3-8, Anticipated Permits and Approvals, lists the State Lands Commission requirement for a New Land Use Lease and Amended Land Use Lease for the uses described in the comment, among the many approvals CalAm is expected to pursue prior to project implementation (see Draft EIR/EIS page 3-65).

CSLC-2 In response to this and other comments on the Draft EIR/EIS, the quoted text in the comment has been deleted from Mitigation Measure 4.11-1 and the measure has been revised as shown in response to comment USEPA-4 in Section 8.3.5. Based on these revisions to the mitigation measure, the analysis also has been revised to conclude that, with mitigation, the proposed project's impacts with respect to GHG emissions would be less than significant.

8.4.5 Responses to Comments from State Water Resources Control Board

SWRCB-1 As summarized in the comment and discussed in detail in EIR/EIS Sections 4.3.5 and 4.5.5, the use of slant wells is consistent with the Ocean Plan's preferred technology for desalination plant intakes since they minimize or eliminate marine life mortality during operations over the project life-time. Additionally, construction of the proposed project would avoid and/or minimize impacts associated with marine life mortality and such impacts would be less than significant. Implementation of a retrofit of the existing MRWPCA outfall diffuser to increase the dilution of operational discharges is described under Impact 4.3-5 and Mitigation Measure 4.3-5 in Section 4.3.5. The potential secondary construction-related impacts on marine biological resources from implementing Mitigation Measure 4.3-5 are assessed and described in Section 4.3.5.4. Secondary impacts on benthic organisms and other marine biological resources associated with retrofitting the outfall diffuser with inclined jets would be less than significant.

SWRCB-2 As summarized in the comment and discussed in detail in Sections 4.3.5 and 4.5.5, the proposed project has been sited and designed in a manner that adheres to the requirements of the Ocean Plan regarding the use of multiport diffusers and the comingling brine from the MPWSP with wastewater to protect marine life and water quality within the Monterey Bay National Marine Sanctuary.

SWRCB-3 Two potential sources of mortality of marine organisms associated with discharges of brine were considered in EIR/EIS Section 4.5.5.2: increased salinity and turbulence shear stress. Salinity-related and shear stress-related marine life mortality for brine-only and comingled operational discharges is assessed in detail under Impact 4.5-4. The review of available literature presented in Table 4.5-9 found no reported cases of mortality in experiments that tested organisms at salinities as low as the maxima predicted in the brine discharges at the points of contact with the seafloor. Consequently, the EIR/EIS concluded that no mortality would occur due to the elevated salinities in the brine discharge and no mitigation is necessary.

As described in detail under Impact 4.5-4, the EIR/EIS concluded that for the worst-case brine-only discharge scenario, roughly 0.23 to 0.86 percent of total numbers of plankton flowing over the diffuser could be killed by shear stress, estimated to be roughly 892 million organisms per day or 0.00261 percent of the total area around the edge of Monterey Bay at the depth of 35 meters. As noted in EIR/EIS Appendix D1, the volumes entrained into the proposed brine discharges are much less than are entrained into the existing discharges that only include secondary treated wastewater. This is mainly because the dilution of the treated wastewater is much higher. For the brine-only discharges, the entrainment rates range from 7 to 22 percent of those for the baseline case. Therefore, organism

mortality for the proposed project brine discharges would also be expected to be about 7 to 22 percent of the baseline case. Because the CEQA/NEPA analysis determined that the impacts would be less than significant for discharge related mortality, no mitigation is proposed.

However, while the EIR/EIS does not require mitigation for salinity-related or shear stress-related mortality, the SWRCB might want to impose conditions (mitigation) as part of the permitting process. In order to do so, the area of production foregone (APF) would need to be calculated and it is typically calculated as a percentage of the entrainment losses resulting from the intake analysis. But since the project proposes to utilize subsurface intakes, Empirical Transport Modeling (ETM) was not performed, and Area of Production Foregone (APF) was therefore, not included in that calculation. The APF from the discharge could be estimated by assuming the area between the diffuser port and the edge of the zone of initial dilution (ZID) on both sides of the outfall that exceed 2 ppt above ambient salinity could settle on the seafloor (which model results indicate it would not). That area is calculated to be approximately 2,010 to 7,800 square meters of seafloor (21,635 to 85,800 square feet) or 0.5 to 2 acres. See EIR/EIS Section 4.5.5.2, Impact 4.5-4.

SWRCB-4 The use of additional source water from the intake slant wells is not proposed for flow augmentation to increase the dilution of operational discharges. As described in Mitigation Measure 4.3-5 in Section 4.3.5.2, flow augmentation would be achieved by adding water with densities (i.e., salinity) closer to fresh water. This would decrease the density difference between the operational discharge and the receiving ocean waters and result in increased dilution and mixing. As modeled by Roberts (see EIR/EIS Appendix D1), adding 2.3 to 4.8 million gallons per day (mgd) of freshwater flows, depending on the discharge scenario, could substantially increase minimum dilution at the edge of the ZID, and thus ensure compliance with the water quality objectives defined in the California Ocean Plan. See response to comment MRWPCA-7 in Section 8.5.9 for further discussion regarding the use of Mitigation Measure 4.3-5 flow augmentation to increase the dilution of operational discharges at the outfall diffuser and for further discussion regarding the use of Mitigation Measure 4.3-5 flow augmentation to increase the dilution of operational discharges at the outfall diffuser.

Re: Draft Environmental Impact Report/Environmental Impact Statement
Monterey Peninsula Water Supply Project

Dear Ms. Borak and Ms. Grimmer:

We represent the City of Marina, California ("Marina" or "the City") and hereby provide written comments on Marina's behalf regarding the Draft Environmental Impact Report/Environmental Impact Statement ("Draft EIR/EIS") issued in January 2017 for the Monterey Peninsula Water Supply Project ("Project") proposed by California American Water Company ("CalAm"). Please ensure that these comments are made a part of the administrative record for all state and federal proceedings relating to the Project.

Marina-A

Marina is providing these comments in several different capacities. First, it is a Responsible Agency for the Project under the California Environmental Quality Act ("CEQA") because it will be considering the Coastal Development Permit for the Project in accordance with the California Coastal Act. Cal. Pub. Res. Code §§ 30000, *et seq*. In this capacity, the City will be focusing on the adequacy of the Draft EIR/EIS for this purpose.[1] Second, the City is

[1] The scope of the City's inquiry as a Responsible Agency for a Coastal Development Permit is extremely broad. It includes, but is not limited to, the analysis of potential individual and cumulative impacts to, and mitigation measures for, environmentally sensitive habitat areas; marine/ocean resources and species (including the biological productivity and quality of coastal waters); special land habitat areas and wetlands; archaeological and cultural resources; preventing depletion of groundwater supplies; scenic and visual qualities; erosion and geologic

providing CEQA comments on behalf of its citizens relating to the full range of environmental issues that affect Marina. Third, the City is providing a full set of comments on the adequacy of the Draft EIR/EIS under the National Environmental Policy Act ("NEPA"). The City has organized its comments to track the numbering of sections in the Draft EIR/EIS.

Although the California Public Utilities Commission ("CPUC") and Monterey Bay National Marine Sanctuary ("MBNMS") are being requested to issue permits and/or authorizations for different aspects of the Project, it is important to note that the CPUC and MBNMS each has a legal obligation to assess the full environmental impacts, mitigation measures and alternatives for the entire Project, not just those portions of the Project that are under their respective permitting jurisdiction. Thus, for example, since MBMNS has determined that this is a "major federal action significantly affecting the quality of the human environment" under NEPA, the Project has been federalized for purposes of environmental review, and NEPA review of the entire Project for all federal agencies is mandated.

These written comments are the product of a joint effort by Farella Braun + Martel, Emily Creel and her team at SWCA Environmental Consultants, and City staff. Most of the technical analysis in this letter has been prepared by SWCA and the legal analysis has been provided by Farella.

Marina-A

This letter also transmits to CPUC/MBNMS and relies upon the expert hydrogeologic Memorandum prepared for Marina by Dr. Robert Abrams, a principal hydrogeologist with Jacobson James & Associates, Inc., that is enclosed herewith as Appendix 1. We also enclose two sets of slides that were presented and submitted to the Marina City Council at its meeting on February 7, 2017: (1) Marina Coast Water District presented its "Marina Coast Water District Water Supply Planning Overview" enclosed as Appendix 2; and (2) Stanford Professor Rosemary Knight and two colleagues offered a presentation entitled "The Acquisition of Geophysical Data Along the Monterey Coast" enclosed as Appendix 3.

INTRODUCTION AND SUMMARY

The current Project is the latest in a sequence of proposals by CalAm to develop a desalination plant and associated facilities to supply water to areas that it serves on the Monterey Peninsula. As these proposals have evolved over time and are now focused on a large project located in Marina, the City has become increasingly concerned about the potentially significant and irreversible impacts of the Project on Marina's water supply, water quality, sensitive coastal environment and citizens. Now that the City has had an opportunity to review the Draft EIR/EIS issued in January 2017, it has become clear that the potentially serious, significant and long-term

instability; and public access. Cal. Pub. Res. Code §§ 30116, 30231, 30240, 30251, 30252 and 30253. The City must also examine, for coastal-dependent facilities (if this provision is applicable), whether alternative locations are infeasible or more environmentally damaging, the adverse impacts on public welfare, and ensure that adverse environmental impacts are mitigated to the maximum extent feasible. *Id.* § 30260. The Legislature has further specified that all public agencies administering the Coastal Act must apply environmental justice principles regarding the siting and impacts of projects. *Id.* § 30013; Cal. Gov't Code § 65040.12.

adverse environmental impacts of the Project on the City have not been adequately studied, evaluated or mitigated, and a proper evaluation of the Project alternatives has been undermined by the legal deficiencies in the individual environmental analyses.

Marina is a vibrant, racially diverse community located along the central coast of California. It has special and unique natural resources, including its coastal ecosystems, and values its desirable quality of life. It is officially recognized as a minority community under federal, state and local laws and programs. The City is currently 100 percent dependent for its water supply on groundwater within the Salinas Valley Groundwater Basin. Marina's continued use of and access to this supply is essential to its continued economic vitality.

Marina's comments on the Draft EIR/EIS are set forth in the chapters below. In brief, the Draft EIR/EIS is legally inadequate in many critical subject areas and fails to meet the requirements of CEQA and NEPA. The Draft EIR/EIS also falls far short of meeting the adequacy requirements for the City's use of it as a Responsible Agency. Cal. Code Regs. tit. 14, § 15096 ("CEQA Guidelines"). These shortcomings include the following:

- **Inflated Water Demand:** The Draft EIR/EIS contains a bloated and unsupported water demand "need" for the Project of 10,750 acre-feet per year ("afy"), which by itself exceeds the total water deliveries by CalAm to its customers in each of 2014 and 2015. With the Project, CalAm would have a future water supply of over 16,000 afy, of which only about 9,500 afy is for currently existing demand. The remaining 7,000 afy is for uncertain or unspecified future uses. The Draft EIR/EIS fails to critically analyze and downwardly adjust this "need." CalAm's true "need" for new water is actually much less and could be supplied by other projects. These deficiencies in the Project Objectives and Purpose and Need Statement also improperly skew the environmental impact and alternatives analyses, rendering them legally inadequate. (*See* chapters 1, 2.1-2.5, and 5.)

- **No Water Rights:** It is undisputed that the Project (whose sole purpose is to deliver water to customers) does not have water rights to extract and export the groundwater it admits it will pump from the Salinas Valley Groundwater Basin, which is in a "critical overdraft" condition. Although the Draft EIR/EIS attempts to construct a legal argument that CalAm may be able to establish such water rights in the future and therefore make this a "feasible" project, this is a contrived argument based on an implausible series of future events. Indeed, since there is no "permit" process for CalAm to obtain such rights, any future attempt to extract water and establish rights will certainly be tied up in litigation or other proceedings and very likely will never ripen into actual water rights. This is a "showstopper" issue – the CPUC/MBNMS should not allow the Project to move forward until CalAm can demonstrate that it actually holds rights to extract this groundwater. (*See* chapter 2.6.)

Marina-A

- **SGMA Conflicts:** In 2014, the California Legislature enacted the Sustainable Groundwater Management Act, which adopted a stringent and comprehensive management scheme for California groundwater. The 180/400 Foot Aquifer Subbasin, which the Project would use for groundwater extractions, is one of only 21 California groundwater basins that has been designated as "critically overdrafted" and it is receiving expedited management treatment. The anticipated implementation of this law makes it even less likely that any Project groundwater withdrawals for export can or will occur. The Draft EIR/EIS's failure to analyze this issue is a critical inadequacy. (*See* chapter 2.6.)

- **Direct Legal Prohibitions:** The extraction and/or export of Basin groundwater is directly prohibited by one state law (the Monterey County Water Resources Agency Act), one local ordinance (MCWRA Ordinance No. 3709) and one annexation agreement applicable to the CEMEX Property signed by parties including the City. The Draft EIR/EIS asserts, based on an untested legal argument with no textual support and no analysis, that the Project "would be consistent" with each law and agreement. This unsupported conclusion defies the facts and is legally inadequate under CEQA and NEPA. (*See* chapter 2.6.)

- **Inadequate Project Description:** The Draft EIR/EIS incorrectly and misleadingly identifies the source of the Project's water. The document repeatedly asserts that the source is "seawater from beneath the ocean floor," but the facts reflect that 75-93 percent of the source water will be groundwater in aquifers under land within Marina rather than seawater under MBNMS jurisdiction. The Draft EIR/EIS also fails to disclose or discuss, in either its intake alternative study or its main text, that the proposed slant wells are a risky and unproven technology with no operational track record. Indeed, it appears that no commercial desalination plant in the world uses such wells. The Draft EIR/EIS is inadequate for failing to evaluate in its alternative selection process or disclose to the public the risky and unproven nature of this technology. (*See* chapter 3.0.)

- **Wrong Environmental Baseline:** The Draft EIR/EIS incorrectly chose 2012 environmental conditions as the "baseline" date for environmental analysis. In fact, the environmental baseline should be August 2015 or later for both NEPA and CEQA purposes because that is the time when the Federal Notice of Intent to prepare an EIS was first announced and because of the significant Project changes that have occurred after 2012. (*See* chapter 4.1.)

- **Anticipated Groundwater Impacts:** The best available scientific information indicates that the Project's subsurface slant wells could significantly and adversely diminish the available water supply and water storage in Basin aquifers and cause or exacerbate water quality problems in Basin groundwater. However, instead of acknowledging and addressing these very important issues, the Draft

Marina-A

EIR/EIS erroneously concludes that the extraction of groundwater by the slant wells will have no significant impact on the groundwater basin. These findings lack substantial evidence in the record to support them. (*See* chapter 4.4.)

- **Inadequate Modeling:** As described in Dr. Abrams' technical report, the modeling that the Draft EIR/EIS relies upon to support its "no significance" finding for groundwater impacts is not state-of-the-art and lacks the capability to credibly evaluate the Project's likely range of groundwater impacts. Among other flaws, it fails to analyze impacts to the 900 Foot Aquifer, fails to evaluate the downward vertical migration of seawater into lower aquifers, and fails to incorporate the existing two-dimensional geophysical studies of this coastline by Stanford Professor Rosemary Knight and her colleagues that delineate the pathways between groundwater aquifers and downward seawater migration between them. (*See* chapter 4.4.)

- **Brine Discharge Impacts:** The Draft EIR/EIS fails to adequately assess the environmental impacts from the discharge of 14 million gallons per day of high-salinity brine through an aging outfall diffuser into this diverse and sensitive marine sanctuary environment. These discharges may cause extremely serious impacts, particularly during the six-month period each year when they would not be mixed with the sewage treatment plant effluent. No adequate mitigation measures are proposed for any such impacts. (*See* chapter 4.5.)

- **Coastal Ecosystem Impacts:** The Draft EIR/EIS finds that the Project will have significant impacts on Marina's coastal ecosystem and observes that development of the slant wells, new desalinated water pipeline, transmission main and staging areas would be located in Primary and Secondary Habitat areas (which also constitute Environmentally Sensitive Habitat Areas ("ESHA") under the Coastal Act) where this type of development is directly prohibited (with no exception) by Marina's Local Coastal Plan. However, the Draft EIR/EIS fails to explain credibly how this prohibition will not apply or how it will be reconciled. It proposes only one mitigation measure, which essentially defers to a later time the formulation of a plan for compensatory and other mitigation, which constitutes improper deferral of mitigation under CEQA. (*See* chapter 4.6.)

- **Greenhouse Gas Emissions**: The Draft EIR/EIS concedes that, because of its highly intensive use of electricity for long-term operation, the Project will have significant effects on the environment and climate change and that these impacts are "inconsistent" with climate change laws and an Executive Order by Governor Brown. However, the Draft EIR/EIS fails to propose a legally adequate set of mitigation measures in contravention of CEQA or recent case law decisions. Instead of proposing feasible mitigation, the document immediately jumps to the unjustified conclusion that the impact is "significant and unavoidable," thereby attempting to avoid the requirement to propose mitigation. (*See* chapter 4.11.)

Marina-A

- **Significant Historic Resource Impact:** The Draft EIR/EIS failed to address the Project's impacts to the Lapis Sand Mining Plant (confirmed in June 2014 to be eligible for listing in the National Register) and the Lapis Siding. The document's assertion that no such historic structures are contained within the Project's Area of Potential Effect is untrue and these significant impacts must be addressed and recirculated for public comment in a new Draft EIR/EIS. (*See* chapter 4.15.)

- **Deficient Environmental Justice Analysis:** The NEPA environmental justice analysis and corresponding CEQA analysis as applied to Marina are fatally deficient. In fact, Marina's minority community and its environment will be suffering a wide array of significant adverse environmental impacts, while substantial amounts of its groundwater supply would be exported out of its groundwater basin to customers on the Monterey Peninsula. The Draft EIR/EIS contravenes applicable federal and state law and guidance by concluding that these impacts are less than significant. (*See* chapter 4.20.)

- **Inadequate Alternatives Analysis:** The Draft EIR/EIS alternatives analysis is undermined by its wholesale incorporation of a flawed Project Objective/Purpose and Need Statement, deficient environmental analyses, and inadequate mitigation measures. In fact, an accurate comparison of alternatives is impossible at this point. The Draft EIR/EIS concludes, without substantial evidence, that Alternative 5a (a 6.4 mgd plant at the CEMEX site paired with the Pure Water Monterey Groundwater Replenishment Project) is the environmentally superior/preferred alternative. In fact, a wider set of alternatives should have been selected, including a significantly smaller project that will meet the actual Project "need" and mitigate for significant Project impacts. If a scientifically credible analysis had been performed, several other alternatives, including the Potrero Road alternative, likely would have been designated as the environmentally superior/preferred alternative. (*See* chapter 5.0.)

Marina-A

In view of the key missing information, faulty Project Objective/Purpose and Need statements, inadequate analysis of multiple environmental impacts, deficient mitigation measures, and resulting inability to properly select and evaluate alternatives, this Draft EIR/EIS must be completely redone and recirculated for public review and comment. Each of the four specific criteria for recirculation in CEQA Guidelines § 15088.5(a) is met here, including that "the draft EIR was so fundamentally and basically inadequate and conclusory in nature that meaningful public review and comment were precluded." *See, e.g., Laurel Heights Improvement Ass'n v. Regents of Univ. of Cal.*, 6 Cal. 4th 1112, 1130 (1993); *Mountain Lion Coal. v. Fish and Game Comm'n*, 214 Cal. App. 3d 1043 (1989).

EXECUTIVE SUMMARY

The Draft EIR/EIS's Executive Summary contains a synopsis of the analyses and conclusions from other sections of the Draft EIR/EIS. The City incorporates herein by reference each of its written comments herein regarding those Draft EIR/EIS sections.

The Draft EIR/EIS does not include a Mitigation Monitoring and Reporting Program ("MMRP"). An MMRP identifies the method, timing, and the party responsible for mitigation implementation and verification. The Draft EIR/EIS identified a wide range of potentially significant effects that could occur throughout an extended area and affect numerous agencies, jurisdictions, and other interested parties and established a mitigation program to reduce or avoid significant effects. Many of the significant effects of the Project would occur within the City, yet many of the identified mitigation measures lack sufficient detail to clearly establish the feasibility of implementation and methods in which measures would be implemented. The Draft EIR/EIS should have included the MMRP to provide Responsible Agencies and other interested parties with the opportunity to comment on it. Because of the gravity of the potential effects of the Project, the Draft EIR/EIS should be revised to include the MMRP and be recirculated to allow for Responsible Agency and stakeholder comment.

Marina-1

CHAPTER 1 – INTRODUCTION AND BACKGROUND

CEQA requires that the CPUC prepare an accurate and clearly written statement of the Project's objectives. CEQA Guidelines § 15124(b). This statement is particularly necessary when evaluating mitigation measures and alternatives for the Project. NEPA correspondingly requires that an EIS "specify the underlying purpose and need to which the agency is responding in proposing the alternatives including the proposed action." 40 C.F.R. § 1502.13. NOAA's NEPA Compliance Manual (2017) makes clear that the "decision maker" (MBNMS here) "must clearly identify the purpose and need for the action," that "the 'need' is the underlying problem that the proposed action addresses," and that "a carefully crafted purpose and need statement can be an effective tool in managing the scope of the NEPA analysis." It is important that the agencies carefully use their own judgment in defining the project objectives and needs, rather than simply adopting the "objective" or "need" statements provided by the applicant.

Marina-2

The Project Objectives in chapter 1.3.1 (page 1-5) of the Draft EIR/EIS do not meet these requirements. They include a series of purported objectives – including "sufficient water supplies to serve existing vacant lots of record," providing water supplies so CalAm can "pay back the Seaside Groundwater Basin" with water for 25 years, and to "provide sufficient conveyance capacity to accommodate supplemental water supplies that may be developed at some point in the future to meet build out demand" by unspecified future customers – that appear to merely represent a "wish list" of vague objectives to justify building a Project that will provide CalAm with large amounts of additional water that it does not truly need.

Marina-2 cont.

Although the Project seeks to extract Salinas Valley Groundwater Basin water to produce water far beyond its existing water needs, the CPUC and MBNMS are required to scrutinize and apply a more rigorous standard when evaluating and stating the true amount of Project water needs. The failure to do so here has resulted in a request for water that dramatically exceeds the Project's actual needs as detailed in the City's comments on chapters 2.1 – 2.5 herein. This deficiency has resulted in an unnecessarily inflated water demand that is causing a wide array of significant harmful effects. The CPUC and MBNMS should omit these three project objectives and define the true objectives and needs of the Project.

CHAPTERS 2.1 TO 2.5 – WATER DEMAND AND SUPPLIES

The concerns that the City expressed for Draft EIR/EIS chapter 1 herein become particularly important given the information in chapters 2.1 to 2.5. It appears that the Project "water demand" greatly exceeds CalAm's actual needs, which unnecessarily intensifies all of the Project's environmental impacts and undermines the formulation and comparison of Project alternatives.

These chapters disclose that the proposed desalination Project (9.6 mgd size) is expected to produce 10,750 acre-feet per year ("afy") of water for delivery to CalAm customers. This annual amount exceeds CalAm's total water deliveries to its entire network of customers in both 2014 (10,250 afy) and 2015 (9,545 afy). No figures are provided for 2016; these should be added. In addition to this requested annual amount from the Project, CalAm expects to receive a total of between 5,544 and 6,244 afy of additional water every year in the future, primarily from the Carmel River, Seaside Basin and ASR (even after the anticipated litigations and restrictions are imposed), resulting in a total of between 16,294 and 16,911 afy of CalAm water supply each year. *See* Table 2-4.

Marina-3

The Draft EIR/EIS analysis of water demand is legally inadequate under CEQA and NEPA because:

- The Draft EIR/EIS has selected the wrong existing annual water demand figure based on the information provided by CalAm. Table 2-2 reflects that CalAm's annual service area demand has declined consistently over a ten-year period from 14,176 afy in 2006 to 9,545 afy in 2015. This steady decline is the result of many factors including permanent water conservation measures. There is no reason to believe that these annual declines will not continue in the future. Nonetheless,

CalAm has proposed and the CPUC has apparently accepted the ten-year average of these deliveries, or 12,351 afy, as the appropriate "existing demand" number. In fact, this figure is factually unsupported and should be no higher than 9,545 afy.

- CalAm then adds to its "water demand" request a total of 2,005 afy for "rebound of the Monterey Peninsula tourist industry," water for paper "legal lots" that do not now use water, and potential Pebble Beach water entitlements. The Draft EIR/EIS fails to adequately scrutinize these amounts. The tourist industry rebounded strongly already in 2014-15 (*see* Dean Runyon Associates Study, 2016, discussed on page 6-16), yet CalAm had its lowest customer demand in the last ten years in 2014 and 2015. Thus, this "rebound demand" number is simply not credible. The other two components are also not firm demand amounts, but rather are based merely on future speculation.

- Finally, CalAm confirms that the Project will supply it with an extra amount of between 2,019 and 2,719 afy of water each year that it plans to apply to unspecified "other uses." *See* Table 2-4. There is no demand at all for this water. This surplus and unallocated quantity is obviously not part of CalAm's actual "need" for the Project and should therefore also be subtracted from the asserted water demand for this Project.

Marina-3 cont.

In sum, the Draft EIR/EIS analysis of Project water demand is scientifically and legally inadequate. CalAm does not "need" 10,750 afy from the Project or a total of over 16,000 afy of water supply when its existing total service area demand is 9,545 afy and steadily declining. Since by its own calculations, CalAm will receive up to 6,244 afy of water from other sources in future years, its apparent true demand and need from the Project or other water sources is at most in the range of 3,000 afy.

This incorrect water demand analysis also creates serious water rights and water supply issues because of the overdrafted condition of the Basin and the water supply needs of the Basin's current legal users. The California Constitution provides that "the waste or unreasonable use or unreasonable method of use of water be prevented, and that the conservation of such waters is to be exercised with a view to the reasonable and beneficial use thereof in the interest of the people and for the public welfare." Cal. Const. art. X, § 2. Thus, an attempted export of groundwater that is for a purpose in excess of current needs, and particularly for unspecified or projected future needs, is a prohibited "waste" of groundwater, particularly in an overdrafted basin in which this new user would have the lowest priority rights.

Marina-4

This deficient supply/demand analysis forms the basis of the CEQA project objectives and federal "need" statement defines the nature, intensity and scope of the environmental impacts in many important subject areas, ranging from the physical impacts to the sensitive coastal ecosystem, to the major potential impacts to the Basin aquifers, to the volume and impacts of the brine discharge. It also drastically and unreasonably limits the selection of potential CEQA/NEPA alternatives as summarized in our comments for chapter 5 herein.

Moreover, as discussed in the next section, California water law bars any groundwater extractions that would cause potentially far-reaching water supply and water quality impacts to Marina's groundwater basin to supply CalAm with 7,000 afy of water that it does not currently need.

Marina-4 cont.

CHAPTER 2.6 – WATER RIGHTS

A. Introduction

At the outset, we disagree with the legal contention in the Draft EIR/EIS that water rights is not an appropriate topic for a NEPA EIS or CEQA EIR and only needs to be addressed here in the context of Project "feasibility." Although the Draft EIS/EIR acknowledges that an EIR for a "large scale land use development project" should "show a reasonable likelihood that water will be available from an identified source," it attempts to argue that the cases mandating these legal requirements arise in a different context and should not apply to a water supply project itself. *Id.* at 2-13.

In fact, it is absolutely essential that a water supply project demonstrate that it has a firm right to obtain water from an identified source, particularly since the sole purpose of such a project is to procure water for customers. In many cases under CEQA, courts have invalidated EIRs in which the document does not adequately analyze a project's water rights and sources. *See, e.g., Santa Clarita Org. for Planning the Env't v. Cty. of Los Angeles*, 106 Cal. App. 4th 715, 723 (2003) ("Instead of undertaking a serious and detailed analysis of SWP supplies, the EIR does little more than dismiss project opponents' concerns about water supply. Water is too important to receive such cursory treatment."); *Save Our Peninsula Comm. v. Monterey Cty. Bd. of Supervisors*, 87 Cal. App. 4th 99, 131-33 (2001) (the failure to discuss asserted riparian rights required invalidation of the EIR); *Cadiz Land Co. v. Rail Cycle, LP*, 83 Cal. App. 4th 74, 92-93 (2000) (EIR failed to "discuss the volume of the aquifer groundwater, particularly potable water, which is a valuable and relatively scarce resource in the region" and other water supply information was needed because "an informed decision cannot be made as to whether it is worth taking the risk of subjecting a valuable water source to contamination.").

Marina-5

The Draft EIR/EIS fails to appreciate the tremendous public concern regarding the Project's groundwater supply and contamination issues. It is surprising and inadequate that for a project of this size, complexity and expense, the Draft EIR/EIS would dismiss the importance of carefully addressing within the Draft EIR/EIS CalAm's lack of current water rights to appropriate and export water from the Basin. Instead, the authors apparently assume (in contravention of the best scientific information available and legal precedent) that such groundwater rights will be established in the future. However, in so assuming, the Draft EIR/EIS mistakenly ignores the vital public information role that the document must play on this topic. *See Laurel Heights Improvement Assn. v. Regents of the Univ. of Cal.*, 47 Cal.3d 376, 392 (1988); *California Oak Found. v. City of Santa Clarita*, 133 Cal. App. 4th 1219, 1237 (2005) ("'To facilitate CEQA's informational role, the EIR must contain facts and analysis, not just the agency's bare conclusions of opinions.' This standard is not met in the absence of a forthright

discussion of a significant factor that could affect water supplies. The EIR is devoid of any such discussion.") (quoting *Concerned Citizens of Costa Mesa, Inc. v. 32nd Dist. Agric. Ass'n*, 42 Cal. 3d 929, 935 (1986)).

The City of Marina currently obtains 100 percent of its potable water from the Salinas Valley Groundwater Basin ("SVGB" or "Basin"). In addition, many agricultural and other overlying users of water within the City rely on wells that extract water from the Basin. It is undisputed that the Basin has been in an overdraft condition for decades, which means that there currently is no surplus water available. Indeed, the Department of Water Resources recently designated the 180/400 Foot Aquifer as one of only 21 basins in California that are "critically overdrafted" for purposes of California's new Sustainable Groundwater Management Act. Accordingly, this groundwater aquifer is oversubscribed with no surplus water available for export outside the Basin.

The Marina Coast Water District ("MCWD") recently reported that Marina and other cities/areas that it serves have land use plans that reflect robust projected growth rates, with the population of the MCWD service area anticipated to double in the next 15-20 years. (*See* App. 2 herein.) Future landowners of current lots have overlying rights to the Basin groundwater and the City and MCWD also have corresponding overlying and appropriative pumping rights. And as summarized herein, the water that would be extracted by the slant wells is presumed by California law to be groundwater rather than seawater (see comments on Draft EIR/EIS Chapter 4.4). Thus, there is not now and likely will not for the foreseeable future be any groundwater in this Basin available for export.

Marina-5 cont.

It is also important to note that Marina is a recognized minority community under local, state and federal standards (see comments on Draft EIR/EIS chapter 4.20 herein). The City's access to a clean and sufficient water supply is very important to this community and any injury to or interference with this access will cause serious social and economic impacts to the City because of the prohibitive cost of obtaining any replacement water. In short, it appears that any use of groundwater by the Project could cause serious and unmitigatible impacts to Marina's water supply, water rights and groundwater quality.

B. The Project Does Not Now Have And May Not Be Able To Establish In The Future Any SVGB Appropriative Water Right.

It is undisputed that the Project has no existing rights to extract groundwater in the SVGB. It currently has no significant "overlying rights" to groundwater, no prescriptive groundwater rights and no appropriative right to groundwater. Draft EIR/EIS at 2-30 to 2-31. Rather, despite the critical overdraft condition of the Basin, CalAm apparently plans to just build its facilities and start pumping groundwater from the Basin on the theory that it will later be able to establish such appropriative rights.

Marina-6

In a surprising analysis in chapter 2.6, the Draft EIR/EIS takes the unwarranted position that CalAm will have the right to extract groundwater from the Basin. Although the authors and

CPUC disclaim that they are providing a legal opinion regarding such water rights, and assert that they are only looking at the issue from the viewpoint of whether the Project is "feasible," the document then concludes that "there is a sufficient degree of likelihood" that CalAm will have necessary water rights (page 2-30). However, this speculation is based on a faulty reading of the *Final Review of California American Water Company's Monterey Peninsula Water Supply Project,* State Water Resources Control Board, July 31, 2013 ("State Board Report"), enclosed as Appendix B2 to the Draft EIR/EIS.

The Draft EIR/EIS has mischaracterized the findings of the State Board Report. The Report does not find that such water rights exist. In fact, as detailed below, the Report emphasizes the heavy proof burden that CalAm would have to carry to demonstrate that it would not be causing injury to current or future users of the Basin and to establish any water rights in this critically overdrafted basin. Since the Draft EIR/EIS has not accurately summarized the State Board Report, we will briefly do so here.

The State Board Report explains that there are three successive legal hurdles that CalAm would need to overcome to establish water rights. First, because CalAm proposes to "export" water from the Basin to non-overlying parcels in the Monterey region, CalAm would need to demonstrate that "the water is 'surplus' to existing uses or does not exceed the 'safe yield' of the affected basin." *Id.* at 35. However, since the groundwater in the Basin is in a critical overdraft condition, it is undisputed that there is not any "surplus water" available for export to non-overlying parcels. *Id.* Thus, the only conceivable way to export water is by establishing a new water source (discussed further below).

Marina-6 cont.

The second impediment to establishing water rights is that CalAm must demonstrate that the Project "will not harm or cause injury to any other legal user" of the groundwater. This "no injury" rule has been a bedrock principle of California surface water and groundwater law since the 1800s. It is codified in multiple sections of the Water Code with respect to surface waters. *See, e.g.,* Cal. Water Code § 1702 (a change to an appropriative water right requires a finding "that the change will not operate to the injury of any legal user of the water involved"); *id.* § 1706 (changes can be made "if others are not injured by such change"); *id.* § 1727 (a temporary change requires demonstration that it "would not injure any legal user of the water"). *See also State Water Res. Control Bd. Cases*, 136 Cal. App. 4th 674, 736-44 (2006).

A landmark California Supreme Court case applied the "no injury" rule to exports from groundwater basins. *Allen v. Cal. Water and Tel. Co.*, 29 Cal. 2d 466 (1946). This case was an action by overlying and prior appropriative users to enjoin a water company from exporting water from an underground river basin. The plaintiffs alleged that extraction of the large quantity of water which the company proposed to export would leave insufficient water for other users and would impair the water quality (salinity and other components) for domestic and agricultural use. The trial court agreed and found that there was no surplus available for export because all of the water was necessary to meet the "paramount rights" of the overlying users and prior appropriative rights. Moreover, the court found that the water company could not establish that no injury to water quality or water levels would occur. The Supreme Court affirmed these findings although it adopted slight modifications to the injunction.

The *Allen* case illustrates both the extreme difficulties that a proposed water exporter such as CalAm will face in meeting the stringent "no injury" rule and the likelihood of a court injunction barring its plans based on the current situation. According to the State Board Report, to show lack of injury, CalAm would need to demonstrate no injury to legal users in each of the following subject areas: (1) the amount of fresh water it will use, (2) the lack of pumping impacts to the water table level in existing wells, (3) that pumping is not affecting seawater intrusion within the Basin, (4) the plans for return of fresh water to the Basin if CalAm plans to propose a physical solution, and (5) the potential future impacts of changes in the fresh water and seawater on groundwater rights. Moreover, this demonstration must be made not only for existing users, but also for overlying landowners and other appropriators using the Basin who can be reasonably expected to extract groundwater in the future. State Board Report at 55 (the analysis must examine "all present and potential reasonable potential uses," in part because "[p]otential overlying uses are often inherently implicated in determining whether a long-term surplus actually exists").

The third tier of legal tests that CalAm would need to successfully navigate involves a demonstration that it is developing a new source of water. The exporter must demonstrate that "it is extracting groundwater that no Basin user would put to beneficial use" and any source that is considered fresh water "would not be considered developed water." *Id.* at 36-37. Moreover, it must demonstrate that its developed seawater is a new supply to the existing Basin groundwater resources, that "replacement water methods are effective and feasible," and that the Project "can operate without injury to others." *Id.* at 47.

Marina-6 cont.

The State Board Report does not state that CalAm is likely to meet any of these tests or establish water rights. Rather, the most the Report can state is that it "may be possible" for CalAm to establish a right to extract this groundwater. *Id.* at ii. And the Report repeatedly identifies many areas of missing information that prevented it from drawing any definitive conclusions, including whether the aquifers are confined or unconfined, what the actual extent of water use is, specific information about the aquitards, whether gravity or pumping wells will be used (because pumping wells generally have more extensive impacts), key hydrogeological information, and a credible groundwater model that also examines cumulative impacts. *Id.* at i-iii, 5, 21-23, 50-51. Given these and other "significant unknowns," the Board could not provide any definitive conclusions regarding this Project's water rights or its potential effect on water quality.

The Draft EIR/EIS discussion of CalAm's potential water rights in section 2.6 fails to address or resolve these critical data gaps and legal issues. It confuses the concept of "significant impacts" under CEQA with the "no injury" water law rule (which is not based on or equivalent to a significant impacts CEQA test), fails to address the missing technical information identified by the State Board Report, and simply does not analyze the series of legal hurdles that CalAm would need to surmount to establish such rights. It also ignores the fact that, if there is uncertainty regarding whether a type of injury is occurring, this would prevent CalAm's future establishment of a water right because CalAm would have failed to meet its proof burden. Rather, in contravention of over a century of water rights law, the Draft EIR/EIS turns this proof

burden on its head: the Draft EIR/EIS asserts that since it has not found "significant impacts" to a few water supply and quality issues, then CalAm will meet its burden to show that no injury to legal users is present.

It is not surprising that, after creating this faulty analytical framework, the Draft EIR improperly concludes: "it seems reasonable to conclude that the MPSWP would not cause harm or injury to Basin water rights holders such that CalAm would possess the right to withdraw water from the Basin to produce 'developed water' for beneficial use and under the physical solution doctrine." *Id*. at 2-37. The section also points out that no water right is needed for seawater extraction and states that no permit is needed for groundwater withdrawal (implying that this somehow makes it more likely that the right will exist). These assertions reflect a misunderstanding of water rights procedure and jurisprudence. It is undisputed that the proposed slant wells will extract substantial amounts of groundwater (which the State Board Report asserts could be as high as 762-3250 acre-feet each year), so the seawater point is immaterial. Since no permit system exists for the water right CalAm hopes to establish, CalAm's path to establish such rights will be more difficult and time-consuming than if a permit system was available. Thus, any claim to such water rights likely will be tied up for years in judicial and/or regulatory water rights proceedings, indefinitely delaying the onset of the Project.

In fact, the available hydrogeologic and scientific data strongly indicate that the Project will not be able to surmount the three tiers of legal hurdles for the following reasons:

Marina-6 cont.

- It is undisputed that the Basin is "critically overdrafted" – therefore, no surplus water is available for export.

- Large amounts of groundwater, including some municipal water for the City of Marina, are extracted by current legal users from the 180/400 Foot Aquifers in which CalAm proposes to install its slant wells.

- It appears from scientific studies that there could be injury to water quality in the 180/400 Foot Aquifers and potentially the 900 Foot Aquifer given the communication between these aquifers and other available data.

- The slant wells are a new and unproven technology as described in the comments on chapter 3 herein.

- The groundwater model described in the Draft EIR/EIS does not credibly or sufficiently analyze the impacts of the proposed slant well extractions, thereby failing to demonstrate the lack of injury to legal users.

- The CalAm replacement water proposal recited in the Draft EIR/EIS fails to meet legal requirements. Rather than restoring the groundwater resources in the Basin through injection or other means, it involves delivery of water to a few selected users in the hopes that they will cease pumping groundwater in that amount. It is unworkable and infeasible because it does not restore Basin groundwater

hydrology and supplies, protect a full range of legal users, or contain necessary regulatory controls.

In sum, the Draft EIR/EIS analysis of water rights is inaccurate, legally flawed and factually unsupported and therefore legally inadequate. There are a variety of injuries to present and future legal users of this groundwater that have not been analyzed and, if the technical information is not sufficient to demonstrate that an injury is not occurring, CalAm will not establish any water right. The three tiers of legal criteria that CalAm must navigate to establish an appropriate water right are extremely daunting and must be supported by credible scientific evidence every step of the way. It appears unlikely that CalAm will ever be able to successfully run this legal gauntlet. Although it is theoretically possible (as the State Board Report recognized when it said that it "may be possible" for CalAm to do so), it is highly unlikely that CalAm ever can or will. The absence of any demonstrated water rights is a fundamental Project deficiency that prevents the Project from being "feasible" at the current time within the meaning of applicable law.

Marina-6 cont.

C. The Implementation Of California's New Sustainable Groundwater Management Act Will Likely Prevent Establishment Of Project Water Rights.

The Draft EIR/EIS fails to appreciate or disclose that the State Board Report was written before the enactment and implementation of the Sustainable Groundwater Management Act ("SGMA"), which is the first comprehensive legislation in California history that regulates the extraction and use of groundwater. *See* Cal. Water Code §§ 10720, *et seq*. The adoption of SGMA fundamentally changes the ground rules for the management and use of groundwater and adds an additional important layer of regulation applicable to the Project that was *not* addressed in the State Board Report. Moreover, it is yet further evidence that the Project is unlikely to obtain appropriative groundwater rights to the Basin.

SGMA has established a new regulatory regime for groundwater that is currently being implemented. The general steps in the process consist of classifying the priority of groundwater basins, adopting regulations governing different aspects of the process, forming Groundwater Sustainability Agencies ("GSAs"), and preparing and implementing Groundwater Sustainability Plans ("GSPs"). The baseline condition for purposes of the Act is the condition of a groundwater basin as of January 1, 2015. Cal. Water Code § 10727(b)(4). The Plan prepared by each GSA must ensure that a particular groundwater basin is not subjected to "undesirable effects," which include the following: lowering of groundwater levels; reduction of groundwater storage; seawater intrusion; degraded water quality; land subsidence; and depletions of interconnected surface water. Cal. Water Code § 10721(w). Indeed, the Basin must be managed to "achieve the sustainability goal in the basin within 20 years of the implementation of the plan." *Id*. § 10727(b)(1).

Marina-7

One important cornerstone of SGMA is its commitment to local agency management of groundwater basins. This policy is stated in the first section of the law: "Sustainable groundwater management is best achieved locally through the development, implementation, and updating of plans and programs based on the best available science." Cal. Water Code § 113.

This policy is reflected in several findings by the Legislature, including: "[g]roundwater resources are most effectively managed at the local or regional level" and "[l]ocal and regional agencies need to have the necessary support and authority to manage groundwater sustainably." SGMA is designed to organize and address the many adverse groundwater impacts caused by individual and uncoordinated extractions by private companies, individuals and other entities. The stated intent of the Legislature in enacting the SGMA includes "to enhance local management of groundwater consistent with rights to use or store groundwater…," "to provide local groundwater agencies with the authority and the technical and financial assistance necessary to sustainably manage groundwater," and "to manage groundwater basins through the actions of local governmental agencies to the greatest extent feasible, while minimizing state intervention to only when necessary to ensure that local agencies manage groundwater in a sustainable manner." Cal. Water Code § 10720.1(b), (d) & (h).

The SVGB (from which CalAm hopes to extract groundwater) has been targeted for expedited treatment under SGMA because it is one of only 21 groundwater basins in California (out of hundreds) that is deemed to be critically overdrafted. Given this serious condition, the Basin must have an adopted GSP in place by January 31, 2020. Among other things, the GSP can contain such restrictions as limiting or suspending well extractions, regulating construction of new wells, and establishing groundwater extraction allocations.

Marina-7 cont.

The Draft EIR/EIS attempts to avoid and trivialize the substantial impact of SGMA's new regulatory regime by stating that it does not affect water rights and therefore will not affect the Project. However, this position is inaccurate in two key respects. First, CalAm does not currently have any water rights in the Basin and will not be in any position to attempt to establish them for years. Thus, although it is true that SGMA does not modify "rights or priorities to use or store groundwater" (Cal. Water Code § 10720.5), CalAm does not have any existing rights or priorities. Indeed, SGMA explicitly bars the use of groundwater extraction after January 1, 2015 in high-priority basins (like the SVGB) to establish prescriptive water rights. *Id.* Second, the groundwater extraction limitations and other powers of the GSA for this Basin are highly likely to be implemented quickly for this Basin given its critical overdraft condition and water quality issues.

In sum, the Draft EIR/EIS's attempt to assess the feasibility of the Project from a water rights viewpoint is deficient for its failure to analyze the impact of SGMA's new and comprehensive groundwater legal regime. This legislation will adversely affect CalAm's ability to establish water rights in the first place because it does not have any overlying or prescriptive water rights and must rely on future pumping activity to attempt to establish the rights. Moreover, even if CalAm is able to begin pumping any groundwater from the Basin (which appears unlikely), it is almost certain that the existing groundwater quality and water shortage issues in the Basin will result in imposition by the GSA of strong limitations on the location and volume of CalAm groundwater extractions because it will have the lowest priority of all Basin users.

D. The Project's Plans To Export Water Out Of This Basin Conflict With And Violate The Agency Act And Ordinance No. 3709.

In 1990, the California Legislature adopted the Monterey County Water Resources Agency Act ("Agency Act"). Cal. Water Code App., § 52. Section 21 of the Agency Act states:

> *[n]o groundwater from that basin [Salinas River Groundwater Basin] may be exported for any use outside the basin*, except that use of water from the basin on any part of Fort Ord shall not be deemed such an export. If any export of water from the basin is attempted, [the Monterey County Water Resources Agency] may obtain from the superior court, and the court shall grant, injunctive relief prohibiting that exportation of groundwater. Cal. Water Code App. § 52-21 (emphasis added).

In 1993, in furtherance of the Agency Act, the Monterey County Water Resources Agency ("MCWRA") adopted Ordinance No. 3709, the "purpose" of which is "to prohibit groundwater extractions from extraction facilities located in the northern Salinas Valley with perforations between zero feet mean sea level and -250 feet as of January 1, 1995, so as to reduce the rate of seawater intrusion and allow recharge to raise groundwater levels." *Id.* § 1.01.02.

Marina-8

Both CEQA and NEPA require conflicts with existing plans and law to be identified and addressed. For example, the Council on Environmental Quality ("CEQ") regulations implementing NEPA contain very specific requirements, directly implicated here, that "statements [EISs] shall discuss any inconsistency of a proposed action with any approved State or local plan and laws (whether or not federally sanctioned). Where an inconsistency exists, *the statement should describe the extent to which the agency would reconcile its proposed action with the plan or law*." 40 C.F.R. § 1506.2(d) (emphasis added).

It is undisputed that the Project proposes to extract groundwater from the Salinas Valley Groundwater Basin in the geographic area covered by the Agency Act and Ordinance No. 3709 for export to non-overlying users. Although the Draft EIR/EIS appears to argue that some of the extraction locations may be just outside Monterey County boundaries, the Draft EIR/EIS reflects that in fact all or almost all of the screened areas of the proposed slant wells would extract water from within County boundaries. *See* Figure 3-3a. Accordingly, the proposed Project extraction and export plans are directly prohibited by the Agency Act and Ordinance.

Nonetheless, the Draft EIR/EIS states (page 2-40) that it is "at least preliminarily reasonable to conclude that the project would be consistent with the Agency Act and the Ordinance such that those laws would not impair project feasibility." This conclusion is not based on any specific factual or legal analysis. Rather, it relies solely on a section of the State Board Report which suggests that, because the Project "would return any incidentally extracted usable groundwater to the Basin," there would be no "net effect" in exporting the water, which might provide a legal ground to avoid the water export ban.

This thin analysis is legally inadequate for multiple reasons and does meet the requirements of CEQA and NEPA recited above. First, the State Board has no jurisdiction or special expertise to interpret the Agency Act or Ordinance No. 3709 and would not be accorded any judicial deference for its interpretation. Second, the State Board assumed, when offering these advisory thoughts, that the Project would return any pumped groundwater directly to the Basin itself. However, the Draft EIR/EIS discloses that the Project has changed this plan and now will instead be delivering water to a select group of overlying users and not injecting it back into groundwater. Thus, the factual rationale for the State Board's idea is no longer operative.

Third, neither the Agency Act nor the Ordinance provides any textual support for an argument that a blanket prohibition on export actually means that export is allowed so long as the "net effect" (with return groundwater) is not to take water out. This "net effect" approval focuses only on the total quantity of groundwater in the Basin, not on groundwater quality or other issues. In contrast, the Act has a broad range of groundwater purposes, which include "to increase, and prevent the waste or diminution of the water supply in the agency, including the control of groundwater extractions as required to prevent or deter the loss of usable groundwater through intrusion of seawater" and "to prohibit groundwater exportation" from the Basin. *Id*. § 52-8. Similarly, the Ordinance expresses a wide range of seawater intrusion and groundwater recharge concerns which go far beyond the total amount of water in the Basin, including because "seawater intrusion is most extensive in the Pressure 180 Foot Aquifer and threatens to contaminate lower aquifers which supply drinking water to thousands of Salinas Valley residents" and such intrusion is "in and near these areas."

Marina-8 cont.

In short, the Draft EIR/EIS fails to adequately analyze or reconcile these direct statutory prohibitions on the Project's planned export of Basin groundwater. These are significant legal obstacles which have not been thoroughly assessed and no explicit plan for reconciliation is provided.

E. The Project Is Inconsistent With The CEMEX Property Annexation Agreement.

In 1996, the City entered into an agreement with RMC Lonestar (the owner of what is now sometimes called the CEMEX Property) and other parties entitled *Annexation Agreement and Groundwater Mitigation Framework for Marina Area Lands* ("Annexation Agreement"). The purpose of the Annexation Agreement is to "help reduce seawater intrusion and protect the groundwater resource and preserve the environment of the Salinas River Groundwater Basin" and to provide conditions for annexation of the Lonestar and other properties to MCWRA zones. *Id*. § 1.1. One key Annexation Agreement condition is that "[c]ommencing on the effective date of this Agreement and Framework, Lonestar shall limit withdrawal and use of groundwater from the Basin to Lonestar's historical use of 500 afy of groundwater." *Id*. § 7.2

Marina-9

This provision, which remains applicable to the CEMEX Property, directly limits groundwater extractions from the property to 500 afy. The effective date of the Annexation Agreement is defined as "Subject to paragraph 4, this Agreement and Framework shall be fully

effective when executed by all of the Parties." All of the Parties executed it in 1996 and it thereby became effective at that time. The reference to paragraph 4 does not change the effective date because that paragraph merely provides that Lonestar (the owner of the CEMEX Property at that time) requests immediate annexation of its land. Accordingly, this extraction limitation is binding on all property users and directly prohibits the annual total groundwater extractions by the Project (and CEMEX, to the extent it extracts groundwater) from exceeding 500 afy. This is an important constraint on the Project because, according to the State Board Report, it seeks to extract up to 3,250 afy of Basin groundwater.

In section 2.6.4 of the Draft EIR/EIS, the CPUC and MBNMS mistakenly conclude that this groundwater withdrawal limitation in the Annexation Agreement "does not apply" to the Project. They assert two bases for this position: (1) that the limitation only applies once the Lonestar Property has been formally annexed; and (2) that if the extraction limitation does go into effect in the future, it would be avoided by using the same "net effect" approach discussed in the previous section. Draft EIR/EIS at 2-42.

The Draft EIR/EIS discussion of this issue is both legally incorrect and legally inadequate. First, there is no textual support for its view that annexation of the CEMEX Property is a precondition to the extraction limitation. The document clearly says that it commences on the "effective date" of the Agreement rather than on the date that the later annexation occurs. This difference is vividly illustrated by the parallel extraction limitation for the Armstrong Property, which states, in part: "Armstrong shall limit potable water withdrawn from the Basin ... to no more than 20 afy when this Agreement and Framework becomes effective, 150 afy *upon annexation* to the Zones, and …" *Id.* § 6.9.1 (emphasis added). As you can see, the drafters carefully distinguished between the effective date and the annexation date and, if they wanted annexation itself to be a precondition to an extraction limitation, they said so. Thus, the document's plain language demonstrates that annexation cannot be read into the Agreement as a precondition to the 500 afy limitation for the CEMEX Property.

Marina-9 cont.

Second, even as the Draft EIR/EIS concedes, formal annexation could occur at a future time, so the extraction limitation would become effective at that time and bar extraction of more than 500 afy of Basin groundwater at the CEMEX Property.

Third, the Draft EIR/EIS erroneously contends that, once the extraction limitation is in place, "operation of the MPWSP could still be feasible" because CalAm "could conceivably construct" an injection well on the CEMEX site to return 500 afy of groundwater or it could use the water return program mentioned above to result in "no net effect" to groundwater. Draft EIR/EIS at 2-42. However, these speculative statements are improper and have no textual or legal support.

If CalAm is going to construct a new injection well on the CEMEX Property to inject water back into the Basin, this new component should have been included in the Project Description. Since it is not now in the Project Description and its potentially significant environmental impacts have not been analyzed in the Draft EIR/EIS, this significant change

would require recirculation of the document. Moreover, since the extraction limit is 500 afy, the amount that would have to be returned via injection well would not be 500 afy; rather, it would be at least in the range of 2,750 afy, which is the amount of groundwater over the 500 afy limit that the Project concedes it will extract from the Basin.

Finally, the unsupported statement on page 2-42 of the Draft EIR/EIS that the return water program would "keep the Basin whole, serving the purpose of the Annexation Agreement" is not correct for the same suite of reasons as mentioned in the Agency Act section. The Annexation Agreement is designed to reduce seawater intrusion, protect groundwater resources and preserve the environment of the Basin. It is simply not credible to assert that water injection at the CEMEX Property or delivery of water to Castroville customers will have all of these positive hydrologic and environmental effects on the Basin.

Marina-9 cont.

Therefore, the 500 afy groundwater extraction limitation in the Annexation Agreement poses a significant and potentially fatal impediment to the Project's groundwater extraction plans. In fact, unless groundwater withdrawals are limited to 500 afy, the Project cannot go forward. If the Project plans to address or mitigate for these impacts as part of a legal argument that it will not be violating the Annexation Agreement, any new facilities, mitigation measures and impacts need to be fully discussed and be included in the comparison of alternatives in a new EIR/EIS that is recirculated for public comment.

CHAPTER 3 – PROJECT DESCRIPTION

It is essential that the project description in an EIR/EIS be accurate, stable and include all elements of a Project. *See, e.g.*, *Dry Creek Citizens Coal. v. Cty. of Tulare*, 70 Cal. App. 4th 20, 26 (1999) (an EIR needs to be "prepared with a sufficient degree of analysis to provide decision makers with information which enables them to make a decision which intelligently takes account of environmental consequences"); *County of Inyo v. City of Los Angeles*, 71 Cal. App. 3d 185, 192-93 (1977). The Draft EIR/EIS fails to meet these standards in the respects identified below.

A. The Draft EIR/EIS Incorrectly And Misleadingly States The Location And Source Of The Water For The Project.

Marina-10

The Draft EIR/EIS repeatedly and inaccurately asserts that the Project's water source is seawater. Thus, the text of section 3.2.1.1 claims that the Project's slant wells "would draw seawater from beneath the ocean floor." *Id*. at 3-7. The wells that will accomplish the extraction of seawater under the ocean floor "would be drilled from an onshore location and would extend under the seafloor within MBMNS using a 36-inch- to 22-inch-diameter steel casing." *Id*. at 3-15.

However, these descriptions incorrectly describe the location and source of the Project source water. In fact, only a very small percentage of each well extends beneath the ocean floor within the MBNMS (defined as beyond the mean high water line), ranging from 7 percent to 25

percent of the total length, and one well does not extend under the ocean at all. Table 3-3b. Thus, 75-93 percent or more of the water captured by the wells would be withdrawn from groundwater aquifers within the City of Marina, not from areas under MBNMS jurisdiction. Indeed, as the document concedes, the wells are being screened to extract water from the Dune Sand and 180 Foot Aquifers on land, rather than being located and screened to extract seawater from beneath the ocean floor. *Id.* at 3-15. Thus, a true description is that the slant wells are primarily designed to draw groundwater from two aquifers, with a small seawater component.

This is an important distinction that strikes at a fundamental misconception at the heart of the Draft EIR/EIS's description of the Project. This Project is not an ocean water desalination project. Rather, it is specifically targeted to extract groundwater from the 180/400 Foot Aquifers beneath land under Marina's jurisdiction (rather than the MBNMS) that it recharacterizes as "seawater" based on an argument that it is too saline for use by the current legal users. However, both State Board Resolution No. 88-63 (discussed in the chapter 4.4 comments) and the Water Code establish that all underground water not in a defined channel is groundwater. *See, e.g.*, Cal. Water Code § 10721. The quality of this water may be degraded by seawater intrusion, but that does not somehow transform this groundwater in aquifers underlying the City of Marina into ocean water.

Marina-10 cont.

B. The Draft EIR/EIS Fails To Disclose That The Proposed Slant Wells Are A Risky And Unproven Technology With No Operational Track Record.

The description of the proposed subsurface slant wells in section 3.2.1.1 is flawed because it does not disclose to the reader that slant wells are a new and unproven technology whose long-term reliability is unknown.

The Independent Scientific Technical Advisory Panel (ISTAP) appointed by the California Coastal Commission to examine subsurface intake technologies for the potential Huntington Beach seawater desalination plant concluded that slant well technology is unproven and "the long-term performance of the technology has yet to be confirmed." ISTAP, *Phase 1, Final Report: Technical Feasibility of Subsurface Intake Designs for the Proposed Poseidon Water Desalination Facility at Huntington Beach, California* (2014). Another 2016 technical study concluded, in connection with assessing intake options for the proposed Santa Barbara desalination facility, that "no full-scale desalination plants exist that employ slant wells for source seawater collection." Carollo, *Subsurface Desalination Intake Feasibility Study, Technical Memorandum No. 1*, at 3-19 (Mar. 2016) ("Carollo Report"). This and other factors led to the choice of an open-water intake rather than a sub-surface intake for the Santa Barbara Plant.

Marina-11

Apart from the CalAm test slant well, the only other known location as of March 2016 where this technology has been field tested is at a Dana Point, California pilot desalination facility. Carollo Report at 3-19. In fact, the Dana Point slant well experience raises important red flags relating to its use for the Project. The Carollo Report states that the system "did not collect only seawater but instead a mix of seawater and fresh water from the alluvial aquifer in

the vicinity of the intake location." *Id*. Moreover, over time, the content of iron and manganese in the source water increased to levels "which would require complex pretreatment to implement at full scale" and the source water had very low dissolved oxygen concentration, which would require reaeration before being sent to the outfall. *Id*. The construction time for the slant well was unusually long, estimated to take approximately one year for a single well and two years for a multiple well program.

Nowhere in the Draft EIR/EIS are these technology, reliability and performance issues for subsurface slant wells discussed. The technical document (App. I2) that discusses the intake options for the Project fails to make any mention that this is a new and unproven technology with no track record at any desalination plant in the world, and it does not allude to any of the performance or environmental issues identified in the Huntington Beach and Santa Barbara intake option studies referenced above. In fact, all of the other intake options except for open water intake were eliminated, without any discussion of technical performance or track record factors, because of the supposedly superior performance and lesser environmental impacts of the slant well option. The failure to address such issues renders the selection of intake alternatives legally inadequate.

Marina-11 cont.

Since the track record, performance and reliability of such an important component of the Project is a critical factor to impact assessment, alternative selection, and feasibility here, the failure to disclose this information in the Project Description and to analyze it sequentially in the environmental impact assessments and alternatives analyses is a significant inadequacy that requires full disclosure and recirculation of a new Draft EIR/EIS.

C. There Are Other Inaccuracies In The Project Description That Need To Be Corrected Or Clarified To Meet CEQA/NEPA Requirements.

The Project Description contained in chapter 3.0 of the Draft EIR/EIS is missing key information and needs clarification of other significant issues. Our comments are organized by reference to the applicable section number or table.

Section 3.1 (Page 3-2, Paragraph 4)

Marina-12

This paragraph fails to state when CalAm constructed the test well. Please clarify when the test well was constructed and how long it has been operational. This section also fails to provide any discussion of the test well pumping results. The test well was approved by the CCC (over the objections of the City) due to CalAm's purported need for a test well to confirm feasibility and inform design of the MPWSP. The Project Description should be revised to disclose and discuss the results of the test well pumping program, including impacts that occurred as anticipated and any that varied from modeled/anticipated effects of the pumping. The ways in which the Project has been modified (if any) to account for the test pumping results should be clearly identified.

Section 3.1 (Table 3-1, Page 3-10)

The Brine Storage and Disposal section generally states that "The brine aeration system would maintain dissolved oxygen concentrations in the brine at acceptable levels." Please clarify what threshold is being employed to determine what the acceptable levels are. Marina-13

In addition, this section describes the location of the slant wells as being in a "retired" mining area of the CEMEX facility. Please describe what is meant by "retired mining area." Have all mining operations ceased? Is future mining prohibited in this area? Marina-14

Table 3-1

Table 3-1 describes the location of the proposed wellheads "along the back (inland) side of the dunes." However, the entire CEMEX Property is comprised of a large dune complex and the slant wells and wellheads would be located in the middle of the dune complex. The Project's location in the middle of this significant dune complex should be accurately stated and the related impact analysis should be revised accordingly. The incorrect location of the wells as being "inland" of the dunes is also repeatedly stated in section 3.2.1.1. Marina-15

Table 3-1 describes the Terminal Reservoir and its intended purpose to store desalinated water and ASR product water. However, there is no new pipeline proposed to convey desalinated water to the Terminal Reservoir location. How would the desalinated water be conveyed to the Terminal Reservoir and, if no new pipelines are proposed, has the capacity of existing infrastructure been analyzed? Marina-16

Figure 3-3a

The graded access road shown in this figure does not connect to any other roadways. How was its location determined and how will access to existing roadways and the proposed graded roadway be maintained during the life of the Project? This component is not mentioned in any other portion of the Project Description. Due to the shifting nature of the dunes, this road will require frequent and routine grading to maintain, resulting in additional long-term disturbance of sensitive dune habitat and resources. Impacts related to long-term maintenance of the road (i.e., disturbance of ESHA, potential take of sensitive plant species, conflicts with mining operations, maintenance trips and emissions) do not appear to be addressed anywhere in the Draft EIR/EIS. They should be addressed in a revised, recirculated Draft EIR/EIS. Maintenance of the road would be required for frequent and regular inspections of the slant wells, much more frequently than the described maintenance of the slant wells every 5 years. The Draft EIR/EIS fails to identify and analyze this increase in the severity of long-term impacts in the dunes. Additional mitigation should be required to reduce and avoid impacts to the greatest extent feasible. Marina-17

Section 3.2.1.2

This section references "well clusters." This reference is unclear and the wells should be described consistently throughout the document. Marina-18

If it is intended that the Draft EIR/EIS provide CEQA/NEPA clearance for the Source Water Pipeline optional alignment, this area should be included in the Project area boundary and associated impacts must be analyzed.

Section 3.2.2

The MPWSP Desalination Plant Site Plan includes a Salinas River Overlook Tour Rest Stop, yet this component is not described in this section. If public tours of the plant are proposed, this proposed use must be described and the impacts associated with the use must be analyzed in the Draft EIR/EIS. Marina-19

Section 3.2.2.5

This section describes temporary storage where brine could be stored for up to 5 hours. This temporary storage appears inadequate. What would trigger the need for temporary storage? Repairs to the outfall could last much longer than 5 hours – where would the brine be stored if temporary storage in excess of 5 hours were necessary? Have water supply issues been addressed in the Draft EIR/EIS in the event of a necessary shutdown of the desalination plant? Marina-20

The last paragraph of this section (page 3-28) states that the outfall diffuser ports vary in height above the sea floor and that the dilution calculations assume they are four feet above the seafloor. Based on the information in this section, it is impossible to determine whether this assumption is appropriate. Identified impacts would be underestimated in any areas in which the ports are less than four feet above the seafloor. The location of the ports should be confirmed so that it can be determined whether or not the dilution analysis is adequate and accurate. This information should be recirculated for public review and comment once accurate information has been provided. Marina-21

Section 3.2.3.3

Figure 3-6 does not appear to match the description provided in this section. The Monterey Peninsula Recreational Trail, as shown, is located east of the Project area boundary. If the New Desalinated Water Pipeline is to be constructed along the west side of the trail (as described), then the identified Project area boundary fails to include the area of disturbance for this component. If this project component is missing in the Draft EIR/EIS analysis, and the surveys, existing condition evaluations, and analysis in the Draft EIR/EIS failed to address impacts in this area, then this component has not been adequately addressed in the Draft EIR/EIS. As shown in Figure 3-6, it appears that the New Desalinated Water Pipeline crosses Marina-22

under the existing railroad tracks near the Lapis Road/Del Monte Boulevard intersection and runs south on the west side of the railroad tracks.

If it is intended that this Draft EIR/EIS provide CEQA/NEPA clearance for the New Desalinated Water Pipeline optional alignment, then this area should be included in the Project area boundary and any associated impacts must be identified and discussed.

Marina-22 cont.

Figures 3-6 through 3-9

The Project area boundary, as reflected in Figures 3-6 through 3-9, does not appear adequate to accommodate necessary access for construction equipment and laydown areas for trenchless construction. The Project area boundary should be revised to conservatively include all areas of potential disturbance and the Draft EIR/EIS analysis should be revised accordingly. If the Project area boundary is adequate to accommodate these construction staging and laydown areas, the Draft EIR/EIS should reflect this more accurately by showing the proposed 50 x 50 foot entry and receiving pits at an accurate scale.

Marina-23

Section 3.2.3.8

This section references potential engineering constraints associated with the proposed Castroville Pipeline connection. What are the constraints? How feasible is the proposed Castroville Pipeline connection? The Draft EIR/EIS should fully describe and disclose the feasibility of this component. If the Castroville Pipeline connection is determined to be infeasible or unlikely to be feasible, the Draft EIR/EIS should disclose why it is being analyzed as part of the proposed Project and the public should have the opportunity to review and comment on whether the return of groundwater from the Salinas Valley Groundwater Basin to the CSIP Pond via the Pipeline to the CSIP pond has been fully analyzed. Engineering constraints and associated engineering design changes could result in additional or more severe environmental impacts which have not been adequately disclosed in the Draft EIR/EIS.

Marina-24

Section 3.3.2.1

This section describes a 6,000 square-foot concrete pad for discharge piping. This pad and those required for each wellhead vault should be shown on all Draft EIR/EIS graphics and quantified in the Project Description and throughout the Draft EIR/EIS, so that the extent of disturbance within the dune complex is accurately and clearly stated.

This section also states that the wellheads would be accessible at grade level upon completion. The Draft EIR/EIS inadequately describes the wellheads (will they be built above grade or subsurface?) and omits analysis of maintenance requirements related to the continuously changing elevation and grade of the dunes in which the wellheads would be placed. What type of “at grade” access is proposed and how will it be maintained through the lifespan of the Project? How will changes in surface grade be monitored and addressed throughout the Project life?

Marina-25

Section 3.3.2.1

This section describes the proposed disposal of drilling spoils generated during the lower portion of slant well drilling by spreading the spoils within the disturbed dune area. This unnecessarily worsens and increases impacts on the sensitive dune habitat where the slant wells would be located. There is no evaluation of what types of spoils material would be generated by drilling to the proposed depths and whether or not disposal of up to 100 cubic yards of drilling spoils within the dune complex would adversely affect sensitive dune habitat or species. The disposal of drilling spoils in the dunes should be considered a permanent impact to sensitive dune habitat (ESHA); identified impacts and necessary mitigation requirements should be revised accordingly in a recirculated Draft EIR/EIS. Marina-26

Section 3.3.6

The Project area boundary surrounding the proposed Terminal Reservoir as shown in Figure 3-9b does not appear to be based solely on construction of the reservoir and the 6 acres of disturbance described in this section. What is proposed in the remainder of this area? Additional activity planned in this area must be described in the Project Description and analyzed in the Draft EIR/EIS. Is there existing infrastructure at this location that would connect to the proposed Terminal Reservoir? How would this reservoir be accessed? These components must be fully identified and described in the Draft EIR/EIS. The graphic should also be revised to reflect the total Project area boundary in this location, as it is impossible to determine the potential extent of disturbance and impacts in surrounding areas not reflected in the Draft EIR/EIS. The Draft EIR/EIS should be recirculated once the total area of disturbance has been identified so the public can determine whether additional sensitive resources exist in the areas not shown in the Draft EIR/EIS and whether additional or more severe environmental impacts would occur. This omission has deprived the public of a meaningful opportunity to comment upon potentially significant adverse effects on the environment and the feasible ways in which to mitigate or avoid those effects. Marina-27

Section 3.3.9

This section describes the well locations as within the "CEMEX active mining area." References to the mining area as "active" or "retired" should be corrected to accurately reflect baseline conditions and should be consistently described throughout the document. Marina-28

Table 3-6

Why are the wet seasons for injection different for Desalinated Project Water and Carmel River Supplies? Marina-29

Section 3.4

This section fails to identify an operational lifespan of the Project. This information is necessary to identify and evaluate the extent and duration of potential impacts of the Project. Marina-30

Section 3.4.1

Again, this section describes the location of the slant wells as "on the back side of the dunes." This statement is inaccurate and misleading. The slant wells would be located in the center of the large dune complex that comprises the CEMEX Property and routine maintenance activities would directly disturb this dune habitat. Marina-31

Section 3.4.2

This section states that "From the Terminal Reservoir, the water would be injected into the northern subbasin of the Seaside Groundwater Basin." Are injection wells proposed at this location? If so, they must be described and analyzed in the Draft EIR/EIS. If not, the description of ASR operations should be revised to accurately reflect proposed ASR operations and locations. Marina-32

Section 3.4.5

This section describes the electrical power demands of the Project, which would require 51,698 million kilowatt hours per year in additional demand – a more than 450 percent increase over existing demand for CalAm's entire water supply system in the Monterey District Service Area. This large expenditure of energy is not adequately analyzed in the Draft EIR/EIS. Has PG&E indicated it could provide this amount of energy? And if the increased demand is proposed to be partially met through a separate renewable power source, that source must be identified and the feasibility of that source must be analyzed in the Draft EIR/EIS. Any renewable power sources to be constructed to facilitate operation of the Project must be included in the project description and analyzed in the Draft EIR/EIS. Failure to include these Project components constitutes improper CEQA/NEPA piecemealing. Marina-33

CHAPTER 4.1 – ENVIRONMENTAL SETTING OVERVIEW

This chapter contains information regarding several important environmental assessment parameters, including the Project "baseline" and the treatment of Project inconsistencies. We have comments on each topic. Marina-34

The Draft EIR/EIS states that the Project environmental "baseline" for purposes of the Draft EIR/EIS is the existing conditions in 2012, which is five years ago. *Id.* at 4.1-8. This baseline is apparently based on the CEQA Guideline which states the existing physical conditions at the time the Notice of Preparation ("NOP") is published "will normally constitute the baseline physical conditions." CEQA Guidelines § 15125(a).

However, the Draft EIR/EIS makes a fundamental error. This is a situation where a more recent baseline must be utilized because the federal government did not join and notice its intent to make this an EIS for federal purposes until August 2015. Federal law mandates that the baseline for NEPA review be the physical condition at the time the EIS is prepared, which is August 2015 at the earliest. The CEQA Guidelines require that an EIS include the alternative of no action. 40 C.F.R. § 1502.14(d). These and other NEPA authorities require that the condition of the environment at the time the EIS is undertaken or the action will be implemented (which can sometimes be at some point in the future) be utilized for the analysis. There is no authority for using a significantly earlier date such as 2012. When a joint EIR/EIS is being drafted, it is sometimes necessary to have two impact analyses, one for CEQA and one for NEPA, so that the proper baseline is established for each. Thus, since the wrong NEPA baseline was chosen, the NEPA impact analyses need to be redone with the correct baseline and recirculated for public review.

Marina-34 cont.

In fact, this does not qualify as a "normal" situation under CEQA either in which a 2012 baseline should be utilized. Although the original Project NOP was issued in 2012, the proposed Project reflected in the new Draft EIR/EIS was substantially modified in March 2016 from the version originally noticed in 2012 and the public was first notified in late 2015 that the environmental document was now a joint EIR/EIS. Moreover, there have been significant environmental developments, technical studies and new information in the last five years that make a 2012 baseline an improper choice. The Draft EIR/EIS is therefore inadequate because it chose the wrong environmental baseline for both NEPA and CEQA purposes.

In addition, the Draft EIR/EIS description of how inconsistencies of the Project are to be treated under NEPA is incomplete and inaccurate. According to the document, NEPA and CEQA require that there be a discussion of "possible conflicts between the proposed project and the objectives of federal, regional, state and local land use plans and policies." *Id.* at 4.1-9. In fact, NEPA also requires an analysis of any inconsistencies with state and local "laws" and requires a reconciliation analysis when such inconsistencies are found:

> To better integrate environmental impact statements into State or local planning processes, statements shall discuss *any inconsistency of a proposed action with any approved State or local plan and laws (whether or not federally sanctioned).* Where an inconsistency exists, the statement should describe the extent to which the agency would reconcile its proposed action with the plan or law. 40 C.F.R. § 1506.2(d) (emphasis added).

Marina-35

This federal inconsistency and reconciliation analysis requirement is very important because all or at least portions of the Project are inconsistent with, and in fact directly prohibited by, state or local laws and plans which are discussed in more detail in our comments for sections 2.6 and 4.6 herein.

CHAPTER 4.2 – GEOLOGY, SOILS AND SEISMICITY

One major deficiency in this Draft EIR/EIS section is its failure to analyze the Project's potential acceleration or exacerbation of coastal erosion and dune retreat, thereby causing damage to nearby dunes, properties and coastal environment. We agree with the stated threshold of significance and accompanying impact question no. 4.2-10, which ask whether the Project will "accelerate and/or exacerbate natural rates of coastal erosion, scour, or dune retreat, resulting in damage to adjoining properties or a substantial change in the natural coastal environment." However, the impact section inexplicably fails to address this question.

Instead, the document states that "the primary concern" in this area is whether the natural rate of coastal retreat associated with sea level rise will result in the slant wells and associated facilities becoming uncovered or located on the beach within the Project lifetime. *Id.* at 4.2-68. The analysis of this issue is then carried through and a mitigation measure (discussed below) is adopted to address this impact. Remarkably, however, the document never returns to discuss the major potential impact posed by this question, which is whether the Project slant wells and other facilities located in this coastal strip will accelerate or exacerbate coastal erosion or dune retreat, or otherwise damage nearby beaches and properties. This is an important and appropriate topic for CEQA and NEPA analysis, particularly because it does not address the impact of the environment on the Project – rather, it evaluates the impact of the Project on the ongoing natural processes. The complete failure to address this issue requires a full analysis in a new Draft EIR/EIS that is recirculated for public comment. Marina-36

The second legal infirmity in this section relates to the apparent insufficiency of Mitigation Measure 4.2-9 that is proposed to evaluate the coastal retreat impacts on the Project components that were analyzed in this section. In brief, this measure provides that the rate of coastal retreat will be monitored and the slant wells will be removed from service before they are exposed. However, this measure does not address basic Project questions relating to this measure, including: (1) can the Project operate without one or more slant wells in service; (2) will new slant wells need to be drilled to replace the out-of-service wells and where and how will that be accomplished; and (3) what is the exact procedure for slant well abandonment and replacement? The mitigation measure is incomplete without this information. Marina-37

CHAPTER 4.3 – SURFACE WATER HYDROLOGY AND WATER QUALITY

A. The Description Of Applicable Laws And The Evaluation Criteria Are Inadequate.

The Regulatory Framework (section 4.3.2) mentions that the California Coastal Act contains applicable legal requirements applicable to the Project, but fails to describe in detail any of the specific requirements of the Act, such as all of the Public Resources Code Sections which are identified in footnote 1 of this comment letter. A similar omission is made in the evaluation criteria in section 4.3.3. The criteria are inadequate because they fail to include relevant Coastal Act requirements (e.g., Public Resources Code Section 30231). Marina-38

B. The Analysis Of Alternative Brine Discharge Systems Is Deficient.

The existing MRWPCA ocean outfall was not designed for brine discharge. The outfall has horizontally-oriented discharge ports rather than inclined diffusers, which are preferred for brine disposal and—as the Draft EIR/EIS admits—"increase[] dilution substantially." *See* Draft EIR/EIS at 4.3-105; Southern California Coastal Water Research Project , *Management of Brine Discharges to Coastal Waters: Recommendations of a Science Advisory Panel*, 23-27 (Mar. 2012) ("SCCWRP Report"). Accordingly, use of inclined diffusers should be a required component of the Project, rather than just potential mitigation.

Marina-39

Impacts related to surface water hydrology and water quality generally relate to water intake and brine discharge from structures within or beneath Monterey Bay. Water quality impacts from brine discharge are evaluated based on modeling for the existing MRWPCA ocean outfall pipeline and diffuser, but it appears from the Draft EIR/EIS that no such modeling was performed for alternative brine discharge systems. Modeling and analysis at a comparable level of detail should be provided for each alternative that is evaluated to allow the public to compare the various brine discharge alternatives.

C. Mitigation Measure 4.3-4: Operational Discharge Monitoring, Analysis, Reporting, And Compliance Is Legally Deficient In Multiple Ways.

First, Mitigation Measure 4.3-4 illegally defers mitigation and lacks adequate performance standards. A Mitigation Monitoring & Reporting Plan must be published and circulated along with Draft EIR/EIS; thus, the Draft EIR/EIS must be re-circulated here once the MMRP is prepared. An opportunity for public comment on the MMRP is essential where so much of the mitigation is deferred and the potential impacts are both extremely uncertain and potentially very significant, particularly considering the unique, protected ecosystem into which the Project plans to discharge 14 million gallons of brine daily—totally undiluted during at least half of each year. Not only does this Mitigation Measure thus illegally defer mitigation, but it also lacks performance standards by which to measure the mitigation.

Marina-40

Second, Mitigation Measure 4.3-4 purports to do things that should have been done as part of assessing the environmental baseline per CEQA's requirements. The Mitigation Measure states, "The Plan shall establish protocols to establish baseline biological conditions at the discharge location as well as at a reference location outside the influence of the discharge for at least one year prior to commencement of project construction." (page 4.3-69.) But assessing, establishing and monitoring baseline environmental conditions is a mandatory step in CEQA and NEPA analysis, and cannot be deferred until after Project approval. CEQA and NEPA prohibit a lead agency from deferring the analysis of potential impacts by claiming they will monitor those impacts just before the Project is constructed and figure out at that later date if mitigation measures are needed. Moreover, an impacts analysis that is based on an inadequate evaluation of the environmental baseline is necessarily flawed. Thus, not only is Mitigation Measure 4.3-4 itself flawed in that it illegally defers mitigation, but the impacts analysis underlying Impact 4.3-4 is also flawed and must be redone after a proper assessment of the environmental baseline that

Marina-41

includes biological conditions at the discharge location as well as the vicinity of the discharge location. Marina-41 cont.

Third, Mitigation Measure 4.3-4 states monitoring may cease after five years if a certain salinity performance standard is met for a period of 45 days at the end of the five years of monitoring. Does this mean that the standard must be met for any 45-day period during the entire five-years? If not, the measurement for the standard is unclear and must be explained. Also, if the standard is not met at the end of five years, additional mitigation should be required in order to meet the standard, and yet the Mitigation Measure apparently does not require any. Marina-42

D. Mitigation Measure 4.3-4: Operational Discharge Monitoring, Analysis, Reporting, and Compliance; and Mitigation Measure 4.3-5: Implement Protocols to Avoid Exceeding Water Quality Objectives Should Be Applied To All Alternatives.

These mitigation measures address water quality impacts to Monterey Bay through water quality studies before implementing operational discharges, incorporating supplemental water treatment components, and implementing a discharge monitoring and mitigation plan. Both mitigation measures are identified as applying only to operational discharges associated with the Project desalination plant through the existing Monterey Regional Water Pollution Control Agency outfall (i.e., the Project and Alternatives 1, 2, and 5a/5b). On page 5.5-50, the Draft EIR states that the salinity impact to Monterey Bay under Alternative 3 (new outfall at Moss Landing) would be reduced to less than significant (same impact conclusion as the Proposed Project) with the implementation of Mitigation Measure 4.3-4. On page 5.5-56, the Draft EIR states that the salinity impact to Monterey Bay under Alternative 4 (new outfall at Moss Landing) would be significant and unavoidable (increased impact compared with the Proposed Project) and Mitigation Measure 4.3-4 is not mentioned. The narrative descriptions for Mitigation Measures 4.3-4 and 4.3-5 are general enough that it seems they could be applied to any brine discharge system, and therefore any Alternative. The Draft EIR/EIS should apply the mitigation measures consistently to the Project and Alternatives following the assumptions listed for the mitigation measures, and impacts should be determined accordingly. Marina-43

CHAPTER 4.4 – GROUNDWATER RESOURCES

A. The Factual Predicate For The Groundwater Analysis Is Inadequate Because It Fails to Discuss Key Facts And Hydrology Concepts And Thereby Undermines The Discussion Of Project Impacts And Mitigation Measures.

The Draft EIR/EIS is deficient because it fails to mention, discuss and properly analyze important facts and hydrology concepts affecting the Project's impacts on groundwater resources. Marina-44

First, chapter 4.4.2 fails to identify and discuss the application of State Board Resolution No. 88-63, which provides that all "ground waters of the State are considered to be suitable, or potentially suitable for municipal or domestic water supply and should be so designated by the

Regional Boards. . . ." A Regional Board may de-designate this beneficial use, but only if it is demonstrated that the water being de-designated consists of a TDS concentration exceeding 3,000 mg/L (5,000 uS/cm, electrical conductivity). However, unless and until a formal de-designation of this beneficial use occurs for a particular location (which involves a complex Regional and State Board process), all groundwater in an aquifer is presumptively considered suitable for municipal or domestic water supply use under California law. Since none of the aquifers in this Basin have been de-designated for this MUN beneficial use, all groundwater in the SVGB is presumptively groundwater, potentially suitable for the MUN beneficial use, not seawater.

Marina-44 cont.

Second, the Draft EIR/EIS does not clearly define what it means by its use of the term "brackish water" (see, e.g., page 4-4.8) and this confusion leads to analytical deficiencies later in the chapter. The text implies that brackish water cannot be used for domestic, agricultural or industrial purposes, which is not true. For example, the premise of Resolution No. 88-63 is that a legal user such as a water district could extract and treat groundwater to meet MUN uses. A related ambiguity is present in the seawater intrusion charts marked as Figures 4.4-10 and 4.4-11, which are intended to show "seawater intrusion" into the 180/400 Foot Aquifers. However, since the term "seawater" is not defined, it gives the erroneous impression that the entire groundwater area out to the identified limits on the Figures exceeds applicable State Board standards and is supposedly not suitable for any beneficial uses. Moreover, the accompanying text refers to "the leading edge of the inland seawater intrusion front," but again does not define what this means or how it is even relevant to the analysis. The information being gathered by Dr. Rosemary Knight and her colleagues very clearly shows that the extent, degree, and location of seawater intrusion in the areas immediately surrounding the proposed slant well intake system is much more complex than reflected in Figures 4.4-10 and 4.4-11 and the accompanying Draft EIR/EIS analysis (refer to Section E, below).

Marina-45

In fact, the aquifers in this Basin are the proposed water supply source for the Project. The Draft EIR/EIS relies on the conclusion that "the groundwater in the Dune Sand, 180-FTE, and 400-foot Aquifer is therefore unsuitable for potable supply" to support a determination that the Project would have a less than significant impact on groundwater supplies from the SVGB (pages 4.4-59, 60), while also identifying these exact same water resources as the water supply source for the Project. This irreconcilable discrepancy reflects an unpersuasive attempt, as improperly re-stated and supported in the Draft EIR/EIS, to establish a feasible legal right to pump groundwater from the SVGB.

Third, the Draft EIR/EIS is inadequate because it does not clearly state the amount of "groundwater" that it anticipates extracting from the groundwater aquifers. The State Board Report, which was based on a previous version of the Project, states that the CalAm's calculation was that 762 to 3,250 afy of groundwater would be extracted (although this was before the slant wells were moved landward, which will increase the groundwater portion substantially). App. B2 at 29. The Draft EIR uses a 0-12 percent figure for calculating the amount of groundwater as a percentage of total extracted water, but does not state a daily or annual amount. However, assuming that 24 mgd of total water is extracted 365 days per year by the slant wells and using

Marina-46

the 12 percent figure utilized in the Draft EIR/EIS, the "groundwater" extracted supposedly could be 1,152,000 gallons per day and 3,226 acre-feet per year.

However, these groundwater extraction amounts and percentages appear to be vastly understated. The slant wells have been repositioned further inland, so the groundwater component recited by the State Board is significantly higher, probably closer to the 75-93 percent figure recited in our chapter 3 comments. Further, State Board Resolution 88-63 provides that all water pumped from under land (as distinguished from under the ocean) is presumptively groundwater, not seawater. In addition, the 0-12 percent groundwater calculations appear to have been based on a "groundwater" standard linked to a TDS value of 420 mg/L, rather than on use of the 3,000 mg/L potential MUN de-designation standard. If the water actually extracted by the slant well is less than the projected seawater TDS value for the extracted water, the amount of "groundwater" extracted under the Project's calculations could be multiples of the maximum 12 percent value utilized in the Draft EIR/EIS. Marina-46 cont.

In this context, it is also important to point out that, for purposes of the Agency Act, Ordinance No. 3709 and the Annexation Agreement, all extraction and/or export of groundwater is prohibited, regardless of the TDS concentration of the water. Accordingly, the calculations made by the Draft EIR/EIS on what it believes is "groundwater" for purposes of sending return water to the Basin does not alter the fact that all groundwater in this Basin being extracted landward of the mean high tide line, regardless of the amount or percentage of TDS it contains, is groundwater which cannot be extracted and exported pursuant to these laws and agreement. Marina-47

We know that MCWD and other users extract a substantial amount of groundwater from the 180 and 400 Foot Aquifers, and therefore that much of the "brackish" water identified is available to support the applicable domestic, agricultural and industrial beneficial uses. Indeed, Table 4.4-3 reveals that a total of between 103,000 and 130,000 acre feet of water has been extracted from these entire groundwater aquifers each year since 2008. It also apparent from the technical studies that the water in the aquifers within the identified areas contains large areas of higher quality groundwater, so it is neither hydrogeologically nor legally appropriate to state that this water cannot be extracted to support the three designated beneficial uses. Marina-48

Fourth, the Draft EIR/EIS's limited description of Professor Rosemary Knight's work (page 4.4-31) is inadequate and the Draft EIR/EIS failure to discuss and incorporate its findings is unwarranted. These issues are discussed in greater detail in Subsection E herein. Marina-49

Fifth, the brief mention of the applicability and implications of SGMA (page 4.4-37) is incomplete and inadequate. It fails to state that the 180/400 Foot Aquifer has been classified under SGMA as one of only 21 California aquifers that is "critically overdrafted." The Draft EIR/EIS text wrongly claims that SGMA "does not have a direct impact on the MPWSP." It also improperly attempts to trivialize the new groundwater law's impact by summarily concluding without support that "[t]he proposed project would not adversely affect groundwater management in the Basin, because it would not be extracting groundwater that is not presently being used as a potable or an irrigation supply." It then concludes that the Project will have a "positive contribution" to managing groundwater in the Basin. Marina-50

This explanation oversimplifies and reflects a misunderstanding of how SGMA is designed and works, which we have described in out comments to chapter 2.6 above. The legal inadequacies in this portion of the Draft EIR/EIS include:

- It fails to recognize that the "undesirable results" that SGMA is designed to avoid include seawater intrusion, degraded water quality, lowering of groundwater levels and reduction of groundwater storage. In stating that SGMA will not have a direct impact on the Project because it is supposedly not extracting groundwater presently being used applies the wrong benchmark to this situation. The real question is whether the Project may directly or indirectly cause seawater intrusion, degradation of water quality, lower groundwater levels or reduced groundwater storage. If the Project will contribute to any of these conditions (as the current scientific information indicates it likely will), the Project will be directly affected, if not foreclosed, by SGMA. Marina-50 cont.

- In stating (without any support) that the Project may have a positive contribution to groundwater management in this Basin, the Draft EIR/EIS and CalAm appear to attempting to substitute their own private views for the technical decisions on groundwater management by the GSA. This approach expressly contravenes the local agency groundwater management goal of SGMA and is an impermissible judgment by a private outside third party as to "what is right" for the Basin and its users. The Draft EIR/EIS lacks the best available science and the local history and experience to make any such judgment for this Basin. Marina-51

- The application of SGMA could have a dramatic impact on the Project. Management measures will be decided upon by the GSA based on a comprehensive data set. These measures could well include a prohibition on new groundwater extractions in the basin, severe restrictions on such withdrawals and a variety of other measures that could include many measures that prohibit or restrict the Project's hoped-for extraction activities. Marina-52

- It is untrue, and contradictory to other statements in the Draft EIR/EIS, to state that the Project will not extract groundwater that is used as a potable or irrigation water supply. In fact, the Draft EIR admits that the water the Project will pump would consist of between 1 and 12 percent of groundwater from these aquifers (and these withdrawals could be even greater if state-of-the-art models are used). And, as discussed above, all of the water is presumptively groundwater, not seawater, and it is defined as usable for the applicable beneficial uses under State Board standards. Marina-53

- For the reasons set forth in Dr. Abrams' report, the groundwater model on which the Project relies to support this conclusion is too simplistic (and not state-of-the-art) and fails to address the key potential groundwater impacts of the Project. Marina-54

B. The Thresholds Of Significance For Groundwater Impacts Are Inadequate.

Section 4.4.3 of the Draft EIR/EIS delineates thresholds of significance (which it terms "evaluation criteria") to evaluate potential impacts of the Project on groundwater resources. It lists two threshold criteria and then, confusingly, lists nine further "descriptions" to "elaborate on how these criteria are applied." These collective "criteria" reflect several important deficiencies.

First, the first overall threshold of significance targeted to interference with groundwater supplies or recharge is incorrectly formulated because it defines (for no apparent reason) a supply or recharge interference as a "net deficit in aquifer volume." By gerrymandering the interference concept in this manner, it automatically characterizes the Project's projected extractions of groundwater to not qualify as a significant environmental effect because it plans to "return" an equivalent amount of water to selected recipients within the Basin area. However, in so doing, it mistakenly fails to analyze the impacts of its pumping on a range of water availability and recharge issues, particularly since the delivered groundwater will not be reinjected into the aquifer.

Marina-55

Second, although we agree that a threshold of significance should be whether the proposed slant well extractions "degrade groundwater quality," the further interpretation of this criteria on page 4.4-21 to be that it "adversely affected groundwater quality by exacerbating seawater intrusion in the SVGB" dramatically and improperly limits its scope. As discussed in subsection C below, the Draft EIR/EIS attempts to condense this water quality degradation inquiry into a narrow analysis of whether the extractions will move the "seawater/freshwater interface" in the 180/400 Foot Aquifers, which is neither factually appropriate nor a true measure of all potential groundwater quality impacts. The threshold of significance, and all interpretive descriptions, should be whether the slant wells will degrade groundwater quality for any current or future legal user in any of the 180/400/900 Foot Aquifers.

Marina-56

Third, these evaluation criteria are inadequate because they do not address the water rights and SGMA management criteria in this "critically overdrafted" subbasin, and therefore do not provide any factual basis for assessing such environmental impacts when evaluating Project feasibility. Thus, for example, one evaluation criterion should be whether the slant well extractions may cause any short-term or long-term harm to any current or anticipated future legal user of this groundwater basin. Companion criteria should be adopted for each potential groundwater impact issue identified in our comments in section 2.6 herein.

Marina-57

C. The Draft EIR/EIS Fails To Adequately Assess The Project's Groundwater Quality Impacts And Therefore Erroneously Concludes That They Are Less Than Significant.

Marina-58

The preceding discussion of potential groundwater impacts of the Project in the contexts of water rights and SGMA make it clear that the Draft EIR must analyze a full array of environmental impacts from groundwater extraction. For purposes of water rights, the inquiry is whether the Project will cause harm or injury to any current or future legal user of the

groundwater, including water quality impacts, seawater intrusion impacts, water table impacts and the expected impacts over time. *See* section 2.6 herein. Under the comprehensive groundwater management scheme in SGMA, the undesirable results of the Project to groundwater that must be evaluated include lowering of groundwater levels, reduction of groundwater storage, seawater intrusion, degraded water quality, land subsidence and depletions of interconnected surface water. Cal. Water Code § 10721(w).

Unfortunately, the analysis in the Draft EIR/EIS fails to adequately address these issues. It focuses primarily on the question of whether extraction from the wells would affect "drawdown" in nearby wells by lowering the groundwater levels. *Id.* at 4.4-57, *et seq.* It briefly raises the topic of seawater intrusion, but for unexplained reasons confines its discussion to the "location of the seawater/freshwater line," which it mistakenly believes is a surrogate for a discussion of seawater and water quality impacts. *Id.* at 4.4-78. It also refers to several contaminated groundwater plumes that originated at Fort Ord, but proposes a monitoring program which supposedly mitigates these impacts to less than significant levels. *Id.* at 4.4-86.

This limited analysis of groundwater quality impacts is patently insufficient and legally inadequate. It is inappropriate to limit the discussion of seawater intrusion impacts to the location of the "seawater/freshwater interface," because the location of this line does not describe the quality of groundwater within or beyond this line, only that chloride concentrations exceed a certain level at this line. The Draft EIR/EIS appears to make the mistaken assumption that all groundwater seaward of this line is not fit for beneficial uses and, therefore, draws the erroneous conclusion that so long as the progressive horizontal inland migration of that front does not continue, the Project is not causing significant impacts to groundwater quality. In fact, however, the available data (including information generated by Professor Knight discussed herein) demonstrate that there are large areas of good quality water available for beneficial uses seaward of this line, so use of the line in this manner avoids analyzing Project groundwater impacts in any close detail.

Marina-58 cont.

Dr. Abrams shows in his Memorandum (App. 1) that there are MCWD wells in the 900 Foot Aquifer that currently supply drinking water for the City of Marina, both inside and just outside the seawater intrusion line in the 180/400 Foot Aquifer. Moreover, there are overlying users within the City who utilize wells within the seawater intrusion area. One important question, that remains unaddressed by the Draft EIR/EIS, is how the future water quality (including salinity) of these wells will be affected by the pumping of 24 million gallons per day ("mgd") of water by the slant wells. If, as appears entirely likely, the water quality in these wells will be adversely affected by the Project pumping, the MCWD and City water supply will be adversely affected. This potential significant impact is entirely missing from the Draft EIR/EIS analysis.

In short, the "Impact Conclusion for Groundwater Quality" on page 4.4-86 conducted an unreasonably restrictive scope of analysis for potential seawater intrusion impacts both inside and outside the seawater intrusion point it identifies and fails to assess the full range of water quality impacts for legal users of the aquifer. The resulting conclusion that the Project will have

no impacts on groundwater quality is not supported by substantial evidence and cannot stand. Accordingly, a comprehensive water quality impact analysis must be performed and a new Draft EIR/EIS needs to be recirculated to provide the public with an opportunity to review and comment on the analysis.

Marina-58 cont.

D. The Draft EIR/EIS Is Inadequate Because It Completely Fails To Analyze the Potential Impacts Of The Project On Groundwater In The 900 Foot Aquifer.

The 900 Foot Aquifer (sometimes referred to as the Deep Aquifer) is a confined aquifer that lies below the 180/400 Foot Aquifers in and near the City of Marina. This aquifer represents a very important water resource for MCWD and the City and, as shown in Dr. Abrams' Memorandum, there are three MCWD wells in this aquifer seaward of the "seawater intrusion" line in the 180/400 Foot Aquifers and another such well just outside this line in the 180 Foot Aquifer According to Dr. Abrams, the 900 Foot Aquifer consists of a thick sequence of alternating layers of sand-gravel mixtures and clays.

The Draft EIR/EIS essentially ignores any discussion of the nature, function or potential Project impacts with regard to the 900 Foot Aquifer. The document devotes only three uninformative sentences to a description of the hydrogeology of this aquifer. *Id.* at page 4.4-12. The Groundwater Elevation and Flow Direction section (page 4.4-14) does not cover groundwater flow or response to pumping for the 900 Foot Aquifer. Indeed, this section only discusses lateral groundwater flow – it conspicuously fails to include any discussion of vertical groundwater flow in the aquifer system or flow in the 900 Foot Aquifer. The Groundwater Extraction Summary Table No. 4.4-3 does not cover extractions from the 900 Foot Aquifer. And there is no discussion of the 900 Foot Aquifer in the Groundwater Quality section (section 4.4.1.4). Not surprisingly, there is no analysis of potential impacts to this groundwater aquifer in the Project operational impact or mitigation sections.

Marina-59

The Draft EIR/EIS's failure to discuss the potential impacts of the Project on groundwater in the 900 Foot Aquifer is an unexplained and significant omission. In fact, given the importance of the aquifer, the discontinuous nature of the aquitards above it, the hydrogeologic findings in Professor Knight's studies (see Subsection E herein), and the evidence of vertical seawater contamination reflected in the best available hydrogeologic information, the failure to address the potentially important set of groundwater impacts is a significant gap in the environmental analysis and must be addressed in a new, recirculated Draft EIR/EIS.

E. The Draft EIR/EIS Failed To Utilize, Without Explanation, The Important Electrical Resistivity Tomography Studies Prepared By Professor Knight And Her Colleagues.

Marina-60

As described in Dr. Abrams' Memorandum, Stanford University Professor of Geophysics Rosemary Knight, with her colleagues and other researchers, has utilized electrical resistivity tomography ("ERT"), a standard and accepted field test methodology, to characterize seawater intrusion into the subsurface along the Monterey County coastline in the immediate vicinity of

the Project. ERT is a type of geophysical survey that can provide valuable groundwater quality data to "fill in the gaps" that exist when only well datapoints are used. Despite the fact that Professor Knight conducted a coastline study in the immediate vicinity of the Project area that provided a vertical two-dimensional image reflecting the distribution of seawater intrusion at different depths and concentrations in the 180/400 Foot Aquifers, the Draft EIR/EIS failed, without any explanation, to utilize its data and scientific findings.

It is undisputed that the results of Professor Knight's studies were available to the public long before the Draft EIR/EIS was issued, but were not utilized in formulating the Draft EIR/EIS. Indeed, these studies and results were presented to the public in a series of forums, including the following:

- In October 2014, Professor Knight announced that she was planning to use the ERT technology to investigate seawater intrusion into groundwater aquifers along a 24-mile stretch of coastline that includes the proposed CalAm slant well site. The key details relating to this work was made available in permit applications to a variety of public agencies and was publicized in the press.

- On May 26, 2015, at the Hopkins Marine Station in Pacific Grove, Professor Knight and Adam Pidlisecky presented a public lecture entitled "Salt Water Imaging Along the Monterey Coast" in which they discussed their research techniques and results to date regarding saltwater intrusion into groundwater aquifers.

- On November 1, 2016, at the Hopkins Marine Station, Professor Knight and a colleague presented a program entitled "Geophysical Imaging of Saltwater Intrusion Along the Monterey Coast." This lecture covered the geophysical methods and results that they used to create images of the distribution of saltwater and freshwater hundreds of feet into the ground along the coastline area where the Project would be built.

Nonetheless, despite the public availability and widely shared information regarding this research work, it was not carefully analyzed and incorporated into the Draft EIR/EIS. The Draft EIR/EIS (on page 4.3-3) devotes only three sentences to Professor Knight's study. Two sentences attempt to describe briefly what she studied and the third sentence states: "The study found that the electrical resistivity readings positively correlate with measured TDS concentrations to a depth of 500-feet in four area groundwater wells." In short, the Draft EIR/EIS attempts to create the erroneous impression that Professor Knight's study essentially corroborated the findings of the Draft EIR/EIS analyses and essentially ignores, without explanation, all of its findings. Dr. Knight, in a presentation before the Marina City Council on February 7, 2017 (see slide deck attached as App. 3), stated that this statement in the Draft EIR/EIS failed to accurately reflect the extent of uncertainty remaining in the Draft EIR/EIS analysis and the substantial additional information that would be provided through the use of ERT.

Marina-60 cont.

In fact, the work by Professor Knight and her colleagues is directly relevant to the important seawater intrusion and groundwater quality issues that are posed by the Project and which are, at this point, inadequately analyzed in the Draft EIR/EIS. Among other things, as explained more fully in Dr. Abrams' Report, the previously published studies by Professor Knight and her colleagues reflect:

- There are physical gaps in the aquitards separating the 180, 400 and 900 Foot Aquifers that provide pathways that allow migration of contaminants between each of these aquifers. According to Dr. Abrams: "the results show that there are numerous locations where pathways exist for migration of seawater and seawater-impacted groundwater from shallower to deeper levels of the aquifer system…." In short, these aquifers appear to be in hydraulic communication with each other more than previously believed or as apparently assumed by the Draft EIR/EIS.

- The ERT results delineate the extent of seawater in the 180 and 400 Foot Aquifers at the specific locations along the coast and reflect that "the distribution of seawater intrusion in these aquifers is highly variable horizontally and vertically." Thus, even at the coastline, there are large pockets of low-saline groundwater in the shallower aquifers as well as substantial evidence of seawater migration downward into the deeper aquifers in which many of the City of Marina's water supply wells are located.

Marina-60 cont.

These studies are directly relevant to the groundwater quality issues that are at the heart of potential Project impacts. They undercut the assumptions in the Draft EIR/EIS regarding the vertical and horizontal distribution of seawater impacts and indicate that pathways exist for vertical and horizontal contamination of aquifers at the Project location. Given the inability of the current groundwater modeling relied on by the Draft EIR/EIS to analyze these issues and the complete lack of any analysis of the 900 Foot Aquifer in the document, this information (which was available to the drafters before the Draft EIR/EIS was released) must be utilized to inform the discussion of these potentially significant impacts. Since ERT is a standard and accepted methodology that can feasibly be used to assess the significant groundwater aquifer impacts of the Project, the CPUC and MBNMS must assess this impact. *See Berkeley Keep Jets Over the Bay Comm. v. Bd. of Port Comm'rs*, 91 Cal. App. 4th 1344, 1370 (2001).

In addition, as the CPUC and MBNMS are aware, Professor Knight and her colleagues are in the midst of a new ERT study, using the SkyTEM methodology, that will provide a three-dimensional image of seawater intrusion in the groundwater in a wide area underneath and around the City. This new study (whose field work is scheduled for May 2017) will provide a three-dimensional depiction of the distribution and extent of seawater intrusion in the immediate Project area and will facilitate determining the evaluation of the likelihood of adverse impacts from Project pumping to area groundwater wells in all aquifers. The CPUC and MBNMS should obtain the results of this study and incorporate them into a new Draft EIR/EIS that is recirculated for review and comments by Responsible Agencies (such as Marina) and the public.

F. The Groundwater Modeling Used By The Draft EIR/EIS Is Inadequate To Determine The Potential Harm To The Wells That Serve Marina And Its Citizens.

One critical groundwater impact question is whether the Project may cause harm to current and future legal users of the three groundwater aquifers. As Dr. Abrams describes in his Memorandum, the model that forms the basis of the impact analysis in the Draft EIR/EIS cannot be effectively utilized to address this question. The deficiencies include:

- The model does not analyze the probability of adverse impacts to water used by Deep Aquifer wells.

- The model fails to address the key water rights and/or SGMA "harm" subject areas of water quality, seawater intrusion or water supply limitations at the various wells. Rather, it only addresses drawdown in nearby wells and looks at seawater only in a horizontal, not a vertical, direction. Professor Knight's work demonstrates that there are many locations where seawater appears to move downward where aquitards are absent.

- The model does not include the detailed heterogeneity indicated by the geophysical data which can provide increased certainty regarding the hydrogeologic characterization of these aquifers.

- The site-specific model contains important conceptual flaws that impair its ability to provide a reliable work product.

- Dr. Abrams believes that the parameterization of the model "is too simplified to fully evaluate the potential or probability of adverse impacts to groundwater users in the City of Marina from proposed MPWSP pumping" and that this "is especially relevant in light of the newly available information regarding the heterogeneous, vertically-connected nature of the aquifer system, the presence of significant downward vertical hydraulic gradients, and the potential for exacerbated seawater intrusion."

Marina-61

In short, the "superposition" model used as the basis for the groundwater impact analysis in the Draft EIR/EIS fails to meet the requirements and CEQA and NEPA. The model is not a precise and state-of-the-art hydrogeologic conceptual model (as demonstrated by Professor Knight's findings) and it is not well calibrated to evaluate the impact of the Project on a wide range of potential groundwater harms.

G. The Draft EIR/EIS Analysis Fails To Take Into Account The Anticipated Future Impact Of Ongoing Seawater Intrusion Mitigation Efforts On Groundwater Flow Directions.

As explained by Dr. Abrams in his Memorandum, the Monterey County Water Resources Agency has implemented for many years a concerted and successful effort to increase groundwater levels to slow, halt or reverse seawater intrusion. This effort has been significantly financed and supported by Marina citizens and other water customers in these water zones. Dr. Abrams provides the following explanation of the likely outcome of these efforts:

> If these mitigation efforts continue to be successful, as will likely be required under the Sustainable Groundwater Management Act (SGMA), the magnitude of the landward hydraulic gradient will decrease as inland groundwater levels increase, thus the shape of the capture zone and extent of the source area for the proposed slant wells will change substantially.… Thus, the continued success of ongoing seawater-intrusion mitigation projects could potentially strand the MPWSP desalination plant from its source of seawater.… Possible future groundwater conditions such as those described above were not evaluated or discussed in Appendix E2 of the Draft EIR/EIS, even though the goal of MCWRA's ongoing seawater-intrusion control efforts is to increase inland groundwater levels, and such conditions may be considered to be reasonably foreseeable. As such, the Draft EIR/EIS failed to consider that a more substantial fraction of freshwater resources may be captured during feedwater pumping than has been assumed

Marina-62

It is undisputed that the groundwater model described in Appendix E2 of the Draft EIR/EIS that was used for the groundwater analysis assumed that the regional groundwater flow direction at the Project subsurface slant wells was in the landward gradient direction. However, if these significant ongoing mitigation efforts continue to be successful, it is entirely possible that the current groundwater flow direction will reverse and be in exactly the opposite direction from what the groundwater model assumed. Even if groundwater flows do not reverse, flows from the seaward direction could substantially slow or disappear. The implications and results of this change in groundwater flow were not evaluated or discussed in this Appendix or the Draft EIR/EIS itself. As a result, the calculations of the amount of inland groundwater captured by the Plant could be significantly higher and, as Dr. Abrams describes, the continued success of these projects "could potentially strand the MPWSP desalination plant from its source of seawater."

This is a critical factor from both water rights and "injury to legal user" viewpoints. In the water rights arena, the State Board Report was absolutely clear that, to establish future water rights, the Project would need to address its future groundwater impacts, which has not been done adequately here without this analysis. From the viewpoint of a legal user of this Basin's groundwater, the reasonably foreseeable reversal of the landward groundwater flow direction

could mean that most and possibly all of the water pumped by the slant wells would be groundwater from the Basin rather than seawater, regardless of how those concepts are defined.

In sum, the Draft EIR/EIS's failure to discuss and analyze these developments, and to incorporate them into the groundwater modeling effort, makes the groundwater impact analysis legally inadequate.

Marina-62 cont.

CHAPTER 4.5 – MARINE BIOLOGICAL RESOURCES

A. The Draft EIR's Analysis Of Impacts To Marine Resources Is Inadequate.

1. The Project Is Sited In A Unique Marine Ecosystem Protected By Numerous Laws.

The Project is located in a unique ecological area that encompasses both a national marine sanctuary (MBNMS) and a national estuary (Elkhorn Slough National Estuarine Research Reserve). Draft EIR/EIS at 4.5-32. The MBNMS was established for the purposes of research and monitoring, education and outreach, public use and resource protection. It includes a variety of habitats that support highly productive biological communities, including extensive marine life: 34 species of marine mammals, over 180 species of seabirds and shorebirds, at least 525 fish species, four sea turtle species, 31 different invertebrate phyla, and over 450 species of marine algae. It hosts one of the highest levels of marine biodiversity in the world, and includes 27 federally listed threatened and endangered species. *Id*. at Section 4.5.1.

Marina-63

A number of laws protect the area affected by the Project. The National Marine Sanctuaries Act ("NMSA") prohibits a person from destroying, causing the loss of, or injuring any sanctuary resource managed under law or regulations for that sanctuary. The NMSA prohibits discharge of brine effluent. The Magnuson-Stevens Conservation and Management Act ("Magnuson Act") requires all federal agencies to protect areas designated as "Essential Fish Habitat." Monterey Bay is designated as "Essential Fish Habitat" under four Fishery Management Plans. In addition, the Marine Mammal Protection Act and the Federal Endangered Species Act protect numerous species that occur in Monterey Bay and in the Study Area in particular.

The area is also protected by several state laws. The California Endangered Species Act, the Marine Life Protection Act, and the Marine Life Management Act all operate to protect species and fisheries in the Study Area and the vicinity of the Project. In addition, the California Ocean Plan ("Ocean Plan") establishes water quality objectives and beneficial uses for waters of the Pacific Ocean within three miles of the California Coast. The Project is subject to all Ocean Plan water quality objectives, including: marine communities, including vertebrate, invertebrate, and plant species shall not be degraded; waste management systems that discharge into the ocean must be designed and operated in a manner that will maintain the indigenous marine life and a healthy and diverse marine community; and waste discharged to the ocean must be essentially free of substances that will accumulate to toxic levels in marine waters, sediments, or organisms.

Of particular relevance here, MBNMS, in collaboration with the California Coastal Commission ("CCC"), Regional Water Quality Control Board ("RWQCB"), and NOAA Fisheries, published a 2010 report entitled *Guidelines for Desalination Plants in Monterey Bay National Marine Sanctuary* ("MBNMS Guidelines"). The MBNMS Guidelines were developed to help ensure that any future desalination plants in the MBNMS would be sited, designed, and operated in a manner that minimizes impacts on the marine environment. Several guidelines are relevant to minimizing impacts on marine resources, as discussed further below.

Marina-63 cont.

2. The Draft EIR/EIS Fails To Adequately Describe The Baseline.

CEQA requires an adequate description of the existing environmental baseline. CEQA Guidelines § 15125(a). In addition, the Ocean Plan requires an assessment of baseline biological conditions before construction of a new desalination plant. *See* State Water Resources Control Board, *California Ocean Plan*, at M.4(a)(2) (2016). The Draft EIR/EIS fails to meet this basic but essential prerequisite of both CEQA and the Ocean Plan in at least three key ways.

Marina-64

First, the Study Area is too narrowly drawn. In particular, the Study Area for marine biological resources should extend to the Monterey/Seaside/Pacific Grove shorelines. The EIR provides no explanation or rational basis for drawing the boundaries as narrowly as it does. To exclude the area extending from the existing Study Area to the Monterey/Seaside/Pacific Grove shorelines, the EIR must explain why the Project will not have direct or indirect impacts south of the northern limits of Sand City. The northern boundary of the Study Area also appears too limited, and the Draft fails to explain why the Project's impacts will not extend beyond the Salinas River. Furthermore, the Study Area appears to extend from the shoreline outward five miles toward the ocean, but the Draft fails to explain why the Project will not have effects beyond those nearshore waters.

Second, the Study Area must be surveyed to determine exactly what the environmental baseline is. For example, the Study Area should be investigated for cold water seeps. The Draft EIR/EIS states there are no "known" cold water seeps in the area (page 4.5-2), but does not clearly state whether the Study Area was actually surveyed for cold water seeps, and if it was not, why it was not. Even more critical is the dearth of information describing the existing environmental baseline near the point of brine discharge. Given the Project's undeniable significant environmental impact on the water quality and marine resources in the area near the discharge, documentation of the environmental baseline in this area is particularly critical. Yet the Draft EIR/EIS merely contains a general, minimal description of the ecosystem in the area.

Marina-65

Indeed, it appears only extremely limited sampling was conducted, which is inadequate to determine the environmental baseline. For example, the Draft EIR/EIS states that analysis of impacts on plankton near the outfall is based on sampling of small zooplankton conducted on one day in Spring 2016 (pages 4.5-6-7). This sampling is wholly insufficient. Sampling should be conducted multiple times, and throughout the year due to the variability in the marine ecosystem as the Draft EIR/EIS states elsewhere (see, e.g., section 4.5.1.1). Also, the Draft

EIR/EIS does not explain why only small zooplankton were surveyed, and why other plankton (e.g., macro zooplankton, phytoplankton) and other organisms (invertebrates, fish, mammals) were not sampled/surveyed. Inadequate data precludes sufficient analysis of impacts, and renders the whole analysis of the Project's brine discharge impacts on marine resources inadequate.

Furthermore, the Draft EIR/EIS should require monitoring and period surveying of the ecosystem in the vicinity of the outfall so that the impacts of the Project can be determined, measured, and mitigated "to the maximum extent feasible," as required by law. *See, e.g.*, Coastal Act, Cal. Pub. Res. Code § 30260.

The Draft EIR/EIS does contain an opaque reference to rocky habitat that "coincides with the ballast rock that is used to secure the MRWPCA outfall on the seabed." *Id.* at 4.5-9. But it is not entirely clear from the language in the Draft EIR/EIS whether this means that productive, species-rich habitat such as that observed during the 2014 NOAA inspection occurs near the outfall: the language on pages 4.5-9, 4.5-11, and 4.5-28 suggests that it does, but then Figure 4.5-2 does not show any hard substrate habitat near the outfall (page 4.5-10). If Figure 4.5-2 is inaccurate, then the Draft EIR/EIS should be recirculated with a corrected version of Figure 4.5-2 that clearly shows all areas where rocky substrate habitat are found in the Study Area. In addition, assuming it is true that a diverse, rich assemblage of organisms lives at the outfall, then this area should be more closely inspected and surveyed to determine what organisms live there and exactly what species' habitats exist near the outfall. The Draft EIR/EIS must also be revised accordingly to address impacts of the Project on these habitats, and mitigate them per CEQA and other legal requirements (*e.g.*, Cal. Pub. Res. Code § 30260).

Marina-65 cont.

Third, the Draft EIR/EIS is inadequate because it fails to explain the basis for determining several species' potential to occur in the Study Area, and/or provides inconsistent information regarding their potential to occur. As a result, any evaluation of impacts to those species is inadequate in that the Draft EIR/EIS fails to recognize their potential presence in the Study Area and thus fails to address potential impacts and mitigate them. For example:

1) **Stellar sea lion.** Because there is a known breeding population of stellar sea lion in the Project vicinity and known occurrences within the MBNMS, there is no rationale for the "Not Expected" potential for occurrence within the Study Area. The Draft EIR/EIS's conclusion here is unjustified at best, and likely incorrect. Moreover, the analysis is insufficient to the extent that no surveys were conducted to determine the presence (or absence) of this species in the Study Area.

2) **Northern fur seal.** Because this species has been observed within 5 km of the Study Area, the Draft EIR/EIS is inadequate in that it fails to explain the assumptions and evidence that support the Draft EIR/EIS's determination that this species is not expected to occur within the Study Area, and because it fails to address impacts on the species due to an incorrect conclusion about its likelihood of occurring in the Study Area.

Marina-66

3) **Northern elephant seal.** Because the Draft EIR/EIS states that this species is widely distributed in MBNMS waters and rookeries are present north and south of the Study Area, the Draft EIR/EIS's conclusion that this species has a low potential to occur within the Study Area appears incorrect. The Draft EIR/EIS is then inadequate because it fails to address impacts on the species due to an incorrect conclusion about its likelihood of occurring in the Study Area. At the very least, this conclusion needs explanation of the assumptions/evidence that support the determination that this species has a low potential to occur within the Study Area.

4) **Guadalupe fur seal.** The Draft EIR/EIS states that this species has been sighted in MBNMS waters and stranded on beaches within the Study Area, and yet concludes that this species has a "Not expected to low" potential to occur within the Study Area. This inconsistency suggests the conclusion is incorrect, and that the species actually has a higher potential to occur in the Study Area, and thus the Draft EIR/EIS should analyze impacts to this species. At the very least, this conclusion needs explanation of the assumptions/evidence that support the determination that this species has a "Not expected to low" potential to occur within the Study Area.

5) **Minke whale.** The Draft EIR/EIS states that there have been numerous sightings of Minke whale species in nearshore waters of Monterey Bay, and yet concludes that the potential for this species to occur is only "low-moderate." This incongruity suggests the conclusion regarding the species' likelihood to occur is incorrect, and that the species actually has a higher potential to occur in the Study Area (and thus, that the Draft EIR/EIS should analyze impacts to this species). At the very least, this conclusion needs explanation of the assumptions/evidence that support the determination that this species has only a low-to-moderate potential to occur.

6) **Olive Ridley sea turtle and Loggerhead sea turtle.** The Draft EIR/EIS is flawed in that it fails to explain what assumptions or evidence (beyond geographic distribution) support the determinations that these species are not expected to occur (Olive Ridley Sea Turtle) or have a low potential to occur (Loggerhead Sea Turtle) within the Study Area. Consequently, the Draft EIR/EIS may be inadequate for failing to analyze potential impacts to these species.

7) **Leatherback sea turtle**. The Draft EIR/EIS asserts in Table 4.5-4 that this species has low potential to occur in the Study Area, but provides no basis for this conclusion. Indeed, the Draft EIR/EIS states that leatherback sea turtles are "most commonly seen in Monterey Bay from July to October" and that <u>all</u> of Monterey Bay is leatherback sea turtle critical habitat (page 4.5-23), which is strong evidence that this species may be seasonally likely to occur in areas affected by the Project. This point must be discussed and impacts to the leatherback sea turtle and its critical habitat must be addressed and mitigated.

Marina-66 cont.

8) **Chinook Salmon (Central California ESU).** If the Draft EIR/EIS is correct that the current range of Chinook salmon still extends into Monterey Bay, why is the potential to occur within the Study Area determined to be low? Shouldn't it be moderate, similar to Chinook winter run? The Draft EIR/EIS appears to be incorrect here, and flawed for not analyzing impacts to this ESU. At the very least, the basis for this determination regarding low potential to occur must be discussed and explained.

9) **Cowcod.** If juveniles were documented within the Study Area, the "potential to occur" determination should be high rather than moderate. The Draft EIR/EIS must explain what assumptions/evidence support the determination that this species has a moderate potential to occur.

10) **Calico rockfish, copper rockfish, gopher rockfish, grass rockfish, kelp greenling, monkeyface prickleback, olive rockfish, quillback rockfish, California scorpionfish, treefish.** The Draft EIR/EIS fails to explain what assumptions and evidence (beyond geographic distribution) support the occurrence determinations for these species. The Draft EIR/EIS must be revised accordingly.

11) **Kelp rockfish.** The Draft EIR/EIS fails to set forth what assumptions/evidence (beyond geographic distribution) support the high potential for occurrence determination for this species. The Draft EIR/EIS must be revised accordingly.

12) **Mammals.** This section appears to be deficient because it fails to provide a detailed explanation for why the additional mammal species known to occur in Monterey Bay are not likely to occur or rarely occur within the Study Area. General geographic distribution is insufficient supporting evidence for potential to occur.

13) **Turtles.** This discussion states that the potential for these species to occur is "very low," which is inconsistent with the potential occurrence determinations in Table 4.5-2. This inconsistency must be resolved and any analysis contingent on the incorrect information/assumptions must be corrected, revised, and/or developed (as appropriate).

14) **Fish.** The sentence that states "Chinook salmon, depending on the run, is State endangered or threatened, federally endangered or threatened and has a moderate to high potential to occur in the Study Area" is inconsistent with Table 4.5-2, which states Chinook salmon have a low to moderate potential to occur. This inconsistency must be resolved and any analysis reliant on incorrect information/assumptions must be corrected. In addition, this section appears to be missing a discussion for tidewater goby and white shark potential to occur within the Study Area: General information is provided, but a discussion related to the Study Area is not. If tidewater goby occurs seasonally in Elkhorn Slough, why is that species identified as only having a low potential to occur? The Draft EIR/EIS is inadequate unless the assumptions and evidence that support this determination are fully explained.

Marina-66 cont.

3. The Draft EIR/EIS's Analysis Of The Impacts Of The MPWSP's Brine Discharges Is Inadequate And Incorrect.

The MPWSP will produce up to 14 *million* gallons *per day* of high-salinity brine discharge during the desalination process. The Project plans to discharge the brine effluent directly into the federally protected Sanctuary. The brine discharges will result in significant adverse impacts to the environment, but the Draft EIR/EIS's assessment and analysis of such impacts is insufficient. First, the Draft EIR/EIS claims the Project would be consistent with the MLMA (page 4.5-39), despite the admission that it would result in the decimation of 2,010-5,900 square meters of market squid habitat (page 4.5-61). The Draft EIR/EIS attempts to label this impact as less than significant by comparing the amount of lost habitat to the total area of suitable spawning ground on the sea floor south of Monterey Submarine Canyon, but there is no justifiable basis for this comparison. Indeed, tellingly, the Draft EIR/EIS completely omits any explanation of why the proper comparison of area is the entire sea floor south of the Monterey Submarine Canyon. In any case, the elimination of so much suitable spawning habitat is certainly a significant impact that must be mitigated. Marina-67 cont.

Although the Draft EIR/EIS admits the Project will have adverse impacts to squid (which the Draft EIR/EIS wrongly describes as less than significant), the Draft EIR/EIS fails to sufficiently consider and analyze impacts to other species in the same area. Instead of conducting a thorough analysis, the Draft EIR/EIS writes off such impacts by referring to "unanticipated effects" on "benthic and pelagic communities in the vicinity of the discharge" (page 4.5-61). This is an inadequate analysis of one of the Project's most significant effects: the brine discharge. The inadequacy of this analysis is likely a result of the Draft EIR/EIS's incomplete and insufficient description of the environmental baseline (see above), particularly in the area where the brine will be discharged. Without inclusion of information necessary to understand the Project's potential impacts, the EIR is defective. *See Berkeley Keep Jets Over the Bay Comm.*, 91 Cal. App. 4th at 1382-83.

4. The Draft EIR/EIS's Conclusion Regarding Impacts To Essential Fish Habitat Under The Magnuson Act Is Fatally Flawed.

As noted in the Draft EIR/EIS, "*All* of the coastal waters of Central California and Monterey Bay are identified as Essential Fish Habitat for [several fish species]." *Id.* at page 4.5-24 (emphasis added). As such, all federal agencies are *required* to protect these areas under the Magnuson Act. The Draft EIR/EIS summarily states that the Project "would be consistent with the MSA because the construction and operational impacts of the proposed project are not expected to result in any degradation of essential fish habitat within Monterey Bay" (page 4.5-31), but fails to support this with any data or substantive analysis. This clearly violates both CEQA and NEPA, which require that documents' conclusions regarding environmental impacts be based on actual scientific information and that agencies take a "hard look" at potential adverse environmental impacts. Marina-68

5. The Analysis Of Impact 4.5-1 Is Inadequate.

The Draft EIR/EIS must clarify if the ambient underwater noise levels present in the San Francisco study are similar to or substantially different from the ambient underwater noise levels present in the Study Area. The Draft EIR/EIS must also clarify whether the temporary change in noise levels from ambient conditions as a result of Project construction is expected to be consistent. If there is a potential risk for accidental discharge of drilling fluids into the marine environment from the use of drilling additives during drilling of the slant wells, which could constitute a significant impact to marine resources, the Draft EIR/EIS must identify and require any available mitigation to address that potential accidental condition. If no mitigation is required, the Draft EIR/EIS must clarify why mitigation would not be appropriate or feasible to prevent what could be a significant adverse impact to marine resources. Marina-69

Also, the Draft EIR/EIS is unclear as to whether changes in underwater noise levels were measured during construction of the test slant well. If they were, the results of those measurements and any increase in noise should be included in the Draft EIR/EIS and that data should be incorporated into the analysis of impacts to marine biological resources.

CHAPTER 4.6 – TERRESTRIAL BIOLOGICAL RESOURCES

A. The Draft EIR/EIS's Analysis Of The Project's Impacts On Terrestrial Biological Resources Is Inadequate.

1. The Project Has Significant Adverse Impacts On Terrestrial Biological Resources Because It Permits Development Inconsistent With The LCP And The Coastal Act.

The dune habitats in the Project area support several rare and endangered plant and wildlife species. The City's Local Coastal Plan ("LCP") requires any development within protected species' habitat to be evaluated at a project-specific level to determine the presence of "Primary Habitat" and "Secondary Habitat" areas. Primary Habitat includes "habitat for all identified plant and animal species which are rare, endangered, threatened, or are necessary for the survival of an endangered species" and "all native dune vegetation, where such vegetation is extensive enough to perform the special role of stabilizing Marina's natural sand dune formations." City of Marina, Ca, *Coastal Plan* (1982). Secondary Habitat (or support habitat adjacent to areas of Primary Habitat) must also be identified. Marina-70

The LCP mandates that Primary Habitat be protected and preserved. The City's LCP prohibits development in Primary Habitat that is not protective of and dependent upon that habitat: "Primary habitat areas shall be protected and preserved against any significant disruption of habitat values and only uses dependent on those resources shall be allowed within those areas." *Id.* All development in Secondary Habitat must be sited and designed to prevent significant adverse impacts on the adjacent Primary Habitat areas.

In 2014, SWCA identified Primary and Secondary Habitat in the Project area. Section 4.6.10 inaccurately reflects the location of primary habitat within the CEMEX Property and is inconsistent with the conclusion of the California Coastal Commission in its review of the test slant well. In the staff report for the test slant well California Department of Public Health ("CDP") permit application, the CCC found that although the project is proposed to be located in portions of the CEMEX Property that have been subject to disturbance, the entire area in which the Project would be located is primary habitat and ESHA under the LCP. Therefore, the Draft EIR/EIS is inadequate in that it omits or understates the severity of potentially significant impacts to primary habitat and ESHA.

Despite the CCC's finding in its staff report for the test slant well and the plain language of the City's LCP, the Project proposes to locate several project components in areas classified as Primary and Secondary Habitat. Accordingly, the Project would result in direct impacts to both Primary and Secondary Habitat.

For example, the Project's activities would disturb nesting habitat for the Western snowy plover (federally listed as threatened and also a California species of special concern), host plants for Smith's blue butterfly (federally listed as endangered and protected under the Endangered Species Act ("ESA")), and sandy habitat for the silvery legless lizard (a California species of concern). Project activities would also exacerbate dune erosion and could result in spills of hazardous materials in sensitive habitat areas. Moreover, construction and operation of the subsurface slant wells would permanently disturb up to six acres of central dune scrub and ice plant mats. And the full construction impact area would be disturbed anew every five years when slant well heads would need maintenance. *Id.* at 4.6-235. This would amount to a permanent loss of habitat for the special-status species that have the potential to re-colonize the slant well head area.

Marina-70 cont.

In addition, construction of the Source Water Pipeline, Desalinated Water Pipeline, Transmission Main, and the staging area at Beach Road have the potential to temporarily adversely impact Primary and Secondary Habitat. As the Draft EIR/EIS admits, there is no way to reduce these impacts to a less than significant level. The Draft EIR/EIS proposes compensatory mitigation to reduce the impacts on special-status species habitat, but there are numerous problems with the proposed mitigation measure, as discussed below in our comments relating to chapter 4.8. In sum, the Project is inconsistent with the LCP's habitat protection requirements and cannot be approved as proposed.

Recognizing this irreconcilable conflict, the Draft EIR/EIS suggests that this legal obstacle to the Project may be circumvented because Section 30260 of the Coastal Act "encourages coastal-dependent industrial uses and provides for resolution of conflicting Coastal Act policies where such development is concerned." The CCC relied on this provision in its prior approval of one test well at the CEMEX location. *Id.* at 4.6-224. However, the Project contemplates a vastly greater impact area than was at issue with just one test well, and it is highly unlikely that it would apply to permit the Project when there are alternatives that avoid such fatal flaws. Moreover, operation of the test well has revealed the Project would have several significant adverse impacts not anticipated at the time of approval of the test slant well.

2. The Draft EIR/EIS Fails To Provide An Adequate Description Of The Environmental Baseline.

CEQA requires an adequate description of the existing environmental baseline. CEQA Guidelines § 15125(a). The Draft EIR/EIS fails to meet this fundamental and critical prerequisite to an adequate analysis of impacts to biological resources. The designated Study Area encompasses only a 50-foot buffer around the Project area. The Draft EIR/EIS offers only this explanation of the boundary: "A 50-foot buffer around the project area was established as the survey area to ensure biological resources within the project area and immediate adjacent vicinity were assessed for potential direct and indirect project impacts." But the Study Area must be large enough to enable an accurate assessment of the environmental baseline. A 50-foot buffer is undoubtedly insufficient. For example, noise impacts from construction will travel beyond 50 feet and may adversely and significantly impact special status animal species.

Marina-71

3. The Draft EIR/EIS's Analysis Of The Impacts Of The Subsurface Slant Wells Is Inadequate.

Section 4.6.5.1 reflects an analysis of the old project design, including references to an electrical control panel and electrical control building. The analysis must be revised to account for the current proposed Project design. Once the analysis has been updated to accurately reflect the Project, the Draft EIR/EIS must be recirculated to the public can review and comment on the analysis.

This section also inaccurately describes the location of the slant wells at "the eastern side of the vegetated sand dunes." In fact, the slant wells would be constructed in the middle of the large dune complex that comprises the CEMEX Property. Construction of the slant wells would require increased disturbance and human activity in the center of this highly sensitive dune complex. Per this section, the increased disturbance and human activity could occur year-round during construction. Due to the intrusive type and duration of construction activity, the Project could have indirect long-term effects on the behavior of sensitive species in this area of dunes, particularly Western snowy plover. These impacts are improperly dismissed in the Draft EIR/EIS as "temporary." These impacts must be fully analyzed and disclosed in the Draft EIR/EIS. The potential effects of one year (or more) of excavating, drilling, and other slant well construction activities on sensitive species in the long-term must be evaluated.

Throughout this section and others, the Draft EIR/EIS states that the disturbance area for construction of the well "may overlap" with a portion of the Source Water Pipeline disturbance area. Why has it not been determined whether or not these areas overlap? This information should be readily available and the quantified areas of disturbance must be disclosed.

Marina-72

4. The Draft EIR/EIS's Analysis of Impacts 4.6-1 And 4.6-2 Is Inadequate.

These sections fail to identify and address potential impacts to special status species and sensitive habitats as a result of the proposed disposal of up to 100 cubic yards of drilling spoils within the dune habitat at the CEMEX Property as a result of slant well drilling. This proposed

Marina-73

Project component must be identified in this section and analyzed as a potentially permanent disturbance of sensitive habitat and what extent that disturbance could affect sensitive species in the area of disposal and surrounding areas. Adverse impacts related to the type and quantity of material to be disposed of in the on-site dunes (ESHA) should be clearly identified and mitigated. Once properly accounted for in the Draft EIR/EIS, these new and more severe impacts must be analyzed and the document then recirculated for public review.

Marina-73 cont.

5. The Analysis of Impact 4.6-C Is Inadequate.

The discussion of Impact 4.6-C inadequately analyzes the Project's potential cumulative impacts on native dune habitat and central dune scrub. The analysis incorrectly determines that cumulative impacts would be less than significant with mitigation due to the (1) limited extent and duration of effects at any MPWSP component site, (2) the prevalence of such habitats within the geographic scope of analysis relative to the areas of the MPWSP effect, and (3) the nearby availability of such habitats for use by species displaced during the construction period. The purported evidence of a less than significant cumulative impact in item number (1) fails to account for the permanent and ongoing operation-related disturbance that would occur in sensitive native dune areas at the CEMEX site. Item number (2) fails to reflect that native dune habitat and central dune scrub are limited and finite resources. According to the Western Snowy Plover Recovery Plan (USFWS 2007), the management potential for plovers in the Lonestar Beach subarea is second only to the Salinas River National Wildlife Refuge (Zander 2013).

Marina-74

Therefore, plover habitat comparable to that at the CEMEX (formerly Lonestar) Property may only be located in one other place in Central California: the Salinas River National Wildlife Refuge. The purported "prevalence" of these habitats in the project vicinity, and the nearby availability of such habitats for use by displaced species, both during construction and permanently as a result of Project operations (though not considered in the Draft EIR/EIS) is a gross misstatement. The permanent loss of 6 acres of coastal dune scrub, native dune habitat, and snowy plover habitat is a considerable contribution to cumulative loss of habitat for this species statewide. In fact, it is difficult to imagine a project that would result in greater cumulative impacts to this species. Based on the historic cumulative loss of suitable habitat and decline in species population, the Project's cumulative impacts to Western snowy plover and its habitat should be considered significant and unavoidable.

6. The Analysis of Operational And Siting Impacts Is Inadequate.

Section 4.6.5.2 fails to address the adverse effects that would occur as a result of routine maintenance and grading of the slant well access road. Due to the shifting nature of the dunes, the access road would require regular grading and maintenance. The Draft EIR/EIS fails to identify the level of disturbance necessary to maintain the road to provide access and accommodate routine inspections and site visits at the slant well heads conducted in addition to the 5-year periodic maintenance activities. The evaluation of operational impacts is invalid because it fails to account for potentially significant adverse effects that would result from this activity.

Marina-75

7. The Analysis of Impact 4.6-6 Is Incorrect And Inadequate.

It is unclear why or how the Draft EIR/EIS determined that only 1.6 acres of Smith's blue butterfly habitat would be disturbed during ongoing maintenance activities. Coast buckwheat, host plant for Smith's blue butterfly, occurs throughout the CEMEX Property and has the potential to occur throughout the entire 6 acre area of disturbance. Unless it can be clearly established that the majority of the disturbance area does not provide habitat for Smith's blue butterfly, the Draft EIR/EIS significantly understated the level of impact to Smith's blue butterfly habitat. The Draft EIR/EIS should identify the actual amount of habitat that would be affected; if all six acres of the disturbance area would be affected, the Draft EIR/EIS should be revised to accurate state the level of impact and recirculated to disclose the substantial increase in the severity of this effect.

Marina-76

The discussion of Impact 4.6-6 also fails to explain how and to what extent identified mitigation measures would be applied prior to each five-year slant well maintenance operation. Would a new Hazardous Materials Management Plan ("HMMP") and compensatory mitigation be required each time to minimize impacts related to project disturbance?

B. The Draft EIR/EIS's Mitigation Of The Project's Impacts On Terrestrial Biological Resources Is Inadequate.

1. The Project's Mitigation Measures Are Inadequate Because They Are Not Enforceable.

CEQA mandates that proposed mitigation measures be "fully enforceable." Cal. Pub. Res. Code § 21081.6(b); CEQA Guidelines § 15126.4(a)(2). Several of the proposed mitigation measures directly contravene this CEQA requirement, thus invalidating each of the Draft EIR/EIS's conclusions regarding the significance of the Project's adverse environmental impacts that rely on any of the mitigation measures suffering from this critical flaw.

First, the Draft EIR/EIS's General Avoidance and Minimization Measure (MM 4.6-1c) states that erosion shall be remedied, but fails to specify what counts as erosion, how the erosion shall be remedied, and fails to set performance standards for determining whether the erosion has in fact been remedied. (page 4.6-166). Perhaps most notably, the language of the mitigation measure limiting erosion that must be remedied to only erosion that has been "detected" without requiring any kind of monitoring for erosion (at all, much less someone qualified to monitor for such impacts), guts any mitigation this measure could have possibly effected. Thus, this mitigation measure is wholly inadequate to minimize erosion impacts to less than significant levels.

Marina-77

Mitigation Measure 4.6-2b suffers from a similar flaw. This measure purports to reduce direct impacts on sensitive natural communities and the special-status species that utilize them. However, it is completely inadequate to do that. The specific measures in MM 4.6-2b are all subject to the significant caveat, "to the extent feasible" (see page 4.6-207), which—as with MM 4.6-1c—essentially guts the mitigation measure. Without any standard for what constitutes

feasibility or non-feasibility, the developer and its contractors are free to completely disregard these mitigation measures by claiming compliance is not feasible. Furthermore, specific elements of this mitigation measure contain even more feasibility qualifiers, such as for salvaging topsoil "to the extent feasible." *Id.* at page 4.6-208. In addition, see, for example, page 4.6-131 (purported avoidance of special-status plants and host plants only "to the extent feasible"); page 4.6-134 (supposedly avoiding impacts on non-nesting birds by limiting construction to the non-nesting season only "when feasible'); page 4.6-137 (similar).

Mitigation Measure 4.6-1j relating to badgers contains the same critical flaw. This measure provides:

> 4. If the biologist determines that any potential dens identified during the preconstruction surveys are inactive, the biologist shall excavate the dens by hand with a shovel to prevent use by badgers during construction.
>
> 5. If active badger dens are found during the course of preconstruction surveys, the following measures shall be taken to avoid and minimize adverse effects on American badger:
>
> a. Relocation shall be prohibited during the badger pupping season (typically February 15 to June 1).
>
> b. Construction activities shall not occur within 50 feet of active badger dens. The Lead Biologist shall contact CDFW immediately if natal badger dens are detected to determine suitable buffers.

Marina-77 cont.

As written, these measures do not provide a reasonable threshold or parameter for the biologist to determine that the den(s) is inactive. The survey would likely be conducted in the daytime, when any badgers are down in the den; therefore, the biologist would not be able to verify the den is inactive before collapsing the den. Accordingly, this measure should be revised to include the use of game cameras on the potentially active den(s) for at least three nights prior to the den(s) being collapsed. Then, only after badgers were not photographed entering or leaving a den for three nights, may that den be collapsed.

In sum, the Draft EIS/EIR's mitigation—and thus the impact conclusions relying on such mitigation—is inadequate under the law. All mitigation measures containing "requirements" that would only be implemented "to the extent feasible," "to the extent possible," or "where practicable" (or similar) must be reassessed to determine the actual extent the measures would be implemented and rewritten accordingly. Only after the level of actual implementation has been determined can a valid analysis be conducted on whether and to what extent significant adverse impacts have been mitigated.

2. Mitigation Of Impacts On Protected Bird Species Is Inadequate.

The Project area includes significant Western snowy plover habitat, such as the CEMEX Property to be disturbed by the proposed slant well construction, operation, and maintenance. *Id.* at 4.6-50, 4.6-129. The Project area also includes "numerous" native birds protected under the MBTA and California Fish & Game Code (4.6-41, 59-62), including habitat of California species of special concern, the tricolored blackbird, the short-eared owl, and the western burrowing owl (4.6-59-60). There is no doubt that the Project has the potential to have a very significant adverse impact on these bird species. *See, e.g.*, 4.6-129-131.

While the Draft EIR/EIS contains mitigation measures purportedly designed to reduce impacts to these species, these mitigation measures are wholly inadequate. First, MM 4.6-1i, Avoidance and Minimization Measures for Nesting Birds, is insufficient to mitigate the Project's impacts on nesting birds. The preconstruction surveys are only required within 14 days of the commencement of construction, leaving two full weeks for birds to start nesting in between the survey time and the start of construction. This mitigation measure must be revised to require surveys to be conducted within no more than 48 hours of the commencement of construction. In addition, the MM should be revised to specify what type of survey methodology is required.

Marina-78

MM 4.6-1h, Avoidance and Minimization Measures for Western Burrowing Owl, is also inadequate as currently proposed. First, as noted for MM 4.6-1i, this MM should be revised measure to require surveys to be conducted within no more than 48 hours of the commencement of construction. Permitting construction to start 14 days after surveys were conducted is not sufficiently protective of the species. Second, the MM currently states that temporarily disturbed habitat shall be restored to pre-construction conditions, "if feasible." But as discussed above, without a clear standard as to what "feasible" means, this mitigation measure is fatally vague and fails to guarantee any *effective* mitigation.

In addition, Mitigation Measure 4.6-6 is inadequate because it fails to make implementation of bird deterrents enforceable, by requiring that such deterrents "should" be used rather than "shall" be used. The use of bird deterrents should be made a requirement, not a suggestion, in order to ensure mitigation is enforceable and will actually reduce adverse impacts to a less than significant level.

3. Mitigation Of Impacts To Sensitive Communities And Their Special-Status Plant And Animal Inhabitants Is Inadequate.

The Draft EIR/EIS identifies potential impacts to sensitive communities and special-status plants and animals that occupy or may occupy the communities. Some of these impacts will require the Project proponent to obtain an Incidental Take Permit under the California Endangered Species Act ("CESA") and an Incidental Take Statement under Section 7 of the Federal Endangered Species Act ("ESA"). The impacts to sensitive communities and special-status resources are expected to vary from permanent loss of habitat and species individuals to temporary disturbance of habitat or species individuals. However, the Draft EIR/EIS does not

Marina-79

quantify the amount of permanent impact or temporary impact to sensitive communities and/or species.

To reduce these impacts to less than significant levels under CEQA, the Draft EIR/EIS heavily relies on the preparation and implementation of a Habitat Mitigation and Monitoring Plan (Mitigation Measure 4.6-1n). Mitigation Measure 4.6-1n requires the Habitat Mitigation and Monitoring Plan ("HMMP") to be reviewed and approved by the permitting agencies. Since the Project is anticipated to result in permanent impacts, the HMMP is supposed to address the need for compensatory mitigation (Item 17 in MM-4.6-1n).

However, because the Draft EIR/EIS does not quantify the anticipated permanent impacts to the sensitive resources, the Draft EIR/EIS cannot verify that the Project proponent has, under its ownership or via other property rights, sufficient lands to implement compensatory mitigation for permanent impacts to sensitive resources at a ratio that is adequate to reduce the impacts to less than significant levels under CEQA. In order for the proposed mitigation to adequately reduce the identified impacts to be less than significant, the Draft EIR/EIS must include the following:

1. Quantification of permanent and temporary impacts to sensitive resources;
2. Ratios for mitigating the estimated impacts;
3. Methods of mitigating the identified impacts (restoration, enhancement, land acquisition, preservation, etc.);
4. Success standards for the proposed mitigation measures and an enforcement mechanism that ensures those standards are met;
5. Contingency measures that will be triggered if the success standards are not achieved; and
6. Identification of available, accessible mitigation lands.

Marina-79 cont.

Due to the size of the Project, magnitude of potential impacts, and the need for an Incidental Take Permit from the California Department of Fish & Wildlife ("CDFW"), it is likely that the HMMP will need to include the acquisition and transfer of habitat management lands. The Draft EIR/EIS is flawed in that it fails to identify whether the Project proponent has the lands required to implement compensatory mitigation. *See, e.g., Kings Cty. Farm Bureau v. City of Hanford*, 221 Cal. App. 3d 692, 727 (1990) (mitigation agreement that called for purchases of replacement groundwater supplies without specifying whether water was available was inadequate measure for mitigating project's effect on groundwater supplies). The Draft EIR/EIS needs to quantify the potential impacts, propose mitigation ratios for the impacts, and identify where and how the impacts will be mitigated in sufficient detail to verify that the Project proponent has the means to implement the HMMP. Without this verification, MM-4.6-1 may not be feasible or adequately mitigate impacts. As a result of the above deficiencies, the Draft EIR/EIS's conclusion that the permanent and temporary impacts to sensitive communities and special-status species are mitigated to less than significant is incorrect and invalid.

This measure also improperly defers mitigation by failing to identify appropriate performance standards that would be included in the HMMP to ensure that any potential impacts would be mitigated to less than significant levels. This contravenes CEQA, which mandates that mitigation not be deferred unless the relevant measure specifies performance standards and further action to carry the project forward is contingent on meeting those specific performance criteria. CEQA Guidelines § 15126.4(a)(1)(B); *Endangered Habitats League, Inc. v. Cty. of Orange*, 131 Cal. App. 4th 777, 794 (2005) (rejecting mitigation measure that did not include any criteria or standards); *Sacramento Old City Ass'n v. City Council*, 229 Cal. App. 3d 1011, 1029 (1991) (mitigation may only be deferred if specific performance criteria are articulated at the time of project approval and the project may not move forward unless it meets them).

Marina-79 cont.

Mitigation Measure 4.6-1 not only defers the preparation of the HMMP, but also defers identification of appropriate performance standards "by which successful completion of mitigation can be assessed in comparison to a relevant baseline . . . and by which remedial actions will be triggered." But if the performance standards are not known, it cannot be determined that they would adequately reduce potentially significant impacts to less than significant levels. Thus, this impact must be properly mitigated or identified as significant and unavoidable. Any added performance standards must be recirculated so they public, interested stakeholders, and Responsible Agencies have the opportunity to comment on the feasible ways to mitigate or avoid the substantial adverse effect.

Many of the impacts identified in this section rely back on Mitigation Measure 4.6-1n to support a less than significant impact determination. Each of these determinations is inadequately supported due to the multiple shortcomings of this measure.

4. Mitigation Measures Involving Capture And Relocation Must Be Revised.

Mitigation Measure 4.6-1o requires capture and relocation of ESA and CESA protected species, but does not clearly state that ESA and CESA issued incidental take permits are necessary prior to capturing these species. The EIR section does identify the need for the applicant to obtain an Incidental Take Permit ("ITP"); however, this requirement is not carried into the mitigation measure. This mitigation measure should be revised to include requirements for the Project to be covered by ITP and to clarify that the implementing biologist must be approved under the ITP.

Marina-80

Similarly, Mitigation Measure 4.6-1g states: "The Lead Biologist shall appoint a qualified biologist possessing a Scientific Collecting Permit issued by CDFW for black legless lizard, silvery legless lizard, and coast horned lizard to conduct preconstruction surveys for legless lizards and coast horned lizards within 24 hours prior to the initiation of ground disturbing activities or vegetation clearing in suitable habitat…" However, possession of a CDFW Scientific Collection Permit does not authorize an individual to capture and/or relocate sensitive species for CEQA compliance. Thus, this measure does not adequately mitigate impacts on these lizard species.

5. Mitigation Measures Must Be Revised To Correct Improper Deferral Of Mitigation.

Numerous measures throughout sections 4.6.5.1 and 4.6.5.2 improperly defer to the discretion of United States Fish & Wildlife Service ("USFWS") and CDFW to define the extent and limits of what would be required as mitigation. These mitigation measures are inadequate because identified minimum performance standards are not defined in a way that would be enforceable by the lead agencies. Minimum performance standards are provided in an exemplary manner, subject to future reduction or removal by CDFW or USFWS. In the absence of enforceable mitigation measures, it cannot be stated that impacts would be reduced to less than significant. These measures should be rewritten to identify the minimum performance standards with certainty that would be met by CalAm and which could not be further reduced through future negotiations with outside regulatory agencies. Until the minimum mitigation possible is identified (i.e., compensatory mitigation ratios of no less 2:1 would be required), it cannot be established whether mitigation would reduce potentially significant impacts to less than significant levels.

Marina-81

6. Mitigation Measure 4.6-1d Is Inadequate.

This measure states that CalAm will identify and secure access rights and other approvals to implement the HMMP. CalAm's ability to secure access rights and necessary approvals may not be feasible, rendering this mitigation potentially infeasible. The Draft EIR/EIS does not provide substantial evidence that suitable, similarly valuable, dune habitat is available for compensatory mitigation in the Project vicinity. Most of the dunes on the Monterey Peninsula have been disturbed or lost due to population growth and development. The dune complex at the CEMEX Property constitutes one of the biggest and best preserved stretches of dune habitat in the entire County and Central California. The Draft EIR/EIS fails to identify the lack of comparable areas suitable for compensatory mitigation as a constraint to implementation of mitigation and improperly concludes that the identified mitigation would reduce potential impacts to a less than significant level. As a result, Mitigation Measure 4.6-1d is flawed and must be redone. *See, e.g., Kings Cty. Farm Bureau*, 221 Cal. App. 3d at 727 (mitigation agreement that called for purchases of replacement groundwater supplies without specifying whether water was available was inadequate measure for mitigating project's effect on groundwater supplies).

Marina-82

This measure requires annual monitoring to ensure restoration is successful but fails to identify appropriate performance standards for "success" or the duration of annual monitoring. Would monitoring in perpetuity be required to ensure the restored area of dunes is forever preserved and protected for the benefit of the sensitive species that rely on this habitat? The failure to identify standards on which the determination of "successful" restoration would be met renders this mitigation measure useless; it is impossible to determine whether restoration activities as required by identified mitigation measures would, in fact, reduce significant impacts resulting from the disturbance and permanent loss of ESHA during project construction. Therefore, this impact should be considered significant and unavoidable. Even the proposed

mitigation ratio of 2:1 is not made mandatory by the measure, which provides that this ratio could always be renegotiated at a later date. CEQA does not allow a lead agency to merely cite to later processes and approvals (i.e., from USFWS) to establish that an impact would be properly mitigated. If USFWS fails to require adequate mitigation and restoration, the impact would be significant and unavoidable. Deferral of mitigation is prohibited where the agency fails to commit itself to specific performance standards. *See POET, LLC v. State Air Res. Bd.*, 218 Cal. App. 4th 681, 688 (2013) (an agency must commit to "specific performance criteria for evaluating the efficacy of the measures implemented"). At the very least, an EIR must identify methods the agencies will consider for mitigating impacts, and indicate the expected outcome. CEB, *Practice Under the California Environmental Quality Act* § 14.12, p. 14-18.

This measure also provides for alternative mitigation through the payment of funds to a mitigation bank. There is no logical reason provided to show why on-site restoration activities should not also be required to mitigate significant impacts on sensitive species and ESHA to the greatest extent feasible. Restoration should be a required and enforceable mitigation requirement in the Draft EIR/EIS regardless of whether in lieu fees are also required. Due to the permanent loss of dune habitat and ESHA at the site that can never be restored, both restoration and payment of in lieu fees should be required.

The Draft EIR/EIS states that this measure would apply to periodic maintenance of the subsurface slant wells but does not provide any explanation of how that would minimize impacts. Would a separate HMMP be prepared prior to every occurrence of 5-year maintenance activities? Would the HMMP consider disturbance associated with maintenance "new" disturbance, subject to the restoration and compensatory mitigation requirements? This creates an even more blatant feasibility concern, as the area of disturbance for routine maintenance (6 acres) would require CalAm to find 12 acres of land (assuming a 2:1 ratio) suitable for compensatory mitigation every 5 years, or approximately 96 acres of dune habitat for restoration and ongoing monitoring into perpetuity over an estimated 40-year Project lifespan. Do the Project proponents have any evidence to support the feasibility of this requirement? If the identified mitigation is infeasible, the impact should be identified as significant and unavoidable. The mere payment of fees for protection of off-site resources would not reduce the impacts to sensitive biological resources and ESHA to less than significant levels.

Numerous additional mitigation measures in this section state that the measure would also apply to periodic maintenance of the subsurface slant wells. The Draft EIR/EIS must explain exactly how those measures would be applied and whether or not CalAm would be required to meet the full extent of every measure prior to each 5-year periodic maintenance period. The Draft EIR/EIS's failure to do so makes it impossible to determine whether impacts resulting from periodic maintenance would in fact be reduced to less than significant. Failure to include this information also deprives the public of a meaningful opportunity to comment upon substantial adverse environmental effects of the Project and feasible ways to mitigate or avoid such effects.

Marina-82 cont.

7. Mitigation Measure 4.6-1e Should Apply More Broadly.

Mitigation Measure 4.6-1e should apply to all Project areas that contain sensitive plan species and/or habitats. The Draft EIR/EIS's failure to include this measure for Project components other than the Terminal Reservoir inadequately mitigates the extent of impacts. Marina-83

CHAPTER 4.7 – HAZARDS AND HAZARDOUS MATERIALS

A. This Section Fails To Properly Analyze Project Inconsistencies With Hazardous Waste Regulations And Describe How They Will Be Resolved.

Many of the consistency determinations throughout chapter 4.7 state that, because contractors would be required to comply with the relevant regulations, the Project would be consistent with those regulations. This reasoning is circular and not useful. There is no attempt to establish that the proper procedures and protocols are in place to ensure the contractor would follow the required regulations and the Project would be consistent with the referenced regulations. There is no evaluation as to whether Project redesign or modifications would be necessary to ensure compliance with a particular regulation, the impacts of which would need to be evaluated in the Draft EIR/EIS.

Section 4.7.2 states that contractors are required to comply with the water main separation regulations in Cal. Code Regs. tit. 22 § 64572, which would make the Project consistent. This is circular and not useful, as described above. In addition, this section states that new water supply lines shall not be within 10 horizontal feet of any parallel pipeline carrying secondary-treated wastewater. The proposed source water pipeline runs parallel in very close proximity to the existing MRWPCA outfall (which conveys treated wastewater) and in at least one location, crosses the outfall. It is physically impossible for the crossing location to comply with Section 64572 regulations and it is unclear whether the remainder of the source water pipeline maintains the required 10-foot minimum distance from the outfall. This issue should be clarified and the proposed means for addressing the inconsistency must be identified and analyzed in the Draft EIR/EIS. Are exceptions to this requirement permitted? Would Project redesign be required to ensure consistency? Marina-84

The analysis of "Chapter 15.56 – Digging and Excavation the Former Fort Ord" in Table 4.7-3 states that the Project would be potentially inconsistent with this policy. Regardless of whether previously unknown contamination may be discovered, there is no reason why the Project should not be required to comply with this policy. The policy requires acquisition of permits prior to disturbance, special standards and procedures prior to digging and excavation, and standard noticing and reporting requirements. The potential for discovery of previously unknown contamination would not create inconsistency with this policy; any potential inconsistency with this policy reflects inadequate mitigation of potential project effects and/or failure to comply with required City of Marina Municipal Code special standards and procedures.

In addition, this table states that the Project would be consistent with City Municipal Code Section 8.12.050, which sets registration and filing requirements for any use that involves hazardous materials for any one time during the year. The Project would require containment of hazardous materials during construction and routine maintenance of the slant wells, resulting in a potential inconsistency with this policy. The analysis seems to assume the requirement only applies to long-term storage of hazardous materials. This section should be rewritten to address short-term storage of hazardous materials and the application of this code section to those uses.

Marina-84 cont.

B. The Draft EIR/EIS Fails To Analyze Project Interference With Adopted Emergency Response Plans.

Section 4.7.3 screens out analysis of the Project's potential to physically interfere with an adopted emergency response plan or emergency evacuation plan. As discussed in section 4.9.6, the Project would result in significant and unavoidable traffic and circulation impacts during Project construction due to increased traffic and transportation network disruptions and potentially concurrent construction of the Project and other foreseeable projects listed in Table 4.1-2. The section states, "concurrent construction of these projects could create traffic safety hazards for vehicles, bicyclists, and pedestrians on public roadways. Access to adjacent land uses and streets for both general traffic and emergency vehicles could be disrupted." These identified effects indicate that the Project could physically interfere with an adopted emergency response plan or emergency evacuation plan due to significant and unavoidable traffic impacts.

Marina-85

The Draft EIR/EIS should include a thorough evaluation of this issue, including a discussion of any applicable emergency response and evacuation plans, identification of the evacuation areas included in those plans, discussion of the emergency response and evacuation routes identified in the plans, identification of alternative emergency response and evacuation routes in the event of loss of access due to Project-related impacts (lane closures and/or access restrictions due to increased congestion), and evaluation of identified measures that would be implemented to ensure no significant impacts would occur (if feasible).

C. There Are Other Deficiencies In The Hazardous Waste Impact Analysis.

Section 4.7.4

The approach to this analysis is inadequate in that it only assumes that "[s]ignificant impacts would occur if the location or activities of project components resulted in conflicts with known hazardous materials sites." Project-related conflicts with unknown hazardous materials sites could result in significant, adverse, and in fact, catastrophic, environmental effects. Other significant impacts, not related to any hazardous materials sites (known or unknown) could also occur due to project construction and operation. The approach to this section should be revised and the analysis revised as necessary to account for all potentially significant impact thresholds identified under CEQA.

Marina-86

Section 4.7.5.1

This section inadequately addresses the potential for frac-out during drilling operations. Frac-out is a potential concern when horizontal directional drilling ("HDD") is used, as is proposed in certain locations throughout the Project area. These areas should be evaluated to determine their sensitivity in the event of a frac-out. If sensitive resources (biological, cultural, hydrological) are present in the areas of proposed HDD, the Draft EIR/EIS must identify potential frac-out as a potentially significant impact to these resources and mitigate the impact accordingly. The Draft EIR/EIS does not specify what type of "drilling fluid" would be used during HDD, but even non-toxic materials such as bentonite (a fine clay material commonly used as a drilling lubricant) can adversely affect sensitive resources. Marina-87

Mitigation Measures 4.7-2a and 4.7-2b

These measures are inadequate in that they do not identify appropriate performance standards that would have to be met in order to ensure potential impacts are mitigated to less than significant. For example, Measure 4.7-2a states that maximum exposure limits for known and reasonably foreseeable site chemicals would be summarized, but there is no requirement that the exposure limits meet acceptable public safety thresholds. Measure 4.7-2b does not include any maximum exposure limits and fails to incorporate RWQCB or California EPA human health screening levels; thus, the measure fails to mitigate a potentially significant impact to worker and human health, and also confirms that the Project would be unnecessarily inconsistent with the identified Environmental Screening Levels ("ESLs") and California Human Health Screening Levels ("CHHSLs") discussed in section 4.7.2.2. Marina-88

Mitigation Measure 4.7-2b

Why does this measure not apply to the slant wells? The Draft EIR/EIS does not support a basis for determining that the potential for exposure to hazardous materials is decreased or absent at this location and, therefore, the mitigation is needed at the slant well location. Since the drilling spoils are proposed to be disposed of on-site by percolating and spreading the excavated material across the sensitive dune sands, the potential for impacting sensitive biological resources as a result of hazardous contamination is increased at this location, justifying more stringent mitigation controls. Marina-89

Impact 4.7-3

This impact discussion understates the potential significance of an unanticipated discovery and detonation of unexploded ordnance, a situation which could not only cause extensive damage to the surrounding environment, but that could also be fatal. Despite compliance with all identified regulations (which is the only mitigation identified to minimize this potential impact), there is still a possibility that a Project-related disturbance in the former Fort Ord Seaside MRS could result in the inadvertent detonation of unexploded ordnance ("UXO"). The Draft EIR/EIS should require that all remedial actions to take place within the Marina-90

proposed area of disturbance should be completed prior to any Project-related disturbance. This requirement would reduce the potential for unanticipated discovery of UXOs due to Project construction. Alternatively, this impact should be considered significant and unavoidable and risks associated with disturbance within the Seaside MRS should require the lead agencies to make overriding considerations. Marina-90 cont.

Impact 4.7-5

Impacts under this section related to the potential unanticipated disturbance and detonation of UXOs and resulting potential wildfires that could occur, are similarly understated. Although the potential for the impact to occur is reduced through compliance with existing regulations, the potential is not eliminated and the resulting effect would be severe. The Draft EIR/EIS should identify all feasible mitigation available to avoid and minimize this potential impact, including for example, a requirement that site remediation activities be completed before Project-related disturbance is allowed within the Seaside MRS. Alternatively, this potential impact should be considered significant and unavoidable. Marina-91

Section 4.7.5.2, ASR-5 and ASR-6 Wells, and Terminal Reservoir

This section does not adequately address potential groundwater impacts associated with injection of chlorinated water into groundwater aquifers. The Draft EIR/EIS cites to a single test injection well to support a determination of less than significant impacts that could result from proposed injections; the test injection well showed that by-products increased during the first 60 days of storage before declining slowly over the following 90-150 days (3-5 months). The Draft EIR/EIS should, first and foremost, identify the location of the test injection well; second, discuss the factors that cause the formation of disinfection by-products as a result of injection; and third, provide substantial evidence that supports the assumption that conditions and findings at the test injection well would apply and be consistent with potential effects at the proposed ASR injection locations. The fact that groundwater extracted for drinking water supply would have to meet drinking water requirements does not mitigate potential groundwater contamination impacts related to groundwater injection. Marina-92

Section 4.7.6

This section fails to address potential cumulative effects of the Project related to the physical interference with an adopted emergency response plan or emergency evacuation plan. This issue area must be evaluated in the Draft EIR/EIS, particularly in consideration of the identified significant and unavoidable traffic, access, and congestion-related issues during Project construction. Marina-93

CHAPTER 4.8 – LAND USE, LAND USE PLANNING, AND RECREATION

The City is a Responsible Agency for the Project because it will be considering the Coastal Development Permit for the Project according to its Local Coastal Program as authorized by the California Coastal Act. Cal. Pub. Res. Code §§ 30000, *et seq*. It is absolutely essential Marina-94

that the environmental information contained in the EIR/EIS for the Project be adequate in all respects so that the City can properly exercise its discretionary approval power over the Project. *See* CEQA Guidelines § 15096. Among other things, a full and complete description of the legal authorities relating to this decision must be contained in the document. Unfortunately, this section of the Draft EIR/EIS does not contain a sufficient description of the relevant California Coastal Act provisions (page 4.8-16 to 17) or of the City's Local Coastal Plan (page 4.8-18).

Marina-94 cont.

This chapter concludes that the Project is consistent with the Coastal Act policies and with the City's Local Coastal Plan. However, for the reasons set forth in the comments for chapter 4.6 herein, these conclusions are unsupported and inadequate.

CHAPTER 4.9 – TRAFFIC AND TRANSPORTATION

There are several inadequacies in the Draft EIR/EIS analysis of traffic and transportation that are discussed in this section.

Mitigation Measure 4.9-6

The Draft EIR/EIS should explain why pre-project road conditions have not been evaluated yet and potential necessary rehabilitation measures have not yet been identified. By deferring the roadway evaluation and identification of suitable mitigation, the extent of potential impacts has not been adequately identified and the feasibility of appropriate mitigation is unknown. Necessary mitigation could be determined infeasible and/or could have secondary impacts associated with necessary road rehabilitation improvements that have not been addressed. The existing roadway evaluation should be conducted and this mitigation measure should be revised to identify any necessary road rehabilitation measures and associated secondary impacts prior to finalizing the Final EIR/EIS.

Marina-95

Staging Area (Page 4.9-33) and Mitigation Measure 4.9-7

This discussion states that the proposed staging areas would occupy portions of parking lots (e.g. a lot that serves Cal State Monterey and a Walmart parking lot). Mitigation has been applied that requires the construction contractor to coordinate with the affected jurisdictions (i.e., Cal State Monterey and the cities of Marina and Seaside) to design staging areas to avoid or minimize parking impacts in the publicly used parking lots. This mitigation measure should be revised to require coordination with the affected Walmart store to design staging areas to avoid or minimize parking impacts in the Walmart parking lot.

Marina-96

CHAPTER 4.10 – AIR QUALITY

There are a variety of inadequacies in the air quality impact analysis and associated mitigation that are discussed in this section.

Marina-97

Impact 4.10-1 and Mitigation Measure 4.10-1a

The discussion of mitigated construction emissions of NO_x assume that compliance with Mitigation Measure 4.10-1a would result in equipment emissions that would be equivalent to those that would be associated with engines that comply with Tier 3 engine standards. However, Mitigation Measure 4.10-1a only requires CalAm and/or its construction contractor to make a "good faith effort" to use available construction equipment that meets the highest USEPA-certified tiered emission standards. Therefore, the Project would not be required to use only equipment that meets the Tier 3 standard and construction emissions could be even higher than the stated mitigated quantity of 324 pounds per day, which is already 187 lbs above the daily threshold of 137 lbs (by more than double).

Since the Project would result in construction emissions of NO_x that would constitute a significant and unavoidable impact with mitigation, Mitigation Measure 4.10-1a is inadequate in failing to require the use of construction equipment that meets the Tier 3 engine standards (as opposed to requiring a "good faith effort" to use Tier 3 construction equipment). CEQA requires lead agencies to mitigate potentially significant impacts to the extent feasible. The Draft EIR/EIS should have incorporated or provided clear information showing why the following feasible mitigation measures, included in the MBUAPCD's CEQA Air Quality Guidelines, are not feasible or otherwise not included as mitigation to reduce construction emissions of NO_x.

Marina-97 cont.

<u>Feasible Mitigation Measures:</u>

- Limit the quantity of equipment.
- Limit the type of equipment.
- Limit the rate and quantity of fuel consumption and/or process throughput.
- Limit the number of hours of operation per day.
- Apply RACT or BACT to stationary sources unregulated by the District.
- Limit the pieces of equipment used at any one time.
- Minimize the use of diesel-powered equipment (i.e., wheeled tractor, wheeled loader, roller) by using gasoline-powered equipment to reduce NO_x emissions.
- Limit the hours of operation for heavy duty equipment.
- Undertake Project during non-zone season (November 1 – April 30).
- Off-site mitigation.

For specific control technologies, the Draft EIR/EIS should refer to and incorporate CAPCOA's BACT Clearinghouse, the South Coast Air Quality Management District's BACT Clearinghouse, or EPA's AP-42 Compilation of Air Pollutant Emission Factors (Volume I). The CEQA lead agency cannot simply identify a significant and unavoidable impact when feasible mitigation options are available. There are numerous mitigation options available for the agency to implement to reduce NO_x emissions, which the Draft EIR/EIS fails to implement to reduce impacts of the MPWSP. These must be identified in the Draft EIR/EIS and the resulting emissions must be quantified to establish whether impacts have been reduced to less than significant. If they have not, then additional mitigation should be required. If minimization of impacts to less than significant is not feasible through implementation of on-site mitigation, then off-site options should be considered.

Marina-97 cont.

Impact 4.10-1 and Mitigation Measure 4.10-1c

In Mitigation Measure 4.10-1c, replanted vegetation should be required to be native, drought-tolerate species.

The Draft EIR/EIS is inadequate in that it fails to incorporate or clarify why the following feasible mitigation measures, included in the MBUAPCD's CEQA Air Quality Guidelines, are not included as components of the Construction Fugitive Dust Control Plan to reduce construction emissions of PM_{10}.

Marina-98

Feasible Mitigation Measures:

- Prohibit all grading activities during periods of high wind (over 15 mph).
- Plant tree windbreaks on the windward perimeter of construction projects if adjacent to open land.
- Limit the area under construction at any one time.

Impact 4.10-3; Sensitive Receptor Exposure to *Coccidioides* Spores

The California Department of Public Health identifies Monterey County as having a high rate of Valley Fever: (http://www.cdph.ca.gov/HealthInfo/discond/Documents/EnglishValleyFeverBrochure.pdf). If construction activities that include ground disturbance have the potential to release *coccidiodes immitis* spores and result in the exposure of sensitive receptors (i.e., construction personnel) to these hazardous conditions, this section should include mitigation that requires CalAm or the construction contractor to prepare and implement a worker training program that describes potential health hazards associated with Valley Fever, common symptoms, proper safety procedures to minimize health hazards, and notification procedures if suspected work-related symptoms are identified during construction. The worker training program should identify safety measures to be implemented by construction contractors during construction.

Marina-99

Additionally, this section should specify what any additional measures would be implemented between June 1 and November 30, when Valley Fever rates of infection are the highest, such as additional water or the application of additional soil stabilizer, prior to and immediately following ground disturbing activities if wind speeds exceed 15 miles per hour (mph) or temperatures exceed 95 degrees Fahrenheit. The Draft EIR/EIS should fully analyze the potential impacts and risks associated with Valley Fever. Once the necessary analysis has been provided, it should be recirculated to provide the public an opportunity to review and comment on the potential impacts and proposed mitigation measures to reduce those impacts.

Marina-99 cont.

Impact 4.10-C

The reader should refer to Impact 4.10-1 and Mitigation Measure 4.10-1a discussion above. While mitigation may not be available that would reduce the Project's contribution to less than cumulatively considerable, the Draft EIR/EIS must identify and ensure all feasible mitigation measures have been applied to the Project to reduce construction emissions to the greatest extent feasible. Mitigation Measure 4.10-1a is inadequate in that it does not require the use of construction equipment that meets the Tier 3 engine standards (rather than only requiring a good faith effort to use Tier 3 construction equipment). The document should also either incorporate or clarify why the previously listed standard feasible mitigation measures, included in the MBUAPCD's CEQA Air Quality Guidelines, are not included as mitigation to reduce construction emissions of NO_x and PM_{10}.

Marina-100

There are numerous mitigation options available to reduce significant air quality impacts associated with the Project. Unless it can be shown, and supported by substantial evidence, that available mitigation options are not feasible, the Draft EIR/EIS must incorporate any feasible measures to reduce potentially significant impacts. The Draft EIR/EIS is inadequate in that it fails to properly identify and include feasible mitigation measures to reduce potentially significant project-specific and cumulative impacts on air quality.

CHAPTER 4.11 – GREENHOUSE GAS EMISSIONS

Desalination plants and their associated facilities are well known for their highly intensive use of electricity. This chapter concludes that greenhouse gas emissions from the long-term operation of the Project, primarily due to "indirect emissions from the project's use of electricity, which would be provided by the local PG&E electrical power grid," will be a significant environmental impact. Draft EIR/EIS at 4.11-17. The analysis proposes a single Mitigation Measure (MM 4.11-1) that supposedly addresses this impact, but then concludes that the impact is significant and unavoidable, even with mitigation. However, this approach is legally inadequate.

Marina-101

First, the Draft EIR/EIS fails to suggest an appropriate mitigation measure for this significant impact. An EIR must propose and describe mitigation measures to minimize significant environmental effects. Cal. Pub. Res. Code § 21100(b)(3); CEQA Guidelines,

§ 15126.4(a)(1) ("An EIR shall describe feasible mitigation measures which could minimize significant adverse impacts, including where relevant, inefficient and unnecessary consumption of energy"). Indeed, due to the importance of reducing greenhouse gas emissions in California, the CEQA Guidelines contain a special section relating to mitigation measures for greenhouse gas emissions. *See* CEQA Guidelines § 15126.4(c).

Neither the Energy Conservation Technologies nor the Renewable Energy components of Mitigation Measure 4.11-1 meets these legal requirements. The Energy Conservation Technologies requirement in 1(a) requires CalAm to have a qualified professional prepare and submit a GHG Emissions Reduction Plan prior to the start of project construction activities, which would include a detailed description of the carbon footprint for all operational components of the approved project (e.g., slant well pumping, the MPWSP Desalination Plant, transmission of source and product water, ASR system) based on manufacturer energy usage specification data for each piece of equipment and the most current PG&E power system emissions factor for GHG emissions. The future Plan would include a summary of state-of-the-art energy recovery and conservation technologies available for utility scale desalination facilities and a commitment by CalAm to incorporate all available feasible energy recovery and conservation technologies; or, if CalAm finds that any of the technologies will not be feasible for the Project, the Plan would clearly explain why such technology is considered to be infeasible.

This Mitigation Measure is effectively deferring the detailed identification of the operational carbon footprint and consideration of energy-efficient technologies. The Draft EIR/EIS should provide the quantitative carbon footprint information, evaluate the feasibility of all possible energy conservation technologies and practices, include implementation of the feasible energy conservation technologies and practices as mitigation, and explain why additional available energy conservation measures are not feasible.

Marina-101 cont.

The Renewable Energy component in section (b) requires CalAm to make good faith efforts to ensure that at least 20 percent of the approved project's operational energy use requirements are achieved with "clean" renewable energy. However, no concrete commitment is made to achieving that performance standard beyond "good faith efforts." If the performance standard is to ensure at least 20 percent of the approved project's operational energy use requirements are achieved with "clean" renewable energy, the mitigation measure should include specific steps for achieving that performance standard that will be feasible for this Project to implement and achieve. The Energy section of the Draft EIR/EIS should quantitatively evaluate proposed energy consumption and the effectiveness of proposed mitigation for reducing consumption by at least 20 percent to demonstrate feasibility.

Substantial evidence that a 20 percent reduction would reduce potential impacts to less than significant levels should be provided, particularly in light of recent case law decisions in *Ctr. for Biological Diversity v. Cal. Dept. of Fish & Wildlife*, 62 Cal. 4th 204 (2015) (EIR's finding that greenhouse gas emissions would be less than significant under threshold of significance must be supported by "a reasoned explanation based on substantial evidence"), *Cal. Clean Energy Comm. v. City of Woodland*, 225 Cal. App. 4th 173 (2014), *Ukiah Citizens for*

Safety First v. City of Ukiah, 248 Cal. App. 4th 256 (2016), and *Spring Valley Lake Ass'n v. City of Victorville*, 248 Cal. App. 4th 91 (2016). Marina-101 cont.

CHAPTER 4.12 – NOISE AND VIBRATION

This section addresses a variety of deficiencies in the impact analyses and mitigation measures for noise and vibration impacts.

Impact 4.12-1

The impact discussion generally states that "the proposed pipelines and pump station would be constructed during daytime hours to the extent feasible." The Draft EIR/EIS should clarify what the anticipated timeframe of daytime construction operations would be; specify start and stop times. The severity of noise impacts would vary depending on the time of construction; this information is critical to support significance determinations in the Draft EIR/EIS. Marina-102

Pipelines North of Reservation Road

This section states that nighttime construction could be required at certain locations to meet the Project schedule or avoid peak hour traffic impacts. This section concludes that significant impacts would not occur because the maximum noise levels at any one location would be limited to a period of 1 to 3 days and would not exceed the two-consecutive-weeks threshold. However, this impact discussion does not specify how local noise ordinances pertaining to nighttime construction operations would be achieved. Clarity is needed on how the contractor(s) will ensure that nighttime thresholds will not be exceeded, to clearly establish measures are feasible and that impacts would be less than significant. Marina-103

ASR-5 and ASR-6 Wells

This impact discussion concludes that nighttime noise impacts would remain significant and unavoidable even with implementation of mitigation. The Draft EIR/EIS should clarify why construction of ASR-5 and ASR-6 cannot feasibly be restricted to daytime hours when mitigation can feasibly reduce noise levels below the threshold to avoid the significant impact associated with nighttime construction noise. It seems that this impact is avoidable through appropriate modification of the proposed construction schedule. Why is this solution not included as feasible mitigation to reduce the significant impact to be less than significant? Marina-104

Impact Conclusion

Refer to the ASR-5 and ASR-6 comment above. Although CalAm may not want to alter its identified construction schedule, it seems that nighttime noise impacts are avoidable through appropriate modification of the proposed construction schedule. The Draft EIR/EIS should explain why this solution is not included as feasible mitigation to reduce the significant impact to be less than significant, and it should include an analysis of all feasible construction techniques Marina-105

and options for avoiding nighttime construction.

Marina-105 cont.

Mitigation Measure 4.12-1a

This measure is inadequate in that it fails to identify the types of feasible measures that "could be implemented to correct the problem." Would construction activities stop? Would different, quieter construction equipment be brought in to address the issue? Are other measures available that would reduce noise in the event of a complaint? Or would a CalAm representative merely respond to the complaint by saying there's nothing they can do about it? This non-specific mitigation measure does not meet the specificity requirements of CEQA/NEPA and also fails to adequately protect nearby residents. A target response time should be specified for addressing reported noise complaints.

Marina-106

Mitigation Measure 4.12-1c

This measure fails to identify appropriate performance standards that would ensure impacts are reduced to the greatest extent feasible. What if moveable noise screens, noise blankets, or other suitable sound attenuation devices do not reduce noise levels below 60 dBA? What other mitigation measures are available? The Draft EIR/EIS must specify why additional suitable noise control procedures have not been identified and included as mitigation.

The Draft EIR/EIS fails to identify suitable mitigation measures that could further avoid and reduce potentially significant impacts. For example, exhaust mufflers and steel muffling sleeves and similar equipment should be required to the greatest extent feasible. All construction equipment should be "quiet" or "whisperized" type equipment to the greatest extent available. All equipment should be electrically powered rather than gasoline or diesel powered to the extent feasible. Sound barriers should be constructed of materials and in a manner to achieve the highest level of noise reduction. Electric power in lieu of internal combustion engine power should be required. Equipment should be maintained to reduce noise from excessive vibration, faulty mufflers, or other sources. All engines should be required to have properly functioning mufflers. Engine shrouds should be required. Noisy equipment, lay-down and vehicle staging areas should be required to be kept as far away from noise-sensitive site boundaries as possible. Vehicles should not be allowed to idle. Construction crews should be prohibited from playing radios, using amplified sound, or other similar items at the construction site. The noisiest construction activities and haul truck activities should be scheduled during periods of the day that would have the least impact on adjacent sensitive receptors.

Marina-107

Clearly, there is a multitude of additional mitigation that could be applied to the Project to further reduce potentially significant impacts. The Draft EIR/EIS should evaluate all feasible mitigation measures available to reduce potentially significant noise impacts to the greatest extent possible. The current mitigation program is wholly inadequate, and the Draft EIR/EIS appears to fall back on the "significant and unavoidable" impact determination without attempting to implement all feasible mitigation. This is also true for the weak mitigation programs set out in the Air Quality, Greenhouse Gas Emissions, and Energy Consumption

sections of the Draft EIR/EIS. Marina-107 cont.

Mitigation Measure 4.12-1d

This mitigation measure states that "acoustic barriers and/or enclosures shall be used with a goal of reducing noise from well drilling activities to 60 dBA, L_{eq} or less at a distance of 50 feet from the construction work area." Ultimately, this mitigation measure would not ensure noise from well drilling activities would be reduced to 60 dBA, L_{eq} or less at a distance of 50 feet from the construction work area: it only requires the use of acoustic barriers and/or enclosures. This mitigation measure should be revised to require monitoring to ensure noise levels are reduced to 60 dBA, L_{eq} or less at a distance of 50 feet from the construction work area. In the event the "goal of reducing noise from well drilling activities to 60 dBA or less at a distance of 50 feet" is not being met, the Draft EIR/EIS should specify additional mitigation requirements necessary to avoid or reduce the potentially significant impacts (including stopping drilling activities). Marina-108

MPWSP Desalination Plant

This section states that the proposed desalination plant would be potentially inconsistent with the following standard noise protection measures included in the Monterey County General Plan:

- Construction shall occur only during times allowed by ordinance/code unless such limits are waived for public convenience;
- All equipment shall have properly operating mufflers; and
- Laydown yards and semi-stationary equipment such as pumps or generators shall be located as far from noise-sensitive land uses as practical. Marina-109

The impact discussion concludes that impacts would be less than significant because mitigation addresses these "policy-driven mitigation measures by prohibiting equipment with unmuffled exhaust and requiring that staging areas and stationary noise sources be located as far from nearby receptors as possible." While mitigation may address the second and third noise protection measures, they do not address the first. As stated on page 4.12-23, "Construction at the MPWSP Desalination Plant site on Charles Benson Road would occur over 24 months construction period and would require 24-hour construction." The Project is inconsistent with the first standard noise protection measures included in the Monterey County General Plan and mitigation has not been included to address this impact; therefore, the impact discussion pertaining to this project component is not adequate.

The Draft EIR/EIS must address this issue and provide suitable mitigation that will ensure consistency with the standard noise protection measures included in the Monterey County General Plan, or revise the impact determination to be significant and unavoidable if the impact

cannot be mitigated. If the impact cannot be mitigated, the Draft EIR/EIS should provide clear substantial evidence that available mitigation is not feasible. Marina-109 cont.

Mitigation Measure 4.12-5

This mitigation measure should be revised to clarify the frequency of monitoring and the reporting protocol for results. Marina-110

Impact 4.12-C

Refer to ASR-5 and ASR-6 and Impact Conclusion comments above. It appears that nighttime noise impacts are avoidable through appropriate modification of the proposed construction schedule or other available mitigation measures and the Draft EIR/EIS is inadequate due to the failure to include additional feasible mitigation for this Project component. Please explain why this solution is not included as feasible mitigation to reduce the significant impact to be less than significant. Marina-111

CHAPTER 4.13 – PUBLIC SERVICES AND UTILITIES

This section addresses inadequacies in the impact analyses and associated mitigation measures for public services.

Impact 4.13-2

Excess spoils and construction debris generated during the construction phase of the Project could be contaminated from previous mining activities and/or construction activities and could require specific disposal methods. The Draft EIR/EIS fails to incorporate mitigation, or clarify why mitigation was not incorporated, which would require spoils to be tested prior to landfill disposal to ensure they meet nonhazardous waste disposal criteria. Marina-112

Impact 4.13-4

Exceed Wastewater Treatment Requirements

The Draft EIR/EIS must specify which ten individual constituents did not have sufficient data to form a compliance determination with the Ocean Plan water quality objectives and are conservatively assumed to exceed Ocean Plan water quality objectives. Additionally, it should clarify why baseline conditions were not already evaluated as part of the Draft EIR/EIS preparation and why this data gathering, Ocean Plan compliance assessment, and potentially necessary design feature and/or operational measure(s) to achieve the required minimum dilution of discharge are incorporated as Mitigation Measure 4.3-5. It seems that project design and impact evaluation included in this Draft EIR/EIS would benefit from the results of the data gathering, especially if the results of the data collection could necessitate a change in project design to achieve compliance with the Ocean Plan water quality objectives. Marina-113

Wastewater Treatment Plant and Outfall Capacity

We understand that the MRWPCA outfall and junction box were damaged substantially during recent storm events and required emergency repair. The Draft EIR/EIS should clarify if and how the results of the Outfall Capacity Evaluation conducted in 2012 by Trussell Technologies are still accurate based on these storm events, current information regarding the potential wave run-up/storm surge/coastal erosion areas at the CEMEX Property, and the recent repair and planned relocation of that infrastructure. The Draft EIR/EIS should disclose how design of the Project has been changed to account for the recent damage (and/or disclose exactly why no siting/design changes could or would be made). Marina-114

The Draft EIR/EIS should confirm if the existing outfall capacity is still 81.2 mgd and if the outfall is still capable of supporting the Project's discharge when combined with instantaneous peak flows of wastewater effluent from the MRWPCA Regional Wastewater Treatment Plant. Please confirm that the analysis of the outfall capacity of the MRWPCA outfall to service the MPWSP for the life of the Project includes the increase in wastewater flows that would occur as a result of the growth-inducing effects of the Project.

Impact 4.13-5

MRWPCA Ocean Outfall – Offshore Segment and Mitigation Measure 4.13-5a

We are aware that the MRWPCA outfall and junction box were damaged substantially during recent storms and required emergency repair. Please clarify if and how the results of the evaluation of the existing condition of the junction box and offshore outfall segment and potential for increased corrosion due to the addition of brine discharge completed by E2 Consulting Engineering (2015) are still accurate based on current conditions of the existing infrastructure. Considering emergency repairs were required and the physical condition of the infrastructure has been substantially altered since the 2015 evaluation took place, the assessment of existing conditions in this impact discussion no longer seems accurate. Based on the recently compromised structural condition and integrity of these project components, we request that the study prepared by E2 Consulting Engineering in 2015 and this impact discussion be updated to reflect the current conditions of this infrastructure and the impacts that the proposed Project could have on these modified features. The need and applicability of Mitigation Measures 4.13-5a should also be reevaluated based on the new conditions of the infrastructure and revised impacts of the Project, and retained/removed as appropriate. Marina-115

MRWPCA Ocean Outfall – Land Segment and Mitigation Measure 4.13-5b and 4.13.5.4 Secondary Impacts of Mitigation Measure 4.13-5b

The Draft EIR/EIS should clarify why an evaluation of the offshore segment of the outfall was conducted in 2015, but an evaluation of existing conditions of the 13,000-foot-long land segment is planned but has not been conducted yet and has instead been deferred as Marina-116

Mitigation Measure 4.13-5b. The existing condition of part or all of the land segment could be compromised beyond what can be repaired by an epoxy lining, as proposed in Mitigation Measure 4.13-5b. Without proper evaluation, how is the epoxy lining determined to be the appropriate solution for any problematic conditions that may be found? Additionally, without proper evaluation, how can the feasibility of installing 13,000 feet of epoxy lining be determined? An evaluation of existing conditions of the land segment prior to approval of the Project, rather than deferring the evaluation to "prior to operation of the MPWSP Desalination Plan" (as stipulated by Mitigation Measure 4.13-5b) would better inform the need, or lack thereof, for suitable mitigation.

Additionally, the proposed remedy to any problematic conditions found during the assessment of the land segment, the installation of an epoxy lining, could have significant secondary impacts beyond what have been evaluated in section 4.13.5.3. Considering installation of the epoxy lining could last 4 to 6 months, any construction activities or vehicle use required for this task could contribute to project air quality and greenhouse gas emissions, soil erosion, hydrology impacts, traffic impacts, and noise impacts. Additionally, considering the length of the land segment and proposed duration of installation, Mitigation Measure 4.13-5b should clearly specify the timing and frequency of "site surveys" to be completed by qualified biologists. The proposed staging area at Armstrong Ranch should be described in more detail (i.e., location, size, graded, etc.). All potential secondary impacts of the epoxy lining installation need to be thoroughly evaluated, particularly air quality, greenhouse gas emissions, soil erosion, hydrology impacts, traffic impacts, and noise impacts. Additionally, if additional repairs are needed in addition to an epoxy lining, the Draft EIR/EIS must identify what exactly would be required and evaluate any potential impacts associated with these repairs.

Marina-116 cont.

4.13.6.2 Cumulative Impacts during Project Operations

The RUWAP Recycled Water Element cumulative project could reduce the volume of wastewater discharged through the outfall and diffuser during the summer months, while the RUWAP Desalination Element could increase the volume of brine effluent discharged through the outfall and diffuser. Implementation of either project would result in an increase in the proportion of effluent that is composed of brine.

As discussed under Impact 4.13-5, "the salinity of brine is estimated to range between approximately 57 and 58 parts per thousand (ppt), compared to salinity of seawater in Monterey Bay, which ranges from 33.1 to 34.2 ppt. The "brine only" discharges and combined discharges of brine and wastewater effluent would expose submerged metals and concrete in the outfall and diffuser to high salinity water." Please clarify what evidence supports the justification in section 4.13.6.2 that "although the total volume of brine would increase with the Project and RUWAP Desalination Element, the salinity would not be expected to change substantially." Was any modeling or quantification of salinity concentrations performed to support this conclusion?

Marina-117

CHAPTER 4.14 – AESTHETIC RESOURCES

Figure 4.14-1

This figure and this section inappropriately categorize certain areas of the Project area within landscape units that understate the visual quality of the area and understate the associated potential significance of visual impacts. For example, large areas north of Charles Benson Road consist of active agricultural operations with little to no development or use (i.e., intensive row crops and grazing areas). Other sections of the Draft EIR/EIS clearly identify this area as "agricultural land" (refer to, *e.g.*, section 3.2.1.2 of the Project Description). This figure and this section inaccurately refer to this agricultural land as "urban and built up" land, or lands in "surrounding unincorporated areas that are considerably built-up" and "characterized by the predominance of anthropogenic features (i.e., urban development)." Even the site of the proposed desalination plant is identified as "urban and built-up" land, despite being entirely undeveloped and consisting of nothing more than natural vegetation.

The landscape unit classifications used to support the visual analysis fail to accurately identify existing on-site land uses, visual characteristics, and existing levels of development (or lack thereof) within this portion of the Project area. Did the preparer of this section conduct any field work in this area or other areas of the Project? This classification appears to reflect a lack of understanding and familiarity with the Project site. Marina-118

Section 4.14.2.2 states that "Due to the high level of anthropogenic modifications, [the urban and built-up] landscape unit is generally considered to be of low visual quality." This section should be revised to accurately identify and categorize land within landscape units that accurately reflect on-site visual conditions and quality. The categorization of all lands within the city limits of Monterey, Marina, Seaside, and Carmel Valley is clearly inadequate for a visual analysis under CEQA, as lands within these boundaries can have significantly different visual characteristics and qualities. Once the visual setting and baseline conditions have been properly identified, the impact analysis should be revised accordingly to accurately identify the potential impacts of the Project. This substantial change in the Draft EIR/EIS analysis requires recirculation of the Draft EIR/EIS so the public has an opportunity to evaluate the Draft EIR/EIS's evaluation of the Project's potential impacts on existing scenic resources. This is especially critical in areas proximate to the most visible components of the Project (such as the desalination plant, which will be visible from adjacent public roadways and the agricultural areas north of Charles Benson Road – all of which have been inaccurately described as "considerably built-up").

The figure also makes it impossible to distinguish between the different landscape units. The figure should be revised to more clearly distinguish the different units and should use current aerial images as a background, so the reader can determine whether the identified landscape unit actually reflects the existing land use and baseline visual characteristics of the site.

Figure 4.14-2

The acronyms used in this figure are not properly identified. What does "PL" refer to? What is "NM"? What is "TF"? What is "AG"? Why do "Oak Woodland" and "TF Forested Hills" look virtually identical? Why do "PL Urban Builtup Monterey" and "Hillside Residential" look virtually identical? How does the photograph of "Hillside Residential" reflect the description of this unit (i.e., residential housing on large lots, distinguished from the Urban and Built-up landscape unit by the substantially greater distance between dwellings)? Marina-119

Section 4.14.2.3 Subsurface Slant Wells

This section inaccurately describes the baseline visual setting at the CEMEX Property. The large majority of the CEMEX Property is undisturbed dune habitat. The CEMEX property encompasses approximately 400 acres in total. Of those, approximately 104 acres have experienced some disturbance associated with sand mining activities that have occurred at the site since 1906. Currently, approximately 50 acres experience heavy levels of disturbance associated with ongoing mining activities. The remainder of the site consists of undeveloped areas and dune habitat with varying degrees of disturbance (moderate to low). The City's LCLUP describes the area just north of the Project site as the best preserved area of Marina Dune native habitat. The dunes provide a distinct contrast to the pattern of agricultural and urbanized lands in adjacent areas. This area of north Marina is considered the "scenic gateway to the Monterey Peninsula" (City of Marina 1982). Visual quality of this area of dunes should be considered high.

The Draft EIR/EIS fails to recognize the visual sensitivity of this portion of the Project site. Although the small disturbed area of the CEMEX Property that is currently mined provides a somewhat degraded view, the Draft EIR/EIS fails to accurately account for the breadth and extent of the public viewshed at this location, which would largely be comprised of a vast, relatively undisturbed dune complex unlike any others on the Monterey Peninsula. Marina-120

This section describes the site as "devoid of vegetation" and "sparsely vegetated" and also provides a representative photo of the site that shows dune slopes entirely covered by vegetation (*see* Figure 4.14-3a, Photo 1). The information in this section is inconsistent and misleading.

Figure 4.14-3a Photo 1 does not represent the public vantage point from the beach as stated in this section (section 4.14.2.3, first paragraph). Rather, this vantage point is taken from within the privately-owned CEMEX mining area. These private views from within the mining area reflect a higher level of disturbance than is actually visible from surrounding public views. Views from the public beach are dominated by predominantly undisturbed dunes and views of the internal graded CEMEX access road are limited. Public views of this area are inaccurately described in this section. Information regarding the site's visual character, quality, and visibility must be accurately stated in the Draft EIR/EIS. A revised Draft EIR/EIS should be recirculated so the public has an adequate opportunity to review and comment on potentially significant

impacts on this important visual resource. Marina-120 cont.

Section 4.14.2.3 MPWSP Desalination Plant

This section understates the aesthetic resource value of this site due to the inaccurate determination that the site is "urban and built-up" land. Marina-121

Sections 4.14.6.1 and 4.14.6.2

These sections improperly understate the severity of the potential visual impacts of the project due to the improper classification of the CEMEX Property and Project desalination plant location as having low to moderate visual resource value. Marina-122

CHAPTER 4.15 – CULTURAL AND PALEONTOLOGICAL RESOURCES

This chapter fails to identify and address a major impact on historic resources and therefore wrongly concludes that construction of the Project will not have a significant impact on such resources. This omission constitutes significant new information and a significant change in the potential for such impacts, thereby requiring a new analysis and recirculation of a revised Draft EIR/EIS.

This section of the Draft EIR/EIS inaccurately concludes that "No historical resources listed in or eligible for listing in the California Register or historic properties listed in or eligible for listing in the National Register are within the direct or indirect APE of all project components. Therefore, no impact on historical resources or historic properties would result from construction of any project facilities." *Id.* at 4.15-45. This determination fails to recognize that the Source Water Pipeline and Well Site 1 are located in the center of the Lapis Sand Mining Plant Historic District. Marina-123

SWCA Environmental Consultants, in conjunction with the City of Marina and Monterey Bay National Marine Sanctuary, evaluated the Lapis Sand Mining Plant for eligibility for listing in the National Register of Historic Places ("NRHC") in connection with the test slant well CDP permit application and concluded that it was eligible for listing as a historic district containing nine contributing built environmental resources (e.g., structure, infrastructure) under criteria A and C, with a period of significance from 1906 to 1960 (SWCA 2014). The appropriate Department of Parks and Recreation ("DPR") forms were prepared and in June 2014 the State Historic Preservation Officer ("SHPO") at the Office of Historic Preservation concurred with SWCA's findings, including the eligibility for listing on the NRHP as a historic district under Criteria A and C with a period of significance from 1906-1960.

In addition to the Draft EIR/EIS's failure to identify the presence of a previously recorded eligible historic district in the direct and indirect APEs, the analysis in this section also fails to address the Project's potential impacts to contributing structures built near environmental resources associated with the district. Construction and maintenance related disturbances could

inadvertently affect contributing historic structures associated with the district, a potentially significant impact. The Draft EIR/EIS failed to identify and address this potentially significant impact.

In addition, as described in the DPR forms prepared by SWCA, the direct APE includes the historically significant Lapis Siding, a single- and double-track rail siding that was constructed circa 1906 to connect the Lapis Sand Mining Plant with the former Southern Pacific Monterey Branch to the east. From its eastern terminus at the eastern boundary of the Lapis Sand Mining Plant, the segment consists of two parallel metal rail lines that merge into one line at a rail switch approximately 135 feet to the west. The segment continues along a general northwesterly course for approximately 285 feet before it becomes covered by sand and dirt. Since its decommission in the late 1980s, the recorded segment has been overgrown by vegetation and partially buried, and as a result no ballast or ties were visible at the time of SWCA's evaluation. Historic topographic maps indicate that the Lapis Siding extended much further west and north than was observed during the course of the 2014 survey and additional segments of the Lapis Siding are visible along the eastern side of the Sorting Plant in current aerial images. Archival research conducted by SWCA was unable to determine if the rails, ties, and/or any associated infrastructure of the larger rail siding were removed. Because of the constantly shifting sand dunes, there is potential that other intact segments may be buried underneath the changing landscape.

Marina-123 cont.

Trenching and construction of the Source Water Pipeline in the area between the visible portion of the Lapis Siding and the Sorting Plant has the potential to damage or destroy buried portions of the resource that remains. The Draft EIR/EIS failed to identify or address this potentially significant impact.

The failure to identify and address potential impacts to the Lapis Sand Mining Plant Historic District, a known historic district eligible for listing in the NRHP, renders the analysis in this section inadequate. The Draft EIR/EIS fails to disclose the presence of this historical resource within the direct and indirect APEs for the Project – a substantial omission, as disclosure would result in a new significant environmental impact. The omission also constitutes significant new information that deprives the public of a meaningful opportunity to comment upon a substantial adverse environmental effect of the Project and feasible ways to mitigate or avoid such effects. The Draft EIR/EIS failed to determine whether or not the Lapis Siding extends through the area proposed for trenching for construction of the Source Water Pipeline and fails to provide any evidence that construction of the proposed Project would have no impact on historical resources or historical properties associated with implementation of the proposed Project. The Draft EIR/EIS is invalid and must be recirculated once these issues have been properly addressed.

CHAPTER 4.16 – AGRICULTURAL RESOURCES

Marina-124

This section addresses impacts and mitigation measures for agricultural resources.

Section 4.16.1.1 Farmland Mapping and Monitoring Program

Table 4.16-1 shows agricultural conversion between 2010 and 2012; this information is over five years old. The CDC's 2012 to 2014 conversion information should be utilized. The most recent information should be used, particularly in light of recent constraints to agriculture, including the extreme drought conditions that have occurred since 2012 and the constraints to agricultural pumping and groundwater. The more recent conversion data reflects a loss of 146 acres of Prime Farmland in Monterey County between 2012 and 2014; therefore, conversion of Prime Farmland is an issue in the County.

Marina-124 cont.

Section 4.16.4

The Draft EIR/EIS states that agricultural crop production and livestock grazing is the largest industry in Monterey County, and that over 80 percent of the total land designated for agriculture in the County is used for grazing. The conversion of grazing lands in the County, particularly the cumulative conversion as reflected in the FMMP agricultural conversion data (a loss of 2,307 acres between 2010 and 2012, and a loss of 739 acres between 2012 and 2014) should indicate a potentially significant impact to this important County resource. The Draft EIR/EIS fails to provide support for the conclusion that the conversion of grazing land would not be a potentially significant impact under CEQA and why it does not deserve consideration in the Draft EIR/EIS. Although not specifically identified as a threshold under Appendix G of the CEQA Guidelines, given the significance of the resource in Monterey County, the level of impact should be evaluated and the public should be provided an opportunity to comment on the proposed conversion of grazing lands. The Draft EIR/EIS should also account for impacts associated with the gradual conversion of undeveloped, grazing, and/or agricultural lands that historically have provided a buffer from more urbanized uses within the City of Marina and surrounding areas.

Marina-125

Section 4.16.5.1 and 4.16.5.2

These sections fail to identify and analyze the potential for significant impacts associated with changes in the existing environment that, due to their location or nature, could temporarily disrupt agricultural activities or result in the permanent conversion of farmland to non-agricultural uses as a result of Project operation. As described in other sections of this document, operation of the Project could result in increased seawater intrusion, damaging groundwater resources upon which regional agricultural uses rely. The Project could also result in the illegal pumping of groundwater from the Salinas Valley Groundwater Basin, which would deplete the groundwater available for agricultural uses in the Project area. Any adverse effect of the Project on groundwater quality or quantity could disrupt agricultural activities and/or result in the permanent conversion of farmland to non-agricultural uses as a result of Project operation.

Marina-126

The potential for these impacts to occur must be discussed in this section. The scope of this section is inappropriately narrow throughout the analysis, in that it only includes areas within the direct area of disturbance and adjacent parcels. Adverse impacts to groundwater

quantity and quality, as described in these comments, could potentially result in substantially farther-reaching impacts on agricultural uses in the Project area. Marina-126 cont.

Section 4.16.4.2 MPWSP Desalination Plant

This section fails to discuss the potential indirect constraints to agricultural development and use of the remainder of this site for agricultural production as a result of Project construction and operation. Although prime farmland in the northern portion of the site would not be directly impacted, conversion of the parcel to an industrial use could limit and/or prevent any future agricultural uses within prime farmland. Indirect impacts on the future use of this agricultural resource should be evaluated in the Draft EIR/EIS and all feasible mitigation to reduce potential impacts should be identified. This analysis should be recirculated so the public can comment on the potential for fallowing large areas of prime farmland as a result of Project implementation. Marina-127

Impact 4.16.3 MPWSP Desalination Plant

This section relies on the fact that the desalination plant site has been idle for five or more years, yet no information is provided as to why the land was fallowed or whether historically it supported viable agricultural production. The site supports prime farmland – land that has the best combination of physical and chemical characteristics for long-term crop production. Therefore, the site is clearly suitable for agricultural uses. The Draft EIR/EIS should clearly describe the site's agricultural history and provide an explanation for why the site is no longer used for agricultural production. For example, it is currently unclear whether CalAm purchased the site 5 years ago and let it go fallow in order to assert there would be no impact on on-site agricultural uses. This would clearly be an improper baseline upon which to measure the significance of impacts on agricultural resources at the desalination site. If the site has been historically used for active agricultural production, but was fallowed 5 years ago because of the drought or some other constraint, this information should be disclosed. Marina-128

Without any information on the reason the site is idle, the Draft EIR/EIS cannot rely on the fact that it is idle to support a conclusion that no impact on agricultural uses would occur. If the site is idle because of constraints to agricultural use, the Draft EIR/EIS should clearly document and disclose those constraints that make agricultural use of the area infeasible. If the site was not fallowed as a result of constraints, the Draft EIR/EIS should assume the site is viable for agricultural uses and identify a potentially significant impact associated with conversion of valuable agricultural soils to industrial/public facility uses. All feasible mitigation should be identified to reduce the potentially significant impact and the Draft EIR/EIS should be recirculated to provide the public an opportunity to comment on the Project's potential effects on this resource.

CHAPTER 4.18 – ENERGY CONSERVATION

This section addresses the description, impacts and mitigation measures in the energy conservation subject area.

Impact 4.18-2

The Project Description states that the Project would recover energy from the brine stream using pressure-exchange technology, which would lower overall energy consumption during the RO process. However, the Project is still expected to result in a substantial increase in electrical power demand (net increase of 51,698 MWh per year, an over 450 percent increase in CalAm's total energy demand in its Monterey District Service Area). Beyond the pressure-exchange technologies included in the proposed RO process for energy recovery, it does not appear that other energy conservation technologies have been included in the Project Description or considered as feasible mitigation. The Project Description states that CalAm may eventually use renewable energy sources to power the MPWSP Desalination Plant and briefly discusses the consideration of pursuing a landfill-gas-to-energy option. Although included, the possibility of pursuing the landfill-gas-to-energy option is a moot point as it is not considered in this Draft EIR/EIS, not a requirement of project mitigation, and any necessary interconnection improvements would require additional environmental review.

This impact discussion concluded that the impact was less than significant because the use of energy for operation of the Project is necessary to provide a reliable supply of water to meet existing demand for the Monterey District, and concluded that no mitigation was necessary. This conclusion is unwarranted for two reasons. First, as described in our comments on chapters 2.1 to 2.5 herein, the use of this amount of energy for operation of the Project is not necessary to provide a reliable supply of water to meet existing demand for the Monterey District. Second, the Draft EIR/EIS is inadequate in that it fails to evaluate whether the Project's net increase in energy demand itself is unnecessary, wasteful, or inefficient, especially when all feasible energy conservation mitigation options are not being employed. "Under CEQA, an EIR is 'fatally defective' when it fails 'to include a detailed statement setting forth the mitigation measures proposed to reduce wasteful, inefficient, and unnecessary consumption of energy.'" *Cal. Clean Energy Comm. v. City of Woodland*, 225 Cal. App. 4th at 209. Therefore, the substantial increase in electrical power demand (net increase of 51,698 MWh per year) and lack of inclusion of all feasible energy conservation technologies/measures (beyond pressure exchange technology) could constitute a potentially significant impact and require additional mitigation.

Marina-129

Pursuant to Appendix B Local Action of the California Air Resources Board 2017 Scoping Plan (January 2017), the following construction and operation mitigation measures should be considered for inclusion by individual projects under CEQA, and implemented if feasible. The Draft EIR/EIS should include an explanation as to why these measures were not evaluated as potential mitigation to avoid or reduce unnecessary consumption of energy and/or why they are not applicable/feasible for the Project:

Construction

1. Enforce idling time restrictions for construction vehicles.
2. Require construction vehicles to operate with the highest tier engines commercially available.

3. Divert and recycle construction and demolition waste, and use locally-sourced building materials with a high recycled material content to the greatest extent feasible.
4. Minimize tree removal, and mitigate indirect GHG emissions increases that occur due to vegetation removal, loss of sequestration, and soil disturbance.
5. Utilize existing grid power for electric energy rather than operating temporary gasoline/diesel powered generators.
6. Increase use of electric and renewable fuel powered construction equipment and require renewable diesel fuel where commercially available.
7. Require diesel equipment fleets to be lower emitting than any current emission standard.

Operation

1. Comply with lead agency's standards for mitigating transportation impacts under SB 743.
2. Require on-site EV charging capabilities for parking spaces serving the Project to meet jurisdiction-wide EV proliferation goals.
3. Allow for new construction to install fewer on-site parking spaces than required by local municipal building code, if appropriate.
4. Dedicate on-site parking for shared vehicles.
5. Provide adequate, safe, convenient, and secure on-site bicycle parking and storage in multi-family residential projects and in non-residential projects.
6. Provide on- and off-site safety improvements for bike, pedestrian, and transit connections, and/or implement relevant improvements identified in an applicable bicycle and/or pedestrian master plan.
7. Require on-site renewable energy generation.
8. Prohibit wood-burning fireplaces in new development, and require replacement of wood-burning fireplaces for renovations over a certain size developments.
9. Require cool roofs and "cool parking" that promotes cool surface treatment for new parking facilities as well as existing surface lots undergoing resurfacing.
10. Require solar-ready roofs.
11. Require organic collection in new developments.
12. Require low-water landscaping in new developments. Require water efficient landscape maintenance to conserve water and reduce landscape waste.
13. Achieve Zero Net Energy performance targets prior to dates required by CALGreen.
14. Require new construction, including municipal building construction, to achieve third-party green building certifications, such as the GreenPoint Rated program or the LEED rating system.
15. Require the design of bike lanes to connect to the regional bicycle network.
16. Expand urban forestry and green infrastructure in new land development.
17. Require preferential parking spaces for park and ride to incentivize carpooling, vanpooling, commuter bus, electric vehicles, and rail service use.
18. Require a transportation management plan for specific plans which establishes a numeric target for non-SOV travel and overall VMT.

Marina-129 cont.

19. Develop a rideshare program targeting commuters to major employment centers.
20. Require the design of bus stops/shelters/express lanes in new developments to promote the usage of mass-transit.
21. Require gas outlets in residential backyards for use with outdoor cooking appliances such as gas barbeques if natural gas service is available.
22. Require the installation of electrical outlets on the exterior walls of both the front and back of residences to promote the use of electric landscape maintenance equipment.
23. Require the design of the electric boxes in new residential unit garages to promote electric vehicle usage.
24. Require electric vehicle charging station (Conductive/inductive) and signage for non-residential developments.
25. Provide electric outlets to promote the use of electric landscape maintenance equipment to the extent feasible on parks and public/quasi-public lands.
26. Require each residential unit to be "solar ready," including installing the appropriate hardware and proper structural engineering.
27. Require the installation of energy conserving appliances such as on-demand tank-less water heaters and whole-house fans.
28. Require each residential and commercial building to equip buildings with energy efficient AC units and heating systems with programmable thermostats/timers.
29. Require large-scale residential developments and commercial buildings to report energy use, and set specific targets for per-capita energy use.
30. Require each residential and commercial building to utilize low flow water fixtures such as low flow toilets and faucets.
31. Require the use of energy-efficient lighting for all street, parking, and area lighting.
32. Require the landscaping design for parking lots to utilize tree cover.
33. Incorporate water retention in the design of parking lots and landscaping.
34. Require the development project to propose an off-site mitigation project which should generate carbon credits equivalent to the anticipated GHG emission reductions. This would be implemented via an approved protocol for carbon credits from California Air Pollution Control Officers Association (CAPCOA), the California Air Resources Board, or other similar entities determined acceptable by the local air district.
35. Require the Project to purchase carbon credits from the CAPCOA GHG Reduction Exchange Program, American Carbon Registry (ACR), Climate Action Reserve (CAR) or other similar carbon credit registry determined to be acceptable by the local air district.
36. Encourage the applicant to consider generating or purchasing local and California-only carbon credits as the preferred mechanism to implement its offsite mitigation measure for GHG emissions and that will facilitate the State's efforts in achieving the GHG emission reduction goal.

Marina-129 cont.

Impact 4.18-3

Impact 4.18-3 states that, based on PG&E's preliminary review of the proposed Project's maximum electrical demand, PG&E has indicated that it has adequate capacity and infrastructure to support the proposed Project. PG&E, 2016c. "PG&E, 2016c" refers to a personal communication between Jose Saldana, Pacific Gas and Electric Group Project Manager with Distribution Services, and Matt Fagundes, Environmental Science Associates Energy Analyst, on September 9, 2016. This statement is vague and uncertain. Due to the very high energy demands of the desalination process, the capacity of PG&E to service the Project should be confirmed and supported by substantial evidence. The EIR/EIS must clarify if a service agreement or will-serve letter has been issued by PG&E to satisfy the proposed Project's maximum demand for electrical power. Marina-130

Impact 4.18-C Cumulative Impacts

Impact 4.18-C states that "During project operation, various energy conservation measures would be implemented (see section 4.18.4) as part of the proposed project to reduce energy waste, ensuring that operational impacts associated with energy use would not be unnecessary, wasteful, or inefficient." Section 4.18.4.2 refers to the aforementioned pressure exchange technologies that would be implemented to recover energy in the RO system, and asserts that the Project would supplement these technologies in the MPWSP Desalination Plant. Building support systems would comply with Title 24 Building Energy Efficiency Standards. This impact discussion concludes that, based on the technologies proposed to be employed, compliance with Title 24 Building Energy Efficiency Standards, and indication by PG&E via personal communication that adequate capacity and infrastructure would be available to support the Project, that cumulative operational impacts would be less than significant. Marina-131

Although the Building Code addresses energy savings for components of new commercial construction, compliance with the Building Code does not, by itself, constitute an adequate assessment of mitigation measures that can be implemented to address the energy impacts during construction and operation of the project. *Cal. Clean Energy Comm. v. City of Woodland*, 225 Cal. App. 4th at 209.

Based on the Project's substantial increase in net energy demand, the lack of inclusion of all feasible energy conservation measures (as listed under Impact 4.18-2 above) identified in Appendix B Local Action of the California Air Resources Board 2017 Scoping Plan (January 2017), and reliance on compliance with Title 24 Building Energy Efficiency Standards, the Draft EIR/EIS inadequately analyzed potential impacts related to energy consumption, contrary to the requirements of CEQA and NEPA. This section should be revised to (1) accurately reflect the potential for a significant project-specific and cumulative impact associated with unnecessary energy consumption; (2) include all feasible energy conservation mitigation options into the Project; (3) provide substantial evidence to support any finding that any mitigation options are not feasible for this Project; and (4) provide a conclusion as to whether or not the potentially

significant impact is sufficiently mitigated or significant and unavoidable. This substantial new information and analysis must be recirculated for additional public review and comment.

Marina-131 cont.

CHAPTER 4.20 – SOCIOECONOMICS AND ENVIRONMENTAL JUSTICE

Both NEPA and CEQA contain strong requirements for the assessment of environmental justice and socioeconomic impacts. Since they address these subjects in slightly different ways, we will discuss them separately below. As described below, the Draft EIR/EIS fails to sufficiently assess or mitigate for socioeconomic and environmental justice impacts.

NEPA requires that in an EIS, federal agencies analyze the disproportionately high adverse impacts of a project on minority and low-income populations. NEPA defines project "effects" to include "economic, social, or health [impacts], whether direct, indirect, or cumulative." 40 C.F.R. § 1508.8. In 1994, President Clinton issued Executive Order 12898, entitled "Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations." This Order, as described on the NOAA Fisheries website, "requires each federal agency to identify and address, as appropriate, disproportionately high and adverse human health or environmental effects of its programs, policies and activities on minority and low income populations." In 2011, a large group of federal agencies, including the Department of Commerce (the parent agency of MBNMS), signed a Memorandum of Understanding to implement this policy at each signatory agency.

In 1997, the President's Council on Environmental Quality issued an important guidance document that has governed NEPA environmental justice analyses ever since. *Environmental Justice: Guidance Under the National Policy Ac*t (1997). According to the Guidance:

Marina-132

- A federal agency must consider the "multiple, or cumulative [environmental justice] effects, even if certain effects are not within the control or subject to the discretion of the agency proposing the action."
- The agency must "recognize the interrelated cultural, social, occupational, historical or economic factors that may amplify the natural and physical environmental effects of the proposed agency action."
- The federal agency must "analyze how environmental and health effects are distributed within the affected community" and the agency is encouraged to display data visually through a GIS for effective visualization of the distribution of effects.
- The federal agency must utilize an identified disproportionately high and adverse environmental impact "as a factor in determining the environmentally preferable alternative."
- The federal agency "should elicit the views of the affected populations on measures to mitigate a disproportionately high and adverse human health or

environmental effect" on a minority population and "carefully consider community views in developing and implementing mitigation strategies."

The Draft EIR/EIS fails to meet these NEPA requirements in multiple respects. It is undisputed, as stated on page 4.20-6 of the Draft EIR/EIS, that Marina qualifies as a minority community.

First, the Draft EIR/EIS fails to properly analyze the environmental justice impacts on the Marina community. It trivializes the impacts at the outset by stating only that Marina "could be" affected by construction activities (page 4.20.1). It then reaches the incorrect conclusion that "no disproportionately high and adverse" impact from facility siting, operation or construction of the Project would occur in any minority community, including Marina. In making this finding, the document fails to establish appropriate threshold standards and fails to sufficiently evaluate the Project's multiple and cumulative impacts in a wide variety of areas.

In fact, Marina is burdened with a major share of the short and long-term environmental impacts of the Project without receiving any corresponding benefit. The Project's slant wells would be sited in Marina's sensitive coastal habitat and would likely accelerate coastal erosion on Marina's beaches. A large number of source water, desalinated water, and return water pipelines would be constructed in Marina. The hypersaline brine discharge will occur through a pipe from Marina's coastline and deposit effluent just offshore of Marina. Most significantly, the groundwater basin that is currently the sole source of Marina's water could be significantly adversely impacted by the Project. In fact, rather than being a "no disproportionate impact" situation as represented by the Draft EIR/EIS, this is a classic example of a minority community being saddled with a wide range of severe environmental impacts from the siting and operation of a Project with all of the benefits going to distant communities.

Marina-132 cont.

The Draft EIR/EIS contains a series of legal errors that have led to this deficient analysis. First, the agencies have not established any credible criteria to determine whether a "disproportionately high and adverse" impact is occurring. Second, the Draft EIR/EIS has misanalyzed the environmental impacts in a variety of ways. Some impacts the Draft EIR/EIS discounted entirely, as in the case of its conclusion that Project groundwater impacts in the City of Marina are less than significant because the City's groundwater is located seaward of the seawater intrusion line (see chapter 4.4 comments herein). It simply ignored other impacts. Third, due to its conclusion that no such significant impacts exist, it failed to adopt any mitigation measures. Fourth, it failed to analyze cumulative impacts in the environmental justice context.

The Draft EIR/EIS magnified these problems by taking a segmented approach to evaluating these impacts. It inexplicably parceled out an analysis of the environmental justice implications of impacts into 19 other sections rather than making a complete analysis in section 4.20. As a result, it never analyzed the composite and cumulative impacts of all of the environmental impacts on the City of Marina. By taking this segmented approach, it never asked or answered the question "What are the high and disproportionate total impacts of the Project on the City?" Had it done a proper analysis, it would have determined that Marina is bearing a

disproportionate brunt of the environmental impacts now and indefinitely into the future, particularly in regard to the potential depletion and contamination of its water supply, the potential destruction of its coastal ecosystem, and the traffic, noise and aesthetic impacts.

Marina-132 cont.

It is clear that environmental justice analysis in the Draft EIR/EIS fails to meet any of the applicable NEPA requirements explained above. First, MBNMS cannot turn a blind eye to the environmental impacts of the land-based impacts of the Project, including the potential depletion and degradation of Marina's groundwater supply, which the Draft EIR/EIS improperly dismisses without evaluation under the assumption that the water CalAm is proposing to pump is unsuitable for municipal or domestic use (while also maintaining this water is an appropriate water source for the municipal and domestic uses proposed to be served by the Project). CEQA's Guidance specifies that it must take into account impacts outside its immediate permitting jurisdiction. Second, the segmented analysis in the Draft EIR/EIS fails to analyze the multiple and cumulative "interrelated" impacts of the Project on Marina. Third, the Draft EIR makes no attempt to identify or quantify spatially the Project impacts on Marina or the other two minority populations – rather, it hides those impacts by blurring them across all communities. Fourth, the Draft EIR/EIS does not take environmental justice impacts into account in selecting the environmentally superior/preferable alternative and fails to adopt a single mitigation measure to reduce their impacts.

Marina-133

In addition, the Draft EIR/EIS also fails to consider the potential socioeconomic impacts the Project may have on the City. The City currently has a secure affordable water source. As discussed in the comments above, the Project could exacerbate seawater intrusion and other water quality impacts in the groundwater aquifers underlying the City of Marina, thereby resulting in potentially higher costs to treat the City's groundwater or forcing the City to look for a more expensive alternative source of water. The Draft EIR/EIS must consider the economic impacts on the City related to the cost of increased treatment and the potential costs for finding replacement water. Since the Draft EIR/EIS fails to consider the complexity of groundwater conditions seaward of the "seawater/freshwater interface" in the 180/400 Foot Aquifers (which is neither factually appropriate nor a true measure of all potential groundwater quality impacts), the Draft EIR/EIS has failed to specifically consider the potential groundwater impacts to areas of the aquifer specifically underlying the City of Marina. These impacts must be fully analyzed, and the potential additional socioeconomic effects on the City must be disclosed.

Marina-134

In addition to the failure of the Draft EIR/EIS to accurately identify the high proportion of potential environmental and socioeconomic burdens that would be imposed on Marina as a result of the Project, the City feels that this Project is just one of a string of projects proposed by other jurisdictions on the Monterey Peninsula that impose a disproportionate environmental burden on the community of Marina, including the Monterey Regional Water Pollution Control Agency's facilities (including its wastewater treatment plant), the proposed advanced treatment plant for Pure Water Monterey, the Monterey Peninsula Regional Waste Management District's facilities (including its regional landfill and authorized composting operations), methane and other greenhouse gases from livestock ranching adjacent to Marina residential areas, and emissions from drift of pesticides, fertilizers, and other soil amendments from agricultural

Marina-135

operations adjacent to or proximate to City of Marina residential areas. These cumulative impacts matter a great deal to residents of and visitors to Marina for health and environmental justice reasons. There are currently frequent complaints from this City's residents of offensive odors apparently coming from north of the City and this is but one example of existing conditions from existing or planned future facilities affecting the City's environment.

The Draft EIR/EIS should describe current conditions of potential nuisances, impactful uses in areas immediately surrounding the City, and unhealthy odors and emissions proximate to the City in the context of environmental justice. The Draft EIR/EIS should disclose the total emission of existing and planned facilities (such as those listed above), and include their individual totals, their cumulative total, and relevant numeric emission standards/metrics/thresholds in an additional table such as a new Table 4.20-7. These emissions should be compared to other areas of the County and other cities on the Monterey Peninsula to meaningfully compare emissions that the City of Marina is subjected to with emissions other areas of the County, particularly those that would benefit from the MPWSP, are subjected to.

Marina-135 cont.

No relevant numeric emission standards/metrics/thresholds are listed in section 4.20 including Table 4.20-6. The Draft EIR/EIS should include a column or columns in Table 4.20-6 for relevant numeric standards/metrics/thresholds.

The City is concerned that the City's discretionary approval authority over actions proposed within the City's limits has been and will be undermined. This has resulted in development within the City limits that (1) provides absolutely no benefit to the community of Marina, (2) has the potential to severely impact Marina resources, and (3) community members have repeatedly and overwhelmingly objected to.

The Project represents a large industrial use with the potential to result in severe irreversible impacts to the City, particularly in regards to potential depletion and contamination of its water supply, the destruction of its coastal ecosystem, and the traffic and noise impacts of the Project, which provides no benefit to the community of Marina. The City residents would be forced to bear a disproportionate brunt of the environmental impacts of the Project now and indefinitely into the future.

Marina-136

The City wants the lead agencies, as well as the California Coastal Commission, to consider and protect their coastal and groundwater resources with the same level of scrutiny as is enforced on other communities and has been enforced for proposed developments within the City in the past. The City should not be the preferred location for all of the largest industrial uses in Monterey County. Environmental justice issues should require the municipalities and jurisdictions that would benefit from the Project also bear the environmental burden of the Project, including through siting of the proposed slant wells outside of the City's aquifers and coastal areas.

CHAPTER 5.0 – ALTERNATIVES SCREENING AND ANALYSIS

A. Key Legal Requirements

The analysis of alternatives is one of the key components of an environmental review document under both CEQA and NEPA. Indeed, the alternatives and mitigation sections are "[t]he core of an EIR." *Citizens of Goleta Valley v. Bd. of Supervisors*, 52 Cal. 3d 553, 564 (1990). The CEQA Guidelines provide that the EIR must "describe a range of reasonable alternatives to the project, or to the location of the project, which would feasibly attain most of the basic objectives of the project but would avoid or substantially lessen any of the significant effects of the project, ..." CEQA Guidelines § 15126.6(a). Although alternatives should be designed to meet most project objectives, it is not required that an alternative meet all of them. *See, e.g., Mira Mar Mobile Comty. v. City of Oceanside*, 119 Cal. App. 4th 477, 489 (2004) ("alternatives need not satisfy all project objections, they must merely meet 'most' of them"); *Habitat & Watershed Caretakers v. City of Santa Cruz*, 213 Cal. App. 4th 1277, 1304 (2013) (a "limited water" alternative project "could not be eliminated from consideration solely because it would impede to some extent the attainment of the project's objectives").

The California Supreme court has emphasized the importance of a legally adequate alternatives analysis:

> An EIR's discussion of alternatives must contain analysis sufficient to allow informed decision making. [Citation.] [¶] ... [¶] ... Without meaningful analysis of alternatives in the EIR, neither the courts nor the public can fulfill their proper roles in the CEQA process.... 'To facilitate CEQA's informational role, the EIR must contain facts and analysis, not just the agency's bare conclusions or opinions.' [Citations.] An EIR must include detail sufficient to enable those who did not participate in its preparation to understand and to consider meaningfully the issues raised by the proposed project.

Laurel Heights Improvement Assn., 47 Cal.3d at 404-05.

NEPA and its implementing regulations also require the development and discussion of alternatives. 40 U.S.C. §§ 4332(2)(C)(iii) and(2)(E); 40 C.F.R. § 1502.10(e). In fact, NEPA requires an exceptionally robust discussion of alternatives, which the regulations describe as "the heart of the environmental impact statement." 40 C.F.R. § 1502.14. Among other things, the regulations prescribe that the document "[r]igorously explore and objectively evaluate all reasonable alternatives" and that this discussion include "reasonable alternatives not within the jurisdiction of the lead agency." *Id*.

B. The Draft EIR/EIS's Failures To Adequately State Project Objectives/Need Or To Adequately Analyze Project Environmental Impacts Fatally Undermine The Alternatives Analysis.

The adequacy of an EIR/EIS alternatives analysis is critically dependent upon a proper statement of project objectives (CEQA) and purpose and need (NEPA), a complete and stable description of the project, an adequate analysis of project impacts, and a full slate of feasible mitigation measures. If any of these components is missing, it is not possible to complete a legally adequate alternatives analysis. Unfortunately, for all of the reasons set forth in other sections of these comments, these legal predicates are missing, which fundamentally impairs the entire alternatives analysis. We will specifically address two examples of these inadequacies below.

1. Project Objectives/Purpose and Need – Water Demand

As set forth in Marina's comments on chapters 2.1-2.5 and 3 herein, the water "demand" for the Project is stated to be 10,750 afy, which is a number that is not supported by substantial evidence and which the CPUC and MBNMS have not properly scrutinized and modified as required by CEQA and NEPA. Although the list of Project Objectives in chapter 1 does not explicitly state this "need" number, it is apparently incorporated from the "water demand" analysis in chapters 2.1 to 2.5 and carried forward into the alternatives analysis. As described above, CalAm's true existing "need" from all water sources is no more than 9,545 afy and the other identified water "needs" are for a few possible future needs plus over 2,000 afy of water for unspecified "other uses." Since CalAm will receive up to 6,244 afy of water from other identified sources each year (even with all of the anticipated Carmel River and Seaside Basin restrictions), its true water "need" from the Project is in the range of 3,000 afy to meet existing demand. Marina-137

As described in the next section, this flawed water demand/need analysis has resulted in an across-the-board elimination of any Project alternative that does not result in a total Project water production number of 10,750 afy. Although the 6.4 mgd desalination plant alternatives in Alternatives 5a and 5b would produce less desalinated water, they are only considered in the context of another 3,500 afy of water from the GWR Project. These two smaller plant alternatives are not being considered without the GWR Project because they do not meet CalAm's asserted "need" for a total of 10,750 afy of water. Thus, the deficient project objectives/need statement has improperly foreclosed consideration of any Project alternative that produces less water.

2. Groundwater Resource Impacts

Another example of how a legally inadequate prior analysis of an issue undermines the alternatives analysis relates to the Project's groundwater impacts. For all of the reasons in Marina's comments to chapter 4.4 herein, the Draft EIR/EIS analysis of Project impacts to the groundwater aquifers are legally inadequate and the resulting conclusion that they are "less than Marina-138

significant" is not supported by substantial evidence in the record. In fact, it appears that there is a high risk of significant impacts to groundwater supply, groundwater quality and groundwater storage as a result of the Project, particularly in the aquifer areas underlying Marina. Thus, these impacts should have been identified as significant and comparatively evaluated across all alternatives.

The critical problem that inevitably occurs in the Draft EIR/EIS when this failure to recognize the significance of the Project's groundwater impacts is carried through to the alternatives analysis is that any discussion of groundwater resource impacts is dropped out of the comparison of alternatives. Thus, alternatives which would have demonstrably less impacts on Marina's groundwater (such as the Potrero Road and ocean water intake alternatives) are not recognized for this advantage – rather, they are incorrectly categorized as having the same "less than significant impact" to groundwater resources that the Project supposedly would. It is remarkable that one of the Project's most significant environmental impacts is thus neutralized and of no consequence in the alternatives selection process.

Marina-138 cont.

C. The Draft EIR/EIS's Screening Of Alternatives Is Fatally Flawed.

The Draft EIR/EIS fully evaluates only six alternatives (treating Alternatives 5a and 5b as separate alternatives) to the Project plus the No Project Alternative. The screening and evaluation process that led to these alternatives is described in chapters 5.2 and 5.3.

The alternative screening process followed in the Draft EIR/EIS basically involved two types of reviews. First, in section 5.2, certain previously identified projects (such as the Coastal Water Project and the MCWRA Interlake Tunnel and Water Supply Project) were rejected on a variety of grounds. Second, in section 5.3, the Draft EIR/EIS utilized a "development, screening and evaluation process" to identify other alternatives. However, for reasons that are not explained, this selection process had an unreasonably narrow scope: it focused only on options for the source water "intake" component. The Appendices that contain this analysis (I1 and I2) only examined these component options and one option of siting the desalination plant on another property.

Marina-139

1. The Draft EIR/EIS Is Legally Inadequate For Failing To Include A Smaller Project Alternative.

There are many critical deficiencies in this analysis that improperly screened out several alternatives that should have been evaluated, three of which we will discuss here. First and foremost, there is *no* Project alternative (including Alternatives 5a and 5b) which constitutes a Project with a smaller total water "demand" target that aligns with the actual Project water needs. No screening of any kind occurred with regard to a smaller Project that would dramatically lower the type and intensity of the Project's environmental impacts. Instead, the Draft EIR/EIS rejected at the outset the only Project alternative that would produce less than 10,750 afy (the "Pure Water Monterey Groundwater Replenishment Project") because it would only produce

Marina-140

3,500 afy of water, which is supposedly "about 6,250 afy short" of meeting the Project's supposed need of 10,750 afy of water. Draft EIR/EIS at 5.2-6.

The failure of the Draft EIR/EIS to consider any alternative standalone Project that would generate less than 10,750 afy of water is a critical deficiency in the alternatives analysis, particularly given the wide range of potentially very significant impacts to the groundwater aquifers and sensitive coastal ecosystem caused by such a large Project. The CEQA and NEPA case law is clear that only "most," not "all," of a Project's objectives (CEQA or NEPA) need to be met by an alternative. For example, a court invalidated an EIR alternatives analysis under CEQA because the public agency failed to evaluate any "limited water" alternative because it did not meet the primary project objective of high-density housing – the court ruled that this alternative should have been included because it was a feasible alternative that would avoid some of the Project's significant environmental effects. *Habitat &Watershed Caretakers*, 213 Cal. App. 4th at 1303-04. Similarly, a federal court invalidated a NEPA alternatives analysis for a private landfill project in California because an unduly limited "purpose and need" statement (which the court criticized because the federal agency allowed the private interests to define most of the scope of the proposed project) improperly restricted the scope of the alternatives that were considered in the EIS. *Nat'l Parks & Conservation Ass'n v. Bureau of Land Mgmt.*, 606 F.3d 1058, 1061 (9th Cir. 2010).

Marina-140 cont.

Therefore, the failure of the Draft EIR/EIS to include any alternative that would not meet the 10,750 afy water demand request from CalAm (which is not even a figure adequately supported or even identified in the Project Objectives) incorrectly and unreasonably limited the scope of the alternatives analyzed, thereby undermining the legal adequacy of the alternatives analysis.

2. The Intake Option Analysis Omitted Key Technology Considerations.

A second major deficiency in the screening process involved the factors used in the selection of the intake options. The options analysis did not consider a full range of factors because it excluded any consideration of reliability and past success rate (if any) of the intake technology chosen, as discussed in our comments for chapter 3 herein. This complete failure to take into account these fundamental technology considerations – which have played an important role in desalination plant intake analyses conducted for many other California projects – unreasonably skewed the selection of alternatives in favor of the proposed slant well intake option.

Marina-141

3. No Alternatives Were Selected To Avoid Or Lessen Significant And Unavoidable Impacts.

A third major deficiency in the screening process relates to the failure to propose alternatives to avoid or lessen significant and unavoidable environmental impacts. The CEQA Guidelines specify: "Because an EIR must identify ways to mitigate or avoid the significant effects that a project may have on the environment (Public Resources Code § 21002.1), the

Marina-142

discussion of alternatives shall focus on alternatives to the project or its location which are capable of avoiding or substantially lessening any significant effects of the project, even if these alternatives would impede to some degree the attainment of the project objectives, or would be more costly." CEQA Guidelines § 15126.6(b). There is no evidence here that the alternatives chosen are designed to avoid or lessen such impacts.

The Project would result in significant and unavoidable impacts related to air quality and greenhouse gas emissions, and potentially significant impacts related to energy conservation, yet none of the alternatives evaluated in section 5 would reduce impacts associated with these issue areas. Despite the fact that one primary Project objective is to "Minimize energy requirements and greenhouse gas emissions per unit of water delivered" (page 5.1-5), anticipated impacts to air quality, greenhouse gas emissions and energy conservation are either similar or increased compared to the proposed Project for every alternative evaluated in section 5. An alternative should have been developed to reduce impacts related to these impacts. For example, the Landfill-Gas-to-Energy Option (section 4.18.4.3) was not explored further as a potential Alternative project component for consideration by the lead agencies. Instead, it was only briefly discussed as a possibility in section 4.18 and identified as requiring separate environmental review.

Marina-142 cont.

D. The Description Of The Projects Evaluated In Detail Is Legally Deficient.

Chapter 5.4 of the Draft EIR/EIS discusses each of the seven final alternatives (including the No Project Alternative) that it decided to carry through to this level of analysis. Each individual discussion contains a section entitled "Ability to Meet Project Objectives." Several of these alternatives are stated flatly to not meet the Project need for water because they do not meet CalAm's request for a Project that generates 10,750 afy of water. These conclusions are reached for the No Action Alternative (page 5.4-10), the Potrero Road slant well alternative (page 5.4-15) and the reduced size alternatives (5a and 5b) standing on their own (page 5.4-57). However, as explained above, these analyses are inadequate because they are based on a legally deficient statement of Project objectives and needs.

Marina-143

E. The Alternatives Impact Analyses Are Legally Inadequate.

Section 5.5 of the Draft EIR/EIS attempts to compare the seven alternatives to the Project across each category of environmental impact discussed earlier in the document. However, most of these comparative analyses cannot be done properly because of the inadequacies in the underlying environmental impact discussions. For example, our comments on chapter 4.15 demonstrate that the Project will potentially cause a significant impact to historic resources. The Draft EIR/EIS failed to identify these historic resources and wrongly concluded that no such impact will occur. This deficiency is carried through into this alternatives comparison because the Draft EIR/EIS wrongly concludes that other alternatives which have no impacts on such resources have the same lack of impact as the Project and are therefore equivalent on this parameter. These same types of deficiencies are present in many of the analyses, rendering any meaningful comparison impossible.

Marina-144

One comparative impact discussion bears particular attention. The comparison of alternatives across the groundwater resource parameter are entirely inaccurate because of the range of deficiencies identified in our comments to chapter 4.4. For example, since the Draft EIR/EIS incorrectly concludes, without substantial support in the record, that the Project's potential impacts to groundwater quality and exacerbation of seawater intrusion are supposedly "less than significant" (page 5.5-83), it incorrectly takes the position that Project alternatives that clearly do not pose any risk to groundwater quality or seawater intrusion impacts, including all the open water intake options, are the same as the Project on this parameter because they too will have a less than significant impact on groundwater resources. This approach improperly eliminates any analysis of the relative impacts of the alternative projects on the groundwater aquifers.

Marina-144 cont.

F. The Selection Of The Environmentally Superior/Preferred Alternative Is Legally Inadequate Due To The Accumulated Deficiencies In The Project Description, Impact Analyses, Mitigation Measures And Selection Of Alternatives.

The selection of the environmentally superior alternative (or preferred alternative under NEPA) is based on a comparison of the alternatives based on all the factors discussed above. Where, as here, the Project objectives/needs and individual impact analyses are inadequate, the selection of an environmentally superior alternative cannot be made. For these reasons, the critical deficiencies in the prior analyses makes it impossible to make such a selection and the one made here is legally inadequate.

Nonetheless, chapter 5.6 of the Draft EIR/EIS concludes that Alternative 5a, which includes a 6.4 mgd desalination plant with slant wells at the CEMEX site in Marina, and if and only if combined with 3,500 afy from the GWR project on certain conditions, is the environmentally superior alternative. It is explicitly stated not to be the environmentally superior alternative as a standalone project because it would not generate the total water demand sought by CalAm (page 5.6-7).

Marina-145

This selection of the environmentally superior alternative is notable for its brevity (only two pages of text). The discussion, which incorporates some of the analyses in prior sections, appears primarily based on which alternatives can produce a total of 9.6 mgd of water. It also substantially downgrades any open ocean intake alternative, such as the open water intake alternative at Moss Landing, because they supposedly will cause "permitting complexities and delay" due to the permits required. However, this new "permit complexity and delay" comparison factor is inconsistent with its approach to the Draft EIR/EIS's analysis of the Project, which faces substantial permitting complexities and delays because the Project lacks any water rights and its planned water extraction is directly prohibited by laws, an ordinance and an annexation agreement. The failure to evaluate all alternatives on a level playing field with regard to permitting complexities and delays further undermines this analysis.

The comparative impact analysis for the Potrero Road Alternative (Alternative 1) is particularly deficient. This alternative involves installing the subsurface slant wells at the Potrero Road site and running the source water pipeline from that location to the desalination plant. In the discussion of the impacts caused by each alternative (page 5.6-5), this alternative is stated to have "significant and unavoidable impacts" because it supposedly captures groundwater that would flow into Elkhorn Slough. However, this conclusion is not supported by substantial evidence. The prior impact discussion on which it is based (page 5.5-86) states only that slant well pumping at this location "may" draw in groundwater that could recharge the Slough, but then adds: "However, quantification of such an effect is not feasible within the context of the model given the location of Elkhorn Slough relative to the northern boundary of the NMGWM." Marina-146

In short, the groundwater model used for assessing groundwater impacts was unable to make any analysis of whether slant wells at Potrero Road would cause the speculative impacts to Elkhorn Slough. These impacts have no scientific basis and the initial conclusion was they "may" have such an effect, but no verification was attempted or made. Unfortunately, this "may have an impact" conclusion then was improperly translated in the alternative comparison section to be that it "would result in significant and unavoidable impacts." In fact, this "finding," which was the primary reason why Alternative 1 was not chosen as the environmentally superior alternative, lacks substantial evidence in the record and fatally undermines this comparison of alternatives.

It appears that several of the alternatives that are identified – possibly including the Potrero Road alternative and the ocean intake alternatives – would in fact be an environmentally superior alternative if a full and legally adequate set of environmental impact analyses had been prepared. Moreover, if Project alternatives that produced less than 9.6 mgd of water had been evaluated, there is no doubt that they would be environmentally superior to the current designated environmentally superior option because of the lessened size and scope of their environmental impacts. However, these potential alternatives were eliminated based on the agencies' failure to properly scrutinize CalAm's inadequately supported request for a project that generates 10,750 afy of water. Marina-147

In sum, the selection of the environmentally superior alternative (CEQA) and preferred alternative (NEPA) is invalid because the necessary factual and legal analyses that underpin the selection criteria and comparison are legally inadequate. This alternatives analysis must be completely redone and recirculated for public comment in a new Draft EIR/EIS that addresses all of these deficiencies.

CHAPTER 6.0 – OTHER CONSIDERATIONS

This section addresses the description, impacts and mitigation measures relating to the Project's growth-inducing impacts.

Section 6.1

The reader should refer to comments on sections 4.10 (Air Quality), 4.11 (Greenhouse Gas Emissions), and 4.18 (Energy Conservation) regarding impact conclusions and mitigation measures. Marina-148

Section 6.3 Growth-Inducing Impacts

The reader should refer to comments on Sections 2.1 to 2.5. As stated in those comments, the need for the Project appears to be vastly overstated. It is disingenuous to claim that the need for the project is 10,750 afy but the potential for growth inducement is limited to the availability of only an additional supply of 2,005 afy to be provided by the Project. This apparent discrepancy should be resolved. Marina-149

In addition, in the event CalAm ever stops its illegal pumping on the Carmel River and the Seaside Basin, there would potentially be more water supplies available from those currently overdrafted sources for legal users that could further induce growth in Monterey County. The Draft EIR/EIS fails to address these potential growth-inducing impacts and other impacts related to the surplus of water to be supplied to CalAm through implementation of the Project. Marina-150

Section 6.3.6 Secondary Effects of Growth

This section fails to include a discussion pertaining to the potential substantial increase in wastewater generated by indirect growth inducement (residential development enabled by elimination of water restrictions) and need for new or expanded wastewater collection and treatment facilities and associated secondary effects. The capacity of existing infrastructure should be identified and evaluated against the anticipated project-generated demands. Any constraints or impacts should be clearly identified. Marina-151

Table J2-1

This section lacks introductory information that is needed to explain what this information is intended to show. Table J2-1 appears to merely show the impacts of growth as identified in EIRs and MNDs for previously prepared General Plans in the Project area. This table and this Appendix do not provide a project-specific analysis of the secondary effects of growth that would result from implementation of the Project. These impacts must be adequately addressed on a project-specific basis. Referring to the EIRs and MNDs of previously adopted General Plans is inadequate unless it can be shown and supported by substantial evidence that the effects of growth in those General Plans assumes the availability of water supplies that the MPWSP would make available. Otherwise, the MPWSP would further remove a constraint to growth and result in substantially more severe growth inducement and secondary effects of growth than identified in the previous EIRs and MNDs. These issues must be fully disclosed in the Draft EIR/EIS. Marina-152

Further information is needed in this section to describe why some impact determinations in Table J2-1 reflect two levels of significance (i.e., LS/U). The table also fails to reflect the level of significance after implementation of all feasible mitigation measures.

Marina-152 cont.

Impacts on Carmel River

The Draft EIR fails to identify changes that would occur as a result of CalAm's reduced pumping on the Carmel River. Would river flows increase? Would riparian areas and habitat adjacent to the River be impacted? Would downstream areas be affected by increased capacity of the River? Would infrastructure be removed from the Carmel River? What would that entail? What would the environmental effects of decommissioning these existing components be?

Marina-153

CONCLUSION

The City of Marina appreciates the opportunity to provide these comments regarding the Draft EIR/EIS for the Project. Please contact the City, its consultants or Farella if you have any questions.

Very truly yours,

Paul P. "Skip" Spaulding, III

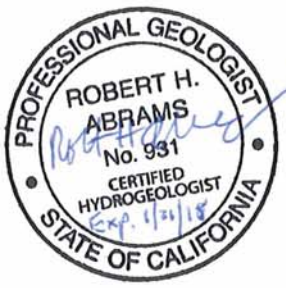
MEMORANDUM



Date: March 27, 2017

Prepared By: Robert H. Abrams, PhD, PG, CHg

Reviewed By: Jan Jacobson and Michael Tietze, PG, CEG, CHg

Subject: Comments on behalf of the City of Marina regarding the Draft EIR/EIS Monterey Peninsula Water Supply Project, Monterey County, California

Jacobson James & Associates (JJ&A) has prepared this memorandum to provide technical comments on behalf of the City of Marina regarding the California American Water Company (CalAm) Monterey Peninsula Water Supply Project (MPWSP or Project) Draft Environmental Impact Report/Environmental Impact Statement (Draft EIR/EIS), issued on January 13, 2017 by the California Public Utilities Commission and the Monterey Bay National Marine Sanctuary. All comments herein are professional opinions of JJ&A regarding material contained within or relevant to the Draft EIR/EIS.

1.0 INTRODUCTION

The proposed MPWSP includes a desalination plant with ten subsurface, seaward-facing slant wells to produce raw feedwater for the plant (Figure 1). These slant wells would pump up to 24.1 million gallons per day (MGD) of subsurface water from beneath the Monterey Bay coastline. The wells are proposed to be located on the CEMEX sand-mining property in Marina, California. The Draft EIR/EIS assumes that the plant feedwater will consist primarily of seawater that infiltrates through the seabed offshore from the CEMEX property. A test slant well is currently operating on this property. Alternative 5a, which has been designated the California Environmental Quality Act (CEQA) environmentally superior alternative and National Environmental Policy Act (NEPA) preferred alternative, would use seven slant wells on the CEMEX sand-mining property to pump up to 15.5 MGD of subsurface feedwater from beneath the Monterey Bay coastline.

To prepare these comments, JJ&A reviewed the project description and portions of the Draft EIR/EIS relating to groundwater resources, published peer-reviewed scientific research focused on the application of geophysical techniques to evaluate subsurface conditions in and around the Project area, and a video transcript of a presentation to the Marina City Council by geophysics professor Rosemary Knight.[1] JJ&A finds the evaluation of potential impacts to groundwater resources, water

[1] Presented at Marina City Council meeting, February 7, 2017 (https://sites.google.com/site/ampmediacenter/amp-programming/marina-video-on-demand-1).

quality, and water supplies in the Draft EIR/EIS to be incomplete from a technical perspective, leading to the conclusion that potential adverse impacts to groundwater supplies in the City of Marina have not been adequately evaluated. In our opinion, the technical deficiencies identified herein should be addressed and a revised Draft EIR/EIS prepared before certification by the CPUC and MBNMS.

1.1 Comment Organization and Overview

A primary concern for stakeholders in the MPWSP area is the effect of proposed Project pumping on existing and future seawater intrusion in the groundwater aquifers that provide water to the citizens of Marina and others, who rely exclusively or primarily on groundwater for their water supplies. Surface water resources in the region are fully allocated and scarce for all municipal, agricultural, industrial, and domestic water uses; therefore, protection of groundwater resources is imperative. The environmental analysis in the Draft EIR/EIS did not adequately assess the possibility of adverse impacts to groundwater quality and the City of Marina's drinking water supply from exacerbated seawater intrusion and other effects caused by the proposed MPWSP pumping.

JJ&A's findings and conclusions may be grouped into the following five comment areas:

1. Recent and ongoing geophysical investigations in the project vicinity related to seawater intrusion, although briefly mentioned in the Draft EIR/EIS, were not considered in the impact analysis. These studies provide substantive data that are necessary to adequately understand potential water quality impacts to drinking water supplies. As such the Draft EIR/EIS evaluation of potential impacts to groundwater quality and supplies is incomplete and inadequate.
2. Ongoing seawater intrusion control efforts in the area could have a significant effect on the feedwater source area for the proposed slant wells. As a result, a much greater percentage of feedwater may be extracted from inland areas of the local aquifers than has been assumed. The potential for this to occur was not considered in the Draft EIR/EIS.
3. Potential impacts to the 900-Foot Aquifer, a primary water source for the City of Marina, were not evaluated or discussed.
4. Alignments of proposed slant well casings appear to be mostly within the city limits of Marina and not substantially beneath the seafloor, as was assumed in the evaluation included in the Draft EIR/EIS.
5. The groundwater modeling effort conducted for the Draft EIR/EIS is too simplistic and insufficiently designed to adequately evaluate the potential impacts of feedwater pumping on water quality in the 180-Foot, 400-Foot, and 900-Foot aquifers. In addition, the approach used does not consider cumulative impacts and is insufficient for their evaluation.

These comment areas are discussed in detail in Section 2 of this memorandum.

1.2 Background

Using designations defined by the Monterey County Water Resources Agency (MCWRA), the proposed MPWSP is located in the Pressure Subarea of the Salinas Valley Groundwater Basin (SVGB) (Figure 1).[2] Using California Department of Water Resources (DWR) designations, the MPWSP area is located in the 180/400-Foot Aquifer Subbasin of the SVGB.[3] Wells operated by Marina Coast Water District (MCWD) that supply drinking water to the City of Marina are located in the Monterey Subbasin designated by DWR, which is located within the boundary of the Pressure Subarea of the SVGB designated by MCWRA (Figure 1). The MCWD wells are screened in the 180-Foot, 400-Foot, and 900-Foot aquifers.

1.2.1 Local Hydrogeology

A regionally extensive series of clay layers known as the Salinas Valley Aquitard (SVA) is present in the shallow subsurface within the Pressure Subarea of the SVGB. Above the SVA a zone of generally poor-quality groundwater occurs in the shallow or Dune Sand Aquifer. The 180-Foot Aquifer underlies the SVA. Where the SVA is absent, such as in the immediate area of the test slant well and the proposed Project slant wells, the Dune Sand Aquifer directly overlies the 180-Foot Aquifer and 180-Foot Equivalent Aquifer (180-FTE Aquifer).[4]

DWR characterizes the 180-Foot Aquifer as a confined aquifer within the 180/400 Foot Aquifer Subbasin. However, a recent report prepared for the MCWRA characterizes groundwater in this aquifer as predominantly confined, except where the overlying SVA is absent.[5] The Draft EIR/EIS states that the Dune Sand Aquifer and the 180-FTE Aquifer are unconfined at the CEMEX site, because there are no extensive overlying low-permeability clay units at this location. This means that in the MPWSP area, the Dune Sand Aquifer and the 180-FTE Aquifer are likely in direct hydraulic communication.

The 180-Foot Aquifer is separated from the underlying 400-Foot Aquifer by a zone of discontinuous aquifers and aquitards.[3] The primary aquitard separating the 180-Foot Aquifer and 400-Foot Aquifer is a clay layer known as the 180/400-Foot Aquitard, which varies in composition, depth, and thickness (typically 50 to 100 feet thick), and is absent in some areas.[5] The 400-Foot Aquifer, which on average is 200-feet thick,[3] is generally considered to be semi-confined to confined. Where the 180/400-Foot Aquitard is thin or absent, the 180-Foot Aquifer and 400-Foot Aquifer are in direct hydraulic communication.

Variability in the thickness and quality of the 180/400-Foot Aquitard and the existence of possible gaps in the aquitard have been noted. For example, two small "holes" in the aquitard, one under the Salinas River near Blanco and another under the old Salinas River bed near the coast have been documented. Other gaps in the 180/400-Foot Aquitard have been noted near the mouth of the Salinas River and near Fort Ord, as well as several areas between Castroville and the coast, where the aquitard is thin or

[2] http://www.mcwra.co.monterey.ca.us/groundwater_level_monitoring/groundwater_level_monitoring_overview.php
[3] http://www.water.ca.gov/groundwater/bulletin118/basindescriptions/3-04.01.pdf
[4] The 180-Foot Equivalent Aquifer is stratigraphically equivalent and hydraulically connected to the 180-Foot Aquifer, and has similar hydraulic properties, although it is depositionally different than 180-Foot Aquifer.
[5] http://www.mcwra.co.monterey.ca.us/hydrogeologic_reports/documents/State_of_the_SRGBasin_Jan16_2015.pdf

absent.[5] If the SVA is also absent in these same areas, the 400-Foot Aquifer would be unconfined in those areas and in hydraulic communication with the Dune Sand Aquifer. The Draft EIR/EIS states that the 180/400-Foot Aquitard is present beneath the CEMEX site, but also states that the 400-Foot Aquifer at the CEMEX site is within the unconfined Aromas Sand, suggesting that the three uppermost aquifers in this area behave essentially as a single aquifer system.

The 900-Foot Aquifer is present in the lower Salinas Valley. A clay aquitard separates this aquifer from the overlying 400-Foot Aquifer. The 900-Foot Aquifer consists of a thick sequence of alternating layers of sand-gravel mixtures and clays, rather than a distinct aquifer and aquitard.[3] The 900-Foot Aquifer is reported to be confined.

1.2.2 Seawater Intrusion and the Potential for Adverse Impacts

Seawater intrusion has been well-documented in Monterey County since at least the 1940s.[6] For example, the Seaside Subbasin is adjudicated due to overdraft and the threat of seawater intrusion. Various entities, including the MCWRA and its predecessor agency, have studied and evaluated the extent of seawater intrusion and proposed or constructed projects with the goal of limiting, halting, or reversing movement of seawater intrusion further inland.[7]

The extent of seawater intrusion in the 180-Foot and 400-Foot aquifers has been monitored by MCWRA for many years, by measuring various groundwater quality parameters at a designated set of monitoring and other wells. The measurements at these wells are point values, which are used to develop two-dimensional concentration contour maps to assess the lateral extent of seawater intrusion in the principal aquifers by interpolating between these point values. MCWRA publishes maps every two years, showing the position of the seawater intrusion front based on the location of the interpolated 500 mg/L chloride concentration contour line (Figures 2 and 3). These maps show the location of the seawater intrusion front beginning in 1944 in the 180-Foot Aquifer and 1959 in the 400-Foot Aquifer. The most recent maps available at this time show the position of the seawater intrusion front through 2013, based on data from the designated wells. The 2013 data indicate that the seawater intrusion fronts are in approximately the same locations they were in 2011; indicating that seawater intrusion did not advance further inland between 2011 and 2013.

Groundwater quality monitoring at wells provides valuable information about the two-dimensional extent of seawater intrusion in the principal aquifers through time, but must be supported by an adequate understanding of the actual seawater migration pathways in three dimensions to adequately inform aquifer and groundwater resource management decisions and impact analyses. As discussed later in this memorandum, the MCWRA seawater intrusion maps alone do not provide a clear understanding of the actual three-dimensional distribution of groundwater degraded by seawater intrusion, or of the lateral and vertical seawater migration pathways.

[6] http://www.mcwra.co.monterey.ca.us/seawater_intrusion_monitoring/seawater_intrusion_monitoring.php
[7] See for example, http://www.mcwra.co.monterey.ca.us/salinas_river_diversion_fac/salinas_river_diversion_fac.php, http://www.mcwra.co.monterey.ca.us/salinas_valley_water_project_I/salinas_valley_water_project_I.php, http://www.mcwra.co.monterey.ca.us/salinas_valley_water_project_II/salinas_valley_water_project_II_overview.php.

The analysis in the Draft EIR/EIS relies on the MCWRA maps alone, and does not consider data in the third dimension (i.e., variability with depth within and between principal aquifers) from other existing sources that would allow the threat to groundwater wells to be evaluated more adequately. Assessment of the probability of water quality degradation and adverse impacts to the City of Marina's drinking water supply and other groundwater users should be conducted using all of the substantive data available, and by developing models capable of addressing the range of possible future impacts, rather than simplistic interpolations based on monitoring data alone.

Marina-JJ&A-01

Figures 2 and 3 show the locations of wells operated by MCWD that supply drinking water to the City of Marina relative to the documented seawater intrusion fronts. Known gaps in the confining clay layers above and between the 180-Foot and 400-Foot Aquifers, and the fact that the clay layers are absent in some areas potentially leave these water-supply wells vulnerable to seawater intrusion from both vertical and horizontal migration of seawater-intruded groundwater. It should be noted it is not clearly known at this time if vertical pathways exist for groundwater flow from the 400-Foot Aquifer to the 900-Foot Aquifer.

The groundwater resources impact analysis in the Draft EIR/EIS is primarily focused on changes in groundwater levels, or drawdown, caused by proposed Project pumping. Discussion of the potential impacts resulting from exacerbated seawater intrusion is limited in the Draft EIR/EIS, and these impacts are evaluated only in terms of the potential for MPWSP feedwater pumping to change the rate of horizontal inland migration of the seawater intrusion front (as defined by 500 mg/L chloride concentration) based on a simplistic assessment of lateral groundwater flow within the principal aquifers alone. Vertical groundwater flow that will likely be induced between the aquifers by the MPWSP was not adequately evaluated, leading to an incomplete understanding of potential adverse impacts to groundwater quality and wells. In our opinion, it is important to evaluate the potential migration of seawater intrusion that could be caused by MPWSP pumping, and the impact these events could have on groundwater wells in the City of Marina.

Marina-JJ&A-02

2.0 DISCUSSION OF COMMENT AREAS

Section 2 of this memorandum provides detailed discussions of the five comment areas identified by JJ&A, which led to our conclusion that the Draft EIR/EIS does not adequately evaluate the potential for adverse impacts to groundwater resources and supply wells in the City of Marina.

2.1 The Importance and Relevance of Local Geophysical Investigations

Geophysical methods are widely recognized as useful tools to fill critical data gaps between point values when a three-dimensional perspective is required. Addressing these data gaps and developing a more complete conceptual understanding of three-dimensional groundwater flow is a crucial and valuable complement to the seawater-intrusion monitoring data collected at wells in Monterey County, for the purpose of informing groundwater management decisions and impact analyses. Such geophysical surveys are typically validated by utilizing groundwater quality parameters collected in the field at point locations. Stanford University Professor of Geophysics Rosemary Knight and colleagues, as well as many other researchers, have reported extensively on the use of electrical resistivity tomography (ERT) and

Marina-JJ&A-03

other geophysical methods to characterize seawater intrusion in the subsurface.[8] Much of this research has been conducted along the Monterey Bay coastline in Monterey and Santa Cruz counties, near the MPWSP area.

Section 4.4 of the Draft EIR/EIS mentions briefly the use of geophysics and ERT along the coastline of Monterey Bay near the CEMEX site. Page 4.4-31 of the Draft EIR/EIS states that:

> *"Professor Knight's initial survey was conducted along a 4-mile segment parallel to the beach between the cities of Seaside and Marina. The study found that the electrical resistivity readings positively correlated with measured TDS concentrations to a depth of 500 feet in four area groundwater wells."*

Marina-JJ&A-03

As noted above, field data are used for validation purposes, so correlation of the geophysical results with measured values is expected. No other discussion is provided in the Draft EIR/EIS. This brief statement fails to recognize the key importance of recent ERT analyses to inform the impact analysis conducted for the Draft EIR/EIS, and ignores the principal conclusions of those studies. There is no mention in the Draft EIR/EIS that work by Professor Knight's group has added considerable value, advancing the characterization of aquifers, aquitards, and seawater intrusion along the Monterey Bay coastline, by assessing the subsurface *between and beyond* monitoring wells both laterally and vertically. Furthermore, the 4-mile segment mentioned in the Draft EIR/EIS was a precursor to a much larger study that was occurring before and during the preparation of the Draft EIR/EIS. Both of these studies revealed details of the distribution of subsurface seawater impacts that cannot be characterized by a monitoring well network, as described below. The results of these geophysical investigations have greatly improved the characterization of local hydrogeology and seawater intrusion and should have been integral parts of the evaluations conducted for the Draft EIR/EIS.

2.1.1 Existing Geophysical Investigations in the MPWSP Area

Marina-JJ&A-04

Pidlisecky et al. (2016) present results of ERT imaging over a 7-kilometer (4.3 miles) profile of the Monterey Bay coastline, which extended to a depth of approximately 150 meters (490 feet) (Figure 4). The color-coded plot of electrical resistivity across this area in Panel (a) of Figure 5 shows clearly the different resistivities associated with salt water (red) and fresh water (blue) in the principal aquifers. When combined with lithologic interpretations shown on Panels (b) and (c), the resistivity results delineate the aquifers, aquitards, and horizontal and vertical extents and migration pathways of

[8] See, for example, the following peer-reviewed scientific papers and references cited therein:

Pidlisecky, Moran, Hansen, and Knight, 2016. Electrical resistivity imaging of seawater intrusion into the Monterey Bay aquifer system. Groundwater, Vol. 54, No. 2, p. 255-261.

seawater intrusion along this section of the Monterey County subsurface. The ERT results provide a vertical cross-sectional image of seawater intrusion and migration in the 180-Foot and 400-Foot aquifers at this location.

Two principal conclusions of this work are that the subsurface geology is more highly variable and spatially heterogeneous than was previously understood, including the aquitards between and overlying the aquifers, and that the distribution of seawater intrusion in these aquifers is also highly variable horizontally and vertically. There are numerous locations where pathways exist for migration of seawater and seawater-impacted groundwater from shallower to deeper levels of the aquifer system, as well as locations where such pathways do not exist and fresh water is present at depth. Pidlisecky et al. (2016) note the constrained nature of the salt water layer on the southern end of the profile suggests the presence of a thin clay aquitard, which impedes downward migration of salt water from the shallow aquifer in that area. On Figure 5, Panel (b) shows the interpreted location of this thin clay aquitard. Moreover, the pathways and deeper occurrence of salt water at other locations exist in part because aquitards are not present at all locations, and downward vertical flow and transport of degraded groundwater has apparently occurred.

This interpretation is corroborated by information in the Draft EIR/EIS that was not considered in the water quality impact analysis. Figure 4.4-3 of the Draft EIR/EIS shows the presence of significant downward vertical hydraulic gradients observed at four monitoring wells in the MPWSP area on September 10, 2015. Because the SVA is largely absent in this area, downward flow of degraded groundwater between the Dune Sand Aquifer and the 180-Foot Aquifer must be occurring. As shown on Figure 4.4-3 of the Draft EIR/EIS, the presence of the 180/400-Foot Aquitard in most of this area is speculative, and it was noted elsewhere in the Draft EIR/EIS that the 400-Foot Aquifer is unconfined in the MPWSP area, indicating that the 180/400-Foot Aquitard and SVA are absent. Thus, downward flow of seawater-intruded groundwater from the 180-Foot Aquifer to the 400-Foot Aquifer is likely to continue and could be exacerbated by the MPWSP.

Marina-JJ&A-04

Goebel et al. (2017) extend the work of Pidlisecky et al. (2016) to greater depths (280 meters, or 920 feet), and a significantly longer profile that extends 40 kilometers (25 miles) across three groundwater basins (i.e., the Santa Cruz Mid-County, Pajaro Valley, and Salinas Valley groundwater basins) spanning Santa Cruz and Monterey Counties. This additional study was not considered in the Draft EIR/EIS. The findings of this study were also the subject of the presentation noted above, given by Prof. Knight to the Marina City Council on February 7, 2017, and presented in other local venues prior to this date. Several sections of this extended profile were shown during the presentation, which illustrated similar patterns observed in the earlier work, except that these profiles show imaging of salt water intrusion at depths of 920 feet, i.e., significantly deeper than the 180-Foot and 400-Foot aquifers. As with Pidlisecky et al. (2016), the profiles in Goebel et al. (2017) show clearly where pathways exist for potential downward migration of seawater and seawater-impacted groundwater from shallower to deeper levels of the aquifer system, as well as locations where such pathways do not exist and fresh water is present at depth.

The resistivity image in Goebel et al. (2017) that covers the same region as the profile in Pidlisecky et al. (2016) indicates a vertical flow barrier deeper in the section that has prevented the downward flow of the higher-salinity water (Goebel et al., 2017). Importantly, this vertical flow barrier is not regionally extensive, thus downward vertical flow of seawater-intruded groundwater from shallower to deeper levels of the aquifer system appears to occur and could be exacerbated by project pumping. The presence of salt water down to depths of 920 feet can be seen on the profiles presented to the Marina City Council by Dr. Knight.

Marina-JJ&A-04

Dr. Knight noted during her February 7, 2017 presentation to Marina City Council that her research team was prevented from crossing the CEMEX property for purposes of conducting ERT measurements, which is where the test slant well is located and is also the site of all proposed Project slant wells. As a result, there is a noticeable data gap at one of the locations where such information is likely to be needed the most.

2.1.2 Near-Future Geophysical Investigations in the MPWSP Area

The existing ERT profiles discussed above give vertical profiles of seawater intrusion for specific locations in the groundwater aquifers (i.e., along the Monterey Bay coastline); however, Dr. Knight and her colleagues are undertaking a new ERT study that will give three-dimensional images of seawater intrusion across a wide area in and around the City of Marina and the MPWSP area. This work is scheduled to occur in May 2017, using the SkyTEM methodology.[9]

These new data will provide valuable insight into the hydrogeological heterogeneity and extent/distribution of seawater in the immediate MPWSP area. Moreover, the new data will reduce the uncertainty associated with the current characterization of the subsurface, and will facilitate a more adequate evaluation of the likelihood of adverse impacts from the proposed MPWSP feedwater pumping to groundwater wells that supply drinking water to the City of Marina. Dr. Knight's upcoming project is planned to include detailed groundwater modeling that accounts for hydraulic parameter uncertainty evaluations.

Marina-JJ&A-05

2.2 Effects of Seawater Intrusion Control Efforts on MPWSP Feedwater Source Areas

The transient North Marina Groundwater Model (NMGWM) was used for the Draft EIR/EIS to evaluate the drawdown impacts caused by proposed MPWSP feedwater pumping. As part of the groundwater modeling effort described in Appendix E2 of the Draft EIR/EIS, a capture-zone, or feedwater source-area, analysis for the proposed MPWSP slant wells was conducted using particle tracking, a steady-state version of the NMGWM, and three different average values for the regional background hydraulic gradient. These average gradients were artificially imposed on the groundwater flow model.[10] Each of these three hydraulic gradients were oriented in the same direction and assumed that the regional groundwater flow direction in the MPWSP area is from the subsea portions of the Dune Sand Aquifer

Marina-JJ&A-06

[9] http://skytem.com/geophysical-surveys/

[10] As explained in Appendix E2 of the Draft EIR/EIS, the hydraulic gradients were artificially imposed because in the superposition model used for the forecast scenarios, the initial water levels and boundary conditions were set to zero. Consequently there was no regional background hydraulic gradient in the simulations.

and the 180-Foot Aquifer toward the inland portions of these aquifers, i.e., landward gradients. Under these conditions, feedwater for the desalination plant would largely be drawn from the subsea portions of the aquifers beneath Monterey Bay. However, it is important to note that concerted and successful efforts have been underway for many years, led by the MCWRA and its predecessor agency, to increase groundwater levels in the inland, seawater-intruded areas of the SVGB to slow, halt, or reverse seawater intrusion.[7] If these mitigation efforts continue to be successful, as will likely be required under the Sustainable Groundwater Management Act (SGMA), the magnitude of the landward hydraulic gradient will decrease as inland groundwater levels increase, thus the shape of the capture zone and extent of the source area for the proposed slant wells will change substantially.

Marina-JJ&A-06

A hypothetical capture zone in the presence of a landward regional hydraulic gradient is shown conceptually on Figure 6a (i.e., conceptual in the sense that it is not drawn to scale and not calculated based on specific pumping rates). The capture zone depicted on Figure 6a is an idealized version of the capture zones shown on Figure 5-6 of Appendix E2 of the Draft EIR/EIS. Current groundwater conditions in the SVGB are such that the capture zone for the proposed slant wells would be conceptually similar to Figure 6a, and the source area for the slant wells would predominantly be the subsea portions of the aquifers. This hydraulic gradient direction occurs because inland groundwater elevations are currently below sea level in a substantial portion of the SVGB.

Two conceptual illustrations of possible future changes to the slant-well capture-zones are shown on Figures 6b and 6c. For purposes of understanding the three conceptual illustrations on Figure 6, the only difference between the three is the direction of the regional hydraulic gradient. Furthermore, the illustrated changes in gradient direction from Figure 6a to Figure 6b and Figure 6c are caused only by increases in inland groundwater elevations. Figure 6c shows the orientation of a hypothetical slant-well capture-zone that would occur if inland groundwater levels were to increase above sea level. Any and all changes to inland groundwater elevations would alter the geometry of the source area for the proposed slant wells. Thus, there are an infinite number of capture-zone geometries that could occur between the end-members illustrated in Figures 6a and 6c. Figure 6b shows an intermediate hypothetical case that would occur if inland groundwater elevations increase to exactly sea level. Thus, the continued success of ongoing seawater-intrusion mitigation projects could potentially strand the MPWSP desalination plant from its source of seawater.

Marina-JJ&A-07

Possible future groundwater conditions such as those described above were not evaluated or discussed in Appendix E2 of the Draft EIR/EIS, even though the goal of MCWRA's ongoing seawater-intrusion control efforts is to increase inland groundwater levels, and such conditions may be considered to be reasonably foreseeable. As such, the Draft EIR/EIS failed to consider that a more substantial fraction of freshwater resources may be captured during feedwater pumping than has been assumed.

2.3 Insufficient Evaluation of the 900-Foot Aquifer

Discussion of the 900-Foot Aquifer is limited in the Draft EIR/EIS. The lack of discussion implies to the reader that potential impacts or harm to the 900-Foot Aquifer from proposed MPWSP feedwater pumping were assumed to be negligible; however, this is not clearly stated. The 900-Foot Aquifer is a

Marina-JJ&A-08

significant water resource for the City of Marina and others in the area. Therefore, discussion of the potential implications of the MPWSP project on this resource should be an integral part of the overall evaluation and should be discussed in detail.

Marina-JJ&A-08

The groundwater modeling evaluations conducted for the Draft EIR/EIS do not address potential impacts to the 900-Foot Aquifer from proposed MPWSP pumping. First, the higher-resolution CEMEX area model described in the April 2015 Draft EIR (DEIR) for the MPWSP did not extend deeper than the 400-Foot Aquifer, and in any case was not included for evaluation purposes in the Draft EIR/EIS. The NMGWM described in both the April 2015 DEIR and the current Draft EIR/EIS does not evaluate the 900-Foot Aquifer beyond a cursory level. For instance, aquifer parameters in model layers 5 through 8 (which are used to represent the 400-Foot Aquifer, the 900-Foot Aquifer, and overlying aquitards) are treated as single zones. Gradational hydraulic conductivity values were used for model layers 5 and 6, but there is no explanation of how the gradational patterns were determined. Hydraulic conductivity in model layers 7 and 8 were assigned single values and the spatial distribution of hydraulic conductivity was considered to be homogeneous, even though all available data indicate that the entire thickness of the aquifer system in the MPWSP area is extremely heterogeneous.

Marina-JJ&A-09

Other deficiencies in the evaluation of the 900-Foot Aquifer include the following:

- The potential impacts of downward vertical flow from shallower seawater-contaminated aquifers (identified during the geophysical investigations discussed earlier in this memorandum) were not discussed or evaluated, despite clear evidence that vertical flow is known to occur in the MPWSP area (e.g., in Figures 4.2-3 and 4.4-3 of the Draft EIR/EIS).
- The discussion in the Draft EIR/EIS section on Groundwater Elevations and Flow Directions (Section 4.4.1.3) does not cover groundwater flow or response to pumping with respect to the 900-Foot Aquifer.
- The Direct and Indirect Effects section of the Draft EIR/EIS (Section 4.4.5) does not mention the 900-Foot Aquifer:
    - Evaluation with regard to the effect of groundwater extraction from the shallow aquifers does not include analysis of the impact of changes to groundwater flow and water quality in the 900-Foot Aquifer;
    - There is no discussion of mitigation measures for potentially degrading or reducing the water supply in the 900-Foot Aquifer; and
    - Potential changes in groundwater flow in the 900-Foot Aquifer as a result of injection at the new Aquifer Storage and Recovery (ASR) wells were not discussed and no impact analysis was provided.

Marina-JJ&A-10

2.4 Alignments of Proposed Slant Wells Not Substantially Beneath the Seafloor

In the Draft EIR/EIS, the proposed MPWSP slant wells are described as being components of the seawater intake system for the desalination plant and as being beneath the seafloor of Monterey Bay, which implies that the slant wells will be extracting seawater. It should be noted, however, that the proposed alignments of the slant wells, as shown on Figure 3-3a of the Draft EIR/EIS, are under the

Marina-JJ&A-11

beach and not the seafloor. The proposed slant wells would be completed in the Dune Sand Aquifer and the 180-FTE Aquifer, largely within the City Limits of the City of Marina.

The length of well casing that would extend offshore was estimated in the Draft EIR/EIS by plotting a projected year 2020 mean high water (MHW) line on a satellite-image map of the beach. The offshore portion was considered to be the portion of the well casing that would be seaward of this projected MHW line (see Table 3-2 and Figure 3-3a of the Draft EIR/EIS). The design details for the proposed slant wells were not included in the Draft EIR/EIS or the supporting publically-available documents.[11] However, Figure 3-3b of the Draft EIR/EIS gives a well length of 970 feet for nine of the proposed slant wells and 684 feet for the test slant well. The estimated offshore portion of the slant wells is based on climate change scenarios in which the high sea-level rise was predicted to be 8.1 centimeters (3.2 inches) by 2020 (see Table 3-2 of the Draft EIR/EIS). It is stated in the Draft EIR/EIS that the screened intervals of these wells will be less than the casing lengths given on Figure 3-3b of the Draft EIR/EIS. Nevertheless, these lengths can be used to estimate the percentage of well casing that would be seaward of the MHW line.

Table 3-2 of the Draft EIR/EIS provides additional factors that increase the length of well casings and portions of the wells considered to be seaward of the MHW line; however, the document does not explain how these factors were derived. It is not explained in the Draft EIR/EIS how the "envelope" length was determined, nor was the rationale for adding these lengths explained in enough detail to assess their validity. A second estimated length intended to account for erosion from a "100-year storm" was also added to the length of well casing that would be considered seaward of the MHW line. However, no explanation is given as to how or why the impact of a storm or erosion would permanently affect the position of the MHW line. Both of these added lengths act to show increased estimates in Table 3-2 of the Draft EIR/EIS of the length of well casing that would be seaward of the MHW line.

Marina-JJ&A-11

For illustration, JJ&A estimated the percentages of the proposed MPWSP slant well casings that would be seaward of the MHW line shown in the Draft EIR/EIS. For purposes of our analysis, we did not include the additional lengths estimated for the "envelope" or "100-year storm," because the rationale for these additional casing lengths is not explained in the Draft EIR/EIS. The range of well-casing lengths seaward of the MHW line given in Table 3-2 of the Draft EIR/EIS is 0 to 278 feet. Based on the total length of the proposed well casings of 970 feet and the length of the test slant well casing of 684 feet (also given in Table 3-2 of the Draft EIR/EIS), the percentage of casing of individual wells seaward of the MHW line ranges from 0 percent to 29 percent, with a non-zero low of 7 percent and an average of 18 percent. Therefore, an average of 82 percent of the individual well casing lengths of the proposed MPWSP slant wells would be landward of the projected 2020 MHW line and in the City of Marina; i.e., not under the seafloor.

[11] On page 28 of Appendix E2 of the Draft EIR/EIS, it is stated in footnote 79 that Geosciences Support Services provided design details of the proposed slant wells and layout to the current groundwater modeling consultant in a written communication.

2.5 Groundwater Modeling Deficiencies

JJ&A finds six areas for which the groundwater modeling effort conducted for the Draft EIR/EIS, and reported in Appendix E2, is deficient for evaluating the potential for adverse impacts to existing groundwater users in the City of Marina from proposed MPWSP pumping. These deficiencies are due at least in part to the use of a legacy model (the NMGWM) that was not developed and constructed for this specific purpose, and that does not include newly available information regarding the heterogeneous and vertically-connected nature of the aquifer system.

The Draft EIR/EIS used a revised version of the same model that was used to evaluate the potential for impacts to existing groundwater users from proposed MPWSP in the previous DEIR. According to Appendix E2 of the April 2015 DEIR for the MPWSP,[12]

> *"The NMGWM was constructed by integrating the SVIGSM aquifer parameters, recharge and discharge terms, boundary conditions and predictive scenarios to ensure consistency between the two models. It has been used previously to evaluate several proposed projects in the region…"*

Marina-JJ&A-12

The SVIGSM (Salinas Valley Integrated Groundwater Surface Water Model) was developed for the MCWRA approximately 25 years ago using a modeling platform that is generally no longer used, and has been replaced by a more up-to-date platform that addresses several perceived deficiencies. For its time, and considering the available computing resources, it was a detailed model of Salinas Valley hydrology. However, it is important to recognize that by today's standards the SVIGSM is obsolete and is not capable of providing the level of analysis required of modern models. It is no longer used by the MCWRA, which is currently collaborating with the U.S. Geological Survey (USGS) on a new, modern model that is nearing completion (i.e., the Salinas Valley Integrated Hydrologic Model, or SVIHM).

The NMGWM is refined compared to the SVIGSM, however it was developed for a similar primary purpose: to evaluate the impact of water projects on water supply and groundwater storage at a regional scale.[13] For "water-supply models," the required level of detail is much less than models designed to evaluate project impacts that could degrade water quality, such as impacts due to exacerbated seawater intrusion. This is primarily because of the level of detail needed to achieve the modeling objectives for differing purposes. The tracking of particular parcels of water and inclusion of specific or possible migration pathways are generally not necessary for water-supply projects, because the modeling objectives are typically tailored to evaluate bulk volumetric water supply and the project-related changes to groundwater levels and storage.

Marina-JJ&A-13

Conversely, particular parcels of water must be tracked accurately to evaluate the water quality impacts due to project-related degradation of water quality. Such models must also simulate the appropriate processes as well as preferential migration/flow pathways in heterogeneous systems. In the case of the proposed MPWSP, the ability to simulate and evaluate potential adverse impacts caused by exacerbated

Marina-JJ&A-14

[12] http://www.cpuc.ca.gov/Environment/info/esa/mpwsp/deir_toc.html
[13] See page 7 of Appendix E2 of the Draft EIR/EIS.

seawater intrusion requires inclusion of density-dependent flow and solute transport, neither of which are included in the NMGWM described in the Draft EIR/EIS. An additional requirement of a focused site-specific model is that it must provide sufficient spatial resolution. For a finite-difference model like the NMGWM, the model cell dimensions would need to be much smaller than 200 foot by 200 foot cells used in the NMGWM (e.g., cells on the order of 20 feet by 20 feet would be needed).

Water-supply models typically perform very well for calculating the response of water levels and changes in groundwater storage to pumping. As might be expected for a water-supply model of this type, which was used for the Draft EIR/EIS, it is stated in Appendix E2 that the NMGWM performance assessment was conducted for the purpose of supporting the calculation of water-level changes in response to slant well pumping, and not for evaluating the potential adverse impacts from exacerbated seawater intrusion.

Marina-JJ&A-14

The six areas for which the NMGWM was found to be deficient are discussed in detail in the following subsections.

2.5.1 Modeling Objectives

Modeling objectives succinctly define the purpose of a modeling effort, so that detailed characterization can be focused on those parts of the model that most control outcomes related to the stated purposes of the model. Although not stated clearly in the Draft EIR/EIS, the modeling objectives for the revised NMGWM are implied in Appendix E2 to be (1) delineate the area where drawdown is 1-foot or greater in response to proposed MPWSP pumping, (2) determine the source area(s) from where feedwater for the proposed MPWSP desalination plant would be extracted, and (3) determine if proposed MPWSP pumping would exacerbate seawater intrusion in the SVGB. As such, specific evaluation of potential groundwater quality degradation in the City of Marina resulting from the MPWSP does not appear to have been an objective of the modeling study.

JJ&A's review of Appendix E2 and other portions of the Draft EIR/EIS indicate these modeling objectives are insufficiently defined or incompletely addressed. Thus, the potential for adverse impacts to wells in the City of Marina from the proposed MPWSP has not been adequately evaluated by the modeling studies in the Draft EIR/EIS.

Marina-JJ&A-15

2.5.1.1 Modeling Objective 1

The first modeling objective essentially defines the area where Project drawdown effects will occur (the Area of Project Effects or APE) that will be further evaluated to determine their significance based on the predicted drawdown within the area. To achieve the first modeling objective (delineating the area where drawdown is 1-foot or greater in response to proposed MPWSP pumping), a "superposition" version of the NMGWM was utilized. Importantly, the superposition technique used analyzed *only* the effects of proposed MPWSP pumping, without considering cumulative pumping in the area or the numerous other stresses on groundwater that have occurred and will continue to occur in the SVGB. The modeling methodology may be adequate to define the APE and to evaluate interference drawdown impacts to existing wells in the area, but it is not sufficiently refined to be useful for evaluating the

Marina-JJ&A-16

potential for water quality impacts to water supplies from proposed MPWSP feedwater pumping within the defined area. In addition, the approach is not useful for informing the analysis of cumulative impacts.

Marina-JJ&A-16

Proposed MPWSP pumping will never be the only stress on the aquifers in the vicinity of the Project. It is the cumulative combination of all the groundwater stresses in the SVGB that will have impacts on the DWR-designated medium-priority Monterey Subbasin and the critically overdrafted 180/400-Foot Aquifer Subbasin. Without consideration of these other stresses, such as seasonal trends, municipal and agricultural pumping, and droughts, the cumulative impact of proposed MPWSP pumping on groundwater levels that will control the migration of degraded groundwater in the Project vicinity cannot be determined accurately. For example, the totality of current stresses might be manageable at the basin level, but the addition of MPWSP pumping could potentially cause the new state of stresses to be unmanageable and to induce migration of seawater or degraded groundwater to new areas. Furthermore, the hydrogeological conceptual model used for the NMGWM is not defined with enough precision to support determining the potential for adverse water quality impacts to groundwater in the City of Marina, especially considering newly available information regarding the heterogeneous and vertically connected nature of the aquifer system. Finally, the 180/400-Foot Subbasin is designated as being in a state of critical overdraft, which means that adverse impacts are occurring to which the project would make a cumulatively considerable contribution unless mitigated or accepted.

Marina-JJ&A-17

2.5.1.2 Modeling Objective 2

The second modeling objective, determine the source area(s) where feedwater for the proposed MPWSP desalination plant would be extracted, examines only one possible scenario and ignores other planned and reasonably foreseeable changes (as described above in Section 2.2). This single scenario is based on current regional groundwater flow patterns, in which the natural, pre-development seaward groundwater flow direction has been reversed due to pumping, which has led to extensive inland seawater intrusion in the SVGB. Current groundwater conditions cause the primary source area for the proposed MPWSP wells to be the subsea portions of area aquifers. However, efforts to control seawater intrusion are based on actions intended to cause inland groundwater levels to increase. If mitigation efforts continue to be successful and inland groundwater levels increase, the source area for the proposed MPWSP wells will be modified concomitantly and will include an increasing amount of water from inland areas. If the natural regional groundwater flow direction is restored, the primary source area for the proposed MPWSP wells will be from the inland areas, not from the subsea portions of the aquifers. Thus, this modeling objective was incompletely addressed.

Marina-JJ&A-18

2.5.1.3 Modeling Objective 3

The third modeling objective, determine if proposed MPWSP pumping would exacerbate seawater intrusion in the SVGB, cannot be adequately evaluated with the NMGWM (see Section 1.2.2 above). The NMGWM does not have the capability to simulate density-dependent subsurface flow and does not include solute transport, which are two of the governing processes for groundwater flow and water-quality impacts in seawater-intruded aquifers. Furthermore, the NMGWM does not sufficiently

Marina-JJ&A-19

characterize the degree of aquifer heterogeneity or the actual distribution of seawater-intruded groundwater. This modeling objective was incompletely addressed.

Marina-JJ&A-19

2.5.2 Model Construction and Revisions

Most of the groundwater modeling analysis reported in Appendix E2 of the Draft EIR/EIS is focused on updating and revising the previous version of the NMGWM,[14] which as noted above appears to have been originally developed as a water-supply model for other purposes. MODFLOW-2000 was utilized in the revised version of the NMGWM used for the Draft EIR/EIS. Among the many modifications and revisions was the inclusion of the Fort Ord Salinas Valley Aquitard (FO-SVA). Appendix E2 states that the FO-SVA and a transition zone west of the FO-SVA were added as new hydraulic conductivity zones to Layer 3 of the NMGWM. These two new zones are shown in map view on Figures 3.4a and 3.4b of the Draft EIR/EIS. One or both of these zones should be identifiable on Figures 3.2b, 3.2c, or 3.2f of the Draft EIR/EIS, which are vertical cross-sections through the NMGWM, but they are not shown.

Marina-JJ&A-20

Appendix E2 of the Draft EIR/EIS states that MODFLOW has limitations for simulating steep vertical gradients, which occur in the MPWSP area and are important for evaluating the potential for groundwater degradation in the City of Marina as a result of the Project. JJ&A is unaware of any inherent inability of MODFLOW to simulate steep vertical gradients. Such difficulties can, however, arise in models that use a quasi-three-dimensional approach[15] (which is not the case for the NMWGM), or models with an insufficient number of model layers. It should be noted that the number of model layers in the NMGWM was not refined.

Marina-JJ&A-21

With these deficiencies in model construction, especially in light of the newly available information regarding the heterogeneous and vertically-connected nature of the aquifer system, the model used for impact evaluation in the Draft EIR/EIS cannot adequately support the evaluation of potential adverse impacts to existing groundwater users in the City of Marina. The potential or probability for adverse impacts cannot be effectively evaluated with the NMGWM in its current form.

Marina-JJ&A-22

2.5.3 Subsurface Seawater Flow and Intrusion

Seawater is denser than fresh water, which imparts a significant downward vertical gradient and driving force for the movement of seawater and brackish groundwater in aquifer systems that are intruded by seawater in shallower levels, such as in the MPWSP area. For the modeling effort described in Appendix E2 of the Draft EIR/EIS, the effects of variable water density were assumed to be negligible. This may be a correct assumption for simulating drawdown and groundwater storage changes due to MPWSP pumping. It is unlikely to be true for evaluating the potential exacerbation of seawater intrusion, especially if the exacerbation is due to vertical flow of seawater and degraded groundwater from shallower to deeper levels of the aquifer system in the MPWSP vicinity.

Marina-JJ&A-23

[14] The previous version of the NMGWM is not discussed in detail in this memorandum. A detailed review of this previous version was conducted by Lawrence Berkeley Laboratory and is reported in Appendix E1 of the Draft EIR/EIS. A report on the development and application of the previous version of the NMGWM was included in Appendix E2 of the April 2015 Draft EIR for the MPWSP (http://www.cpuc.ca.gov/Environment/info/esa/mpwsp/deir_toc.html).

[15] In the quasi-three-dimensional approach, aquitards are not included as individual model layers as a simplifying assumption. This is common in water-supply models.

Vertical migration of seawater-intruded groundwater is known to occur from the 180-Foot Aquifer to the 400-Foot Aquifer.[16] Downward vertical gradients in the MPWSP area are due to existing groundwater pumping and the density difference between seawater and fresh water. Because pumping in the 900-Foot Aquifer to date has not been as widespread or extensive as in the 400-Foot Aquifer, it is not known if significant vertical migration of seawater-intruded groundwater has occurred or will occur to the 900-Foot Aquifer from the 180-Foot or 400-Foot aquifers.

Although there are no well data currently available that indicate seawater intrusion in the 900-Foot Aquifer, the ERT data in Goebel et al. (2017) indicate that in many areas of the Monterey Bay coastline, salt water is present to at least a depth of 920 feet. Proposed MPWSP pumping could redistribute seawater-intruded groundwater in and around the City of Marina in unpredictable ways, due to heterogeneity in the spatial distribution of seawater-intruded groundwater and hydraulic conductivity (as discussed in Section 2.1 above).

Marina-JJ&A-24

Deficiencies in the parameterization of hydraulic conductivity and the lack density-dependent groundwater flow and solute transport prevent the NMGWM from supporting adequate assessment of the potential adverse impacts to existing groundwater users in the City of Marina from MPWSP pumping. Further details with regard to hydraulic conductivity parameterization are discussed below in Section 2.5.4.

2.5.4 Parameterization, Model Calibration, Performance Assessment, and Uncertainty Analysis

Parameterization refers to the manner in which aquifer parameters in a model, particularly hydraulic conductivity, are assigned to individual model cells. The simplest method is the homogenous case, in which the same value of hydraulic conductivity is assigned to all model cells. In recognition of geologic variability and to make parameterization more realistic, models are often divided into parameter zones, in which each zone is assigned a single, different hydraulic conductivity. More sophisticated parameterization methods use statistical approaches to assign spatially variable parameter distributions to model cells. Such methods can be applied to an entire model domain defined as a single zone, or different parameter distributions can be assigned to each of multiple zones within a model domain, in which the zones generally represent different geologic or hydrogeologic units.

Marina-JJ&A-25

The NMGWM was constructed using the zoned approach in model layers 2 through 4, in which single values of aquifer parameters were assigned to individual zones within each layer.[17] In model layers 5 and 6, zones were not used and the spatial distribution of hydraulic conductivity was defined to be variable across each layer, but the method that was used to determine the spatial distribution is not described. The bottom two layers, which include the 900-Foot Aquifer, were assigned single values for each entire layer. As noted above, this type of model construction may be adequate for a "water-supply" model, but it does not support adequate assessment of the potential adverse impacts to existing groundwater users in the City of Marina from MPWSP pumping.

[16] Kennedy/Jenks Consultants, 2004. Hydrostratigraphic analysis of the northern Salinas Valley. Prepared for the Monterey County Water Resources Agency by Kennedy/Jenks Consultants, dated May 14, 2004.
[17] Model layer 1 was used only to simulate the influence of Monterey Bay.

After initial parameter values are assigned to model cells, model performance is typically evaluated using several statistical criteria that compare simulated values to observed values of model variables such as groundwater levels. Parameter values are then updated during model calibration in an effort to improve model performance by minimizing residual differences, i.e., minimizing the differences between simulated and observed values. Detailed procedures for calibrating groundwater flow models can be found in several references.[18] Briefly, recommended procedures include conducting a parameter sensitivity analysis, trial-and-error (manual) adjustment of calibration parameters, automated parameter estimation to improve initial calibration, and conducting an uncertainty analysis.

Marina-JJ&A-25

Performance of the NMGWM was assessed in Appendix E2 of the Draft EIR/EIS, but there is minimal discussion of how or if model performance was improved (i.e., if the model was calibrated), or if such improvements were attempted, after the initial assignment of hydraulic conductivity values to the model cells. Appendix E2 lacks discussions of a model calibration procedure that was conducted after a parameter sensitivity analysis, prior to simulating the forecast scenarios.

Marina-JJ&A-26

A large suite of model runs were conducted to evaluate a variety of slant-well pumping and return-water scenarios. Parameter sensitivities for the NMGWM were calculated for horizontal and vertical hydraulic conductivity values. The uncertainty related to these parameters was evaluated by varying the ratio of horizontal to vertical hydraulic conductivity in additional forecast scenario model runs, to evaluate the impact of different values on the model-calculated cone of depression caused by simulated slant well pumping. Automated parameter estimation and the associated uncertainty analysis were not discussed in Appendix E2, relative to minimizing simulation residuals, prior to conducting forecast scenarios. Data uncertainty, hydrogeological conceptual model uncertainty, and uncertainty related to choice of parameterization methods were also not discussed.[19]

Marina-JJ&A-27

Because the NMGWM model was originally developed for other purposes, our opinion is that the parameterization is too simplified to fully evaluate the potential or probability of adverse impacts to groundwater users in the City of Marina from proposed MPWSP pumping. This opinion is especially relevant in light of the newly available information regarding the heterogeneous, vertically-connected nature of the aquifer system, the presence of significant downward vertical hydraulic gradients, and the

[19] Deficiencies such as these were also noted in: Abrams, 2015. Groundwater Model Review, CPUC Monterey Peninsula Water Supply Project DEIR. Technical Memorandum prepared for the City of Marina by Robert H. Abrams, Consulting Hydrogeologist, dated June 29, 2015.

potential for exacerbated seawater intrusion. In addition, insufficient information is provided regarding the model calibration process to understand the reliability or uncertainty of the analysis.

Marina-JJ&A-28

2.5.5 Superposition Approach

As stated in Appendix E2 of the Draft EIR/EIS, because of known "problems with specified initial water levels and boundary conditions" and the "complex nature of simulating recharge and discharge processes in the Salinas Valley Groundwater Basin," the theory of superposition was used in an attempt to remove the impact of these model deficiencies. A superposition version of the NMGWM was implemented by setting the boundary and initial conditions to fixed groundwater elevations of zero. However, it should be noted that model performance is a function of boundary and initial conditions, as well as aquifer parameters. Changing any of these model components changes the model performance. Because of the manner in which the superposition approach was used in the NMGWM to simulate the model forecast scenarios, the model deficiencies identified by the authors of Appendix E2 remain in the model and thus the true model performance on which the forecast scenarios are based is actually unknown.

The success of superposition modeling in estimating drawdown is dependent on using the correct hydrogeological conceptual model, and performing calibration to the extent needed to support the modeling objectives. As discussed above, the NMGWM was not designed at a scale appropriate to evaluate the potential or probability of adverse water quality impacts to groundwater users in the City of Marina resulting from MPWSP pumping. In addition, the superposition approach cannot be used to evaluate the impact of possible exacerbated seawater intrusion. Furthermore, as noted in Section 2.5.1.1 above, the superposition approach cannot evaluate the cumulative drawdown impacts that are inherent in the highly developed SVGB.

Marina-JJ&A-29

2.5.6 Boundary and Initial Conditions

The NMGWM deficiencies identified by the authors of Appendix E2 of the Draft EIR/EIS and noted above are attributed to the SVIGSM, particularly for errors related to initial and boundary conditions. Errors such as these should have been corrected before the NMGWM was used to evaluate the potential or probability of adverse impacts to groundwater users in the City of Marina from MPWSP pumping. Without correcting these errors, the results of NMGWM forecast scenarios for evaluating the impacts of MPWSP pumping are unreliable and cannot be depended upon to predict future impacts.

Marina-JJ&A-30

As noted above, the MCWRA and the USGS have nearly completed a new basin-wide model, SVIHM (developed with MODFLOW-OWHM), to replace the SVIGSM.

Marina-JJ&A-31

This model has far more capabilities than the outdated SVIGSM.[20] One of these capabilities is the ease with which local-scale "child" models with increased spatial resolution can be developed within the regional-scale basin "parent" model using the local-grid refinement technique (LGR). LGR is a more robust method of applying boundary and initial conditions to child models than the procedure used to apply SVIGSM boundary and initial conditions to the NMGWM. LGR allows the stresses simulated in the child model to feedback to the parent model, which allows dynamic adjustment of the boundary conditions at the boundaries between the parent and child models. Furthermore, MODFLOW-OWHM is designed to use the MODFLOW Seawater Intrusion Package, in addition to being able to interface with solute transport models.

Marina-JJ&A-31

3.0 SUMMARY AND CONCLUSIONS

It is the opinion of JJ&A that the Draft EIR/EIS is incomplete from a technical perspective and that the potential impacts to groundwater users in the City of Marina from the proposed MPWSP have not been adequately evaluated. In addition, the cumulative impacts of the project with existing pumping and reasonably foreseeable changes have not been adequately evaluated, especially in the critically overdrafted 180/400-Foot Aquifer Subbasin, where any contribution to existing adverse impacts would be cumulatively considerable. The technical deficiencies identified herein should be addressed and a revised Draft EIR/EIS prepared before certification by the CPUC and MBNMS. These revisions should be undertaken with consideration of all of the substantive available evidence, appropriate modeling techniques, and reasonably foreseeable future groundwater conditions so that the full suite of potential adverse impacts to groundwater resources and water supplies can be evaluated, including exacerbated seawater intrusion and impacts to the 900-Foot Aquifer.

Re: CalAm Monterey Peninsula Water Supply Project - Marina Coast Water District's Comments on the Draft Environmental Impact Report/ Environmental Impact Statement, Prepared for California Public Utilities Commission and Monterey Bay National Marine Sanctuary, January 2017 (SCH No. 2006101004)

Dear CPUC/MBNMS:

Thank you for the opportunity to comment on the Monterey Peninsula Water Supply Project ("MPWSP" or "project") proposed by the California-American Water Company ("CalAm" or "Applicant") in Application ("A.") 12-04-019 before the California Public Utilities Commission (the "Commission" or the "CPUC") and the associated Draft Environmental Impact Report/Environmental Impact Statement ("DEIR/EIS" or "Draft EIR/EIS") issued by the CPUC as lead agency under the California Environmental Quality Act ("CEQA") and the Monterey Bay National Marine Sanctuary (the "Sanctuary" or the "MBNMS") as the lead agency under the National Environmental Protection Act ("NEPA") on January 13, 2017.

The purpose of this letter is twofold.

First, this letter provides the comments of the Marina Coast Water District ("MCWD") on the background, legal framework, and practical necessity of the proposed MPWSP in relation to the anticipated significant environmental impacts of the project and proposed mitigation. As explained in detail herein, the proposed project is legally infeasible because it is either inconsistent with or would violate numerous federal, state, regional, and

MCWD-1

local laws and regulations, including but not limited to: (1) California laws applicable to groundwater, including the Sustainable Groundwater Management Act and Monterey County Water Resources Agency Act; (2) the Federal and California endangered species acts; (3) the California Coastal Act; (4) the City of Marina's Local Coastal Plans (LCP); and (5) Monterey County Code of Ordinances section 10.72.030(B). Most critically, CalAm has no water rights in the project area and cannot obtain the water rights needed to operate the project.

MCWD-1 cont.

Moreover, the proposed project is massively oversized, especially in light of the approved Pure Water Monterey Groundwater Replenishment Project ("GWR"), which is included as a component of Alternatives 5a and 5b. As explained below, even Alternative 5a (the purportedly environmentally superior/preferred alternative), provides substantially more water than is needed to meet all the project objectives. However, because the DEIR/EIS fails to consider alternatives to the 6.4 MGD desalination plant that would meet most or all of the project objectives and reduce the project's significant impacts, neither the public nor decisionmakers can comment on potentially feasible alternatives to the MPWSP in light of the approved GWR project. By only proposing alternatives to the originally proposed 9.6 MGD desalination plant (which assumed the GWR project would not happen), the DEIR/EIS sets up a strawman alternatives analysis that fails to meet the requirements of CEQA or NEPA as discussed below.

MCWD-2

Second, this letter provides MCWD's comments on the adequacy of the DEIR/EIS under CEQA (Public Resources Code § 21000 et seq.), the CEQA Guidelines (Cal. Code Regs., tit. l4, § 15000 et seq.), NEPA (42 U.S.C. §4321 et seq.) and its implementing regulations (40 CFR Parts 1500-1508). As explained herein, the DEIR/EIS does not meet the minimum standards of adequacy under CEQA or NEPA.

The EIR is "the heart of CEQA." (Guidelines, § 15003, subd. (a); *Laurel Heights Improvement Assn. v. Regents of Univ. of Cal.* (1988) 47 Cal.3d 376, 392 ("*Laurel Heights I*").) It "is an 'environmental "alarm bell" whose purpose it is to alert the public and its responsible officials to environmental changes ***before*** they have reached ecological points of no return.' [Citations.]" (*Laurel Heights I, supra*, 47 Cal.3d at p. 392, emphasis added.) "Because the EIR must be certified or rejected by public officials, it is a document of accountability" that ensures "the public will know the basis on which its responsible officials either approve or reject environmentally significant action." (*Ibid.*) Where, as here, the environmental review document does not fully and accurately inform decision-makers, and the public, of the environmental consequences of proposed actions or independently evaluate potentially feasible alternatives that would reduce the project's environmental impacts, the document does not satisfy the basic goals of CEQA. (See Pub. Resources Code, § 21061 ["The purpose of an environmental impact report is to provide public agencies and the public in general with detailed information about the effect that a proposed project is likely to have on the environment; to list ways in which the significant effects of such a project might be minimized; **and to indicate alternatives to such a project**."], emphasis added.)

MCWD-3

Similar to the requirements for EIRs under CEQA, under NEPA "the purpose of the EIS requirement is to ensure that 'to the fullest extent possible' agency decisionmakers have before them and take into proper account a complete analysis of the project's environmental impact." (*City of Davis v. Coleman* (1975) 521 F.2d 661, 673 [quoting *Calvert Cliffs' Coordinating Committee v. United States Atomic Energy Comm.* (D.C. Cir. 1971) 449 F.2d 1109, 1114].) The backbone of NEPA includes "a broad national commitment to protecting and promoting environmental quality." (*Robertson v. Methow Valley Citizens Council* (1989) 490 U.S. 332, 348 (*"Robertson"*); see 42 U.S.C., § 4331.) As such, NEPA requires an agency to prepare an EIS when it proposes "major federal actions significantly affecting the quality of the environment." (42 U.S.C., § 4332, subd. (C); *Robertson, supra,* 490 U.S. at p. 348.) In doing so, the agency must take a "hard look" at environmental consequences of the proposed action. (*Robertson, supra,* 490 U.S. at p. 349.) In this way, NEPA insures that a federal agency has fully contemplated the environmental effects of its action, and "to insure that the public has sufficient information to challenge the agency." (*Robertson, supra,* 490 U.S. at p. 349.)

As discussed in detail below and in the attached technical comments from Hopkins Groundwater Consultants, Inc. ("HGC Comments" – Exhibit # 1), GeoHydros, LLC ("GeoHydros Comments" – Exhibit # 2), Erler & Kalinowski, Inc. ("EKI Comments") – Exhibit # 3), and Intake Works LLC ("Intake Works Comments" – Exhibit # 4), the DEIR/EIS is replete with serious flaws. The DEIR/EIS does not provide an adequate description of the entire project, the environmental setting, or the project's potential impacts, nor does it consider feasible alternatives that would reduce the project's significant environmental impacts. Instead, the DEIR/EIS provides an incomplete project description, a misleading picture of the environmental setting/baseline, and a misleading and unsupported view of the project's potential impacts that would lead any reader to believe the project's environmental impacts are largely benign.

MCWD-3 cont.

For example, the DEIR/EIS leads readers to incorrectly believe the project is designed to pump only seawater, and that while the project "could" incidentally pump a small amount of groundwater, any incidentally pumped groundwater would come from aquifers that are contaminated by seawater and are incapable of supporting beneficial uses. As explained herein, not only is this picture not supported by substantial evidence, but it conflicts with available information that the DEIR/EIS preparers had in their possession but failed to disclose. As a result, the DEIR/EIS fails to provide the necessary evidence or analysis to support its conclusions that the project's direct, indirect, and cumulative groundwater impacts would be less than significant. Moreover, the CPUC and Sanctuary have failed to disclose critical information required by CEQA and NEPA that would allow the public and public agencies to even comment on many of the DEIR/EIS's assumptions, analyses, and conclusions. Therefore, the DEIR/EIS does not meet public disclosure requirements and it does not act as an environmental alarm bell as required by CEQA or take the "hard look"

required by NEPA. Consequently, the CPUC and MBNMS will need to prepare and recirculate a revised DEIR/EIS before making any decisions to approve or deny the MPWSP.

In addition, the DEIR/EIS fails to consider a reasonable range of alternatives that could meet most of the project objectives. Instead, the DEIR/EIS only considers alternatives to CalAm's originally proposed 9.6 MGD desalination plant, which as explained below is massively oversized, especially following the approval of the GWR project and based on a fair assessment of CalAm's own reported supply and demand data. Importantly, there are at least several potentially feasible alternatives that could meet most of the project objectives with the implementation of the approved GWR project that were not considered in the DEIR/EIS. That said, MCWD notes that it cannot support a reduced-sized desalination plant (with GWR[1]) that pumps water from the Marina Subarea[2] of the Salinas Valley Groundwater Basin ("SVGB") absent adequate assurance based on sound science and the most current available data that the Marina Subarea and MCWD's existing vested rights to extract and use SVGB water for the current and future needs of its own service area, will not be harmed by the project. As explained below, the DEIR/EIS falls far short of providing these assurances. MCWD-3 cont.

MCWD's comments provided herein are informed by its in-house and outside experts as well as its understanding of the obligations of: (a) the Commission to act in protection of the public interest in the exercise of its unique and broad authority to regulate privately-owned public utilities in California; and (b) the Sanctuary to protect the coastal ecosystem and cultural resources of the Monterey Bay National Marine Sanctuary. We note that the Commission is required by law, as a fundamental component of its public interest balancing and project approval process, to consider fully the proposed project's "influence on the environment." (Public Utilities Code § 1002(a)(4).) Given these mandates, MCWD does not understand why the CPUC or Sanctuary are considering the originally proposed 9.6 MGD desalination plant in the DEIR/EIS in light of the CalAm's commitment in the MPWSP Settlement Agreement, dated July 31, 2013, and the approval of the GWR project.

---

[1] / MCWD has supported and continues to support GWR Project proposed by the Monterey Regional Water Pollution Control Agency ("MRWPCA") and approved in October 2015.

[2] / The "Marina Subarea" is used in these comments to refer to the combination of (1) that portion of the 180/400 Foot Aquifer Subbasin of the SVGB located south of the Salinas River plus (2) the northwest portion of the Monterey Subbasin that would be impacted by the proposed slant well pumping on the CEMEX property. While the Marina Subarea is not a formally DWR-recognized subarea, it contains highly complex hydrogeological conditions that are very different from the portion of the 180/400 Foot Aquifer Subbasin north of the Salinas River as explained herein. The Marina Subarea is the coastal subarea of the overdrafted SVGB and is the area that would be directly impacted by the proposed project feed water pumping of 27,000 AFY. The Monterey County Water Resources Agency has defined the "Pressure Area" as a combination of the DWR-designated 180/400 Foot Aquifer Subbasin and the former Seaside Area and Corral De Tierra Subbasins (now the new Seaside and Monterey Subbasins). The Pressure Area is not a formally DWR-recognized subarea either, but that term is used throughout the DEIR/EIS as noted below. MCWD-4

I. BACKGROUND, LEGAL FRAMEWORK AND NECESSITY OF MPWSP.

The CPUC and MBNMS are familiar with the historical background of the water supply shortage that has long plagued CalAm's Monterey district, as well as prolonged efforts of numerous stakeholders to solve the problem. (*See, e.g.*, D.10-12-016, pp. 18-30, and orders of the State Water Resources Control Board and Assembly Bill ("AB") 1182 (Stats. 1998, ch. 797) cited therein.) The project, in essence, is intended to cure the significant, ongoing environmental harm to the Carmel River basin that has resulted from CalAm's illegal diversions of Carmel River water. This background is further complicated by the California Legislature's enactment of the landmark Sustainable Groundwater Management Act ("SGMA"), effective January 1, 2015, which effectively vests the protection of groundwater resources in local authorities under their existing and new SGMA police powers. Potential climate-change-related sea level rise must also inform the Commission's and MBNMS's environmental review and ultimate decisions. Here, the Commission must balance its obligation to ensure that CalAm's ratepayers continue to receive convenient and necessary water service against its obligation to comply with CEQA's mandates, carry out the Legislature's mandate to it in AB 1182 to resolve the physical problems presented by CalAm's illegal diversions of Carmel River water, and address the State Water Resources Control Board's orders reducing CalAm's sources of Carmel River Basin water (as the Commission previously acknowledged in D.10-12-016) – all within the sustainable limits of the local groundwater supply, under the SGMA. On the other hand, the MBNMS must evaluate whether it should authorize a prohibited use (16 U.S.C.A. § 1436) under the Sanctuary's Management Plan (http://montereybay.noaa.gov/intro/mp/fmp/02coastal_dev_mp.pdf), which provides that MBNMS should consider public versus private ownership among other factors, and its Guidelines for Desalination Plants in the Monterey Bay National Marine Sanctuary http://montereybay.noaa.gov/resourcepro/resmanissues/pdf/050610desal.pdf, which provide that desalination plants should only be approved when other economically and environmentally preferable alternative water sources are infeasible and should be sized not to induce growth within the coastal areas. As discussed below, the project—as proposed—is not consistent with the obligations of the CPUC or the Sanctuary.

MCWD-5

MCWD-6

Formed by a citizens group in 1958, MCWD is a County Water District organized and operating under section 3000 of the California Water Code servicing residents, businesses and organizations throughout Marina and the Ord Community. The District supplies water to over 8,250 water connections, maintains and operates 105 miles of pipeline, 8 reservoirs, 5 booster pump stations and 8 wells. It is also responsible for maintaining the service area's sewer collection system, which includes 20 lift stations and 110 miles of pipeline. MCWD, as the sole provider of municipal water service for over 33,000 residents in the Marina/Ord community, has a vested interest in the integrity and thoroughness of the Commission's environmental review for the proposed MPWSP in order to protect its own ratepayers. The need for careful scrutiny of the proposed project, alternatives and

MCWD-7

cumulative impacts is particularly grave in this situation in which the Applicant proposes that the Commission approve a project designed to offset CalAm's illegal diversions from the Carmel River by pumping groundwater from the 180/400 Foot Aquifer Subbasin, which is designated by the State of California as a Critically Overdrafted Basin, and by adversely impacting groundwater conditions within the Marina Subbasin, which is MCWD's groundwater source. Of note, the entire SVGB, including the aquifers underling the Marina Subarea, lie outside of CalAm's public utility service area on the Monterey Peninsula. While CalAm's public utility service area would receive the benefit of convenient and necessary water service to be provided by the MPWSP, its source of water would be from the Marina Subarea, which since MCWD's founding is the only source of water supplies it has used to serve its ratepayers.

MCWD-7 cont.

More than six years ago, the Applicant, MCWD and others sought and received the Commission's approval for the Regional Desalination Project, a project that was similar in many practical respects to the proposed project. (*See* D.10-12-016.) However, CalAm determined that it would not pursue the Regional Desalination Project, and the Commission permitted CalAm to change course and pursue the MPWSP instead. (D.12-07-008.) [3] The Commission should bear in mind in its environmental review process that the project it approved in 2010 was also *different* from the proposed MPWSP in several key respects related to environmental impacts:

MCWD-8

- *Water rights* (addressed for the MPWSP in DEIR/EIS Chapter 2) for withdrawal of any groundwater component of source water were present in sufficient quantity to ensure project feasibility for the Regional Desalination Project (subject to test well results, *see, e.g.*, D.10-12-016 at Findings of Fact 83, 163-164, 169-170 and at pp. 84-85 of Appendix B thereto [CEQA Findings of Fact and Statement of Overriding Considerations]), due to MCWD's participation in the project. MCWD's vested rights to pump groundwater from the SVGB (discussed in MCWD's comments on DEIR/EIS Chapter 2, below), as well as MCWD's ability to offset the amount of project source water that was SVGB groundwater by a pumping offset (i.e., a commensurate reduction in its own lawful pumping from the basin) was then assumed to ensure that the project would not adversely affect the basin or impair the existing

MCWD-9

[3] / Section 5.2 of the DEIR/EIS states without an explanation that the Regional Desalination Project was not evaluated in detail as an alternative because it is "incapable of meeting most of the basic project objectives or purpose and need as currently defined," (DEIR/EIS, p. 5.2-1 and 5.2-2.) MCWD disagrees with this unsupported conclusion as discussed in MCWD's comments below. Indeed, a smaller Regional Desalination Project configuration using horizontal directional drilling would appear to meet the project objectives and purpose and need. Moreover, it is quite feasible today with Marina Coast's participation, provided that the project would also remain physically feasible within the confines of the SGMA and the greatly-expanded availability of data concerning the state of the aquifers in the Marina Subarea, which data was not used in the DEIR/EIS.

MCWD-10

rights of other users of SVGB groundwater. (See CalAm Coastal Water Project Final EIR, p. 6.2-16 ("The Regional desalination plant would be operated such that … the plant would deliver desalinated water to the MCWD service area within the SVGB in an amount equal to the volume of SVGB-groundwater…."].) The pumping offset by MCWD, a vested holder of water rights in the SVGB, also helped to ensure that the Monterey County Water Resources Agency Act's ("Agency Act") prohibition of the exportation of SVGB groundwater outside the basin would not be violated. (See *ibid.* ["that portion of the potable product water that originated as groundwater rather than seawater would be used on lands overlying the SVGB …].) As discussed below, the one-to-one return ratio was assumed prior to any test well results and new groundwater data indicating that a greater ratio would be needed to offset all direct, indirect, and cumulative impacts to the Marina Subarea from the proposed slant well pumping if vertical or slant wells (as opposed to horizontal wells) were used as the intake technology.

MCWD-9 cont.

- *Basin return and the non-export* groundwater component of source water, and thus compliance with the non-exportation provision of the Agency Act (addressed for the MPWSP in DEIR/EIS § 2.5.1 and 2.6), was assured by providing for MCWD's allocation of product water from the desalination plant in at least an amount equal to the amount of groundwater withdrawn from the basin as part of the project's source water. (See CalAm Coastal Water Project Final EIR, p. 6.2-16.) As discussed below, more recent groundwater data indicates that a greater return water ratio would likely be required if vertical or slant wells (as opposed to horizontal wells) were used as the intake technology.

MCWD-11

- *Vertical wells* (not evaluated in DEIR/EIS, see Appendix I1, at p. I1-4) and possible slant wells, which involve unproven technology, were to be utilized for testing and considered for intake rather than slant wells only. Indeed, vertical wells were the project proponents' preferred option for source water wells. Thus, the reliability of modeling and operation projections, including the assessment of potential environmental impacts, would generally be more certain and readily ascertainable for the more commonly-used vertical well scenarios, as opposed to the greater difficulty of arriving at reliable modeling and operation projections for comparatively new and largely untested slant well technology.

MCWD-12

- *Well testing and comprehensive groundwater modeling* (addressed for the MPWSP in DEIR/EIS Chapters 2 and 4.4) for the Regional Desalination Project was to commence after Commission approval of the project (D.10-12-016 at Findings of Fact 83, 163-164, 169-170 and at pp. 84-85 of Appendix B thereto) with the participation of public agencies, including MCWD and the Monterey County Water Resources Agency ("MCWRA"), and provided for further Commission action in the event that test results did not confirm pre-approval assumptions. This approach ensured that the testing process would be transparent and that there would be flexibility in the future direction of the project, should test results not bear out the projections relied upon for environmental review and approval. Here, the test well process for the MPWSP is

MCWD-13

proceeding *prior* to Commission approval and under a California Coastal Commission process that MCWD contends is flawed and inadequately informed, which the District is contesting elsewhere.[4] MCWD is concerned that transparency and flexibility are being frustrated rather than fostered due to the failure to utilize complete, current and accurate data in the DEIR/EIS and its modeling, as discussed below in detail. For the MPWSP, the test well results were not used to model the project's groundwater impacts disclosed in the DEIR/EIS. (*See* DEIR/EIS, p. 2-35.) As discussed below, the DEIR/EIS abandoned any attempt to model the project's potential impacts in favor of a simplified superposition model that does not evaluate the amount of groundwater that will be pumped from the Marina Subarea or evaluate the project's cumulative impacts. Moreover, there will be no further opportunity for public review and comment on testing and groundwater modeling or any requirement for disclosure of testing and groundwater modeling results or for changes in project configuration following project approval by the Commission. Nor will there be any way to promptly assess whether the project is causing greater impacts than evaluated or anticipated in the DEIR/EIS. Thus, any further MPWSP evaluation, testing, and modeling for groundwater impacts would proceed in a regulatory vacuum and would be shielded from full public scrutiny in violation of CEQA and the Public Utilities Code.

MCWD-13 cont.

Finally, perhaps the most important difference in circumstances between the MPWSP and the Regional Desalination Project is the recent enactment of the SGMA. MCWD will discuss the importance of this change in the legal framework as it bears on environmental review in greater detail below.

MCWD-14

MCWD does not dispute that additional water supplies are needed to serve the Monterey Peninsula in the face of the mandatory reductions imposed by the State Water Board's orders WR 95-10 and WR 2009-0060. However, even the MPWSP's reduced size alternatives (Alternatives 5a and 5b) provide vastly more water than required to meet the nine primary project objective (Executive Summary, p. ES-3). As explained below, MCWD has analyzed CalAm's 2022 water supply sources and demand in accordance with the nine primary project objectives. Based on this analysis, an additional 1,305 acre-feet per year ("AFY") would provide CalAm with a Reserve Margin of 10%. There are one or more Alternate Water Sources that could be implemented to meet this demand without the high cost, high environmental impacts, high energy use, and high greenhouse gas emissions of the proposed MPWSP.

MCWD-15

[4] / Attached as Exhibit "5" are the Parties' briefs on the merits in *MCWD v. California Coastal Commission*, Santa Cruz Superior Court Case No. CV180839. As explained in the attached briefs the Coastal Commission failed to consider alternatives to slant wells in approving the MPWSP test slant well.

In light of this reality, MCWD cautions the Commission that in considering whether the currently proposed MPWSP is the project that best serves the public convenience and necessity, and in conducting its environmental review process for the MPWSP **and feasible alternatives** as CEQA and the Public Utilities Code demand, the Commission and Sanctuary take care not to view the Applicant's proposed project through so narrow a prism as to abnegate its fundamental public interest responsibilities. The Commission is required to weigh the environmental impact of the proposed project as a "relevant factor" on equal footing with other "relevant factors" affecting its public convenience and necessity determination. (*Northern California Power Agency v. Public Utilities Com.* (1971) 5 Cal.3d 370.)

MCWD-15 cont.

II. PROCEDURAL MATTERS

A. Independent Judgment

As explained in the Introduction to the DEIR/EIS, before considering an approval of the MPWSP or its alternatives, the Commission must "certify" the final EIR. According to the CEQA Guidelines, "certification" consists of three separate steps. The Commission must conclude, first, that the document "has been completed in compliance with CEQA"; second, that the Commission has reviewed and considered the information within the EIR prior to approving the project; and third, that "the final EIR *reflects the [Commission]'s independent judgment and analysis*." (CEQA Guidelines, § 15090, subd. (a); see also Pub. Resources Code, § 21082.1, subd. (c)(3) [lead agency must make finding that the document reflects the agency's independent judgment].) While the courts will uphold an EIR that is not prepared directly by the lead agency if substantial evidence demonstrates that the lead agency has independently reviewed the EIR and exercised its independent judgment over the document, the courts will not permit lead agencies merely to "rubber stamp" analyses prepared by the project applicant or others without independently reviewing the analysis and the evidence in support of the analysis. (See *People v. County of Kern* (1976) 62 Cal.App.3d 761, 775.)

MCWD-16

Here, it does not appear the CPUC exercised its independent judgment over the groundwater modeling that provided the basis for the CPUC's groundwater consultant's superposition modeling relied on in the DEIR/EIS to support its conclusion regarding the MPWSP's potential groundwater impacts. Based on the Public Records Act and data request responses we have received to date,[5] the HWG, including Geoscience, were intimately involved in the decisions regarding the modeling and selection of alternatives for consideration in the DEIR/EIS. This involvement appears to have significantly prejudiced the DEIR/EIS's analysis and conclusions of the MWPSP's potential groundwater impacts and the selection of potentially feasible alternatives that were evaluated in the DEIR/EIS. As

[5] / Attached as Exhibit 6 is a list of all the Public Records Act and data requests responses we have received to date, together with full copies on electronic media of all the documents produced. MCWD understands that additional documents may be produced following the comment deadline.

explained below and in the attached GeoHydros Comments, the DEIR/EIS modeling is unreliable, contrived, and does not evaluate the project's potential groundwater impacts in any meaningful way. Similarly, the DEIR/EIS' rejection of alternative intake technologies for consideration in the DEIR/EIS is not supported by the evidence, as explained below and in the attached Intake Works Comments, and appears to have been improperly influenced (if not decided) by the HWG.

As the CPUC is aware the four members of the HWG are paid by and represent parties with interests in the approval of the proposed project. Mr. Feeney and Mr. Durbin represent agricultural interests (Salinas Valley Water Coalition and Monterey County Farm Bureau). Their clients have an interest in the success of the project because they are likely to receive substantial increases in water supplies under several variations of the MPWSP. Mr. Leffler is CalAm's representative.

Most importantly, while Geoscience (Mr. Williams) was initially the designated and served as the CPUC representative on the HWG, during that time they also has a contract with CalAm and RBF Consulting, Inc. ("RBF" nka Michael Baker International) for the design, as well as supervision of construction and monitoring of the project's slant test well.[6] As the CPUC is aware, it was discovered after the 2015 release of the original Draft EIR for the MPWSP that Mr. Williams owns patents for slant well technology that may be used for the project. (See http://www.montereyherald.com/environment-and-nature/20150620/key-desal-project-hydrologists-slant-well-patents-questioned; see also July 14, 2015 ALJ Ruling and July 15, 2015 errata, A.12-04-019.) Regardless of whether Mr. Williams will receive any direct financial benefits from the project (which should unquestionably be disclosed) over and above the money he receives from CalAm through his consulting contracts, this creates another potential conflict of interest. Thus, while all four members of the HWG are experienced hydrologists, their clients' interests (and possibly their personal interests) may color their analysis. The Commission subsequently indicated that it would treat the work of Mr. Williams and his firm, Geoscience Support Services, Inc., as having been performed on behalf of CalAm rather than the Commission. Nonetheless, Mr. Williams and his firm remained involved in preparation of the 2017 DEIR/EIS, including groundwater modeling and underlying assumptions. (See, e.g., DEIR/EIS Executive Summary, Environmental Setting at sections 4.2 and 4.4, Appendix C3.) Despite the Commission's statements, Mr. Williams' dual advisory-advocacy role in the same proceeding raises an inference that his

MCWD-16 cont.

[6] / Mr. Williams also testified on behalf of CalAm in Santa Cruz Superior Court proceedings relating to the potential impacts of project's slant test well. (See excerpts of testimony attached as Exhibit "7" from *MCWD v. California Coastal Commission*, Santa Cruz Superior Court Case No. Case No. CV180839.) During his testimony, Mr. Williams testified that he was 100 percent confident that pumping had stabilized in the slant test well after three to five days. (*Ibid.*, p. 202-203.) Later monitoring modeling has shown the test well still has not stabilized, over a year after long term-pumping commenced. Martin Feeney also provided several declarations on CalAm's behalf in those proceedings.

views and opinions may be accorded undue weight in the Commission's environmental review and decision-making processes. Therefore, to ensure the objectivity of the MPWSP's modeling and the adequacy of the EIR, and to allow the Commission to exercise the required "independent judgment," MCWD requests the Commission obtain a peer review from a recognized independent hydrologist that does not represent clients with interests in the success of the MPWSP or alternatives.

Moreover, if Mr. Williams has a financial interest in the project, has served as a consultant for both the Commission as the adjudicatory decision-maker and CalAm as the primary advocacy project proponent, and has served as a leading participant in generating the input of the HWG in both capacities, the question arises whether such status renders the Commission's work on the groundwater and modeling aspects of the DEIR/EIS and the input of the HWG subject to an impermissible conflict of interest. (See *Morongo Band of Mission Indians v. California State Water Resources Control Bd.* (2009) 45 Cal.4th 731.) The Commission and the DEIR/EIS fail adequately to investigate, explore, address and resolve such conflict of interest issues.

MCWD-16 cont.

In conclusion, given the importance of the hydrogeological modeling on the project's overall feasibility and the DEIR/EIS's reliance on the modeling to evaluate that project's potential impacts to the over-drafted Marina subarea (discussed in Part III below) and alternatives, MCWD requests the Commission, at minimum, have Lawrence Berkeley independently review the hydrostratigraphy, assumptions, and calibration of Geoscience/HWG's updated modeling that was used in the DEIR/EIS and Hydrofocus's superposition model as they did for the modeling used in the original Draft EIR. An independent expert should also be identified to evaluate potentially feasible alternatives.

B. Unlawful "Parallel Track" used for examining the environmental impacts

MCWD believes the Commission is utilizing an unlawful "parallel track" methodology by examining the environmental impacts of the project in a CEQA process while examining other public interest factors under the closer scrutiny of a separate Certificate of Public Convenience and Necessity ("CPCN") hearing process so as to deprive the parties of an evidentiary hearing on some, but not all, key relevant factors bearing on the public interest. The Commission's approach in this instance has operated to impair, rather than foster, the public disclosure and transparency that is required under CEQA, as well as the fair balancing of all relevant factors, including "influence on the environment," that is required by the Public Utilities Code. (*Northern California Power Agency v. Public Utilities Com.* (1971) 5 Cal.3d 370; Public Utilities Code § 1002(a)(4).)

MCWD-17

III. THE DEIR/EIS IS FUNDAMENTALLY FLAWED AND MUST BE RECIRCULATED

MCWD provides following, specific comments on the DEIR/EIS. These comments are based on MCWD's review of the DEIR/EIS, documents contained in the CPUC's files,

MCWD-18

other public records, MCWD's independent investigation of this matter, its expertise in developing projects like the MPWSP proposed here, and the attached HGC Comments (Exhibit # 1), GeoHydros Comments (Exhibit # 2), EKI Comments (Exhibit # 3), and Intake Works Comments (Exhibit # 4). Based on its fifty-plus years of experience in providing water service in this area, as well as its prior role in the abandoned Regional Desalination Project, MCWD is uniquely qualified to comment on the DEIR/EIS. (See *Consolidated Irrigation District v. City of Selma* (2012) 204 Cal.App.4th 187, 206 [Water District's operations provided it with expertise in groundwater for purposes of commenting on a project's potential environmental impacts on water supplies].) The CPUC must respond separately to each environmental issue raised in this letter and those raised in HGC, GeoHydros, EKI, and Intake Works Comments on the adequacy of the DEIR/EIS and its Appendices (specifically groundwater modeling) in the Final EIR/EIS responses to comments (CEQA Guidelines, § 15088) as must the Sanctuary under NEPA.

MCWD-18 cont.

A. THE DEIR/EIS'S DISCUSSION OF WATER DEMAND, SUPPLIES, AND WATER RIGHTS IS INADEQUATE AND MISLEADS THE PUBLIC.

DWR Bulletin 118, which was issued in 1980, officially divided up the SVGB into eight different subbasins. Pursuant to SGMA, DWR conducted a Basin Boundary Modification process, which finalized new SVGB Subbasin boundaries in October 2016. Those basin boundaries were incorporated into the Bulletin 118 Interim Update 2016. The SVGB Subbasins are now designated as follows: 180/400 Foot Aquifer, East Side Aquifer, Forebay Aquifer, Upper Valley Aquifer, Paso Robles (60% located in San Luis Obispo County), Seaside, Langley, and Monterey. It is generally agreed that subbasin boundaries were drawn using a fat Crayola and not a sharp pointed pen. These are the official subbasins within the SVGB. All eight subbasins are classified by DWR as being either a high- or medium-priority subbasin subject to the Sustainable Groundwater Management Act discussed below. In January 2016, DWR classified the 180/400 Foot Aquifer Subbasin and the Paso Robles Subbasin as Critically Overdrafted Basins, which means that each of the two subbasin must adopt a SGMA-compliant groundwater sustainability plan or coordinated plans by January 31, 2020, or be subject to a State Water Resources Control Board enforcement intervention. All other subbasins have until January 31, 2022. The basin boundary modification resulted in the size of the Seaside Subbasin being reduced to only include lands within the adjudicated Seaside Groundwater Basin, which is managed by the court-supervised Seaside Basin Watermaster and is essentially exempt from SGMA. CalAm is a member of the Watermaster Board. The former northern portion of the Seaside Area Subbasin and the balance of the former Corral de Tierra Subbasin were merged by DWR into the new Monterey Subbasin. The relationship between MCWD's service areas and the 180/400 Foot Aquifer Subbasin, Monterey Subbasin, and Seaside Subbasin is shown on Exhibit 8 [Map of Service area in relationship to the 180/400, Monterey, and Seaside Subbasins]. (See also EKI Comments, Figure 1.)

MCWD-19

The Monterey County Water Resources Agency ("MCWRA") has combined the 180/400 Foot Aquifer Subbasin and the former Seaside Area and Corral De Tierra Subbasins into the so-called "Pressure Subarea." (See e.g., Brown and Caldwell's "State of the Salinas

River Groundwater Basin", dated January 16, 2015, which is included in the DEIR/EIS's list of references.) The CPUC and the public should be aware that reports or studies referring to the Pressure Subarea include substantially more land than within just the Marina Subarea.

CalAm had Geoscience prepare a North Marina Groundwater Model; the geographic area covered by the model is shown on Figure 15 in DEIR/EIS Appendix E2. As indicated in Footnote 1, for purposes of these comments, we have identified the Marina Subarea as the area that would be impacted by the proposed MPWSP slant well pumping.

MCWD-19 cont.

1. Major Failure of DEIR/EIS to Perform an Integrated Total Water System Analysis of CalAm's System With and Without the Proposed MPWSP.

The DEIR/EIS blanketly accepts without independent review or any in-depth analysis CalAm's representations each of CalAm's existing and proposed non-MPWSP water supply sources and fails to examine how each of those water supply sources are currently operated to meet CalAm's existing actual demands (i.e., CalAm's 2016 baseline operations) versus how each of those water supply sources could be operated and optimized to meet the nine primary project objectives.

Operating a water utility has similarities to operating an electric utility in that both have to have water supply or electric generation resources available to meet base, peak, and intermediate demands and both have transmission, sub-transmission, and distribution pipelines or electric lines to deliver the water or electricity from the various water supply or electric generation resources to the ultimate customer. A "base" resource is available, around the clock, every day. A "peaking" resource is available during periods of maximum water or electric usage, which will vary by climatic region, such as afternoons on hot summer days in Sacramento. An "immediate" resource is any remaining resource, which is available above base but below peaking.

MCWD-20

Lacking any adequate explanation in the DEIR/EIS, MCWD would surmise that today CalAm uses its Carmel River water as its base resource and peaks with its withdrawals from the Seaside Groundwater Basin (native groundwater plus ASR recoveries). That is a very simple resource mix compared to what will occur in 2022, especially without the MPWSP being constructed.

a. ***CalAm's Monterey District Reserve Margin Requirements.***

Electric utilities are required to have existing electricity generation capacity reserves that serve as a buffer for unplanned demand fluctuations due to sudden increases in demand or power plant emergency outages and to analyze the probabilities that a system emergency may occur. A reserve margin is a measure of the amount of electricity imports and in-state generation capacity available over average peak demand conditions. Reserve margins are measured at two levels: planning (month-ahead to 10 years) and operating (real-time).

MCWD-21

Except for CalAm Primary Project Objective #4 for this DEIR/EIS, which states, "Develop a reliable water supply for the CalAm's Monterey District service area, accounting for the peak month demand of existing customers," the DEIR/EIS has no discussion of any reserve margin requirements for CalAm's Monterey District. Objective #4 is only a type of planning or month-ahead reserve margin requirement. MCWD would note that the margin requirement is only to meet the peak month demand of existing customers, not of projected customers in 2022. For purposes of these comments, MCWD is assuming a Monterey District reserve margin requirement of ten percent (10%). MCWD-21 cont.

b. ***By 2022, CalAm Will Have a Completely Different Water Supply Mix Even Without the MPWSP.***

The DEIR/EIS fails to consider in its analysis that by 2022, especially without the MPWSP, CalAm will have dramatically shifted from being a Carmel River surface water-centric water system to a Seaside Groundwater Basin-centric system.

Pursuant to SWRCB Order WR 2016-0016, Cal Am is authorized to divert up to 8,310 AFY from the Carmel River through December 31, 2021. That represents 89.5% of its 2016 actual demand of 9,285 AF. Come January 1, 2022, CalAm's legal Carmel River diversions drops to 3,376 AFY or only 36.4% of CalAm's actual 2016 water demand. However, once the GWR Project is operational, the Adjudicated Seaside Basin becomes a comingled pool of native groundwater, Carmel River ASR water, and GWR advanced treated water through both direct injection and in-lieu groundwater recharge. Then 63.6% of CalAm's 2016 demand would be met with Seaside Basin water resources. In-lieu groundwater recharge occurs when advanced treated or recycled water is consumptively used within the Adjudicated Seaside Basin instead of potable water thereby preserving native Seaside Basin groundwater. MCWD-22

This substantial increase in the amount of imported water into the Seaside Basin could significantly improve the groundwater conditions within the Basin thereby allowing for additional pumping by CalAm. The DEIR/EIS does not provided any hydrogeological analysis of the synergistic benefits of all of this out-of-Seaside-Basin water being imported into the Basin.

The DEIR/EIS does not discuss how CalAm could operate its then-available water supply sources in 2022. Instead, the DEIR/EIS basically assumes that CalAm could not meet the DEIR/EIS projected manipulated demand (and not CalAm's actual 2016 demand, which is Primary Project Objective #4) without constructing at least a 6.4 MGD MPWSP. That assumption is false.

CalAm asserts that a minimum 6.4 MGD desalination plant with source water intakes on the CEMEX property coupled with the GWR Project are vitally needed to address the SWRCB's Cease and Desist Order curtailing CalAm's illegal diversions on the Carmel River. While the SWRCB in its Order WR 2016-0016 addressed in part the interrelationship of the

elements of CalAm's Total Water Portfolio, no significant total-water-portfolio-type analysis is contained in the DEIR/EIS. It is essential that the DEIR/EIS closely examine CalAm's existing and proposed elements in its Total Water Portfolio, including how those existing and proposed source elements would interact and be integrated by 2022, and their relationship to meeting the nine Primary Project Objectives.

CalAm has not produced for public review a computer model of its existing water supply sources and demands as they vary by water year type and by month and how it will change come 2022. It is essential that the DEIR/EIS provide such a computer model to allow the CPUC, the public and other decisionmakers to meaningfully evaluate CalAm's water needs and potential alternatives to the MPWSP.

While the Carmel River Legal Limit of 3,376 AFY has been determined by the SWRCB in Order 95-10 and confirmed in Order WR 2016-0016, the DEIR/EIS without significant analysis blanketly accepts CalAm's claims as to the water available from each of CalAm's existing and future non-MPWSP water sources and fails to examine how CalAm's non-MPWSP water sources should be synergistically integrated to maximize their ability to meet the nine Primary Project Objectives. Again, come 2022, CalAm's water system will make a dramatic shift to a Seaside Basin groundwater dependent system, which includes native Seaside Basin groundwater, injected GWR water, injected Carmel River ASR water, and as CalAm proposes an additional 2,100 AFY of injected MPWSP desalinated water. Yet the DEIR/EIS has failed to disclose or perform a month-by-month analysis of how each of CalAm's water supply sources can be utilized in 2022 to optimize the use of each water source both with and without the MPWSP. As discussed below, such an analysis would show that only an additional 1,305 AFY of new water supplies are needed to meet all nine Primary Project Objectives and that the MPWSP is not needed to meet those objectives.

MCWD-22 cont.

i. CalAm's Actual 2016 Demand of 9,285 AF.

Table 2-2, Existing Demand 2006-2015, in Section 2.3.1, page 2-10, shows a 10-year average (2006-2015) of 12,351 AF. Table 2-2, Other Demand Assumptions, page 2-12, shows an "Existing Service Area Demand" of 12,270 AF. The actual 2016 existing demand was 9,285 AF[7], or only 75.7% of 12,270 AF. However, system demand has consistently decreased over the past decade. (See https://www.watersupplyproject.org/system-delivery.) The decrease in demand is apparently due to ratepayer conservation, as well as improvements in system losses due to leaks. (See SWRCB Order 2016-0016, p. 2.) These demand reductions are likely to be permanent, as discussed below.

MCWD-23

The DEIR/EIS' use of 12,270 AFY in its analysis when 9,285 AFY is the actual 2016 demand number is an example of the DEIR/EIS padding the numbers by 2,985 AFY, or 32% more, to justify a larger capacity desalination plant.

[7] / http://www.watersupplyproject.org/system-delivery.

ii. CalAm's Representations as to Its Water Supply.

In Order WR 2016-0016, the SWRCB amended in part Order 2009-0060, the Carmel River Cease and Desist Order by granting CalAm a time extension until December 31, 2021, to terminate all unlawful diversions from the Carmel River. On and after January 1, 2022, CalAm may only divert 3,376 AFY under Order WR 2016-0016 although CalAm and MPWMD jointly will continue to have the right pursuant to SWRCB-issued water right permits 20808A and 20808C to divert up to an additional 5,326 AFY of excess flows for ASR Phases 1 and 2 with an estimated average annual yield of 1,920 AFY.

In Table 2-4, CALAM Monterey District Water Supplies with Proposed MPWSP, page 2-18, CalAm is said to have the following water supply available during the period when CalAm is replenishing/repaying the Seaside Groundwater Basin with a 6.4 MGD Desalination and the GWR Project:

CalAm's Claimed NO MPWSP Water Sources When GWR becomes operational and on January 1, 2022	**Acre Feet per Year**
Carmel River Legal Limit	3,376
Sand City Desalination Plant	94
Aquifer Storage & Recover (ASR) Project Phases 1 and 2	1,300
Groundwater Replenishment (GWR) Project	3,500
Seaside Basin Adjudicated Groundwater Supply	774
Total No MPWSP Water Supply	9,044

MCWD-24

With an actual 2016 existing demand of 9,285 AF, the above 9,044 AF total is only 241 AF or 2.6% short without considering any additional available water supply from Sand City's 300 AFY desalination plant, ASR, GWR, and the Seaside Basin. Such additional available water supply sources are discussed below.

Note that in Section 5.4.2.1, the DEIR/EIS claims that the "total long-term supply under the No Project Alternative would be 6,380 afy," which excludes all GWR water. If the 3,700 AFY GWR water is added to the 6,380 AFY, the total becomes 10,080 AFY.

iii. Sections 2.2.2.2 and 2.2.4, Seaside Groundwater Basin.

MCWD-25

A substantial majority of the lands in the Seaside Basin are within MCWD's Ord Community service area, not within CalAm's service area. MCWD provides potable water and will soon be providing recycled water to the Ord Community within the Seaside Basin. CalAm has major production wells within the Seaside Basin but most of CalAm's Monterey

District customers are outside of the Seaside Basin so CalAm is a net exporter of native Seaside Basin groundwater. The DEIR/EIS ignores these facts. The fastest growing area within Monterey County is within MCWD's Ord Community service area as part of the economic redevelopment of the former Fort Ord, which places even more emphasis on MCWD's need to protect its potable water supply.

As explained above, come 2022, CalAm's water supply portfolio will shift from a Carmel River-centric system to a Seaside Basin-centric system. Once the GWR Project is operational, the Adjudicated Seaside Basin becomes a comingled pool of native groundwater, Carmel River ASR water, and GWR advanced treated water through both direct injection and in-lieu groundwater recharge. This substantial increase in the amount of imported water into the Basin could significantly improve the groundwater conditions within the Basin thereby allowing for additional pumping by CalAm. However, the DEIR/EIS does not provided any hydrogeological analysis of the synergistic benefits of all of this out-of-Seaside-Basin water being imported into the Basin.

MCWD-25 cont.

The DEIR/EIS also fails to analyze and describe how ASR water, GWR water, and MPWSP water will be imported into and exported out of the Seaside Basin by month and how correspondingly the pipeline conveyance system will be operated to accommodate the water flow. For example, during January, Carmel River ASR would enter the 30-inch MCWD-CalAm joint pipeline from the South through the 36-inch Monterey Pipeline at the same time MPWSP product water through a 36-inch pipeline and recovered GWR water will enter the MCWD-CalAm joint pipeline from the North. Since water cannot move both north and south at the same time in the MCWD-CalAm joint pipeline, does CalAm intend to not send water from the North while Carmel River ASR water is moving North for injection into the Seaside Basin or, if not and the water coming from the North will block the Carmel River ASR water coming from the South, will CalAm not then be effectively sending the Carmel River water directly to its Monterey customers and not north for injection?

MCWD-26

In addition, CalAm is proposing to construct new ASR wells 5 and 6. The new ASR wells are not to inject and recover Carmel River water but to inject and recover 2,100 AFY of MPWSP desalinated water. The 2,100 AFY that would be injected each year into the Seaside Basin means (1) that CalAm could pump at least 1,474 AFY from the Seaside Basin or (2) that instead of taking 25 years to repay the Watermaster at 700 AFY, it would only take about 8 years. As more importantly discussed below, however, CalAm has not shown this additional 2,100 AFY of desalinated water is needed to meet the nine Primary Project Objectives and the MPWSP may be downsized accordingly.

MCWD-27

Proposed Transfer of 700 AFY of MCWD's GWR Project Water Entitlement to Seaside Basin Watermaster Instead of 700 AFY of MPWSP Desalinated Water. Section 2.4.2, page 2-17, states that CalAm and the Seaside Groundwater Basin Watermaster have agreed for CalAm to pay back at the rate of 700 AFY for 25 years the volume of groundwater CalAm has pumped in excess of its adjudicated right at the rate of 700 AFY for

MCWD-28

25 years. CalAm is assuming that the entire 700 AFY would come from the MPWSP plant and has accordingly increased the capacity of the MPWSP plant by 700 AFY, which will result in substantial capital and annual operating and maintenance costs for that added capacity. The DEIR/EIS fails to consider any other options, such as the following.

MCWD is entitled to 1,427 AFY of the output of the GWR Project for use by MCWD's customers within the Seaside Basin portion of MCWD's Ord Community service area, which includes the City of Seaside's Bayonet and Blackhorse Golf Courses. This is in addition to up to 3,700 AFY of GWR water, which will be sold to CalAm. A more practical and cost-effective alternative to building the additional 700 AFY of MPWSP plant capacity would be for CalAm to pay the Watermaster to purchase 700 AFY of MCWD's GWR water for use by MCWD's customers within MCWD's Ord Community service area within the Adjudicated Seaside Basin. This would result in a substantial saving for CalAm's customers by avoiding the need to pay for 700 AFY of desalination plant capacity that is not needed.

This more practical and cost-effective option is based upon representations contained at pages 20 and 21 of the Watermaster's May 23, 2016 Status Report to the Monterey County Superior Court prepared by Attorney Russell M. McGlothlin. Section G of the 2016 Court filing discusses "Potential Request for Relief from the 2018-2021 Triennial Rampdown." The basis for the potential rampdown postponement request is an April 2010 Land Transfer and Water Service Agreement between MCWD and the City of Seaside wherein MCWD agreed to supply the City with 2,500 AF total of potable groundwater for the City's same two golf courses. Section 1.11 of the MCWD-Seaside Agreement states, "This program would result in an 'in-lieu' replenishment of the Seaside Bain (sic) by virtue of suspending the production from the Seaside Basin for gold course irrigation." The golf courses are within that portion of MCWD's Ord Community service area within the Adjudicated Seaside Basin. Delivery of Salinas Valley groundwater to portions of the former Fort Ord is expressly exempt from the MCWRA Agency Act's groundwater export prohibition. Mr. McGlothlin stated in the 2016 Status Report that had MCWD sold the 2,500 AF directly to the Watermaster that would have constituted a direct replenishment supply for the Basin's benefit upon which a rampdown could be postponed. The Watermaster's March 2, 2017 Case Management Statement to the Court at pages 20 and 21 specifically references the above 2016 representations to the Court. Here, MCWD is proposing that GWR Project recycled water be used in lieu of potable groundwater for the golf courses and for other customers' non-potable water uses.

MCWD-28 cont.

Sand City Desalination Plant: At the time of the SWRCB's October 20, 2009 Carmel River Cease and Desist Order WR 2009-0060, Sand City was constructing a 300 AFY capacity desalination plant. The Order at page 41 stated,

> Of the 300 afy, 94 afy will be used to replace water being diverted from the Carmel River by CalAm for existing water use within Sand City; thus, once the plant becomes operational the

MCWD-29

> city should no longer receive water illegally diverted from the Carmel River. The balance of the plant's production, 206 afy, is for future growth. **Pending the need for the remaining 206 afy, CalAm may use the water to meet the needs of its customers. (Emphasis added.)**

CalAm operates the Plant. While 206 acre feet of the plant's 300 AFY capacity is reserved exclusively for future Sand City development, that development will occur slowly over time as only in-fill and redevelopment opportunities remain because the city is geographically very small and is hemmed in by existing development. Without the Sand City plant, CalAm as the Sand City residents' water provider would be required to provide water for any new development after December 31, 2021. Presumably the 206 AFY is currently available for CalAm's use outside of Sand City yet the DEIR/EIS provides no analysis in Section 2.4.4, page 2-19, as to the projected availability of that 206 AFY in 2022 and beyond. However, Section 5.4.2.3, page 5.4-7, states, "Continued use of approximately 230 afy provided by Sand City's existing desalination plant (*same as proposed project*)." Therefore, MCWD will use 230 AFY as the amount of water available to CalAm from the Sand City plant.

MCWD-29 cont.

ASR Project Phases 1 and 2: SWRCB-issued water right permits 20808A and 20808C jointly to CalAm and the MPWMD with an authorized Carmel River diversion of up to 5,326 AFY between December and May of each year for ASR Phases 1 (ASR Wells 1 and 2) and 2 (ASR Wells 3 and 4) with an estimated average annual yield of 1,920 to 1,970 AFY.

MPWMD on its website on "Aquifer Storage & Recovery" reports an average yield for Phase 1 of "about 920 AFY" and for Phase 2 of "approximately 1,050 AFY", for a total of 1,970 AFY.[8] The difference between MPWMD's total annual yield amount of 1,970 AFY and Table 2-4's amount of 1,300 AFY is 670 AFY.

After December 31, 2021, CalAm is required to reduce its Carmel River by 4,934 AFY or over 59% from 8,310 AFY to 3,376 AFY. The DEIR/EIS fails to provide any analysis of the amount of additional water and the increased frequency of Carmel River water availability for ASR when that diversion reduction occurs. In addition, at the July 19, 2016 SWRCB hearing on what became Order WR 2016-0016, Rob MacLean stated that the new CalAm pipelines to be constructed would provide an additional 1,000 AFY conveyance capacity for Carmel River ASR water. It appears that CalAm has performed an analysis of the increased availability of ASR water come January 1, 2022, but has not shared that analysis with either the CPUC or the public. For purposes of these comments, the SWRCB's lower estimated annual yield of 1,920 AFY annual yield will be used. The DEIR/EIS should explain why it

MCWD-30

[8] / See http://wwvv.mpwmd.net/water-supply/aquifer-storage-recovery/.

does not use 1,920 AFY for CalAm's future ASR water supply, especially for 2022 and beyond. MCWD-30 cont.

GWR Project Supply: The CPUC has approved a water purchase agreement wherein CalAm would purchase 3,500 AFY of GWR Project supply. MRWPCA has also reserved the right to an additional 200 AFY or a total of 3,700 AFY. The additional element of the GWR Project is that MCWD is entitled to an additional 1,427 AFY of advanced treated water to serve MCWD's Ord Community service area. The Board of Directors of the Fort Ord Reuse Authority (FORA) by Resolution 07-10, adopted on June 8, 2007, allocated the 1,427 AFY to its member jurisdictions served by MCWD, including specifically 453 AFY to the City of Seaside, 280 AFY to the City of Del Rey Oaks, and 134 AFY to Monterey County for use within that portion of MCWD's Ord Community service area within the Adjudicated Seaside Basin. The City of Seaside, including its two golf courses, and the City of Del Rey Oaks are within the Adjudicated Seaside Basin and their 733 AFY combined allocation would result in additional in-lieu groundwater recharge benefits for the Adjudicated Seaside Basin, which fact is totally ignored in the DEIR/EIS. (See Exhibit 8, [Reference Map of MCWD Service Area in Relation to the Adjudicated Seaside Groundwater Basin].)

Phase 1 of the GWR Project provides for the 3,700 AFY to MRWPCA and 600 AFY of the 1,427 AFY to MCWD. Phase 2 of the GWR Project will increase the Advance Water Treatment Plant capacity by up to an additional 827 AFY to provide the balance of the 1,427 AFY for MCWD's Ord Community service area. This DEIR/EIS should examine (1) CalAm paying the Seaside Watermaster to purchase from MCWD 700 AFY of GWR Project Water for use within the Basin by MCWD's customers in satisfaction of CalAm's obligation to repay the Seaside Watermaster 700 AFY for 25 years and (2) transferring additional Phase 1 and 2 advance treated water from MCWD to MPWMD for use by CalAm to the extent not needed by MCWD's Ord Community customers. MCWD-31

The GWR Product Water Conveyance Facilities (pipeline), which will convey the advance treated water from the new treatment plant to MCWD's Ord Community service area and then onto the new GWR injection facilities, will have sufficient capacity to convey more than 5,127 AFY. It should be noted that MCWD's peak use of the Advance Water Treatment plant and the pipeline will be during the summer months so a much greater portion of the treatment plant capacity and the conveyance capacity of the pipeline will be available during the other months to treat and convey water to the GWR injection facilities. Pursuant to the April 2016 Pure Water Delivery and Supply Project Agreement between MRWPCA and MCWD, the pipeline is to be designed, constructed, owned, and operated by MCWD. That Agreement also authorizes MRWPCA to produce an additional 200 AFY of purified recycled water for the GWR Project injection, or an annual total of 3,700 AFY.

iv. The NO MPWSP Option:

For both the SWRCB proceedings and for this DEIR/EIS, MCWD has analyzed the available information, especially those not considered in this DEIR/EIS, and concludes that the proposed MPWSP does not need to be built. The NO MPWSP Option is based upon the following water sources discussed above, which should be available to CalAm when the GWR Project becomes operational and on January 1, 2022:

CalAm's NO MPWSP Water Sources When GWR becomes operational and on January 1, 2022	**Acre Feet per Year**
Carmel River Legal Limit	3,376
Seaside Basin Adjudicated Groundwater Supply[9]	1,474
Sand City Desalination Plant	230
Aquifer Storage & Recover (ASR) Project Phases 1 and 2	1,920
Groundwater Replenishment (GWR) Project	3,700
Total No MPWSP Water Supply	**10,700**

MCWD-32

As shown by Scenario A and B of MCWD's Total Water Portfolio analysis, by 2022, CalAm can achieve both (a) 100% compliance with the SWRCB Cease and Desist Order and (b) have an adequate water supply without the MPWSP. (See also the discussion of No Project Alternative in Part III.D below.)

c. ***CalAm's Total Water Portfolio Options for Meeting the Nine Primary Project Objectives.***

i. Scenario A: Using the Actual CalAm 2016 Water Demand of 9,285 AFY for Comparison Purposes and in accordance with Primary Project Objective #4.

The following is a comparison of CalAm's Total Water Portfolio with the MPWSP as discussed above with the DEIR/EIS's representation of CalAm's Water Supplies using a proposed 6.4 MGD MPWSP and the GWR Project shown in Column 3 of Table 2-4, page 2-18:

MCWD-33

[9] / Assumes that CalAm meets its 700 AFY payback obligation to the Seaside Watermaster by paying the cost of 700 AFY of advanced treated water allocated for use within that portion of MCWD's Ord Community service area within the Adjudicated Seaside Basin.

CalAm Water Sources	No MPWSP Option	CalAm Water Sources from Table 2-4, Col. 3
Carmel River Legal Limit	3,376	3,376
Seaside Basin Groundwater Supply[10]	1,474	774
Sand City Desalination Plant	230	94
Aquifer Storage & Recover (ASR) Project Phases 1 and 2	1,920	1,300
Groundwater Replenishment (GWR) Project	3,700	3,500
6.4 MGD Desalination Plant	NA	7,167
Total No MPWSP Water Supply	10,700	16,211
2016 Actual Demand	9,285	9,285
Excess over 2016 Actual Demand	1,415	6,926
Percent of Water Supply in Excess of 2016 Actual Demand	**15.2%**	**74.6%**

MCWD-33 cont.

Another way of analyzing CalAm's Total Water Portfolio in relationship to the non-MPWSP option is through the following Scenario A spreadsheet analysis based upon the following:

- Total Water Portfolio analysis assuming MCWD's numbers for the Seaside Basin Adjudicated Groundwater Supply, Sand City Desalination Plant, ASR Phases 1 and 2, and GWR Project
- Meeting CalAm Project Objectives 1, 2, 3, 4, 5, 8, and 9, including 100% compliance with the SWRCB Carmel River Cease and Desist Order.
- Objective 4 states, "Develop a reliable water supply for the CalAm's Monterey District service area, accounting for the peak month demand of existing customers," i.e., 2016 customers. (Executive Summary, p. ES-3) Limiting the Objective to "the peak month demand of existing [2016] customers" makes the project not growth

MCWD-34

[10] / Assumes that CalAm meets its 700 AFY payback obligation to the Seaside Watermaster by paying the cost of 700 AFY of advanced treated water allocated for use within that portion of MCWD's Ord Community service area within the Adjudicated Seaside Basin.

inducing and satisfies the Sanctuary's Management Plan requirement that if other economically and environmentally preferable alternative water sources are infeasible, then any new desalination plant should be sized not to induce growth within the coastal areas.

- CalAm's 2016 system deliveries of 9,285 AF as the baseline.
- Proving a Reserve Margin Percentage of at least 10%.

Under Scenario A, MCWD examined four different Total Water Portfolio options, which could be in place by January 1, 2022, with 100% Cease & Desist Order compliance — NO MPWSP, Alternate Water Sources (Alt Water), 6.4 MGD Desal, and 9.6 MGD Desal — in relationship to CalAm's actual 2016 water deliveries. The "NO MPWSP" option assumes that CalAm's MPWSP is not constructed. The "6.4 MGD Desal," and "9.6 MGD Desal" options assumes that CalAm would construct a desalination plant (location of source wells are not assumed to be the CEMEX property or that slant wells would be used) with those respective treatment capacities as discussed in the DEIR/EIS. The DEIR/EIS assumes that a 6.4 MGD plant would produce 7,167 AFY even though CalAm represented in its March 14, 2016 Amended Application to the CPUC that the 6.4 MGD plant would produce 6,252 AFY. Consequently, MCWD assumed a 24/7/365 operating scheme for the desalination plant options.

MCWD-34 cont.

The Scenario A results are as follows:

	No MPWSP	6.4 MGD Desal	9.6 MGD Desal
Total Supply	10,700	17,867	21,450
2016 Demand[11]	9,285	9,285	9,285
Water Supply Reserve Margin	1,415	8,582	12,165
Reserve Margin Percentage (10% assumed needed)	**15.2%**	**92.4%**	**131.0%**

Scenario A meets seven of the nine primary or fundamental objectives of the proposed MPWSP without the need to construct the MPWSP. As demonstrated above, Scenario A without the MPWSP will develop water supplies for the CalAm Monterey District service area to replace CalAm's illegal Carmel River diversions (#1), will reduce pumping from the Seaside Groundwater Basin (#2), will pay back the Seaside Groundwater Basin (#3), will develop a reliable water supply for CalAm's Monterey District service area, accounting for the peak monthly demand of existing customers (#4), and develop a reliable water supply that meets fire flow requirements for public safety

MCWD-35

[11] / Primary Project Objective #4 specifies demand of existing (2016) customer demand. See also III.A.1.b.i below. Does not include any return water demand as alternatives exist that would not require any return water.

(#5). Because the MPWSP desalination plant would not be built, a major new large energy use would be eliminated with a corresponding substantial reduction in greenhouse gas emissions per unit of water delivered (#8). In addition, without the MPWSP, substantial project costs would be eliminated with the resulting beneficial effect for water rates (#9). MCWD-35 cont.

ii. Scenario B: Using 2016 Demand, Pebble Beach Water Entitlements, Legal Lots of Record, and 25% of Hospitality Industry Rebound, a Total of 10,915 AFY, for Comparison Purposes.

The differences from the above Scenario A analysis and from the Table 2-3, page 2-12, CalAm demand assumptions are as follows:

- For the "Existing Service Area Demand," the actual 2016 demand of 9,285 AF was used. CalAm Project Objective 4 states, "Develop a reliable water supply for the CalAm's Monterey District service area, accounting for the peak month demand of existing customers," i.e., 2016 customers.
- The DEIR/EIS "Pebble Beach Water Entitlements" of 325 AF was used.
- The DEIR/EIS "Legal Lots of Record" of 1,180 AF was used.
- Only 25% of the DEIR/EIS's 500 AF for the "Hospitality Industry Rebound Economic Recover," or 125 AF, was used because in Section 2.3.3.2, pages 2-13 to 2-14, the DEIR/EIS admits that "the region's economy has largely recovered" and that some of the 500 AFY would be available for other uses but fails to identify what those other uses would be and whether that would result in duplicating a CalAm demand. That means that most of the 500 AFY is not needed. Table 2-2 shows a significant progressive reduction in CalAm customers' water as the economy was "recovering." Therefore, MCWD has determined that only 125 AFY, and not 500 AFY, is needed to meet any further Hospitality Industry Rebound to meet Primary Project Objective #7. MCWD has experienced a similar significant progressive reduction in MCWD customers' water use and that has and is occurring even as the number of MCWD's customers continues to grow. Governor Brown has declared, "water conservation must be a part of everyday life."[12] CalAm and MCWD customers have answered that call and implemented water conservation measures in their everyday lives and they will continue to do so. MCWD-36
- Meets all nine Primary Project Objectives, including 100% compliance with the SWRCB Carmel River Cease and Desist Order and with Objective 7 being met as recalculated above.

[12] / http://www.npr.org/sections/thetwo-way/2016/05/09/477392158/california-governor-makes-some-water-restrictions-permanent

- Under the NO MPWSP Option, the comparison assumes that an additional 1,305 AFY of water would be available as discussed below under Alternative Water Sources.
- Proving a Reserve Margin Percentage of at least 10%.

The Scenario B results are as follows:

	No MPWSP	6.4 MGD Desal	9.6 MGD Desal
Total Water Supply Available	12,005	17,867	21,450
2016 Demand + PB + LOR + 50% of HI Rebound	10,915	10,915	10,915
Water Supply Reserve Margin	1,090	6,827	11,040
Reserve Margin Percentage (10% assumed needed)	**10.0%**	**61.8%**	**94.3%**

MCWD-36 cont.

Scenario B meets all nine primary or fundamental objectives of the proposed MPWSP without the need to construct the MPWSP. As demonstrated above, Scenario B will develop water supplies for the CalAm Monterey District service area to replace CalAm's illegal Carmel River diversions (#1), will reduce pumping from the Seaside Groundwater Basin (#2), will pay back the Seaside Groundwater Basin (#3), will develop a reliable water supply for CalAm's Monterey District service area, accounting for the peak monthly demand of existing customers (#4), and develop a reliable water supply that meets fire flow requirements for public safety (#5). Provide sufficient water supplies to serve existing vacant legal lots of record (#6), and accommodate tourism demand under the already "largely recovered" economic conditions (#7). Because the MPWSP desalination plant would not be built, a major new large energy use would be eliminated with a corresponding substantial reduction in greenhouse gas emissions per unit of water delivered (#8). In addition, without the MPWSP, substantial project costs would be eliminated with the resulting beneficial effect for water rates (#9).

MCWD-37

iii. Scenario A and B Conclusions:

The Scenario A analysis with accompanying spreadsheet and bar graph (Exhibit 10) shows that the MPWSP is not needed to meet CalAm's actual 2016 water demand, and to provide CalAm with a Water Supply Reserve of 1,415 AFY or a Reserve Margin of 15.2%. Scenario A would meet seven (1, 2, 3, 4, 5, 8, and 9) of the nine primary or fundamental objectives of the proposed MPWSP without the need to construct the MPWSP.

MCWD-38

The Scenario B analysis with accompanying spreadsheet and bar graph (Exhibit 11) shows that even if CalAm's actual 2016 water demand is increased by Pebble Beach

Entitlements, Legal Lots of Record, and 25% of the claimed Hospitality Industry Rebound demand, and provide CalAm with a 10% Reserve Margin, that combined demand could be met with an additional 1,305 AFY of water from other sources, which are discussed below under Alternate Water Sources (Alt Water). Scenario B would meet all nine primary or fundamental objectives of the proposed MPWSP without the need to construct the MPWSP.

MCWD-38 cont.

d. ***What CalAm has Done to Increase Water Demand by 54% over the 2016 Actual Demand. CalAm's Existing Customers Should Not be Required to Pay for that Significant Water Supply Cost Increase.***

In Table 2-3, page 2-12, the DEIR/EIS assumes that CalAm's "Existing Service Area Demand" is 12,270 AFY based upon 2010 demands and not the actual 2016 demand of 9,285 AFY as required by Primary Project Objective #4. In other words, the DEIR/EIS assumes an "Existing Service Area Demand," which is 2,985 AFY or over 32% more than the actual existing demand. Table 2-3 then goes on to add an additional 2,005 AFY for Pebble Beach Water Entitlements, Hospitality Industry Rebound Economic Recovery, and Legal Lots of Record. In the Section 2.3.3.2 discussion of Hospitality Industry Rebound, pages 2-13 to 2-14, the DEIR/EIS admits that "the region's economy has largely recovered" and that some of the 500 AFY would be available for other uses. CalAm's actual 2016 water demand was 9,285 AF. The DEIR/EIS' new total water demand is 14,275 AFY, or 4,990 AFY more, which is a 54% increase over the actual 2016 water demand. It should be noted that providing service for Pebble Beach Water Entitlements, Hospitality Industry Rebound Economic Recovery, and Legal Lots of Record are *not* within the scope of objectives listed for the operative Project Description that is on file with the Commission, where the primary stated objective is compliance with SWRCB Order 95-10. (Mar. 14, 2016 Amended Appl., Ex. H.) These further objectives have been added by CalAm, as reflected in the DEIR/EIS project description. (Executive Summary, p. ES-3; see pp. 2-10 through 2-15.)

MCWD-39

The DEIR/EIS fails to explain why CalAm's existing customers should be required (1) to pay a 54% increase in water supply in excess of those existing customers' actual demand or (2) to pay for a desalination plant that will act as a very expensive insurance policy. This is the typical investor-owned utility solution to foster a perceived water supply shortage that it then proposes to solve by building the biggest, shiniest new water supply project at the existing customers' expense and at the expense of the environment – bigger is not better here.

MCWD-40

e. ***The DEIR/EIS Shows that the Proposed 6.4 MGD MPWSP is Not Needed and that a 6.4 MGD Plant is Substantially Oversized even with CalAm's Expanded Project Objectives.***

As discussed above, a MPWSP of any size is not needed to meet the current system demand. Under Scenario A, 6,475 AFY, or 5.78 MGD, of the 6.4 MGD MPWSP plant capacity is not needed to meet seven of the expanded DEIR/EIS Primary Project Objectives. Under Scenario B, 4,845 AFY, or 4.33 MGD, of the 6.4 MGD MPWSP plant capacity is not needed to meet all nine of the expanded DEIR/EIS Primary Project Objectives.

MCWD-41

First, as discussed in MCWD's comments A.1.b.i above, the actual 2016 existing demand was 9,285 AF versus Table 2-2, page 2-12 of the DEIR/EIS shows an "Existing Service Area Demand of 12,270 AF. Under Scenario A, that would represent a 2,985 AFY increase over the actual existing demand. Under Scenario B, that would represent a 1,355 AFY increase over the Scenario B demand of 10,915 AFY. Therefore, under Scenario A, there would be 2,985 AFY of overcapacity and, under Scenario B, there would be a 1,355 AFY of overcapacity.

Second, as discussed in DEIR/EIS Section 2.4.3 on page 2-19 and in Section 3.2.4, page 3-43, CalAm is proposing to construct new ASR Wells 5 and 6. However, the new ASR wells are not to inject and recover Carmel River water but to inject and recover 2,100 AFY of MPWSP desalinated water. The DEIR/EIS has not provided any justification as to why 2,100 AFY more water needs to be injected into the Seaside Basin. For example, the DEIR/EIS does not justify this 2,100 AFY desalinated water as payback water to the Seaside Watermaster. Therefore, the MPWSP plant capacity to produce this 2,100 AFY is totally unnecessary.

Third, as discussed above under Seaside Basin Groundwater Supply, DEIR/EIS Section 2.4.2, page 2-17, states that CalAm and the Seaside Groundwater Basin Watermaster have agreed for CalAm to pay back the volume of groundwater CalAm has pumped in excess of its adjudicated right at the rate of 700 AFY for 25 years. CalAm is assuming that the 700 AFY would come from the MPWSP plant and has increased the capacity of the MPWSP plant by 700 AFY for that purpose. The DEIR/EIS fails to consider any other options and as explained above, a more practical and cost-effective option would be for CalAm to pay the Watermaster to purchase 700 AFY of MCWD's share of GWR Project advanced treated water for use by MCWD's customers within MCWD's Ord Community service area within the Adjudicated Seaside Basin. Based upon the cost of GWR Project water under the CPUC-approved Water Sales Agreement, purchasing this additional GWR Project water would be at a substantial savings to the equivalent amount of MPWSP desalinated water. This would further reduce the need for MPWSP plant capacity by an additional 700 AFY.

MCWD-41 cont.

Fourth, DEIR/EIS Section 2.5.1, pages 2-22 to 2-23, discusses CalAm's Salinas Valley Groundwater Basin Return Water obligation to mitigate for pumping SVGB groundwater if the proposed slant well technology and CEMEX well locations are used. Section 2.5.1 states that the proposed "Settlement Agreement on MPWSP Desalination Plant Return Water" would require CalAm to return 690 AFY if the 6.4 MGD plant is built. The DEIR/EIS does not determine how much return water would actually be needed, but apparently decided to use 690 AFY without a sound scientific basis. An amount greater than 690 AFY is likely as discussed below. As also discussed below, another fatal flaw of the DEIR/EIS is the blatant assumption that returning one AF of desalinated water anywhere in the SVGB, especially north of the Salinas River, could be adequate mitigation for direct, indirect, and cumulative impacts from slant well pumping at the CEMEX property under

environmental, groundwater, and SGMA law. While one reading of the Agency Act may support a one-to-one return ratio, the DEIR/EIS does not discuss anywhere whether a one-to-one return ratio is adequate to mitigate for environmental, groundwater, and SGMA direct, indirect, and cumulative impacts from slant well pumping at the CEMEX property. As discussed in MCWD's comments on Project Alternatives, use of proven Horizontal Wells technology would eliminate the need to provide any return water.

Overcapacity Items	Scenario A AFY	Scenario B AFY
Eliminating Excess Demand in DEIR/EIS' "Existing Service Area Demand of 12,270 AF versus Scenario A or Scenario B Demand	2,985	1,355
Eliminating proposed new ASR Wells 5 and 6 and the need 2,100 AFY of MPWSP product water to inject	2,100	2,100
Elimination of repayment to Seaside Watermaster by instead purchasing 700 AFY of GWR water for use within the Adjudicated Basin	700	700
Elimination of Return Water Obligation	690	690
Total Amount of MPWSP Overcapacity	6,475	4,845
Overcapacity Converted into MGD =	5.78 MGD	4.33 MGD
6.4 MGD MPWSP Capacity Remaining	0.62 MGD 694 AFY	2.07 MGD 2,318 AFY

MCWD-41 cont.

In summary, using the DEIR/EIS' own information, 5.78 MGD of a 6.4 MGD MPWSP plant is not needed to meet seven of the Primary Project Objectives and 4.33 MGD is not needed to meet all nine Primary Project Objectives.

f. ***Alternative Water Sources (Alt Water).***

The DEIR/EIS states that no viable alternatives have been identified that would supply water without a desalination plant being included and dismisses all non-desalination plant alternative water sources with the exception of the GWR Project. (DEIR/EIS, pp. 5.2-1 through 5.2-6.) This conclusion, however, is not supported by the record as discussed above. Under the Scenario A analysis above, MCWD has shown that CalAm does not need a desalination plant of any size to meet 2016 demand going forward and to meet Primary Project Objectives 1, 2, 3, 4, 5, 8, and 9. Under the Scenario B analysis above, MCWD has shown that CalAm would only need approximately 1,305 AFY more from Alternate Water Sources to meet all nine Primary Project Objectives.

MCWD-42

Moreover, as a result of the drought, stormwater capture is the new "low hanging fruit" for additional water supplies. January and February 2017 have demonstrated the availability and viability of Salinas River water for stormwater capture projects; however,

MCWD-43

stormwater flows exist in the Salinas River during other than wet water years. The following two excess river flow capture projects would utilize excess flows in the Salinas River and should be analyzed in the DEIR/EIS as they could provide additional assurances that CalAm could obtain sufficient supplies without building the MPWSP desalination plant.

iv. Salinas River Excess Flow Capture – Groundwater Recharge Project.

As a result of the drought, stormwater or excess flow capture is the new "low hanging fruit" for additional water supplies. January and February 2017 have demonstrated the availability and viability of Salinas River water for excess flow capture projects; however, excess flows exist in the Salinas River during other than wet water years. The following two excess river flow capture projects would utilize excess flows in the Salinas River and should be analyzed in the DEIR/EIS as they could provide additional assurances that CalAm could obtain sufficient supplies without the proposed MPWSP desalination plant.

MCWD agrees that the primary purpose of the Salinas Valley Water Project should be to provide groundwater recharge for the Salinas Valley Groundwater Basin. However, during many water years, there are substantial Salinas River flows to Monterey Bay in excess of SVGB groundwater recharge and Salinas River environmental flow needs. For example, because of the substantial magnitude and occurrence of those flows, MCWRA is proposing the construction of an Interlake Tunnel that would divert water from Nacimiento Reservoir to San Antonio Reservoir – water that would otherwise have been spilled at Nacimiento Dam. While the Interlake Tunnel Project will result in storing more stormwater runoff, a new Salinas River diversion and conveyance system is being proposed to convey that water to a new groundwater recharge area near the City of Salinas. However, MCWRA's Salinas River Diversion Facility (the "rubber dam") is an already permitted diversion facility located near Marina at the MRWPCA's regional tertiary treatment plant and the site of the to-be-constructed GWR Advance Treated Water plant. The MCWRA has existing unexercised SWRCB-issued water rights that could be modified to accommodate additional river diversions at the rubber dam for groundwater recharge. For example, a recharge project could divert some 10,000 to 20,000 AF when there are excess flows in the river. Required bypass flows for the protection of Salinas River steelhead would be at minimum levels during the months of November through March when diversions for this project would normally occur. There are at least four potential uses or combination of uses for this water:

MCWD-43 cont.

1. If a blend of river water and tertiary treated water could be treated at MRWPCA's Advance Water Treatment plant, then a portion of this water could be incorporated into the GWR Project for use by CalAm's Monterey District. MCWRA's Agency Act only prohibits the export of Salinas Valley Groundwater Basin groundwater, not Salinas River water.
2. If Salinas River water could be treated in a desalination plant, then a portion of the river water could be treated at a new desalination plant thereby reducing source water pumping.

3. A portion of the excess river water could be conveyed north of the Salinas River to the Castroville area for groundwater recharge. The river water would be treated (e.g., filtered and chlorinated) to the extent necessary. Despite the many years that the Castroville Seawater Intrusion Project (CSIP) has been in operation, the Castroville Community Service District continues to experience significant groundwater supply problems. A significant cause of the groundwater problem is the pumping depression that has developed to the east of CCSD in the northern portion of the City of Salinas caused by over-pumping in the East Side Subbasin, which causes groundwater underneath the CCSD to flow east instead of naturally flowing west to Monterey Bay. See DEIR/EIS Figure 4.4-6.
4. A portion of the excess river water should remain south of the Salinas River in the Marina area for seawater intrusion protection and groundwater recharge. See Exhibit #3 to these Comments, Erler & Kalinowski, Inc., Memorandum dated 22 March 2017, Section 4.2, Impacts of MPWSP on MCWD's Ability to Implement Groundwater Recharge Augmentation at Armstrong Ranch.

MCWD-43 cont.

Because the 180/400 Foot Aquifer Subbasin of the SVGB is classified as a Critically Overdrafted subbasin, i.2, i.3, and i.4 above should be mandatory projects under the Groundwater Sustainability Plan for the 180/400 Foot Aquifer Subbasin.

MCWD is proposing that the Salinas River Excess Flow Capture/Groundwater Recharge Project be implemented and utilized by CalAm by capturing from 3,000 to 4,000 AF in excess river flow years to supply on the average 1,000 AFY as either additional GWR source water (i.1) and/or direct desalination plant source water (i.2).

v. Additional GWR Project Water and ASR water.

Additional GWR Water. As discussed above under "GWR Project Supply," MCWD is entitled to 1,427 AFY of GWR water and MCWD is proposing that CalAm pay the Seaside Watermaster to purchase from MCWD 700 AFY of MCWD's GWR water for use within the Seaside Subbasin by MCWD's Ord Community customers in satisfaction of CalAm's obligation to repay the Seaside Watermaster 700 AFY for 25 years. To the extent that the remaining 727 AFY of GWR water is not needed by MCWD's Ord Community customers, a portion of that 727 AFY could be sold to CalAm.

MCWD-44

MCWD understands Salinas Valley agriculture's concerns over reductions of their recycled water for the Castroville Seawater Intrusion Project (CSIP) as a result of the GWR Project. MCWD suggests that the above Salinas River Stormwater Capture/Groundwater Recharge Project could provide direct groundwater recharge benefits that would combat seawater intrusion, allow more agricultural pumping, and help recover the Castroville area groundwater. For example, would 4,000 AF of groundwater recharge with stormwater capture occurring one-third of the water years be sufficient to offset an additional 1,000 AFY of GWR water going to CalAm?

MCWD-45

Additional ASR Water. As discussed above under "ASR Project Phases 1 and 2," after December 31, 2021, CalAm is required to reduce its Carmel River by 4,934 AFY or over 59% from 8,310 AFY to 3,376 AFY. The DEIR/EIS fails to provide any analysis of the amount of additional water and the increased frequency of Carmel River water availability for ASR when that diversion reduction occurs. In addition, at the July 19, 2016 SWRCB hearing on what became Order WR 2016-0016, Rob MacLean stated that the new CalAm pipelines to be constructed would provide an additional 1,000 AFY conveyance capacity for Carmel River ASR water. It appears that CalAm has performed an analysis of the increased availability of ASR water come January 1, 2022, but has not shared that information with either the CPUC or the public. MCWD-46

vi. Salinas River Excess Flow Capture — Salinas River Water Treatment Plant.

This is not necessarily low hanging fruit but MCWD has already performed a preliminary analysis of the feasibility of diverting Salinas River water in excess of existing agricultural uses and steelhead needs to meet potable water demands. The project would utilize excess water under MCWRA's water right licenses and permits and could utilize the rubber dam or wells along the Salinas River as CalAm does along the Carmel River. River water would not be available in all water years, but for a 5,000 AFY water treatment plant, 1,000 AFY could be used to meet potable water demands within MCWD's Ord Community and the remaining 4,000 AFY could be made available to CalAm's Monterey District and to Castroville Community Services District for direct use and/or for groundwater recharge. MCWD-47

vii. Small Desalination Plant.

MCWD has proposed constructing its own 3,000 AFY (2.7 MGD) desalination plant, which is generally discussed in the DEIR/EIS on pages 4.4-89 to 4.4-90. Pursuant to the Regional Urban Water Augmentation Program (RUWAP), MCWD is obligated to provide an additional 2,400 AFY of augmentation water needed for the redevelopment of Fort Ord. MCWD has secured 1,427 AFY of that from the GWR Project. The remaining 973 AFY could be provided by a 3,000 AFY desalination plant to be owned by MCWD. MCWD's ownership of the plant would comply with the Monterey County ordinance requiring 100% ownership of desalination plants in the county. (See Monterey County Code of Ordinances, section 10.72.030(B).) The balance of 2,027 AFY (1.8 MGD) could be sold to CalAm for its Monterey Peninsula customers. Any MCWD desalination plant would likely use horizontal or vertical wells and not slant wells. MCWD-48

viii. Alternate Water Sources Conclusion.

The DEIR/EIS just focuses on a 6.4 MGD and 9.6 MDG MPWSP desalination plant. The DEIR/EIS failed to do a 2022 Total Water System analysis for CalAm's Monterey District thereby failing to determine the actual water supply and water demand situation needed to meet all nine Primary Project Objectives because, as MCWD has shown, even a 6.4 MGD desalination plant would produce an excess amount of water making actual demand irrelevant. Because of that, alternate water sources were not analyzed because no additional water sources were needed with a 6.4 MGD plant. As MCWD has shown, only MCWD-49

1,305 AFY of alternate water sources are needed to meet all nine Primary Project Objectives without the need to construct the MPWSP. The Excess Flow Capture/Groundwater Recharge Project could provide a significant amount of additional GWR water and groundwater recharge to combat seawater intrusion, especially north of the Salinas River. Additional GWR water and ASR water should also be available to provide the additional 1,305 AFY.

MCWD-49 cont.

2. The DEIR/EIS's discussion of Plant Capacity vastly underestimates the amount of water that would need to be returned to the SVGB.

The adequacy of the DEIR/EIS's discussion of plant capacity is critical to determining the amount of groundwater that must be returned to the SVGB from the MPWSP's source wells given CalAm's lack of water rights. It is also critical for determining whether the project actually has capacity to return the large amount of groundwater it must return to the Marina Subarea. The DEIR/EIS, however, fails to provide any discussion or support for bracketing the return water percentage between 0% to 12%. As discussed in the attached HGC Comments, it is likely that the return water obligation would be more than 12%, especially in the initial years of operation. (See HGC Comments, pp. 9-10.) Even the NMGWM2016 calibrated model, which likely underestimates the slant wells production of groundwater, predicts up to 22% of groundwater will be produced from the Dune Sand Aquifer and another 3.5% of groundwater will be produced from the 180-FTE Aquifer during the initial time step. (*Ibid.*) Moreover, this does not account for the amount of return water that may be needed to mitigate groundwater impacts in the Marina Subarea.

MCWD-50

Therefore, the DEIR/EIS must be revised to disclose the potential maximum amount of groundwater that must be returned, especially in the early years, of the project to determine whether the presently proposed slant well intakes are actually feasible. Importantly, other subsurface intakes that the DEIR/EIS fails to analyze would like reduce (Ranney Wells) or eliminate (Horizontal Wells) the need for any return water. In addition, both the no project alternative and GWR project would not require any return water component. Therefore, the revised DEIR/EIS should not assume the return water component is part of CalAm's demand in assessing potentially feasible alternatives, as discussed further below.

3. The DEIR/EIS's discussion of Water Rights Is Misleading, Ignores Established Legal Precedent, and Fails to Demonstrate the Project is Legally Feasible.

Any discussion of the applicability of CEQA/NEPA law, groundwater law, and the Sustainable Groundwater Management Act (SGMA) to the proposed MPWSP is very fact dependent. As discussed in MCWD's comments, the DEIR/EIS analysis in Section 4.4, Groundwater Resources, is fatally flawed, being based upon inaccurate data and modeling, and not fully analyzing the direct, indirect, and cumulative adverse impacts of MPWSP's withdrawal of groundwater from the Marina Subarea. MCWD will fully discuss those matters in its comments on Section 4.4. The following discussion provides MCWD's

MCWD-51

comment on the Section 2.6 discussion as to (1) the DEIR/EIS' theoretical understanding of the law and (2) the law as applied to the facts as ascertained by MCWD. MCWD-51 cont.

a. ***The DEIR/EIS' Discussion of CPUC's Role.***

In the introduction to Section 2.6, the DEIR/EIS makes the following statements:

(1) "The CPUC is not the arbiter of whether CalAm possesses water rights for the project and nothing in this EIR/EIS should be construed as the CPUC's opinion regarding such rights,"

(2) "except to the extent that the CPUC must determine whether there is a sufficient degree of likelihood that CalAm will possess rights to water that would supply the desalination plant such that the proposed project can be deemed to be feasible."

(3) "The SVGB is not an adjudicated groundwater basin, so use of the groundwater in the Basin is not subject to existing court decree, written agreements or oversight by an impartial Watermaster."

(4) Three "relevant types of groundwater rights" are:
"(1) overlying rights whereby those who own land atop the Basin may make reasonable use of groundwater on such land; (2) prescriptive rights whereby a water user has acquired another's rights to use water via an open, adverse and sustained use [for at least five years] under a claim of right that such user would otherwise not be entitled to; and (3) appropriative rights whereby the groundwater may be used outside the Basin or for municipal purposes. **While CalAm owns 46 acres of land (the proposed desalination plant location) overlying the Basin, that land would not support sufficient water for the project and would not enable CalAm to use the water beyond the property that it owns.** CalAm has no prescriptive groundwater rights in the Basin. Thus, CalAm would take any Basin water for the project via appropriative rights, which are junior to existing appropriations and to overlying users." (Emphasis added.)

MCWD-52

(5) "If the proposed project is approved and any dispute arises as to whether or not CalAm possesses legal water rights, such dispute likely would be resolved through court action."

(6) "[I]f CalAm did not possess legal rights to use the feedwater for the MPWSP desalination plant, then the desalination plant simply could not operate and the project would not go forward. That is why water rights factors in as a key project feasibility issue."

As to Statements (1) and (2), the DEIR/EIS is correct that the CPUC has no legal authority or jurisdiction to determine whether or not CalAm will have the necessary water MCWD-53

rights for the proposed project. However, the DEIR/EIS fails to explain the precise meaning of "a sufficient degree of likelihood," the standard to be allegedly applied by the CPUC, the legal authority for that statement, and examples of where the CPUC has applied that same standard in other proceedings. MCWD-53 cont.

Given Statements (1) and (5) and the SWRCB's statement that CalAm would have the burden of proof to demonstrate that it will have adequate water rights for the project, the burden at the CPUC must be on CalAm to show by a preponderance of the evidence that it has adequate water rights for the project. The burden of proof is not on the public or pubic agencies like MCWD to show that CalAm does not have adequate water rights. MCWD-54

Statement (3) fails to recognize that the extraction of groundwater from the CEMEX property is governed by a written agreement, i.e., the 1996 Annexation Agreement discussed in DEIR/EIS Section 2.6.4. MCWD strongly disagrees with the DEIR/EIS interpretation of that agreement as explained below. In addition, the actual extraction of groundwater occurs on the CEMEX property and not on the proposed desalination plant location. For the same reason that the DEIR/EIS admits in Statement (4) that CalAm has no right to export groundwater beyond the proposed desalination plant location, CalAm has no right to export groundwater beyond the CEMEX property. MCWD-55

As to Statement (4), so-called developed water is not an appropriative right but a separate right to use and export the amount of actual net new water developed. CalAm is not appropriating native groundwater but developing new water. Being so limited, CalAm would not gain legal status as an "appropriator" vis-à-vis other appropriators of native groundwater within the SVGB. MCWD agrees with the Statement (4) principle, as applied to the CEMEX property, that CalAm would not be able to use any groundwater extracted from the CEMEX property beyond the boundaries of that property. MCWD-56

As to Statement (6), the available data shows that groundwater, which meets Basin Plan standards for beneficial uses, within the aquifers that will be impacted by the proposed slant wells at the CEMEX site and that there are foreseeable direct, indirect, and cumulative adverse impacts to those beneficial conditions as result of groundwater extractions by the proposed 6.4 MGD or 9.6 MGD desalination plants uses (as discussed in comments to Section 4.4). Therefore, CalAm cannot acquire water rights to the groundwater that would be extracted by the proposed slant wells and the MPWSP cannot go forward as proposed. MCWD-57

b. ***Section 2.6.1, State Water Resources Control Board Report.***

CalAm is proposing to pump the source water for the MPWSP from that portion of 180/400 Foot Aquifer Subbasin of the SVGB located south of the Salinas River. MCWD's Central Marina and Ord Community water service areas are within portions of three Subbasins: the newly designated Monterey Subbasin, the Adjudicated Seaside Basin, and the 180/400 Foot Aquifer Subbasin. MCWD's production wells are located along the northwestern boundary of the Monterey Subbasin and pump from the groundwater aquifers MCWD-58

that are within both the 180/400 Foot Aquifer Subbasin and the Monterey Subbasin. A MCWD production well is located approximately 1.6 miles from the CEMEX property. (See Exhibit 8 [Map of MCWD Service area].)

MCWD-58 cont.

MCWD agrees that no groundwater right or other water right are needed to extract 100% seawater from Monterey Bay so long as there are no direct, indirect or cumulative impacts to any existing groundwater condition. A basic and essential problem is that the currently proposed length and location of the proposed slants wells will not extend into Monterey Bay as originally proposed by CalAm but will in fact extract groundwater from the 180/400 Foot Aquifer Subbasin with impacts to the adjoining groundwater aquifers. The DEIR/EIS itself admits that it cannot with any certainty determine the percentage of groundwater to be extracted but models up to 12%. However, as discussed below and in the attached HGC and GeoHydros comments, the total annual amount of groundwater water pumped from the proposed slant wells is likely to be significantly higher than 12% at least during the initial years of operation.

MCWD-59

As the DEIR/EIS admits, CalAm has no existing overlying, appropriative or prescriptive groundwater right or claim of right to pump groundwater from the 180/400 Foot Aquifer Subbasin. The SWRCB issued its Final Review of California American Water Company's Monterey Peninsula Water Supply Project more than 3 ½ years ago, on July 31, 2013 (Final Review).

In the Legal Conclusions section of the Executive Summary to the Final Review, page ii, the SWRCB stated:

> To appropriate groundwater from the [Salinas Valley Groundwater] Basin, the burden is on CalAm to show their project will not cause injury to other users. Key factors will be: (1) how much fresh water CalAm extracts as a proportion of the total pumped amount, (to determine the amount of water, that after treatment, could be considered desalinated seawater available for export as developed water); (2) whether pumping affects the water table level in existing users' wells; (3) whether pumping affects seawater intrusion within the Basin; (4) how CalAm returns any fresh water it extracts to the Basin to prevent injury to others; and (5) how groundwater rights might be affected in the future if the proportion of fresh and seawater changes in the larger Basin area or the immediate area around CalAm's wells.

MCWD-60

The SWRCB stated, "because groundwater in the Basin is in a condition of overdraft, the only way to show there is surplus water available for export to non-overlying

parcels is for a user to develop a new water source" and "[t]he only water that would be available for export is a new supply, or developed water." (Final Review at 35 and 40.)

The SWRCB's Final Review had to speak in general terms because, as the SWRCB itself admitted, the SWRCB lacked the necessary on-site technical information needed to make a legal determination. While emphasizing the need for accurate on-site technical information, the entire Final Review is founded on the misplaced acceptance for legal analysis purposes of CalAm's and now the DEIR/EIS' inaccurate representation of the conditions of the 180/400 Foot Aquifer Subbasin in the vicinity of the CEMEX property. For example, the SWRCB accepted CalAm's allegation that "the seawater intrusion front extends approximately 5 miles landward from the proposed [CEMEX] well locations" (Final Review at 45-46) and that consequently, almost all water pumped will be brackish water and not "fresh water" and that "[t]here is expected to be minimal impact to fresh water sources at start-up and for the first several years of operation as water will certainly be sourced from the intruded portion of the aquifer." (Final Review at 44.) The SWRCB also incorrectly assumes that "it is unlikely that Basin conditions would improve independent of MPWSP operations." (Final Review at 43.) As discussed in our comments on Section 4.4 below and in the attached HGC, EKI and GeoHydros comments, the assumptions have been shown to be wrong.

MCWD-60 cont.

The SWRCB's Definition of "Fresh Water" is Not in Compliance with the SWRCB's own Sources of Drinking Water Policy and Federal and State Law

The SWRCB Final Report states at footnote 40: "Brackish water in this report is defined as groundwater within the seawater intrusion zone that contains chloride levels greater than 500 ppm. Water with chloride concentrations less than 500 mg/L is considered fresh water."

What the SWRCB Final Report completely fails to do is address SWRCB's own Resolution No. 88-63, Adoption of Policy Entitled "Sources of Drinking Water." Resolution No. 88-63 is incorporated by reference into the existing 2011 Water Quality Control Plan for the Central Coastal Basin, which is applicable to the proposed project. (See DEIR/EIS, pp. 4.10-37 to 4-10-38.) The Basin Plan may be found at http://www.waterboards.ca.gov/rwqcb3/publications_forms/publications/basin_plan/docs/basin_plan_2011.pdf. Resolution No. 88-63 is Appendix A-9 of the Basin Plan. Resolution No. 88-63 sets forth the following policy regarding surface and ground water within the project area:

> All surface and ground waters of the State are considered to be suitable, or potentially suitable, for municipal or domestic water supply and should be so designated by the Regional Boards with the exception of:
>
> 1. Surface and ground waters where:

MCWD-61

a. The total dissolved solids (TDS) exceed 3,000 mg/L (5,000 uS/cm, electrical conductivity) and it is not reasonably expected by Regional Boards to supply a public water system, or
b. There is contamination, either by natural processes or by human activity (unrelated to the specific pollution incident), that cannot reasonably be treated for domestic use using either Best Management Practices or best economically achievable treatment practices, or
c. The water source does not provide sufficient water to supply a single well capable of producing an average, sustained yield of 200 gallons per day.

MCWD-61 cont.

In addition, the SWRCB Final Report completely fails to address the Marina Subarea as an underground source of drinking water. The U.S. Environmental Protection Agency ("USEPA") defines "Underground source of drinking water (USDW)" at 40 CFR 144.3 to mean:

An aquifer or its portion:
(a)(1) Which supplies any public water system; or
(2) Which contains a sufficient quantity of ground water to supply a public water system; and
(i) Currently supplies drinking water for human consumption; or
(ii) Contains fewer than 10,000 mg/l total dissolved solids; and
(b) Which is not an exempted aquifer.

The Marina Subarea supplies MCWD's public water system and currently contains a sufficient quantity of groundwater to supply that system with drinking water for human consumption and contains fewer than 10,000 mg/l TDS. Therefore, the Subarea meets the requirements of an aquifer under part 144.3(a) and it is not an exempted aquifer as defined at 40 CFR 146.4.

MCWD-62

Water Code Section 10780, et seq., is the Groundwater Quality Monitoring Act of 2001. Section 10783(a) states, "The Legislature finds and declares that protecting the state's groundwater for beneficial use, particularly sources and potential sources of drinking water, is of paramount concern." Section 10783(g)(2) specifically cites to the above USEPA's definition and states, "an Underground Source of Drinking Water as containing less than 10,000 milligrams per liter total dissolved solids in groundwater." In its June 23, 2015 revised draft Model Criteria for Groundwater Monitoring in Areas of Oil and Gas Well Stimulation, the SWRCB classifies this Underground Source of Drinking Water as "Protected water."

The DEIR/EIS's water rights discussion is founded upon the SWRCB Final Report. Yet the SWRCB Final Report fails to even discuss its own Resolution No. 88-63, which would prevent Cal Am from claiming as new "developed water" for municipal or domestic water supply purposes any feed water to the extent that source water did not exceed 3,000 mg/L TDS. In addition, the SWRCB Final Report fails to discuss the affected groundwater

MCWD-63

subarea as an "underground source of drinking water" containing less than 10,000 mg/l TDS as specified under both Federal and State law. The DEIR/EIS fails to discuss these very important legal parameters and, therefore, the DEIR/EIS must be revised to address both of those parameters and re-circulated for comment.

MCWD-63 cont.

As discussed below and in other parts of MCWD's comments, the SWRCB Final Review and DEIR/EIS factual assumptions about the groundwater conditions within the Marina Subarea are incorrect. The proposed slant well pumping at the CEMEX site would result in near term and long-term direct, indirect, and cumulative injury to legal users of the groundwater and to groundwater conditions within the Marina Subarea.

MCWD-64

c. ***Section 2.6.2, Project Water Rights.***

The entire DEIR/EIS Section 2.6.2 discussion is based upon the incorrect premise on page 2-32 that "The geographic areas from which the project supply wells could draw water inland of the sea are indeed intruded by seawater" and the additional statement on page 2-37 that "The entirety of the geographical area of the Basin that would be affected by the project contains brackish water rather than fresh water." As discussed above, the entire SWRCB Final Report's legal analysis is founded on the misplaced acceptance of these same CalAm's misrepresentations as to the conditions of the 180/400 Foot Aquifer Subbasin south of the Salinas River. The DEIR/EIS then misrepresents the SWRCB's Final Report by claiming that the Final Report provides the definitive description of the conditions of the 180/400 Foot Aquifer Subbasin in the vicinity of the CEMEX property. As explained in MCWD's comments on Section 4.4, the proposed MPWSP pumping will cause direct, indirect, and cumulative adverse impacts to groundwater conditions. Consequently, CalAm cannot acquire adequate water rights to extract groundwater at the CEMEX site for the MPWSP desalination plant, thereby rendering the project infeasible, at least with the current slant well intake configuration at the CEMEX property.

MCWD-65

d. ***Section 2.6.3, Effect of Monterey County Water Resources Agency Act.***

> A primary purpose of the Agency Act was to give to the MCWRA the power: to increase, and prevent the waste or diminution of the water supply in the Agency, including the control of groundwater extractions as required to prevent or deter the loss of usable groundwater through intrusion of seawater and the replacement of groundwater so controlled through the development and distribution of a substitute surface supply ***and to prohibit groundwater exportations from the Salinas River Groundwater Basin***. [Agency Act, Section 52-8, emphasis added.]

MCWD-66

The economic development of the SVGB is based upon a balance between a predominantly agricultural economy and urban development. Therefore, to achieve this balance, the MCWRA has developed a number of groundwater stabilization and conservation projects (e.g., CSIP) to restore the Basin and prevent seawater intrusion as directed by the Agency Act. As the DEIR/EIS recognizes, to meet the Agency Act's directives, MCWRA

also adopted Ordinance 3709, "prohibiting groundwater extraction within the northern Salinas Valley between the depths of 0 mean sea level and -250 mean sea level." (DEIR/EIS, p. 2-46.) MCWRA's efforts, as well as the efforts of other SVGB users (including MCWD) to restore the Basin and prevent seawater intrusion, have resulted in improved water levels and water quality within the SVGB, particularly in the areas near the project site, as demonstrated by the slant test well's monitoring. (See e.g., attached HGC comments, p. 57.)

The DEIR/EIS's perfunctory discussion of the Agency Act, however, misrepresents the location of the MPWSP source well screens in an effort to suggest the Agency Act and Ordinance 3709 may not apply to prohibit the MPWSP proposed export of the project's treated water. Specifically, the DEIR/EIS misleadingly block quotes the SWRCB report as follows:

> … As currently proposed, the project would use slanted wells and have screened intervals located seaward of the beach. Although the project would serve areas within the territory of the MPWSP, the points of diversion for these proposed wells may be located outside the territory of MCWRA as defined by the Agency Act.

MCWD-66 cont.

(DEIR/EIS, p. 2-46, emphasis added.) While the DEIR/EIS does not state what description of the project the SWRCB reviewed, the majority of the MPWSP's proposed slant well's screens are clearly not beneath the ocean floor. (See DEIR/EIS, Figure 3-3b (not to scale).) In fact, at least one of the slant wells (as designed) does not even extend beneath the ocean floor. (*Ibid*.) Plus, the DEIR/EIS acknowledges that it will be required to return the "freshwater portion of the brackish source water that originated from the inland aquifer" that would be pumped by the proposed project. (DEIR/EIS, p. 4.4-49.) Thus, it does not appear there is any question that the well and the well screens are within the jurisdiction of the County and the proposed extractions of groundwater at the CEMEX site for export out of the SVGB is prohibited by the Agency Act. Given the critical importance of this issue, the DEIR/EIS must be re-circulated to disclose to the public and public agencies whether the well screens are located within the jurisdiction of the County.

Without attempting to resolve this issue, the DEIR/EIS suggests it does not matter, stating the SWRCB (while acknowledging that it is not the body charged with interpreting the Agency Act) "opines that the project would appear consistent with the Agency Act and the Ordinance given that the project would return to the Basin ***any quantity of fresh water withdrawn from the Basin***." (DEIR/EIS, p. 2-40, emphasis added.) The DEIR/EIS then concludes without any analysis that it appears at least preliminarily reasonable to conclude that the project would be consistent with the Agency Act and the Ordinance. (*Ibid.*) However, in reaching this conclusion, the DEIR/EIS mischaracterizes both the SWRCB's advisory opinion and Ordinance 3709. First, as explained above, the SWRCB's entire Final Review is founded on the misplaced acceptance for legal analysis purposes of CalAm's and

now the DEIR/EIS' inaccurate representation of the conditions of the 180/400 Foot Aquifer Subbasin in the vicinity of the CEMEX property and the incorrect assumption that a one-to-one return ratio applies. Second, by extracting groundwater that may be beneficially used in accordance with State and Federal law discussed above, the slant wells will cause seawater to contaminate other beneficial use groundwater, which also must be prevented or completely mitigated. Third, the SWRCB Report uses the phrase "incidentally extracted usable groundwater," not "fresh water withdrawn," in reaching its opinion. These are not interchangeable terms. The DEIR/EIS must define and use the Federal and State law definitions of beneficial use groundwater as discussed above in its analysis. As discussed below, it does not appear the MPWSP is feasible if CalAm is required to return all "incidentally extracted usable groundwater" as the SWRCB opined would be required for the project to be consistent with Agency Act and Ordinance 3709. Focusing on extractions also fails to address the requirement to prevent or mitigate reductions in groundwater quality due to the slant wells causing seawater to contaminate beneficial use groundwater. Fourth, the Agency Act and Ordinance 3709 do not differentiate between "usable groundwater" and groundwater. As discussed below and in the attached HGC comments, removing so-called "unusable groundwater" from this area will likely result in the aquifers in the Marina Subarea becoming more saline, which will make "useable" groundwater further inland "unusable" – and increase seawater intrusion. Therefore, the Agency Act and Ordinance 3709 are not unreasonable restrictions given the purpose of the Agency Act. The DEIR/EIS must be revised and re-circulated to address this issue.

MCWD-66 cont.

Moreover, the DEIR/EIS incorrectly assumes that compliance with the Agency Act constitutes compliance with groundwater law and it does not. Compliance with the Agency Act also does not constitute compliance with CEQA, NEPA, or the SGMA. As the SWRCB stated in its Legal Conclusions in the Executive Summary to the Final Report, CalAm has the burden to show that the MPWSP will not cause injury to other users and to existing groundwater conditions. Included in CalAm's burden of proof is to show that the method by which CalAm extract and returns any fresh water it extracts will prevent injury to others and prevent injury to existing groundwater conditions in the vicinity of the CEMEX property. As MCWD's Section 4.4 comments show, "returning" desalinated water to north of the Salinas River does not in any way prevent injury to others or prevent injury to existing groundwater conditions in the vicinity of the CEMEX property.

MCWD-67

What CalAm and the DEIR/EIS are arguing is that even though a person does not have a groundwater right, the person can obtain a groundwater right to extract groundwater from Point X so long as I "return" the same amount of water to Point Y, which is located some eight miles away and across a major river. During our lifetimes, no molecule of water deposited at Point Y will ever appear at Point X given existing groundwater gradients, which causes groundwater in Castroville to flow east and not west to Monterey Bay. No technical or legal authority is cited in support of the proposed North of Salinas River Return Water scheme would fully mitigate for direct, indirect, and cumulative adverse impacts of the slant well pumping at the CEMEX property.

e. ***Section 2.6.4, Effect of Annexation Agreement.***

In Section 2.6.4, the DEIR/EIS incorrectly states that the 500 AFY pumping limitation on the property does not presently apply and that it would not apply until formal annexation. The DEIR/EIS must be revised to correct this inaccuracy, which bears upon the feasibility of the project. The 1996 Annexation Agreement was entered into for the express purposes of groundwater protection and reduction of seawater intrusion. The 1996 Annexation Agreement limits groundwater pumping of non-potable water on the CEMEX property to a total amount of not more than 500 AFY; all of which groundwater can only to be used on the CEMEX property. The owner of the CEMEX property at that time, Lonestar, agreed to limit its then-existing overlying groundwater rights in exchange for other consideration in the agreement and that limitation took effect upon signing of the Annexation Agreement in 1996.

The 1996 Annexation Agreement established "a contractual process for the exercise of regulatory authority by the MCWRA under Water Code App. Section 52-22, and the MCWD under Water Code section 31048." (MCWRA Negative Declaration re: Annexation of Marina Area Lands to Zones 2/2A, dated February 21, 1996, at p. 4.) The purpose of the 1996 Annexation Agreement was to "establish a groundwater mitigation framework for the lands to be annexed, and will provide money from the Marina area for the MCWRA's Basin Management Plan and for Zones 2 and 2A, for management protection of the groundwater resource in the Salinas River Groundwater Basin and to reduce seawater intrusion." (Purpose section, Attachment B-1 to Initial Study for Marina Lands Annexation.) The 1996 Annexation Agreement (Sec. 5.9) required MCWD to pay a $2,849,410 fee to MCWRA less a credit of $400,000 based on a 1990 agreement and the similar credit given to the Army. Standby charges and assessments were then levied and collected by the MCWRA on an annual basis. MCWD-68

Attachment B-1 to Initial Study for Marina Lands Annexation stated the following:

> GROUNDWATER PUMPING LIMITS
> Pumping Limits. MCWD currently pumps about 2,200 afy, and Lonestar pumps about 500 afy. Under the Agreement and Framework, the present MCWD service area would be limited to an additional 820 afy of potable groundwater, and would otherwise be subject to the same pumping regulations and restrictions by MCWRA as the area within the City of Salinas. Non-agricultural use of Basin groundwater on the Armstrong Ranch would be limited to 920 afy, 20 afy when the Agreement and Framework becomes effective, an additional 150 afy upon annexation, and additional increments of 150 afy every two years thereafter. Groundwater underlying approximately 730 acres of the Armstrong Ranch would be limited to agricultural use, except that 20 afy could be used for potable uses, and water

from that area could also be used at the regional treatment plant. Lonestar would limit its pumping to its current use of 500 afy.

* * *

MCWRA POLICY CONSIDERATIONS.

a. Effect of the annexation on the overall water supply of the Salinas Valley. All lands being annexed currently overlie the Salinas River Groundwater Basin, and all currently use water from the Basin. Annexation on the terms and conditions of the proposed Annexation Agreement and Mitigation Framework ("Agreement and Framework") will result in limiting the pumping of groundwater from the Basin to less than the amounts which the Marina Coast Water District, RMC Lonestar, and the J.G. Armstrong Family claim the right to pump and use for beneficial use, potentially decreasing ultimate water use from the Basin and demand on the overall water supply of the Basin. The Agreement and Framework also would establish a planning framework which could lead to better management and use of reclaimed wastewater and the encouragement of alternative supplies such as desalinated seawater, which would enhance the overall water supply of the Basin.

b. Effect on increase or decrease of seawater intrusion. Although the annexation will not have a physical impact on seawater intrusion, annexation on the terms and conditions of the Agreement and Framework will establish contractual guidelines and limits for potable and reclaimed water use that should result in no increased seawater intrusion and enhance the MCWRA's ability to mitigate existing seawater intrusion.

c. Effect on overdraft of the Salinas Valley. Marina Coast Water District currently draws most of its water from the deep (900') aquifer, which has not been shown to be in an overdrafted condition and has not been shown to contribute to the overdraft of the shallower aquifers. Lonestar and Armstrong either are already pumping or have the capability to pump from the shallower aquifers. While the annexation will not physically impact overdraft, pumping limits for the annexed Marina Area lands from the deep and the shallower aquifers will limit overdraft of water resources in the Salinas Valley, and a management framework for reclaimed water will help to mitigate overdrafting in the Salinas Valley.

d. Amount of water presently pumped from the aquifer of the Salinas Valley. MCWD has present operational capacity to pump about 6,000 afy, has an approved Urban Water Management Plan and an approved Urban Water Shortage

MCWD-68 cont.

Contingency Plan to pump 3,020 afy of potable water, and presently pumps about 2,200 afy of potable water, including some potable water for the Armstrong Ranch. Lonestar presently pumps about 500 afy. A new, agricultural well of unknown capacity recently has been drilled on the Armstrong Ranch, and is expected to be operational before the MCWRA's Board of Supervisors acts on the proposed annexation.

e. Quality of the water made available. Annexation will not change the quality of water available either from or to the annexed lands. Lands served by MCWD currently have both potable and nonpotable water available from and to those lands. The Lonestar property currently pumps and uses water that is considered nonpotable from the shallower aquifers, and has the ability to drill a well into the deep aquifer to obtain potable water. Groundwater underlying the Armstrong Ranch is potable. Both potable and nonpotable water might be transported to the Marina Area lands from elsewhere in the Basin whether or not the proposed annexation occurs.

f. Amount of additional groundwater to be used by the annexed area. Annexation will not provide additional groundwater to the annexed area, because the Marina area already overlies the Basin. The net projected change in groundwater pumping for the Marina Area by the year 2010, assuming full implementation of the Agreement and Framework, is about 115 afy. This is based on limits on increased pumping in the annexed area of 1,740 acre-feet/year (afy), and decreased groundwater use of 300 afy in the annexed area from desalination and 1,325 afy in adjacent agricultural areas from reclaimed water management.

g. Water supplies for future growth. Annexation will not change water supplies available for future growth. The Agreement and Framework will provide contractual limits on the use of potable water supplies available from the Basin for future growth. The Agreement and Framework also encourages proactive management of the deep aquifer. Reclaimed water supplies may be managed differently if the Agreement and Framework becomes effective. Non-Basin, potable water supplies are not affected by the annexation or the Agreement and Framework. Agricultural water supply within the area to be annexed is not affected by the annexation.

MCWD-68 cont.

Thus, the Initial Study shows that the prescribed pumping limits/groundwater allocations for the annexed Marina Area lands from the deep and the shallower aquifers

were intended to (1) limit and avoid increasing seawater intrusion, (2) enhance the MCWRA's ability to mitigate existing seawater intrusion, (3) not physically impact overdraft, and (4) help limit the overdraft of water resources in the Salinas Valley.

While Section 7.3 of the 1996 Annexation Agreement provides that the Lonestar Property's annexation to Zones 2 and 2A would not take effect until the Lonestar Property has been approved for annexation to the Zones, the 1996 Annexation Agreement itself, including the 500 AFY limitation on pumping on the Lonestar property, took effect in 1996 upon execution of all of the parties. (1996 Annexation Agreement, Section 2.9, p. 2.) More importantly, the then Lonestar property already had an overlying groundwater right, i.e., a right to pump groundwater from the Lonestar property for use on the Lonestar property. Section 7.4.5 limited Lonestar's purpose of use to non-potable industrial or agricultural use. Lonestar agreed that "All groundwater withdrawn from the Basin by Lonestar may be used only within the Basin." (Section 7.1, p. 17.) Section 7.2 states, "Commencing on the effective date of this Agreement and Framework, Lonestar shall limit withdrawal and use of groundwater from the Basin to Lonestar's historical use of 500 afy of groundwater." Lonestar did not need to sign the Annexation Agreement to pump 500 AFY for non-potable water uses since it already had that overlying right, but it agreed to that limitation in consideration of the right to obtain potable water from MCWD for future urban development on the property on terms set forth in the agreement and to limit seawater intrusion. Lonestar's overlying right does not provide any benefit to CalAm's proposed extraction and then export of the groundwater off the CEMEX property (property it does not own) and out of the Basin.

MCWD-68 cont.

Even if one were to accept the DEIR/EIS' incorrect conclusion that the Annexation Agreement only applies if and when the CEMEX property is actually annexed to MCWD, groundwater law (as opposed to the Agency Act) prevents the export of the groundwater underlying the CEMEX property from the CEMEX property. The DEIR/EIS itself admits on page 2-30 that CalAm has no right to export groundwater beyond the proposed desalination plant location, and for the same reason, CalAm has no right to export groundwater beyond the CEMEX property where the slant wells would actually be located.

MCWD-69

The DEIR/EIS on page 2-42 additionally proposes that "CalAm could conceivably construct and employ an injection well on the CEMEX property to return 500 afy to that property such that the MPWSP would have a net-zero effect on groundwater from the CEMEX land and conceivably could operate regardless of whether the 500 afy groundwater withdrawal limitation were imposed at some point in the future." Interestingly, the DEIR/EIS admits that in order to "have a net-zero effect on groundwater from the CEMEX land," CalAm needs to inject the return water directly at the CEMEX property. This directly contradicts the DEIR/EIS' support for the Return Water Agreement and supports MCWD's position that providing "return" water to north of the Salinas River will not mitigate for the direct adverse impacts to groundwater from the CEMEX property.

MCWD-70

The DEIR/EIS must be revised to correct this inaccuracy, which bears upon the feasibility of the project.

Moreover, as explained in the HGC Comments, there is no evidence to support the conclusion that returning 500 afy to the CEMEX property would ensure that no more than 500 afy groundwater was withdrawn from the project as limited by the Annexation Agreement. In fact, the evidence indicates substantially more groundwater would need to be injected to demonstrate consistency with the agreement. (See HGC Comments, p. 31.)

MCWD-70 cont.

In short, CalAm does not and will not have sufficient groundwater rights or developed water rights for the proposed MPWSP, and the DEIR/EIS fails to explain this aspect of the water rights framework that governs the Marina Subarea of the SVGB. The DEIR/EIS must be revised to reflect the full scope of the water rights framework that governs the proposed project site and that framework's impact on the feasibility of the project.

MCWD-71

f. ***The DEIR/EIS Provides No Scientific Proof or Analysis in Support of its One-to-One Ratio, which Would Not Mitigate for All Direct, Indirect, and Cumulative Impacts from Slant Well Pumping on the CEMEX Property.***

The DEIR/EIS incorrectly and inexcusably assumes without any scientific proof or analysis that a one-to-one return water ratio would be sufficient to fully mitigate for the source well pumping on the CEMEX property, i.e., for every one AF of good groundwater extracted, it must only be replaced with one AF of desalinated water. DEIR/EIS' one-to-one return water ratio appears to be upon the incorrect assumption that the Agency Act only requires a one-to-one return ration and that compliance with the Agency Act constitutes compliance with groundwater law and it does not. Again, compliance with the Agency Act also does not constitute compliance with CEQA, NEPA, or the SGMA.

MCWD-72

Slant well pumping on the CEMEX property draws seawater, brackish water, and groundwater adequate for beneficial uses to the slant wells. The CEMEX property pumping will also draw seawater into beneficial use groundwater areas thereby directly degrading the groundwater into brackish water. The slant well pumping has direct, indirect, and cumulative adverse water quality and water quantity impacts within the groundwater aquifers, as explained in MCWD's comments on Section 4.4. The one-to-one ratio does not adequately mitigate for all of these impacts being based solely upon direct extraction of beneficial use groundwater. Therefore, the use of a one-to-one return ratio by the DEIR/EIS is a fatal flaw.

g. ***The Sustainable Groundwater Management Act (SGMA).***

The DEIR/EIS Section 2.6 inexplicitly fails to discuss SGMA and that law's applicability to the proposed project. SGMA became effective January 1, 2015. SGMA grants local public agencies the authorities to manage groundwater in a sustainable manner and authorizes state intervention, primarily by the SWRCB when local public agencies fail to take required actions by the deadlines set forth in SGMA. SGMA Water Code Section

MCWD-73

10720.5(b) states, "***Nothing in [SGMA], or in any groundwater management plan adopted pursuant to [SGMA], determines or alters*** surface water rights or ***groundwater rights under common law*** or any provision of law that determines or grants surface water rights." Section 10720.5(c) states that water rights may be determined in a groundwater adjudication action pursuant to Code of Civil Procedure Sections 830, et seq. SGMA applies to the proposed project and the application of SGMA's standards and requirements are separate and apart, although related, to any groundwater rights analysis. The DEIR/EIS must include a SGMA analysis.

MCWD-73 cont.

The California Department of Water Resources had previously classified the 180/400 Foot Aquifer Subbasin as a high-priority subbasin and in January 2016, the Subbasin was designated as a Critically Overdrafted Basin.[13] Both the MPWSP's slant wells and desalination plant are located within the 180/400 Foot Aquifer Subbasin. Because of the Critically Overdrafted Basin classification, the 180/400 Foot Aquifer Subbasin is required to adopt a State-approved groundwater sustainability plan (GS Plan) or coordinated GS Plans by January 31, 2020.[14] The GS Plan must include measurable objectives and milestones in increments of five years to achieve sustainability within 20 years of the GS Plan adoption, which would be no later than January 31, 2040, in the case of the 180/400 Foot Aquifer Subbasin.[15]

The terms "sustainability goal," "sustainable groundwater management," "sustainable yield," and "undesirable results" are defined in Water Code Section 10721. They require that the applicable groundwater sustainability agency (GSA) or agencies within the Subbasin adopt and implement a GS Plan or coordinated GS Plans, which manages the use of groundwater within the Subbasin in a manner that can be maintained during the 20-year time horizon without causing any undesirable results. "Undesirable results" applicable to the proposed MPWSP include (1) Chronic lowering of groundwater levels, (2) Significant and unreasonable reduction of groundwater storage through, for example, causing seawater to displace or contaminate existing groundwater thereby reducing available groundwater storage, (3) Significant and unreasonable seawater intrusion, and (4) Significant and unreasonable degraded water quality, including the migration of contaminant plumes that impair water supply and including the migration of seawater into portions of aquifers currently occupied with groundwater. The SGMA baseline conditions date is January 1, 2015.[16]

MCWD-74

MCWD's comments on DEIR/EIS Section 4.4, Groundwater Resources, show (1) that there are existing good groundwater conditions in the vicinity of the CEMEX property not recognized in Section 4.4 and (2) that the proposed 6.4 MGD and 9.6 MGD

[13] / http://www.water.ca.gov/groundwater/sgm/pdfs/COD_BasinsTable.pdf
[14] / Water Code §§ 10720.7(a), 10735.2(a)(2), 10735.2(a)(3).
[15] / Water Code § 10727.2(b)(1).
[16] / Water Code § 19727.2(b)(4).

desalination plants will cause or increase all four undesirable results between January 1, 2015, and January 31, 2040. For example, approval of the MPWSP with slant well pumping on the CEMEX property that increases seawater intrusion and decreases good groundwater conditions in the 180/400 Foot Aquifer Subbasin south of the Salinas River, would be in violation of SGMA.

The proposed MPWSP is intended to be a long-term project with an operating life well beyond the requirement of achieving the required sustainability goal by January 31, 2040, for the 180/400 Foot Aquifer Subbasin. The DEIR/EIS' failure to analyze the proposed project's impacts against SGMA's standards and requirements especially relating to how the proposed project will create or increase undesirable results from January 1, 2015, through January 31, 2040, when the 180/400 Foot Aquifer Subbasin is required to achieve its sustainability goal, is another fatal flaw of the DEIR/EIS.

MCWD-74 cont.

* * *

In summary, CalAm cannot obtain any overlying, appropriative, or prescriptive groundwater rights for the proposed project's feed water whether at the proposed site or anywhere overlying the Marina Subarea utilizing the proposed slant well technology and proposed MPWSP source well locations. The DEIR/EIS would fashion a No-Injury Developed Water Export Right based upon a definition of "fresh water," which is not in accordance with the SWRCB's own Source of Drinking Water Policy and not in accordance with Federal and State law. The CPUC must apply the legal parameters in both (1) the SWRCB's own Source of Drinking Water Policy, which is applicable to the proposed project under the Central Coast RWQCB Basin Plan (DEIR/EIS at 4.10-37), and (2) the Underground Source of Drinking Water as defined in Federal and State law, to calculate the amount of "Protected Water" contained in the feed water that the project would pump. Using the same legal parameters, the CPUC would also need to determine to what extent the slant well pumping would cause seawater to contaminate Protected Water.

MCWD-75

CalAm then has the burden to prove that in creating any new developed water, (1) the proposed MPWSP source well pumping will cause no injury to any legal user of the groundwater within the Marina Subarea, (2) will cause no injury to pre-January 1, 2015 baseline groundwater conditions in the Marina Subarea, including, but not limited to, reductions in the availability and quantity of protected groundwater, reductions in groundwater quality, and increases in seawater intrusion, and (3) will not cause any SGMA undesirable results so as to prevent the 180/400 Foot Aquifer Subbasin from achieving groundwater sustainability by 2040. The DEIR/EIS must be revised to acknowledge these circumstances and their impact on project feasibility.

MCWD-76

Finally, the DEIR/EIS should address the Monterey County Code of Ordinances section 10.72.030(B) and the issues surrounding private ownership of desalination plants. We would also point out that the California Coastal Commission ("CCC") report entitled

MCWD-77

Seawater Desalination and the California Coastal Act (CCC, 2004) cited in the DEIR/EIS, addresses Coastal Act public resources policies related to desalination, including policies relating to public versus private ownership of desalination facilities in Chapter 4. As many of these policies relate to environmental impacts (e.g. public trust doctrine and ecosystem preservation) this issue should be addressed in the revised DEIR/EIS. Notable, the Sanctuary's Management Plan, discussed below, provides that MBNMS should consider public versus private ownership.

MCWD-77 cont.

B. THE PROJECT DESCRIPTION INCLUDED IN THE DEIR/EIS IS DEFICIENT UNDER CEQA.

An accurate, stable and finite project description is necessary for an intelligent evaluation of the potential environmental effects of a proposed activity. (*See San Joaquin Raptor Rescue Center v. County Of Merced* (2007) 149 Cal.App.4th 645, 655 (*Raptor*); *McQueen v. Board of Directors of the Midpeninsula* (1988) 202 Cal.App.3d 1136, 1143; *County of Inyo v. City of Los Angeles* (1977) 71 Cal.App.3d 185, 193 (*County of Inyo*) [an accurate, stable and finite project description is the sine qua non of an informative and legally sufficient EIR].) The DEIR/EIS's description of the project omits critical information needed to evaluate the potential impacts of the project, including but not limited to the intended life or length of project, decommissioning of slant wells after their useful life, potential need to construct additional slant wells over the life of the project, and the amount of return water that would be required for the project. These failures require that the DEIR/EIS be revised and re-circulated.

MCWD-78

First, the DEIR/EIS's project description fails to adequately disclose the temporal length of the project. While MCWD understands that CalAm is requesting permission to operate the MPWSP through 2060, by failing to disclose this information to the public, it is impossible for the public to understand and comment on the potential long term impacts of the project. The Final EIR/EIS must disclose the length of the project and identify whether all impacts were evaluated based on the proposed 40+ year project life.

MCWD-79

Second, the DEIR/EIS states that the project proposes to convert the slant test well to a permanent well, but fails to address the *requirement* of the California Coastal Commission ("CCC") that the slant well be decommissioned. (DEIR/EIS, p. 3-2.) Rather, the DEIR/EIS states: "Construction of the test slant well and operation of the pilot program was covered under separate environmental review… and it is not part of the proposed project being evaluated in this EIR/EIS.…." If the DEIR/EIS is attempting to tier off of CCC's analysis in its CEQA-equivalent document,[17] the DEIR/EIS must expressly state so in the EIR and follow CEQA's tiering requirements. Regardless, the DEIR/EIS must presume the slant test

MCWD-80

[17] / The DEIR/EIS's statement that the City of Marina completed tis CEQA review in November 2014 is misleading. As CalAm and the DEIR/EIS preparers are aware, the City never completed its CEQA review for the test well, but determined it needed to conduct additional environmental review before considering approval of test well.

well will be decommissioned as required in assessing the project's impacts given the CCC's prior environmental review did evaluate alternative locations for the test well and the acknowledgement the test well is located in an Environmentally Sensitive Habitat Area (ESHA) and within the coastal retreat area. The DEIR/EIS and the CPUC should also require CalAm to account for and return all of the groundwater pumped by the test well as all such groundwater has and will be wasted to the ocean as it is part of the larger project.

MCWD-80 cont.

MCWD-81

Third, the Project Description states the slant wells would require maintenance every 5 years, but fails to discuss decommissioning the wells after their useful life or the need to construct replacement wells during the life of the project. (Compare DEIR/EIS, p. 3-57 to 4.2-70 [operational life of the slant production wells anticipated to be 20 to 25 years).) Given that slant wells are an unproven technology[18] and results from the only existing slant well at the Doheny Beach, in Dana Point, CA (see Geoscience, Inc. 2012, Aquifer Pumping Test Analysis and Evaluation of Specific Capacity and Well Efficiency Relationships SL-1 Test Slant Well Doheny Beach, Dana Point, California Prepared for: Municipal Water District of Orange County September 7, 2012 , available at http://www.mwdoc.com/filesgallery/SL_1_Step_Test_Comp._FINAL_TM_Geoscience_12_09_2012.pdf), the DEIR/EIS must disclose, evaluate, and propose mitigation to address how slant wells will be decommissioned after their useful life and how the MPWSP will obtain the required source water over the 40 plus year project when none of the slant wells are anticipated to operate for the full life of the desalination plant.

MCWD-82

Finally, the Project Description fails to disclose the amount of source water that the MPWSP would be required to return to the SVGB. In discussing the Castroville Pipeline, the DEIR/EIS states:

> The 4.5-mile-long, 12-inch-diameter Castroville Pipeline would convey desalinated Salinas Valley return water from the MPWSP Desalination Plant to the CSIP distribution system and the CCSD Well #3. As described in Chapter 2, Water Demand, Supplies and Water Rights, the portion of the water drawn from the subsurface slant wells that is determined to be groundwater originating from the Salinas Valley Groundwater Basin, would be delivered to CCSD as desalinated water in lieu of CCSD pumping an equivalent amount of groundwater. Under the proposed project, the first 800 afy would go to the CCSD and the remaining water would go to the CSIP.

MCWD-83

[18] / Notably, as discussed in Part VIII below, HWG member Mr. Feeney recently participated in another panel for the CCC's "Final Report: Technical Feasibility of Subsurface Intake Designs for the Proposed Poseidon Water Desalination Facility at Huntington Beach, dated October 9, 2014 available at http://www.coastal.ca.gov/pdf/ISTAP_Final_Phase1_Report_10-9-14.pdf.). That panel concluded that slant wells were unproven technology and infeasible. (See *id.*, pp. 37, 56, 64.)

(DEIR/EIS, p. 3-35, emphasis added.) However, as discussed further below, the DEIR/EIS models the possibility of returning 0%, 3%, 6% and 12% pumped water, but never estimates the amount of return water that will be required. Importantly, the amount of groundwater that would likely need to be returned to the SVGB would be significantly higher than 12 % at least in the initial period of project operation – potentially 30% or more. As discussed in our comments below, even this higher estimate is based on DEIR/EIS unreliable modeling and assumptions that fail to address impacts to the Dune Sand Aquifer. (See comments below on Section 4.4 [Groundwater Resources] and HGC comments, p. 59.)

MCWD-83 cont.

Moreover, the DEIR/EIS fails to disclose to the public how the amount of water that would need to be returned to the Marina Subarea would be calculated and by whom. MCWD requests the DEIR/EIS include a detailed explanation of how the calculation would be done (the methodology to be used), whether any portion of the calculation would be subject to CalAm's discretion, and whether and by whom CalAm's calculation would be reviewed, including any judicial review required. In turn, this calculation must be included as a condition of approval or mitigation.

MCWD-84

Given these omissions, the DEIR/EIS must be revised and recirculated. "[O]nly through an accurate view of the project may the public and interested parties and public agencies balance the proposed project's benefits against its environmental cost, consider appropriate mitigation measures, assess the advantages of terminating the proposal and properly weigh other alternatives…." (*City of Santee v. County of San Diego* (1989) 214 Cal.App.3d 1438, 1454.) Without this information it is impossible for the public or public agencies to provide meaningful comments on the DEIR/EIS's review of potential impacts and proposed mitigation and alternatives.

MCWD-85

C. THE DEIR/EIS'S ENVIRONMENTAL ANALYSIS IS INADEQUATE.

1. Preliminary Statement Regarding Groundwater Analysis and Need to Recirculate Revised DEIR/EIS.

Based on MCWD's participation in the Regional Desalination Project and its more recent involvement in the environmental review process and litigation relating to CalAm's slant test well for the MPWSP, MCWD is intimately familiar with the public's long-standing concerns relating to the project's potential groundwater impacts to the SVGB. While all of this history is relevant to understanding the project, we do not have the time or the voluminous space necessary to fully recount it all here. However, we do provide a summary of recent events that should be part of the record and that demonstrate the lack of substantial evidence supporting the DEIR/EIS's groundwater analysis.

MCWD-86

SWRCB's Advisory Opinion Determined the Need for the Slant Test Well to Accurately Characterize the Baseline and Potential Impacts to SVGB. The SWRCB's advisory opinion determined that the following actions to support the conclusion of no harm:

MCWD-87

> Studies are needed to determine the extent of the Dune Sand Aquifer, the water quality and quantity of the Dune Sand Aquifer, the extent and thickness of the SVA and the extent of the 180-Foot Aquifer.

(DEIR, p. 4.4-53.) As discussed in the HGC comments, studies to date have not determined the extent or water quality in the Dune Sand Aquifer, which renders the DEIR/EIS's analysis and modeling grossly inadequate. (HGC Comments, p. 2.)

> The DEIR/EIS further acknowledges that the SWRCB required:
>
> "The effects of the MPWSP on the Basin [i.e., the SVGB] need to be evaluated. Specifically, a series of test boring/wells would be needed to assess the hydrogeologic conditions at the site. ***Aquifer testing also would be needed to establish accurate baseline conditions and determine the pumping effects on both the Dune Sand Aquifer and the underlying 180-Foot Aquifer.*** Aquifer tests should mimic proposed pumping rates."
>
> "Updated groundwater modeling will be needed to evaluate future impacts from the MPWSP. Specifically, modeling scenarios will need to be run to predict changes in groundwater levels, groundwater flow direction, and changes in the extent and boundary of the seawater intrusion front. **Additional studies also will be necessary to determine how any extracted fresh water is replaced, whether through re-injection wells, percolation basins, or through existing recharge programs.** It may also be necessary to survey the existing groundwater users in the affected area. The studies will form the basis for a plan that avoids injury to other groundwater users and protects beneficial uses in the Basin. **To ensure that this modeling provides the best assessment of the potential effects of the MPWSP, it is important that any new information gathered during the initial phases of the groundwater investigation be incorporated into the groundwater modeling studies as well as all available information including current activities that could influence the groundwater quality in the Basin."**

(DEIR/EIS, p. 4.4-53, emphasis added.) As noted in below and in the HGC and GeoHydros Comments, the DEIR/EIS's superposition model cannot and does not model groundwater flow direction or the changes in the extent and boundary of the seawater intrusion. A dual density model is required to meet the SWRCB requirements. (See e.g., HGC Comments, p. 34 and GeoHydros Comments, p. 9.)

MCWD-87 cont.

Testimony from HWG's and CPUC's Representatives during Slant Test Well Environmental Review at City of Marina Led the City and Public to Believe Test Well Data Was Necessary and Would be Used in the DEIR/EIS to Evaluate the MPWSP's Groundwater Impacts. CalAm sought approval from the City of Marina to construct the

MCWD-88

slant test well ostensibly for the purpose of satisfying the SWRCB's requirements of assessing the feasibility of MPWSP's slant wells and compiling baseline information for the project's modeling and environmental review. As part of this process the HWG and CPUC representatives stressed the importance of the test well to validate the MPWSP's modeling so the EIR could accurately assess the MPWSP's potential groundwater impacts. Martin Feeney of the HWG testified:

> **The test well is essential for being able to get the data that allows us to validate the models so that we can actually predict the impacts that go into the EIR.** We're at the point now where you can wave your arms about the geology, but we need some real data. We need to stress the system with the test well and to figure out how the system actually reacts so we can answer the questions about water rights, impacts, all those things come out of the actual testing of the test well and looking at the impacts in the monitoring wells that we're putting in around it to see how the whole system reacts. ***This is about a test well that helps us define the actual response of a system to the pumping so that we can accurately look at the impacts.***
>
> … What is the impact to the basin? You know, what is the impact to existing users? You know, I'm being paid by the farm -- farmers because they are concerned. It's about the impacts to the basin. So we got together, and that's the point is to figure out when you test this well, can it be done without impacts? Can it be done that it only takes seawater? That's the purpose of this. It's a feasibility study.
>
> ***My personal -- my personal opinion is this is a little dicey. It may not work.*** Other people have a different opinion. They think it's going to work fine. That's fine. We're to the point now where it's just opinion among a bunch of qualified experts. We need to actually drill this thing and stress it. That's the point.
>
> **So we get the monitoring wells, we get around the pumping well on all sides, we will be able to see what the draw-down effects are, and to be able to build a better groundwater model so that the full-scale project, should it be moved forward, <u>that the modeling that's in the EIR, the full EIR, can accurately model the impacts of the full-scale project</u>. We can't build a model to look at the full-scale project until we know what the aquifer parameters are, the transmissivity, the storativity, and what the boundary condition does to the well draw-down.** That's the deal.

(City of Marina transcript, pp. 110-111, 295-297, emphasis added.)

MCWD-88 cont.

Eric Zigas, the CPUC's environmental consultant, also testified about the importance of the test well to inform the EIR's analysis:

> And the Hydrogeology Work Group, you just heard Martin tell you, they struggled with concepts and understanding, and they've come to what I think is a common understanding of how the basin works.
>
> … ***But uncertainly really is a -- makes for risky decisions***, and risk can be reduced by gaining knowledge, and the knowledge you can gain from the test well will benefit not only CalAm, it will benefit every basin user.
>
> ***… We will also be able to tell you with certainly what the impacts are associated with their wells, but we will only (sic) be able to model it without the well. We won't have real data. Okay?***
>
> So I do encourage you to learn more about your basin, be better informed. ***When we come back in a year with CalAm's application for the Coastal Development Permit, that conversation should be more informed. It should be informed by data and information, and that information will be obtained through this test well. Reduce your risk.*** Go ahead and learn the knowledge. Learn more about your basin.

(City of Marina transcript, pp. 111-118, emphasis added.)

Given the HWG's and the CPUC's representatives' testimony that the slant test well data was needed to accurately model the impacts in the MPWSP EIR, please explain why it is worth taking the risk to approve the project without the using the TSW data in the project's modeling. Please also explain why after all the efforts to construct the test well and obtain monitoring data, the DEIR/EIR only uses a simplified superposition model that precludes prediction of measurable groundwater elevations associated with the proposed pumping and impacts on water quality, which would provide the only means for stakeholders to validate the model predictions and potential project impacts. (See HGC Comments, p. 34; GeoHydos Comments, p. 9.)

MCWD-88 cont.

Slant Test Well Review at the Coastal Commission. When the City determined that an EIR was required before it could consider granting CalAm's Coastal Development Permit (CDP) application for the slant test well, CalAm chose not to work with the City and appealed the City's denial without prejudice to the California Coastal Commission (CCC). As the DEIR/EIS recognizes, the CCC approved CDPs for the MPWSP's slant test well at the CEMEX site in November of 2014. The CCC issued the approvals over MCWD's (and others) objections that approval of the slant test well was premature because it improperly segmented the test well from the whole of the MPWSP, failed to analyze and mitigate the test well's potential impacts to the SVGB, failed to consider feasible alternatives, and

MCWD-89

usurped the City of Marina's land-use authority, among other defects. (See merits briefs in *MCWD v. California Coastal Commission*, Santa Cruz Superior Court Case No. CV180839, attached as Exhibit "5".) When the CCC approved the slant test well, the CCC overrode the slant test well's significant and unavoidable impacts to ESHA (CCC findings, pp. 3 and 66, attached as Exhibit "9") and the project's inconsistency with the City of Marina's LCP (*id.*, pp. 38, 59, and 62) based on express findings that included the necessity of the slant test well to assess the feasibility, environmental setting, and design of the MPWSP, stating:

> **… pumping and water quality testing to be conducted during the slant well test is necessary to inform the design of a potential full-scale facility. Other actions, such as drilling additional boreholes or conducting additional modeling, would not be sufficient to characterize the site and its potential to provide source water."**

MCWD-89 cont.

(Id., p. 60, emphasis added.) When MCWD sought injunctive relief in its lawsuit to enjoin construction and operations of the slant test well, the CCC, SWRCB, and CalAm argued any delays to the slant well were against the public interest because the information from the slant test well was necessary to inform the MPWSP's feasibility and environmental review.

In light of the statements from the CCC, SWRCB, and CalAm regarding the necessity of the slant test well to inform the CPUC's environmental review, please explain why has the DEIR/EIS used modeling the fully utilizing the information from the operations of the test well? Does the CPUC and Sanctuary disagree with the CCC's and SWRCB's conclusions that detailed analysis of all information from the full term of operations of the slant test well is necessary and relevant to determine the baseline environmental setting and assess the potential impacts for the MPWSP?

2. The DEIR/EIS's Discussion of Groundwater Impacts Does Not Comply with CEQA.

The DEIR/EIS's analysis of groundwater impacts is grossly inadequate as explained below and in the attached HGC Comments (Exhibit # 1), GeoHydros Comments (Exhibit # 2), and EKI Comments (Exhibit # 3).[19] Specifically, the DEIR/EIS baseline description of the Marina Subarea is misleading and conflicts with the best available information; the DEIR/EIS fails to disclose the MPWSP's inconsistencies with applicable laws and regulations; the analysis of groundwater impacts is based on unreliable modeling rather than substantial evidence; and cursory treatment of cumulative impacts does not comply with CEQA or NEPA. These error must be addressed in a revised DEIR/EIS prior the CPUC or Sanctuary's

MCWD-90

[19] / These experts' comments must be responded to separately. While MCWD incorporates by reference these comments into this letter, they are not fully repeated here.

h. ***The baseline description of the Marina Subarea is misleading and conflicts with the best available information;***

CEQA requires an EIR to "delineate environmental conditions prevailing absent the project, defining a 'baseline' against which predicted effects can be described and quantified." (*Neighbors for Smart Rail v. Exposition Metro Line Construction Auth.* (2013) 57 Cal.4th 439, 447.) The baseline is normally the "existing conditions" in the vicinity of the project "as they exist at the time the [NOP] is published." (*Id.* at p. 448.) "Knowledge of the regional setting is critical to the assessment of environmental impacts." (Guidelines, § 15125, subd. (c).) Thus, CEQA Guidelines section 15125 provides that an EIR "must include a description of the physical environmental conditions in the vicinity of the project . . . from both a local and *regional* perspective." (*Id.* at subd. (a), emphasis added.) Furthermore, "[s]pecial emphasis should be placed on environmental resources that are rare or unique to that region and *would be affected by the project*." (*Ibid*, emphasis added.)

MCWD-91

An EIR's description of a project's environmental setting plays a critical role in all of the subsequent parts of the EIR because it provides "the baseline physical conditions by which a Lead Agency determines whether an impact is significant." (Guidelines, § 15125, subd. (a).) Longstanding case law upholds this fundamental principle by recognizing that "[a]n EIR must focus on impacts to the *existing environment*, not hypothetical situations." (*County of Amador* v. *El Dorado County Water Agency* (1999) 76 Cal.App.4th 931, 955, emphasis added.)

"If the description of the environmental setting of the project site and surrounding area is inaccurate, incomplete or misleading, the EIR does not comply with CEQA." (*Cadiz Land Co. v. Rail Cycle* (2000) 83 Cal.App.4th 74, 87 (*Cadiz*).) Here, as is explained below, the EIR's "description and consideration" of the regional setting "is so incomplete and misleading that it fails to meet the standard set forth in . . . Guidelines section 15125." (*San Joaquin Raptor/Wildlife Rescue Center v. County of Stanislaus* (1994) 27 Cal.App.4th 713, 723.)

Here, the DEIR/EIS fails to comply with the fundamental CEQA baseline disclosure requirements for the following reasons and those included in the HGC comments.

(1) The DEIR/EIS fails to provide an accurate and complete description of the Dune Sand Aquifer in the project area and further inland to the extent the aquifer could be impacted by the project as required by CEQA. Instead the DEIR/EIS presents a misleading picture of the aquifer implying groundwater in the Dune Sand Aquifer has no value or uses, stating: "most of the water in the Dune Sand Aquifer has been intruded by seawater due to proximity with the ocean and seawater intrusion and is considered saline to brackish. (See DEIR/EIS, p. p. 4.4-8 [citing 13 year-old study], emphasis added.) As described in the attached HGC comments and EKI Comments, the Dune Sand Aquifer contains potable, freshwater less than a mile from the project site and extends miles inland. These comments further explain how the Dune Sand

MCWD-92

Aquifer plays an important role in recharging the underlying aquifers and preventing seawater intrusion. MCWD-92 cont.

(2) The DEIR/EIS fails to provide an accurate and complete description of the 180-Foot Equivalent Aquifer in the project area and further inland to the extent the aquifer could be impacted by the project as required by CEQA. Instead the DEIR/EIS presents a misleading picture of the aquifer stating it is unconfined and implying groundwater in the 180-foot Aquifer is controlled by seawater at the site and miles inland, stating: "At the CEMEX site, the Dune Sand Aquifer and the 180-Foot Equivalent Aquifer are unconfined, as there are no extensive overlying low permeability clay units.… Based on the recent groundwater testing data discussed in the Groundwater Quality subsection below, the quality of water in the 180-FTE Aquifer is directly influenced by seawater; this influence extends for miles inland, as discussed below in the Seawater Intrusion section." (See DEIR/EIS, p. 4.4-11 [citing without reference to undisclosed recent groundwater testing data].) As described in the attached HGC comments the 180-foot aquifer contains is potable, freshwater less than a mile from the project site. Those comments further explain how the modeling for the project, and thus the DEIR/EIS, assumed the 180-foot aquifer was unconfined despite available information demonstrating otherwise. In fact, the HWG, admitted the 180-foot aquifer is at least semi-confined in the project area. (See HGW Memo, dated June 22, 2015, attached as Exhibit "1".) This error is not insignificant; in fact, this error alone requires re-circulation of the DEIR/EIS with updated modeling. (See HGC comments, p. 36 [describing how change in confinement will dramatically impact modeling – extending the zone of influence/drawdown much further than was modeled and disclosed in the DEIR/EIS].) MCWD-93

(3) The DEIR/EIS fails to provide an accurate and complete description of the 400-Foot Aquifer, stating it "is directly influenced by seawater," which extends for miles inland. (See DEIR/EIS, p. 4.4-11 [citing without reference to undisclosed recent groundwater testing data].) As described in the attached HGC comments [400-foot aquifer contains potable, freshwater less than a mile from the project site]. (See e.g., HGC comments, pp. 57.) MCWD-94

(4) The DEIR/EIS fails to provide an accurate and complete description of groundwater flows and flow direction in the project area. The DEIR/EIS incorrectly suggests that groundwater monitoring from north of the Salinas River shows flows and flow direction in the project area (DEIR/EIS, 4.4-14 - 4.4-16, citing Figures 4.4-5 and 4.4-6.) The cited figures, however, do not cover the project area. (See DEIR/EIS Figures 4.4-5 and 4.4-6.) The DEIR/EIS qualifies this statement for the Dune Sand Aquifer suggesting that while flows in the Dune Sand Aquifer are not known "based on the aquifer depth and geologic structure, it is reasonable to expect that they would be tidally controlled with little to no net horizontal flow in any particular direction." (DEIR/EIS, 4.4-14.) Again, this is inaccurate. As explained in the attached HGC comments, groundwater data show that flows in the Dune Sand Aquifer flow towards MCWD-95

the ocean and thus are protective of seawater intrusion. (See e.g., HGC comments, p. 70; see Figure 6 attached to same.)

MCWD-95 cont.

(5) The DEIR/EIS fails to provide an accurate and complete description of seawater intrusion in the project area and the area impacted. Instead, the DEIR/EIS misleads the public into believing all groundwater in the Marina Subarea, in fact the entire SVGB to Salinas, is seawater intruded and has no beneficial uses stating:

> Figures 4.4-10 and 4.4-11 illustrate the seawater intrusion areas as of 2013 within the 180-Foot and 400-Foot Aquifers, respectively (MCWRA, 2015)
>
> … The 2013 estimates of seawater intrusion within the 180-Foot and 400-Foot Aquifers indicate that seawater has intruded to a maximum of approximately 8 miles and 3.5 miles inland, respectively, inferred from chloride concentrations greater than 500 mg/L. The seawater intrusion has resulted in the degradation of groundwater supplies, requiring urban and agricultural supply wells within the affected area to be abandoned or destroyed (MCWRA, 2001).

(DEIR/EIS, pp. 4.4-28 and 4.4-31.) As explained in the attached HGC Comments and EKI Comments, Figures 4.4-10 and 4.4-11 are inconsistent with monitoring data that shows that numerous wells with area shown to be seawater intruded, in fact, are not. (See also HGC comments, Figures 1-4 attached to same.) Moreover, the HWG itself has acknowledged the lack of data to support the MCWRA inferences. An accurate map of seawater intrusion, particularly within the area affected by the MPWSP's proposed slant wells is needed to understand the project's impacts. In addition, the DEIR/EIS's suggestion that where monitoring and production wells exceed 500 mg/L, there are no beneficial uses for this water must be revised. (See e.g., HGC comments, pp. 56-57.)

MCWD-96

(6) The DEIR/EIS references the CCC's Special Condition 11 requiring the HWG to establish baseline water and TDS levels before the test well could commence operations does not save the DEIR/EIS either. The DEIR/EIS provides a hyperlink to the HWG's Technical Memorandum stating it "established baseline water and TDS levels" in the project area. (DEIR/EIS, p. 4.4-42.) The HWG's Technical Memorandum, however, does not establish baseline water or TDS levels in the project area, much less the required baseline levels for Monitoring Well No. 4 (MW-4) and three other monitoring wells within 2,000 feet of the test well as required by Special Condition 11. (See HWG's Technical Memorandum, p. 14.) Rather, the memorandum includes a cursory discussion of water levels at some of the monitoring wells over a period of weeks (id., pp. 11-12) and then provides a section entitled "Recommended Monitoring of Baseline and TDS Levels," which suggests a method for evaluating impacts without actually establishing baseline water levels. (Id., p. 14.) Specifically, the Technical Memorandum states that in order to determine impacts to water levels at MW-4:

MCWD-97

> If ground water levels at MW-4 show a continuing downward trend but prior to reaching the threshold prescribed by CDP Condition 11, the test slant well will be voluntarily shut off. If the test slant well is the cause of the downward trend in groundwater levels at MW-4, then groundwater levels will show a recovering trend. If the groundwater levels do not recover, then this is indicative of regional and climatic impacts. The data will be reviewed by the HWG for confirmation and the test slant well will resume pumping. If the ground water levels continue to decline after start up, then the data indicative of impacts other the slant well will be submitted to the Coastal Commission Executive Director, prior to reaching the threshold.

(HWG's Technical Memorandum, p. 14.)

MCWD-97 cont.

Did the DEIR/EIS rely on the Technical Memorandum's methodology for assessing impacts to groundwater levels from the MPWSP slant wells in lieu of establishing baseline water levels?

Please explain how the baseline water levels in the Technical Memorandum were used to refine the groundwater models and inform the analysis of the proposed project.

Please identify the baseline water levels in the Dune Sand, 180-FTE, and 400-FTE Aquifers that were used to evaluate the project's potential groundwater impacts (e.g., with the DEIR/EIS's projected drawdown contours).

Similarly, the HWG's Technical Memorandum does not provide TDS levels in the project area, at MW-4, or at the other monitoring well locations. Instead the memo provides three different methods for conducting TDS sampling and states:

> Each method prescribed above will be compared with the data collected by that method to determine whether TDS concentrations remain within acceptable levels or show an increasing trend. Seasonal changes in TDS may result from potential seasonal changes in ground water levels aside from changes potentially induced by groundwater extraction from the test slant well. Changes in TDS will also be compared to changes in groundwater levels to evaluate whether TDS changes represent seasonal water quality change in the underlying aquifers.
>
> If two of the three methods used indicate a rising trend in the MW-4 series monitoring wells, the data will be submitted to the HWG for review prior to reaching the threshold prescribed by

MCWD-98

> CDP Condition. The HWG will evaluate the data to determine whether rising TDS, should it occur, is a result of TSW pumping or from some other cause.

(See HWG's Technical Memorandum, p. 14-15.)

Did the DEIR/EIS rely on the Technical Memorandum's methodology for assessing impacts to water quality from the MPWSP slant wells in lieu of establishing baseline water quality levels?

Please explain how the baseline water quality levels in the Technical Memorandum were used to refine the groundwater models and inform the analysis of the proposed project.

Please identify the baseline TDS/chloride levels in the Dune Sand, 180-FTE, and 400-FTE Aquifers that were used to evaluate the project's potential groundwater impacts (e.g., with the DEIR/EIS's projected drawdown contours).

MCWD-98 cont.

The DEIR/EIS's omissions and misleading statements regarding water levels and water quality in the project area, particularly the Marina Subarea, obscure the project's potentially significant impacts to groundwater. As noted above, the SWRCB found that studies, including aquifer testing, are needed to determine the extent of the Dune Sand Aquifer and to establish accurate baseline conditions. This is also a fundamental CEQA requirement. (See *Cadiz*, *supra*, 83 Cal.App.4th 74, 86, [holding EIR was not in compliance with CEQA because the EIR does not discuss the volume of the aquifer groundwater, particularly potable water, which is a valuable and relatively scarce resource in the region].)

As the Court explained in *Cadiz*: "Despite the [Project] EIR's enormity and the length of time devoted to preparing it, the EIR is not in compliance with subdivision (c) of CEQA Guidelines section 15125 because the EIR does not discuss the volume of the aquifer groundwater, particularly potable water, which is a valuable and relatively scarce resource in the region. The EIR does not provide a sufficient description of the environmental setting or adequate information for the public and governmental agencies to evaluate whether the [Project] presents a significant adverse impact on the groundwater contained in the aquifer. In order to weigh and evaluate the risk of groundwater contamination, the volume of water subject to contamination is required… In turn, an informed decision cannot be made as to whether it is worth taking the risk of subjecting a valuable water source to contamination." (83 Cal.App.4th at p. 92.) The same is true here. The DEIR has not, but must, disclose the volume of the groundwater in the Dune Sand, 180-FTE, and 400-FTE and Deep Aquifers, particularly potable water, that may be impacted by the MPWSP over the life of the project.

MCWD-99

Save our Peninsula Committee v. Monterey County Board of Supervisors (2001) 87 Cal.App.4th 99, 121-122 is also on point. In that case, the court explained that CEQA requires "preparers of [an] EIR [to] conduct the investigation and obtain documentation to support a determination of pre-existing conditions" because "the impacts of the project must be measured against the 'real conditions on the ground.'" There, the developer of a proposed residential subdivision on ranch lands had pumped a significant amount of water in the years right before the start of environmental review, presumably in an effort to establish that water use in existing baseline conditions was already high. The court concluded that "this treatment of baseline water use violated the basic principles of CEQA" because "some of these figures, although generated from recent pumping on the property, did not reflect water actually used for irrigating the property." (*Id.* at pp. 120-121.) The EIR was defective for the further reason that the EIR did not provide a clear, consistent description of historic groundwater use, and thus left the public to guess at the baseline conditions against which the project's impacts were measured.

MCWD-99 cont.

In sum, the DEIR/EIS does not provide an accurate and complete description of existing groundwater conditions and groundwater beneficial uses in the area. Therefore, the DEIR/EIS must be revised and re-circulated to disclose (1) how much groundwater is in the Dune Sand, 180-FTE, and 400-FTE and Deep Aquifers, particularly potable water, that may be impacted by the MPWSP over the life of the project; (2) the baseline water levels in the Dune Sand, 180-FTE, and 400-FTE and Deep Aquifers, in the project area and the areas that will or could be affected by the project; and (3) the water quality in the Dune Sand, 180-FTE, and 400-FTE and Deep Aquifers (percentage that is seawater, brackish, or fresh), that may be impacted by the MPWSP over the life of the project. The DEIR/EIS should also address the importance of the Dune Sand Aquifer as a recharge source for lower aquifers in this part of the Basin (e.g., 180-foot aquifer) and its beneficial use as a protective layer against seawater intrusion. Absent this information, the public and decisionmakers are misled into believing groundwater in the Dune Sand Aquifer has no value or beneficial uses. As a result of the EIR's inadequate description of baseline conditions, the DEIR/EIS fails to fully evaluate impacts to consider potential impacts to the overdrafted Marina Subarea.

i. ***The DEIR/EIS fails to disclose the MPWSP's inconsistencies with applicable State, regional, and local laws and regulations.***

The DEIR/EIS states that Table 4.4-7 describes the state, regional, and local land use plans, policies, and regulations pertaining to groundwater that are relevant to the MPWSP and an analysis of project consistency with such plans, policies, and regulations. The Table, however, does not include any consistency determinations with the regulations described in the Regulatory Section of this Chapter, including the Central Coast RWQCB Basin Plan, the Agency Act, and MCWRA Ordinance 3709. As discussed above in our comments Water Rights, the MPWSP would violate both the Agency Act and Ordinance 3709. This must be disclosed in the Table. The DEIR/EIS should also discuss how the CPUC can approve the project in light of the fact it would violate the Agency Act and MCWRA Ordinance 3709.

MCWD-100

While the DEIR/EIS fails to disclose whether the project would violate the Central Coast RWQCB Basin Plan's water quality objectives, it fails even to mention the project's consistency with Resolution No. 88-63, incorporated by reference into the existing 2011 Water Quality Control Plan for the Central Coastal Basin. (See DEIR/EIS, p. 4.4-32, 4.4-34 and 35.) As noted in our comment on the Water Rights Chapter, Resolution No. 88-63 is Appendix A-9 of the Basin Plan, and is applicable to the proposed project. Resolution No. 88-63 sets forth the following policy regarding surface and ground water within the project area and protects "groundwater considered to be suitable, or potentially suitable, for municipal or domestic water supply and should be so designated by the Regional Boards with the exception of:

> 1. Surface and ground waters where:
> a. **The total dissolved solids (TDS) exceed 3,000 mg/L** (5,000 uS/cm, electrical conductivity) and it is not reasonably expected by Regional Boards to supply a public water system, or
> b. There is contamination, either by natural processes or by human activity (unrelated to the specific pollution incident), that cannot reasonably be treated for domestic use using either Best Management Practices or best economically achievable treatment practices, or
> c. The water source does not provide sufficient water to supply a single well capable of producing an average, sustained yield of 200 gallons per day."

(Emphasis added.) The DEIR/EIS, however, suggests that only the ASR Wells for the project are required only to be consistent with the Basin Plan's groundwater quality objectives, suggesting any groundwater extractions that impact groundwater quality and groundwater that currently does not meet drinking water standards does not have value and cannot be significantly impacted. This is inaccurate. The DEIR/EIS must discuss the amount of water within the project area that is suitable, or potentially suitable, for municipal or domestic water supply and how the project will impact these supplies. Without this information, it is impossible for the public and decisionmakers to understand whether the project, as proposed, would violate the Basin Plan.

MCWD-101

j. ***The Analysis of Groundwater Impacts Is Based on Unreliable Modeling Rather than Substantial Evidence***

On Pages 4.4-39 through 4.4-52, the DEIR/EIS describes the investigation of groundwater conditions and modeling, and provide the following assessment of the "Limitations of Groundwater Models" at Page 4.4-44:

MCWD-102

> Groundwater models simulate aquifer conditions based on a specific set of data that describes parameters such the subsurface characteristics, groundwater flow, and land use. The more robust the data set, the more capable the model will be to accurately simulate subsurface conditions. Most groundwater models use conservative input parameters so that the output overstates the

> actual aquifer response. Nevertheless, groundwater models are mathematical-based computer programs that rely on input parameters and, consequently, there is a degree of uncertainty. However, the models used to analyze the proposed project have been used previously and have benefited from input data derived from site-specific subsurface information. Given that, and given the fact that these models were calibrated with known data, the level of degree of uncertainty for this analysis is considered tolerable.

As discussed in GeoHydros and HGC comments, the level of degree of uncertainty in the DEIR/EIS's modeling is intolerable given the DEIR/EIS's failure to adequately investigate baseline conditions in the Marina Subarea and to utilize the best available information. The DEIR/EIS decision to abandon all the prior modeling efforts and use the superposition model renders the DEIR/EIS's groundwater analysis fatally defective. First, it the superposition model does not fix or improve the problems with the DEIR/EIS's modeling or its reliability. (See HGC Comments, p. 4; GeoHydros, p. 5.) Rather, it is an improper attempt to mask those problems. (*Ibid.*) Moreover, as explained in the GeoHydros Comment, the superposition modeling is inappropriate here because:

MCWD-102 cont.

- it precludes the identification of source water of the MPWSP slant wells, which is a key issue with the application;
- it precludes prediction of measurable groundwater elevations associated with the proposed MPWSP slant wells pumping, which would provide the only means for stakeholders to validate the model predictions and potential project impacts;
- it is unnecessary because it provides no benefit in terms of reliability over the use of the calibrated version of the model for impact assessment, would identify source water of the MPWSP slant wells and predict of measurable groundwater elevations associated with the proposed MPWSP slant wells pumping; and
- it not reliable here to simulate cones of depression in the aquifers created by the proposed MPWSP pumping.

Without addressing the limitations of the superposition model, on Page 4.4-68 the DEIR/EIS concludes:

MCWD-103

> **Conclusion of Impact Analysis - Depletion of Groundwater Supply from the SVGB**
> The proposed project would not deplete groundwater supplies; it would extract primarily seawater and a smaller volume of brackish inland groundwater from a localized area with only minor localized groundwater drawdown. The area influenced by the MPWSP groundwater pumping is within a zone that is degraded by seawater intrusion and therefore unusable for potable water supply due to its high salinity. When desalinated

> water is returned to the basin as part of the MPWSP, groundwater conditions in the 400-Foot Aquifer underlying the CSIP, CCSD, and adjacent areas would improve as water levels increase as a result of in-lieu groundwater recharge. The return water component of the MPWSP would benefit each of the aquifers by either reducing the area of influence or by increasing groundwater levels in other areas. The effects of return water on the basin water levels are discussed below and shown on Figures 4.4-14 through 4.4-16. If the proposed project did not return any water, localized depressed groundwater levels would persist in the three affected aquifers throughout the life of the project. However, the area affected by groundwater pumping would remain localized and the proposed project would continue to extract only brackish, degraded groundwater from the coast and, to a lesser extent, the inland portion of the aquifer. Based on the conclusions of this analysis, this impact would be less than significant.

MCWD-103 cont.

As addressed in the HGC comments, EKI Comments and GeoHydros Comments, the DEIR/EIS's impact conclusion is not supported by substantial evidence. The DEIR/EIS's modeling must be updated to accurately quantify the amount of groundwater that will be pumped and required to be returned to the basin. The modified modeling must also take into account the semi-confined condition of the 180-FTE Aquifer and the elevated head conditions in the semi-perched Dune Sand Aquifer. As noted in the HGC comments, the DEIR/EIS's conclusion does not recognize existing conditions that have developed since cessation of coastal pumping, including protective water levels in the Dune Sand Aquifer along the coast. In addition, Groundwater production should be calculated to include the 3,000 mg/l beneficial use standard provided in the WQCP. The method of groundwater return to the basin must also be specifically indicated and analyzed to determine the effectiveness of its mitigation for the project's groundwater impacts on the Marina Subarea. In additional, the DEIR/EIS must be revised to include a mandatory mitigation measure that requires adequate monitoring to detect changes to groundwater levels and quality in the Marin Subarea. The mitigation must also include a meaningful performance standard to ensure impact to the Marina Subarea remains less than significant. The current Applicant Proposed measure does not satisfy these fundamental CEQA requirements.

Finally, the DEIR/EIS's conclusion that the project impacts to Groundwater Quality is less than significant, as mitigated, is inadequate and must be updated based on new modeling results. As discussed in HGC's comments, EKI Comments. and GeoHydros Comments, the DEIR/EIS impact conclusions relating to groundwater quality are fundamentally flawed and based on modeling incapable of addressing impacts to water quality. In addition, the DEIR/EIS failure to consider the level of confinement in the Marina Subarea, particularly in

MCWD-104

the areas near existing groundwater remediation systems, renders the DEIR/EIS impact conclusion unsupportable.

Nor does the Mitigation Measure Mitigation Measure 4.4-4 mitigate away this failure. Mitigation cannot be deferred until after project approval except under very limited circumstances. CEQA permits deferral of mitigation only when: (1) an EIR contains criteria or performance standards to govern future actions; (2) practical considerations preclude the development of earlier measures; and (3) the lead agency has assurances that the future mitigation will be both "feasible and efficacious." (*Communities for a Better Environment v. City of Richmond* (2010) 184 Cal.App.4th 70, 95 (*CBE v. City of Richmond*). Mitigation Measure Mitigation Measure 4.4-does not meet these standards. First, it is unclear by whom and when the required "determination be made regarding the possibility that the project pumping could affect the extent of the plumes." (DEIR/EIS, p. 4.4-89.) Second, the mitigation states that "In the event that the analysis concludes that the proposed slant wells may affect the extent of the OU1 TCE A-Aquifer Plume and the two OUCTP plumes, then the project applicant shall contact and work with the U.S. Army to address the potential impact by reimbursing the Army for the additional costs to expand the existing treatment systems to include remediating areas where the slant wells have migrated the contamination to previously remediated areas." (Ibid.) Thus, the mitigation is improperly left completely in the discretion of CalAm in violation of CEQA.

MCWD-104 cont.

In summary, the DEIR/EIS's inadequate investigation and disclose of baseline conditions in the Marina Subarea and flaws in its modeling, make it impossible for the public or CPUC to make an informed decision on the project's potential groundwater impacts. As discussed in the HGC Comments, EKI Comments and GeoHydros Comments, the MPWSP will cause significant adverse impacts to groundwater supplies and water quality in the Marina Subarea that must be disclosed in a revised DEIR/EIS. After those impacts are disclosed, the DEIR/EIS must adopt all feasible mitigation or an alternative that would reduce these impacts to a less than significant level.

MCWD-105

k. ***The DEIR/EIS's cursory treatment of cumulative impacts does not comply with CEQA or NEPA.***

The DEIR/EIS concludes using a simple list approach the Project's cumulative groundwater impacts are less than significant stating:

> Because the MPWSP combined with the possible RUWAP desalination element would not result in a significant adverse cumulative impact and may have beneficial consequences, and the Salinas Valley Water Project Phase II and the Interlake Tunnel would have beneficial effects, the cumulative effect of these four possible projects on groundwater resources would be less than significant. Therefore, the proposed project would not

MCWD-106

> have a cumulatively considerable contribution to a significant cumulative impact during operations (less than significant).

(DEIR/EIS, p. Page 4.4-90.) The DEIR/EIS's approach to assessing cumulative groundwater impacts is inconsistent with both CEQA and NEPA requirements.

An EIR must analyze cumulative impacts because "the full environmental impact of a proposed project cannot be gauged in a vacuum." (*Communities for a Better Environment v. Cal. Resources Agency* (2002) 103 Cal.App.4th 98, 114 ("*CBE v. Resources Agency*").) The CEQA Guidelines define cumulative impacts as "the change in the environment which results from the incremental impact of the project when added to other closely related past, present, and reasonably foreseeable probable future projects." (Guidelines, § 15355, subd. (b).) Thus, impacts that are "individually minor" may be "collectively significant." (*Ibid.*)

CEQA requires a lead agency to undertake a two-step cumulative impacts analysis. First, the agency must consider whether the combined effects from the proposed project and other projects would be cumulatively significant. Second, the agency must then consider whether the "proposed project's incremental effects are cumulatively considerable." (*CBE v. Resources Agency*, *supra*, 103 Cal.App.4th at p. 120; Pub. Resources Code, § 21083, subd. (b)(2); Guidelines, §§ 15355, subd. (b), 15064, subd. (h)(1).) This two-part analysis reflects the legal and empirical reality that "the greater the existing environmental problems are, the lower the threshold should be for treating a project's contribution to cumulative impacts as significant." (*CBE v. Resources Agency*, *supra*, Cal.App.4th at p. 120.) Cursory statements of an agency's conclusions are inadequate under CEQA. (*Laurel Heights II*, *supra*, 6 Cal.4th at p. 1124.) The DEIR/EIS's analysis of cumulative impacts to the SVGB violates these CEQA principles in several important ways as discussed below.

MCWD-106 cont.

Similarly, NEPA requires the agency to consider whether "the action is related to other actions with individually insignificant but cumulatively significant impacts. Significance exists if it is reasonable to anticipate a cumulatively significant impact on the environment." (40 C.F.R. § 1508.27, subd. (b)(7).) The Council on Environmental Quality (CEQ) NEPA regulations define "cumulative impact" as "the impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time." (40 C.F.R. § 1508.7.)

The Ninth Circuit frequently cites a NEPA handbook prepared by CEQ—*Considering Cumulative Effects Under the National Environmental Policy Act* [20] (*Considering Cumulative Effects*)—when discussing the adequacy of the cumulative impact analysis in an EIS. (See, e.g., *Kern v. U.S. Bureau of Land Management*, 284 F.3d 1062 (9th Cir. 2002);

[20] / https://ceq.doe.gov/publications/cumulative_effects.html

Te–Moak Tribe of W. Shoshone of Nev. v. U.S. Dep't of Interior, 608 F.3d 592 (9th Cir. 2010); *Northern Plains Resource Council, Inc. v. Surface Transp. Bd.* (9th Cir. 2011) 668 F.3d 1067.) As explained in that document, a cumulative effects analysis should involve a three step process: (1) scoping; (2) describing the affected environment; and (3) determining the environmental consequences. (*Considering Cumulative Effects,* p. 10.) Regarding the description of the affected environment in a cumulative effects analyses, the document explains that a reasonable forecast of future conditions is critical:

> The concept of a baseline against which to compare predictions of the effects of the proposed action and reasonable alternatives is critical to the NEPA process. The no-action alternative is an effective construct for this purpose, but its characterization is often inadequate for analyzing cumulative effect. Much of the environment has been greatly modified by human activities, and most resources, ecosystems, and human communities are in the process of change as a result of cumulative effects. The analyst must determine the realistic potential for the resource to sustain itself in the future and whether the proposed action will affect this potential; therefore**, the baseline condition of the resource of concern should include a description of how conditions have changed over time and how they are likely to change in the future without the proposed action.**

MCWD-106 cont.

(*Considering Cumulative Effects,* p. 41, emphasis added.)

The CEQ guidance also emphasizes that compiling data on stress factors pertaining to each resource or ecosystem is a critical step in describing the affected environment. (*Id*. at p. 27.) For instance, the handbook explains that while describing the affected environment, "the agency should pay special attention to common natural resource issues that arise as a result of cumulative effects." As an example of such stressors, the handbook cites "aquifer depletion or salt water intrusion following the overdraft of groundwater from numerous uncoordinated uses." (*Id.* at p. 25.) "The goal of characterizing stresses is to determine whether the resources, ecosystems, and human communities of concern are approaching conditions where additional stresses will have an important cumulative effect." (*Id*. p. 29.)

Although "a cumulative effects analysis necessarily involves assumptions and uncertainties," the analysis "must be supported by the best data we have or are able to collect." (*Considering Cumulative Effects,* p. 3; *Oregon Natural Resources Council Fund v. Brong* 492 F.3d 1120, 1134 (9th Cir. 2007) ["cumulative effects analysis requires an agency to predict future conditions"].) "NEPA requires that an EIS engage in reasonable forecasting. Because speculation is ... implicit in NEPA, [courts will] reject any attempt by agencies to shirk their responsibilities under NEPA by labeling any and all discussion of future environmental effects as crystal ball inquiry." (*Northern Plains Resource Council, Inc. v. Surface Transp. Bd*. (9th Cir. 2011) 668 F.3d 1067, 1079 [also noting that "reasonably foreseeable future actions need to be considered [in a cumulative impact analysis] even if they are not specific proposals."].) Thus, although an agency may explain specific

projections with reference to uncertainty in its cumulative impact analysis, "it may not rely on a statement of uncertainty to avoid . . . the requisite analysis." (*Oregon Natural Resources Council Fund v. Brong*, 492 F.3d 1120, 1134 (9th Cir. 2005).)

The DEIR/EIS fails to meet both CEQA and NEPA requirements for the following reasons.

First, the DEIR/EIS's analysis of cumulative impacts fails to account for how groundwater conditions have changed over time and how they are likely to change in the future without the project. In fact, the DEIR/EIS acknowledges its modeling "only solves for the groundwater changes due solely to the proposed project." It goes on to expressly state:

> These changes are independent of the effects from the other stresses on the basin such as seasonal climate and agricultural pumping trends, other pumping wells, injection wells, land use, or contributions from rivers. By using superposition, the actual effects of only the proposed project can be isolated from the combined effects of all other basin activity. For example, when the NMGWM reports a 1-foot drawdown in a well, it is understood that the one foot of drawdown would be the effect on the basin of the proposed project only. That well may experience greater drawdown due to other stresses, such as drought or other nearby pumping wells, or may experience increases in water levels due to reduced regional pumping or an extremely wet year. But the proposed project's contribution to that drawdown in the well would remain only 1-foot. Superposition is described in Appendix E2, Section 5.2.

(DEIR/EIS, p. 4.4-47 and 4.4-49.) The DEIR/EIS suggests this limited approach to figuratively assessing the project's potential cumulative impacts to groundwater is permissible because baseline conditions reflect the contributions of past actions on groundwater resources within the geographic scope. As explained in the attached HGC Comments, this approach ignores that groundwater conditions have changed over time under baseline conditions and will continue to change in the future from other stressors. As noted above, the DEIR/EIS acknowledges this possibility. The fact that the modeling exists and has been run for the project (but the results not disclosed) and that it address these additional stressors is inexplicable. Even if the DEIR/EIS preparers believe this modeling provides flawed results, the information must be disclosed (with an explanation regarding the flawed results) so the public can comment on the information and the decision makers can take it into account.

Second, the DEIR/EIS's cumulative impacts analysis for groundwater supply impacts improperly relies on its discussion in Impact 4.4-3 that groundwater levels would be

MCWD-106 cont.

expected to decrease by 5 or more feet within approximately 1 mile of the MPWSP subsurface slant wells as basis for considering which projects to include in its analysis of cumulative impacts on groundwater supply. Based on this incorrect assumption (see comments on Impact 4.4-3 above), the DEIR/EIS then limits its discussion of cumulative impacts to the Salinas Valley Water Project Phase II (No. 1), the RUWAP Desalination Element (No. 31), and the Slant Test Well Project (No. 47) on the basis that these projects are the only other projects that would overlap with the project's presumed drawdown footprint. It then, without disclosing potential combined drawdown effects of these projects on existing wells, states because these three projects would not result in any net decrease to groundwater within the SVGB there would be no potential cumulative groundwater impacts and adopts the same less than significant conclusion reached for Impact 4.4-3. (DEIR/EIS, pp. DEIR/EIS, pp. 5-22 to 5-24.) This approach is inadequate and must be revised to address the following deficiencies.

- The DEIR/EIS fails to address how the project would impact the SVGB, particularly the Marina Subarea of the SVGB, overdraft conditions and state law requirements for the Groundwater Sustainability Plan that must be adopted to address this issue. (See Chapter 2.0 comments above). It is reasonably foreseeable that at least one Groundwater Sustainability Plan will be adopted that regulates groundwater extractions within the project area. Therefore, the DEIR/EIS must be revised to address and mitigate the project's potential adverse impacts on such a Plan's ability to achieve groundwater sustainability within the project area. (See *Friends of the Eel River*, *supra*, 108 Cal.App.4th at p. 872 [EIR failed to comply with CEQA because its cumulative impacts analysis did not consider potential curtailment of water supplies that could result from regulatory proceedings, which result in "an underestimation of the Agency's ability to meet customer demands without negative environmental consequences."].)
- The DEIR/EIS also fails to discuss how the project could adversely impact environmental gains realized by ongoing water conservation projects in the area.
- The DEIR/EIS also fails to address how increased water use from many of the regional projects will affect groundwater supplies. The DEIR/EIS incorrectly assumes that only past, present and future "water supply projects" within the radius of influence of the project will impact the SVGB and Marina Subarea. (Guidelines, § 15130, subd. (b) (3).) As explained in the attached technical HGC and EKI Comments, the DEIR/EIS's analysis of cumulative impacts is woefully inadequate in this respect.
- The project fails to look at the cumulative impacts of the MPWSP's test well on groundwater supplies, groundwater quality, and impacts to biological resources. The CCC's approval of the slant well excluded any analysis of the potential long-term impacts of the slant well based on its conclusion is would

MCWD-106 cont.

be decommissioned after 2 years. The DEIR/EIS must be revised to include this analysis, unless the slant test well will be decommissioned as provided for in the CCC approval.

Finally, the cumulative impacts analysis must be revised to consider reasonably foreseeable projects that will be necessary under the SGMA. See discussion of no project alternative (DEIR/EIS, p. 5.5-84 ["Existing, ongoing regional groundwater pumping would continue throughout the Salinas Valley, as would efforts to develop a sustainable groundwater management plan."]). As a result of these failures, the DEIR/EIS does not accurately consider whether the project's impacts to the SVGB are cumulatively considerable. Instead of following CEQA's mandate, the DEIR/EIS here portrays a fundamental misunderstanding of the statute. The document assumes that if the project's impacts related to groundwater are less than significant (which they are not), then the impacts could not be cumulatively considerable. (DEIR/EIS, p. 5-24.) This approach turns cumulative analysis on its head and is a plain violation of CEQA. An EIR may not conclude that a project will not contribute to cumulative impacts simply because it has a less than significant impact on a project level. (*Kings County Farm Bureau v. City of Hanford* (1990) 221 Cal.App.3d 692, 720-21.)

MCWD-106 cont.

Therefore, the DEIR/EIS's cumulative analysis must be revised and re-circulated because it was reasonable and practical for the DEIR/EIS to analyze the omitted "past, present, and probable future projects producing related or cumulative impacts," and "their exclusion prevented the severity and significance of the cumulative impacts from being accurately reflected." (Guidelines, § 15130, subd. (b)(1)(A); 124 Cal.App.4th at p. 1215.) The DEIR/EIS's cumulative analysis must also be revised based on updated modeling that does not ignore the best available information regarding groundwater conditions in the project area.

3. The DEIR/EIS's Analysis of Terrestrial Biological Resources is Inadequate.

As emphasized by the California Supreme Court, "CEQA broadly defines the relevant geographical environment as 'the area which will be affected by a proposed project.'" (*Muzzy Ranch Co. v. Solano County Airport Land Use Comm.* (2007) 41 Cal.4th 372, 387 (*Muzzy Ranch*), quoting Pub. Resources Code, § 21060.5 ["Environment" means "the physical conditions which exist within the area which will be affected by a proposed project"].) In *Muzzy Ranch*, the Supreme Court flatly rejected the "suggestion that agencies have no obligation under CEQA to consider geographically distant environmental impacts of their activities." (*Id*. at p. 388.) Rather, an EIR must analyze and disclose all potential impacts, both direct and indirect, and cover the entire area where those impacts may occur.

MCWD-107

Here, as explained in the DEIR/EIS, the "study area" for potential impacts to terrestrial biological resources is limited to a 50-foot buffer around the project features. The DEIR/EIS, however, fails to explain why impacts to biological resources would cease at this arbitrary line. At a minimum, the DEIR/EIS must explain and document the screening

analysis or other methodology used to develop the study area wherein all potential impacts of the project would be captured. That simply did not occur; the DEIR/EIS fails to comply with CEQA's informational disclosure requirements by not identifying any methodology or providing any explanation for the unduly narrow study area.

In fact, the evidence shows that the study area under in the DEIR/EIS is far too narrow to account for all of the project's potential impacts to terrestrial biological resources. For instance, as demonstrated from the figures showing the "biological study area," the study area boundaries slice right through dune and other coastal habitat. But the DEIR/EIS fails to explain why impacts would only occur on one side of this arbitrary line but not the other. Indeed, it is only logical that entire connected habitat areas would be affected by the project.

MCWD-107 cont.

Moreover, despite acknowledging that the project would result in a substantial lowering of groundwater levels and increased salinity levels in the project area, the DEIR/EIS fails to disclose or evaluate how that drawdown or increased salinity could impact biological resources that depend on groundwater. Indeed, the DEIR/EIS acknowledges that the area of drawdown and increased salinity would span for several miles—much further than the 50-foot study area. There is simply no justification for excluding this entire area from the analysis. It is well recognized that changes in groundwater levels can adversely affect overlying habitat, and groundwater-dependent ecosystems in particular.[21] For instance, as explained in an a series of articles by researchers from Stanford University, California is home to a diverse and widespread number of groundwater-dependent species and ecosystems, which can be significantly impacted by even minor changes in groundwater levels. (See Stanford Woods Institute for the Environment, Understanding California's Groundwater, 2014.) [22] The articles note that impacts of pumping groundwater on ecosystems can be most intense in coastal counties (generally surrounding the existing effects of municipal and agricultural pumping) and that these types of impacts should be analyzed and mitigated under CEQA and NEPA. (*Id*.) To reduce potential impacts, the authors recommend that "if there is potential to adversely affect groundwater-dependent ecosystems, comprehensive monitoring conditions on projects should be linked to clear and specific remedial management actions, like cease-to-pump rules based on quantified ecological triggers." (*Id.*) The DEIR/EIS, however, fails to analyze, or even mention, these types of impacts.

MCWD-108

[21] / See, e.g., The Nature Conservancy, California's Groundwater Dependent Ecosystems, http://www.groundwatercalifornia.org/; Jeannette Howard and Matt Merrifield (2010) Mapping Groundwater Dependent Ecosystems in California, http://journals.plos.org/plosone/article?id=10.1371/journal.pone.0011249.

[22] / Articles are available at: http://waterinthewest.stanford.edu/groundwater/ http://waterinthewest.stanford.edu/groundwater/overdraft/ http://waterinthewest.stanford.edu/groundwater/conflicts/index.html

Further, the DEIR/EIS acknowledges that there are numerous areas identified as "Potentially USACE, RWQCB, and/or CDFW Jurisdictional" waters. But most of these areas, including wetlands, fall outside of the DEIR/EIS's study area boundaries. As explained above, wetlands and similar ecosystems frequently depend on, and are often interconnected with groundwater, particularly when, as here, the groundwater table is close to the surface. The Sanctuary's *Guidelines for Desalination Plants in the Monterey Bay National Marine Sanctuary* (NOAA, 2010) state that "implementation of subsurface intakes should not cause saltwater intrusion to aquifers ***or adversely affect coastal wetlands that may be connected to the same aquifer being used by the intake***." Nonetheless, the DEIR/EIS makes no attempt to evaluate these potential impacts. As result, the DEIR/EIS fails as an informational document by failing to analyze and mitigate potential impacts to these areas from a lower groundwater table and increased salinity. The CPUC cannot hide behind its failure to gather relevant data. (See *Gentry v. City of Murrieta* (1995) 36 Cal.App.4th 1359, 1378 ["an agency [will] not be allowed to hide behind its own failure to gather relevant data . . . . CEQA places the burden of environmental investigation on government rather than the public."].) And, as explained below, it is insufficient under CEQA to rely on separate regulatory programs or future permitting requirements to justify the failure to analyze and disclose all of the project's potential impacts. (See, e.g., *Preserve Wild Santee v. City of Santee* (2012) 210 Cal.App.4th 260, 280-281.)

MCWD-109

In short, the analysis in the DEIR/EIS must encompass a study area that is supported by substantial evidence and that is adequately explained and justified in the DEIR/EIS. By limiting the biological resources to an arbitrary 50-foot buffer area, the DEIR/EIS fails to meet CEQA's basic requirement of analyzing and mitigating all of the project's potential direct, indirect, and cumulative environmental impacts to biological resources.

MCWD-110

l. ***Mitigation Measures for Impacts to Biological Resources Are Inadequate***

The DEIR/EIS's mitigation for impacts to biological resources fails to comply with CEQA's basic requirements for mitigation in several ways. First, the biological resources section is riddled with improperly deferred mitigation. To comply with CEQA, formulation of mitigation cannot be deferred until after project approval except under very limited circumstances. (CEQA Guidelines, § 15126.4, subd. (A)(1)(b).) "Impermissible deferral of mitigation measures occurs when an EIR puts off analysis or orders a report without either setting standards or demonstrating how the impact can be mitigated in the manner described in the EIR." (*Preserve Wild Santee v. City of Santee* (2012) 210 Cal.App.4th 260, 280-281.) CEQA permits deferral of mitigation only when: (1) an EIR contains criteria or performance standards to govern future actions; (2) practical considerations preclude the development of earlier measures; and (3) the lead agency has assurances that the future mitigation will be both "feasible and efficacious." (*CBE v. City of Richmond, supra*, 184 Cal.App.4th at p. 95; see also *San Joaquin Raptor Rescue Center v. County of Merced* (2007) 149 Cal.App.4th 645,669-71 (*Raptor*) [county improperly deferred mitigation when it allowed a land management plan for special status vernal pool species to be developed with the CDFW and

MCWD-111

USFWS after certification of EIR]; *Gentry v. City of Murrieta* (1995) 36 Cal.App.4th 1359, 1396 [conditioning a permit on "recommendations of a report that had yet to be performed" constituted improper deferral of mitigation].) "Fundamentally, the development of mitigation measures, as envisioned by CEQA, is not meant to be a bilateral negotiation between a project proponent and the lead agency after project approval; but rather, an open process that also involves other interested agencies and the public." (*CBE v. City of Richmond, supra,* 184 Cal.App.4th at p. 93.) Here, many mitigation measures are improperly deferred and the mitigation measures frequently call for the development of future plans or reports, without either setting performance standards or demonstrating how the impact can be mitigated in the manner described in the EIR. MCWD-111 cont.

Second, the mitigation measures are tarnished with impermissible qualifying language for implementation of the measures such as "to the extent practicable" or "where feasible," which renders the measures totally unenforceable. CEQA requires more. "A public agency shall provide that measures to mitigate or avoid significant effects on the environment are fully enforceable. . ." (CEQA Guidelines, § 15126.4, subd. (a)(2); see also *Vineyard Area Citizens for Responsible Growth, Inc. v. City of Rancho Cordova* (2007) 40 Cal.4th 412, 444.) MCWD-112

Third, the DEIR/EIS cannot rely on future coordination with other agencies with jurisdiction over biological resources or a requisite future permitting process as enforceable mitigation. (*Preserve Wild Santee v. City of Santee* (2012) 210 Cal.App.4th 260, 280-281.) Similarly, an agency cannot simply rely on future agency consultation or compliance with regulations to support a less than significant conclusion. (*Ibid*.) This is because there is usually no assurance that granting of permits or compliance with regulation will ensure that impacts are mitigated to a less than significant level. For example, just because the USFWS issues an incidental take permit does not mean the project will not have a significant impact on species. In fact, it means the project will likely have adverse impacts on species, but the agency will permit those impacts to occur. MCWD-113

Fourth, the analysis is defective because it fails to explain how the mitigation measures will mitigate the impacts to a less than significant level. Instead, the DEIR/EIS merely states that an impact may be significant generally, then lists some mitigation measures, and then concludes, without explanation or evidentiary support, that the mitigation measures will reduce the impacts to a less than significant level. In other words, the DEIR/EIS improperly assumes that mitigation will be implemented, will be effective, and will mitigate impacts to a less than significant level. This is not appropriate under CEQA. An EIR must include "sufficient information and analysis to enable the public to discern the analytic route the agency traveled from evidence to action." (*Association of Irritated Residents v. County of Madera* (2003) 107 Cal.App.4th 1383, 1397; see also *Lotus v. Department of Transportation* (2014) 223 Cal.App.4th 645 [improper to assume that mitigation will be implemented as part of the project].) As explained by the California Supreme Court, "[t]o facilitate CEQA's informational role, the [CEQA document] must MCWD-114

contain facts and analysis, not just the agency's bare conclusions or opinions. . . . [It] must include detail sufficient to enable those who did not participate in its preparation to understand and to consider meaningfully the issues raised by the proposed project." (*Laurel Heights Improvement Assn. v. Regents of University of California* (1988) 47 Cal.3d 376, 404.) The absence of this analysis here renders the DEIR/EIS inadequate as an informational document.

MCWD-114 cont.

These problems are pervasive throughout the mitigation measures in this section of the DEIR/EIS. Below are several specific examples.

- Mitigation Measure 4.6-1a. Mitigation Measure 4.6-1a requires CalAm retain a biologist to oversee compliance with the avoidance and minimization measures for special status species and sensitive habitats and document certain activities. This measure does little, if anything, to ensure that the mitigation measures are properly implemented and effective. First, rather than allowing CalAm to retain a biologist at its discretion as the measure permits, the CPUC should select a neutral and independent biologist to serve as the Lead Biologist. This would remove any bias, either actual or perceived, on the part of the biologist because the biologist would not be contracted to CalAm. Further, all reports and documentation (including documentation of violations of the measures and compliance reports) must be made available to the public for review and comment on the MPSWP website. Making this information publicly available is the only way to ensure that the measures are being implemented properly and are effective. This is especially true for the monthly summary monitoring reports, which are intended to document the effectiveness and practicality of the prescribed measures and may recommend modifications to the measures. Moreover, language in this measure suggesting that the "prescribed" mitigation measures might not be practical or of effective, raises serious doubts regarding whether the CPUC has fully evaluated whether the proposed mitigation measures are feasible and will be effective *before* project approval, as CEQA requires.

MCWD-115

- **Mitigation Measure 4.6-1c**. Mitigation Measure 4.6-1c is rife with language allowing improper deferral and precatory language that severely diminishes the likely effectiveness of the measure. As a consequence, the DEIR/EIS cannot rely on the measure to reduce impacts to a less than significant level. For instance, Mitigation Measure 4.6-1c, subpart (1), requires construction areas to be delineated prior to construction and prohibits construction-related disturbance outside the boundaries only when approved by the Lead Biologist. This is improper deferral. Without any performance standards describing when the Lead Biologist can approve construction-related activities outside of the delineated area, this measure is meaningless. The measure must include performance standards that establish objective criteria for determining when project activities could occur outside the delineated boundary. The measure

MCWD-116

should at least require that the additional area be evaluated and delineated before construction activities can occur to avoid impacts. Mitigation Measure 4.6-1c, subpart (5), states that "standard" best management practices ("BMP") shall be employed and provides two examples. To comply with CEQA, however, the measure must state what specific BMPs will be required and include firm language to ensure that the mitigation will be binding and enforceable.

MCWD-116 cont.

- Mitigation Measure 4.6-1d. Mitigation Measure 4.6-1d allows construction to occur at the slant well heads and along the segment of the Source Water Pipeline located west of the CEMEX processing plant during the snowy plover breeding season if approved by USFWS. The measure does not include any enforceable criteria or means by which impacts to plover might be avoided or reduced to a less than significant level. The measure must explain under what circumstances the USFWS might approve such activities and why allowing those activities during the breeding season would not impact snowy plover. This measure is especially troubling because the DEIR/EIS recognizes that any construction activities occurring during plover breeding season could affect the species. There is ample evidence showing that any construction activities during snowy plover nesting and breeding season will adversely affect the species. (See e.g., CCC Staff Report[23].) Further, the measure states that if work cannot be completed during the non-nesting season, a qualified biologist must conduct preconstruction surveys to determine if snowy plover nests are present within 300 feet. But there are no measures to implement if snowy plover nests are discovered. Instead, the measure states that the biologist must consult with USFWS to determine any additional measures that should be implemented. This is improper deferral of mitigation. Compounding this error, there are no performance standards that will ensure impacts to snowy plover will not occur. And there is no reason that enforceable mitigation measures cannot be developed now. During non-nesting season, the measure only requires a biologist to "inform CalAm of wintering plover activity" so they can make construction decisions that avoid or minimize disturbance to plovers. This measure too lacks any performance standard to ensure that impacts to plover will be less than significant. Even if an impacts is "minimized," that does not mean that significant impacts will not occur. The measure also states that temporarily impacted habitat must be "restored," but there is no standard for what type or amount of "restoration" would be sufficient to mitigate the impact. Instead, the determination is improperly

MCWD-117

[23] CCC Staff Report, November 12, 2014, available at https://documents.coastal.ca.gov/reports/2014/11/W14a-s-11-2014.pdf and CCC Staff Report, October 5, 2015 available at https://documents.coastal.ca.gov/reports/2015/10/Tu15a-10-2015.pdf

deferred to a yet-to-be-prepared Habitat Mitigation and Monitoring Plan. There is no reason that the plan cannot be developed now, before impacts occur, as required by CEQA. And the measure allows CalAm to contribute funds to either a mitigation bank or to an existing restoration program "in lieu" of undertaking restoration actions. But there is no explanation why paying funds would reduce the physical impact to snowy plover and its habitat to a less than significant level.

MCWD-117 cont.

- Mitigation Measure 4.6-1e. Mitigation Measure 4.6-1e is riddled with the qualifier "if feasible" which removes any teeth from the measure. If the measure is ultimately determined to be not feasible, it does not need to be implemented. The problem is that the impact conclusion relies on the mitigation measure to reduce the impact to a less than significant level. But since there is no guarantee that the mitigation measure will be implemented and will be effective given the "if feasible" language, it is not appropriate to rely on the measure to support the conclusion. Unless the DEIR/EIS provides firm and enforceable mitigation measures the impact should be found significant and unavoidable. This comment applies to all mitigation measures in this DEIR/EIS that include similar qualifying language. Subpart (2) includes additional flaws. It states that if avoidance is not feasible, additional measures "to be determined" will be implemented. This measure constitutes improper deferral of mitigation. The measures should be identified now and should be imposed as a requirement. Subpart (3) is problematic because it acknowledges the take of protected plant species may occur. If anything, the probability of take and the need for an incidental take permit indicate that a significant impact will occur, even if the take is allowed under the permit. This comment applies for all mitigation measures that acknowledge that a take may occur or that an incidental take permit may be required. Subpart (5) is even worse. It states that compensation in the form of land purchase or restoration "shall be provided to the level acceptable to the resource agencies" and will be determined on a "case-by-case basis." This is deferral of mitigation personified. There is no reason that the minimum level of compensation cannot be established now. The measure must include the minimum level of compensation that would be necessary to mitigate the impact to a less than significant level. Further the measure should include a monitoring program with success criteria to ensure that the compensatory mitigation will actually mitigate the loss of special-status plants. In fact, the very agency that is charged with protecting California's plant and wildlife species—the California Department of Fish and Wildlife (CDFW)—has determined that Mitigation Measure 4.6-1e is not adequate to mitigate impacts to special-status plants. (See CDFW Comments, Julie A. Vance, Feb. 27, 2017.) Among other flaws, DFW explained that reintroduction of sensitive plant species that may be impacted by the project is not recommended for species with sensitive habitats found in the project area and that there is no evidence that the identified

MCWD-118

measures will be successful. (*Id*.) DFW concluded that because there is no information in the DEIR/EIS regarding the success of relocation and relocation of sensitive plants, and because that type of mitigation is generally not successful or recommended for various reasons, the primary measure relied on in the DEIR/EIS is not sufficient to mitigate impact to less than significant. (*Id*.)

MCWD-118 cont.

- Mitigation Measure 4.6-1f. Like many other mitigation measures in this section, Mitigation Measure 4.6-1f, only requires that construction activities avoid impacts where feasible. As noted above, this makes the mitigation measure unenforceable and the DEIR/EIS cannot rely on it to support the conclusion that the impact is less than significant. The measure attempts to remedy this problem by including additional requirements if it is not feasible to avoid impacts during construction, but the additional requirements are also not proper mitigation. First, the mitigation is improperly deferred because it only requires the biologist to create a relocation plan after the project has already been approved. By deferring development of the plan, including the scope of the survey area and identification of appropriate relocation sites, it is impossible to determine whether the mitigation will be feasible or will be effective. And again, requiring approval of the plan by USFWS does not save the measure. Further, although subpart (5) includes what appears to be an attempt at the type of performance standard necessary for deferred mitigation (e.g., a minimum compensatory ratio of 2:1), the standard is negated entirely by the language allowing an alternate compensatory ratio as "otherwise negotiated with USFWS." The measure must state a firm and specific ratio and explain why that ratio is sufficient to mitigate the impact. This cannot be left up in the air in the DEIR/EIS and then decided at a later date after the project has been approved, even if the ultimate determination is made by USFWS.

MCWD-119

- Mitigation Measure 4.6-1g. Mitigation Measure 4.6-1g is improperly deferred because it only requires that a plan for relocation be developed after project approval. There is no reason the relocation plan cannot be developed now before the project is approved. There is similarly no reason why relocation sites cannot be identified and surveyed before project approval to determine if relocation is even feasible. Further, because there is no evidence that relocation is feasible, the DEIR/EIS cannot rely on this mitigation measure to support the conclusion that impacts would be less than significant. Finally, it is unclear whether a biologist would be authorized to perform the required analysis or relocation based on a Scientific Collecting Permit issued by CDFW, since the analysis and relocation is not for scientific study.

MCWD-120

- Mitigation Measure 4.6-1h. Mitigation Measure 4.6-1h also constitutes improper deferral of mitigation by requiring plans to be developed after project approval and, like other mitigation measure in this section, is marred by qualifying language such as "if feasible." Further, subpart (5) is

MCWD-121

unenforceable because it allows ground-disturbing activities to occur "if otherwise authorized by CDFW." Whether another agency might authorize impacts to occur has no bearing on whether the impact is significant. Further, the mitigation specifies a "buffer distance" to be established based on the "level of disturbance." But the measure is silent as to how the level of disturbance might be determined, why the distances were selected, and how they would reduce impacts to less than significant levels. Subpart (6) is similarly deficient because there are no objective criteria to establish the "level of disturbance" and no explanation why the different buffers would be adequate to mitigate impacts. Subpart (7) is wholly unenforceable because it only includes a recommendation, rather than a requirement, that burrowing owls be excluded from burrows. The measure must use firm language (i.e. "shall") to ensure the mitigation is adopted and enforced. Subpart (8) is inadequate because there is no explanation why the measure would reduce the impact below the significance threshold. It simply requires site monitoring to avoid take. Take is not the threshold of significance for this impact. Even if no "take" occurs, there may still be a significant impact to the species. MCWD-121 cont.

- Mitigation Measure 4.6-1i. Mitigation Measure 4.6-1i suffers several flaws. First, it constitutes improper deferral of mitigation by requiring post-approval plans for mitigation. Second, the measure does not require any pre-construction surveys or avoidance measures for construction activities that would be completed entirely during the non-nesting season, but there is no explanation why construction-related impacts would not occur during that time. MCWD-122

- Mitigation Measure 4.6-1j. Mitigation Measure 4.6-1j is improperly deferred because it allows "suitable buffers" to be determined after the project has been approved (subpart (5)(b)). As explained above, the buffer must be established now and included as specific performance criteria. Further, there needs to be an explanation why the buffer was selected and how it will actually reduce the impact to a less than significant level. Further, the measure should include compensation for any temporary or permanent loss of habitat. MCWD-123

- Mitigation Measure 4.6-1k. Mitigation Measure 4.6-1k is similarly inadequate because it requires the biologist to establish a "suitable buffer area" to avoid impact to woodrat nests (subpart (3)). There is no indication what might be considered a suitable buffer or why the buffer might minimize impacts. Further, subpart (4) is improper because it only requires relocation "to the extent feasible," which removes all enforceability from the measure. The measure then states that if relocation cannot be avoided within the peak breeding season, the lead agency shall contact CDFW for further guidance and CDFW's recommendation will be implemented. This is textbook deferral of mitigation and is prohibited under CEQA. There is no evidence that relocation MCWD-124

is feasible and there are no performance standards included in the mitigation that would ensure impacts are avoided. MCWD-124 cont.

- Mitigation Measure 4.6-1l. Mitigation Measure 4.6-1l states that bat roosts that begin during construction are presumed to be unaffected, and no buffer would be necessary. This statement defies logic and is not supported by any evidence. There are a variety of construction activities that would affect bats in different ways; just because bats may roost during some construction activities does not mean they would be unaffected by other activities. Further, the mitigation prohibits the take of "species," but as explained above, take is not the threshold of significance. Even if there is no take, there still may be significant impacts. MCWD-125

- Mitigation Measure 4.6-1m. Mitigation Measure 4.6-1m requires that facilities shall be sited and construction activities planned to avoid impacts on native stands of Monterey pine, but only "to the extent feasible." Although the mitigation includes additional mitigation if avoidance is not feasible, the success of that mitigation relies on the creation of a plan that details the monitoring requirements and success criteria. These are exactly the type of performance criteria that must be established before project approval if deferral of mitigation is to be permitted. The monitoring requirements and success criteria must be established and explained now to ensure that impacts will not occur. MCWD-126

- Mitigation Measure 4.6-1n. Mitigation Measure 4.6-1n requires CalAm to develop a plan for mitigation after project approval. This too is textbook deferral of mitigation. As explained above, an agency may defer the formulation of mitigation only if, among other requirements, the mitigation includes specific performance criteria that will ensure impacts are minimized. Mitigation Measure 4.6-1n, however, explicitly allows, in fact requires, the post approval plan to include "performance standards by which successful completion of mitigation can be assessed and insured." This is exactly what CEQA prohibits. There is no reason that the mitigation plans cannot be developed now, including the requisite "monitoring plans and schedule" or the "reporting requirements and schedule," for example. Further, the measure allows for compensatory mitigation lieu of active restoration without any explanation why this is feasible or would reduce impacts below the identified significance thresholds. This problem is exacerbated by the fact that numerous mitigation measures reference and rely on Mitigation Measure 4.6-1n to ensure impacts will be less than significant. All of those mitigation measures are therefore inadequate as well. MCWD-127

- Mitigation Measure 4.6-1o. Mitigation Measure 4.6-1o is improperly deferred because it because it allows the relocation plan to be developed after project approval, including the identification of relocation sites. There are no MCWD-128

performance standards to ensure that relocation is successful and, because relocation sites have not been identified, there is no evidence that the mitigation is feasible. Further, the mitigation allows red-legged frogs and tiger salamanders to be relocated according to the improperly deferred relocation plan only if authorized by USFWS and CDFW. There is no assurance that those agencies will authorize relocation of the species and, in any event, it is unlikely they will authorize relocation in all instances. Indeed, CDFW has already commented that the mitigation measures for impact to the California tiger salamander are inadequate and questioned whether the mitigation would be in compliance with Fish and Game Code and the California Endangered Species Act (CESA). (See CDFW Comments, Julie A. Vance, Feb. 27, 2017.) Therefore, the DEIR/EIS cannot rely on this mitigation measure to support the conclusion that impacts will be less than significant. This impact, like many others in this section, should be significant and unavoidable.

MCWD-128 cont.

- Mitigation Measure 4.6-1q. Mitigation Measure 4.6-1q is improperly deferred because it only requires a plan to be developed after project approval. The measure acknowledges that a frac-out may occur at the project site, which would cause a significant impact, and only after that occurs would CalAm be required to "consult with" the staffs of the relevant agencies "regarding appropriate incident-specific actions to be undertaken." Again, there are no performance standards or any assurance that this measure would reduce this impact to less than significant.

MCWD-129

m. ***The Analysis and Mitigation for Construction-Related Impacts to Habitats, Including Environmentally Sensitive Habitat Areas (ESHAs), are Inadequate***

Under Impact 4.6-2, the DEIR/EIS claims that various habitat areas, including central dune scrub at the subsurface slant well site and beach adjacent to the site, central dune scrub along the Transition Main Alignment, and other habitat areas that will be effected by project components, *may* be considered primary and secondary habitat under the City of Marina Local Coastal Land Use Plan, and *may* be considered ESHA by the CCC. This is a major understatement that renders the DEIR/EIS inadequate as an informational document. These areas include both primary and secondary habitat under the City's Local Coastal Land Use Plan (LCLUP) and is designated as ESHA by the CCC. (These areas have already been established and delineated by the City and the CCC. The DEIR/EIS must disclose all areas designated as primary or secondary habitat by the City or as ESHA by the CCC and fully explain how the project would affect those habitat areas.

MCWD-130

Further, as part of the project, CalAm intends to convert the temporary test well at the CEMEX site into a production well for the MPWSP. This slant well is located in ESHA. (See e.g., CCC Staff Report.) But the DEIR/EIS ignores this fact and fails to analyze the long-term impacts to ESHA and snowy plover habitat when the slant well is converted into a production well, as proposed. Instead the DEIR/EIS defers the consideration of these impacts by suggesting these issues will be worked out during the Coastal Development

MCWD-131

Permit (CDP) application process. (DEIR/EIS, pp. 4.6-70; 4.6-207.) This is improper deferral of analysis and mitigation under CEQA. Simply stating that the mitigation measures will reduce impacts by "ensuring the project conforms to ESHA policies (including local coastal plan policies)" does not cure this defect. As explained elsewhere, the DEIR/EIS acknowledges that the project will be inconsistent with ESHA policies, including local coastal plan policies. Even if the CPUC or the CCC ultimately decide to override these policies, and are able to make the findings required to do so, that does not mean that significant impacts to ESHA would not occur. Indeed, as acknowledged elsewhere in the DEIR/EIS, the Staff Report for the temporary test well (which will be converted to a production well) found impacts to ESHA and snowy plover habitat to be significant and unavoidable. (DEIR/EIS, p. 6.4-224.) That section of the DEIR/EIS also acknowledges that project facilities "would be inconsistent with the City of Marina LCLUP policies governing protection of Primary and Secondary Habitats," and concludes that this would be "a significant and unavoidable impact." (DEIR/EIS, p. 6.4-224.) Thus, the DEIR/EIS itself is internally inconsistent on this issue.

Moreover, by ignoring the fact that the test slant well (and proposed production well) is already sited in ESHA, the DEIR/EIS overlooks major land use implications. One major oversight in the DEIR/EIS is the fact that the Coastal Act prohibits development in ESHA if there are feasible alternative locations available. (See Pub. Resources Code, § 30260; see also Pub. Resources Code, § 30240, subd. (a) ["Environmentally sensitive habitat areas shall be protected against any significant disruption of habitat values, and only uses dependent on those resources shall be allowed within those areas."].) Because the DEIR/EIS identifies feasible alternatives sites for the slant wells (see DEIR/EIS Chapter 7, Alternatives), the existing slant well must be decommissioned and relocated if slant wells are approved at the CEMEX site. But this is not explained or evaluated in the DEIR/EIS.

MCWD-131 cont.

The discussion regarding conflicts with numerous policies in the City of Marina's LCLUP is also inadequate. Although numerous conflicts are acknowledged (See, e.g., DEIR/EIS, p. 4.6-219, 4.6-260), there is no explanation of whether they are indicative of environmental impacts or how the conflicts will be resolved. Instead the text refers to the discussion under the various impacts, which are entirely conclusory and inadequate as described above.

Further, the DEIR/EIS fails entirely to explain why these impacts would be rendered less than significant after the mitigation. Indeed, for the reasons explained above, the conclusion is unsupportable and is inconsistent with other impact conclusions in the DEIR/EIS, as noted above. Like many impacts in this section, this impact should be identified as significant and unavoidable.

The mitigation measures proposed under Impact 4.6-2 do not cure these problems. And those mitigation measures are also inadequate for additional reasons. The reasons most of the mitigation measure are inadequate or improper are explained above. The few

additional measures included for this Impact 4.6-2 fare no better than the others, and raise a host of additional problems.

- Mitigation Measure 4.6-2a. Mitigation Measure 4.6-2a requires consultation with local agencies and the CCC regarding ESHAs. As noted above, various project elements are proposed in areas already designated as ESHA by the CCC. The DEIR/EIS, therefore, is required to disclose the amount of ESHA that could be disturbed by project activities and the full extent of the potential impacts. This analysis cannot be deferred until after the CPUC approves the project, or be punted to the CCC for later consideration. Moreover, even if the CCC approves a CDP for the project, that does not mean that significant impacts to ESHA will not occur. It would just mean that the CCC decided to make the findings necessary to site the project in ESHA *despite the project's significant impacts*. Even with mitigation proposed in the DEIR/EIS, the impacts to ESHA must be considered significant and unavoidable.
- Mitigation Measure 4.6-2b. Mitigation Measure 4.6-2b only requires the construction contractor(s) to implement the identified avoidance and minimization measures "to the extent feasible." As explained above, this qualifying language renders the measure wholly unenforceable and inadequate under CEQA. Further, the measure requires restoration and compensation in accordance with Mitigation Measure 4.6-1n, which is improper deferral of mitigation, as explained above. There is also no evidence that this mitigation measure is feasible and no explanation why it would be effective. Furthermore, as explained in *Bolsa Chica Land Trust v. Superior Court* (1999) 71 Cal.App.4th 493, 507, impacts to ESHA cannot be mitigated through compensatory mitigation: "the language of section 30240 does not permit a process by which the habitat values of an ESHA can be isolated and then recreated in another location. Rather, a literal reading of the statute protects the area of an ESHA from uses that threaten the habitat values, which exist in the ESHA. Importantly, while the obvious goal of section 30240 is to protect habitat values, the express terms of the statute do not provide that protection by treating those values as intangibles which can be moved from place to place to suit the needs of development. Rather, the terms of the statute protect habitat values by placing strict limits on the uses which may occur in an ESHA and by carefully controlling the manner uses in the area around the ESHA are developed." The mitigation for impacts to ESHA and snowy plover habitat should be revised and the impact conclusion should be changed to significant and unavoidable.

MCWD-131 cont.

Finally, as explained previously, the mitigation measures for impacts to special-status bird species is grossly inadequate. CDFW agrees. (See CDFW Comments, Julie A. Vance, Feb. 27, 2017.) Because there is no evidence that the mitigation measures will be effective and no explanation how they will avoid or reduce the impact to a less than significant level,

MCWD-132

the DEIR/EIS cannot rely on the measures to support the conclusion that impacts will be less than significant. MCWD-132 cont.

n. ***The Analysis and Mitigation for Construction-Related Impacts to Wetlands and Other Jurisdictional Waters is Inadequate***

The DEIR/EIS's analysis of impacts to federal wetlands, federal other waters, and/or waters of the state during construction, suffers numerous flaws. Foremost, as explained above, the DEIR/EIS fails to analyze impacts to all of the wetlands and other jurisdictional waters that could be affected by the project. Although the DEIR/EIS identifies numerous areas that likely constitute jurisdictional waters under the state and federal definitions in close proximity to many project components, the DEIR/EIS fails to analyze impacts to those areas because they are located outside the arbitrary 50-foot study area. There is no explanation or evidentiary support for why the wetlands or other waters beyond 50-foot line would not be affected during construction or operation of the project. MCWD-133

Further, the mitigation included under Impact 4.6-3 suffers the same problems identified above for the other measures in this section of the DEIR/EIS. Most notably, the mitigation is improperly deferred and there is no explanation of why the mitigation is feasible and will be effective. Accordingly, the conclusion that impacts will be mitigated to a less than significant level is not supported by substantial evidence.

- Mitigation Measure 4.6-3. Mitigation Measure 4.6-3 calls for a wetland delineation to be conducted after project approval to determine the extent of jurisdictional waters that will be affected by the project. Because wetlands were not delineated prior to or concurrently with the preparation of the DEIR/EIS, the analysis of potential impacts is perfunctory. There is no way the reader or the CPUC can comprehend the full and accurate extent of potential impacts. Further, the mitigation measure states that compensation shall include the preparation of a Wetland Mitigation and Monitoring Plan (WMMP) to be prepared after project approval. The WMMP will include baseline information, monitoring methods and schedule, and "performance and success criteria." Problems with this measure abound. First, establishing the baseline is the first step in the analysis and cannot be deferred under any circumstance. Second, performance and success criteria must be included as part of the measure itself, if deferral of mitigation is to be permitted. Simply put, this measure does not comply with CEQA's most basic requirements. MCWD-134

o. ***The Discussion of Operation-Related Impacts and Mitigation Measures Are Inadequate.***

The DEIR/EIS states that any disturbance associated with pipeline repairs cannot be determined and therefore is not analyzed at all in the DEIR/EIS. (DEIR/EIS, p. 4.6-234.) CEQA, however, requires analysis of all components of the project and potential impacts that are reasonably foreseeable. Because CEQA is interpreted to afford the fullest possible MCWD-135

protection of the environment (*Friends of Mammoth v. Board of Supervisors* (1972) 8 Cal.3d 247, 259), this is a low bar. As acknowledged in the DEIR/EIS, at least some level of repair work is reasonably foreseeable. Therefore, the DEIR/EIS must at least disclose in general terms the type of repair work that is expected and the potential for environmental impacts. MCWD-135 cont.

Impact 4.6-6 states that noise or disturbance from maintenance activities could directly or indirectly impact wintering plovers. (DEIR/EIS, p. 4.6-235.) But there is no analysis of what potential impacts might occur. Instead the DEIR/EIS attempts to justify the lack of analysis by suggesting impacts would be only short-term and temporary. But CEQA requires analysis of all potential environmental impacts including those that are only short-term or temporary. There must be a full discussion of impacts to snowy plover from maintenance and operations of the project. MCWD-136

Impact 4.6-6 also acknowledges that, over the life of the project, "migratory waterfowl could become sick or die from use of the brine storage basin, a significant impact." (DEIR/EIS, p. 4.6-237.) But the mitigation relied on to mitigate this impact only provides that bird deterrents "should" be utilized at the Brine Storage Basin, the type of bird deterrent "should" be determined by the lead biologist, and "should" be modified if the bird deterrents are either not sufficient at deterring birds from the Brine Storage Basin or pose a risk to wildlife. Because there is no mandatory language in the measure, it is entirely unenforceable. For that reason alone, the DEIR/EIS cannot rely on the mitigation measure to reduce the impact to less than significant. Moreover, the only evidence cited to support the measure is a single sentence stating that "bird deterrent measures (such as use of a falconer, bird whistles, and fine ropes placed over the pond) are used at the adjacent MRWPCA Regional Wastewater Treatment Plant to successfully deter most birds from their ponds," without explaining what "most" birds means. (DEIR/EIS, p. 4.6-237.) Thus, the DEIR/EIS acknowledges that the project will cause an unquantified number of birds to die, but because deterrent devices implemented for another project (similar to those recommended but not required here) successfully deterred most birds (ostensibly meaning more than half), the impact is considered less than significant. This explanation is entirely inadequate under CEQA. What amount of dead birds does the DEIR/EIS consider to be a significant impact? MCWD-137

The DEIR/EIS also fails to disclose impacts to wildlife species that would result from erosion control measures. Notably, as explained in comments from CDFW, the use of certain types of erosion-control methods would likely cause impacts to several species, including reptile and amphibian deaths. This potential impact is ignored entirely. The DEIR/EIS must analyze these potential impacts and require mitigation measures to ensure that the impacts are avoided or reduced. MCWD-138

Moreover, the DEIR/EIS fails to address whether impacts would occur to special status plants and other species that depend on groundwater. Indeed, the DEIR/EIS fails to address any impacts to groundwater-dependent ecosystems despite acknowledging that the project would result in substantial drawdown of groundwater levels and an increase in MCWD-139

salinity levels. These types of changes would obviously have an impact on overlying habitat and species. But these potential impacts are ignored entirely in the DEIR/EIS. MCWD-139 cont.

To address impacts that are identified as significant, the DEIR/EIS relies on many of the same mitigation measures that are fatally defective for the numerous reasons described above. The additional mitigation in this section suffers many of the same problems. There is no explanation why the mitigation measures are feasible or how they will be effective and how they will mitigate the impact to a less than significant level. Again it is not sufficient to acknowledge a significant impact will occur, then list a number of mitigation measures, and then baldly assert that the mitigation will reduce the impacts to a less than significant level. The DEIR/EIS must explain why the selected mitigation measures will work and the conclusion must be supported by substantial evidence. This critical component of the CEQA analysis is missing from every impact discussion in this section. MCWD-140

Impact 4.6-6 and Impact 4.6-7, in particular, rely on the same mitigation measures that are inadequate for the reasons described above. Like the other impacts in this section, there is no supporting evidence at all and no explanation regarding how the mitigation will work and why the impacts will be reduced to a less than significant level. This is a plain violation of CEQA and renders the DEIR/EIS inadequate as an informational document.

p. ***The Analysis and Mitigation for Operations-Related Impacts to Wetlands and Other Jurisdictional Waters is Inadequate.***

Impact 4.6-8 purports to analyze adverse effects on federal wetlands, federal other waters, and/or waters of the state during project operations. But the discussion only addresses impacts related to ground disturbance and maintenance activities. There is zero discussion regarding how the ongoing operation of the facilities (i.e., pumping groundwater) will impact wetlands and other jurisdictional waters overlying the groundwater aquifers. The notion that the significant drawdown caused by the project in the groundwater aquifers underlying, and likely hydrologically connected to, the wetlands and other jurisdiction waters would have no impact defies logic. As noted above, by lowering the groundwater table and increasing salinity levels, the project would likely impact those wetlands and other waters. Yet the DEIR/EIS is silent on this potential impact. MCWD-141

This failure further demonstrates that the 50-foot study area is arbitrary and fails to account for all of the project's potential environmental impacts, as described above. Despite the fact that the DEIR/EIS identifies numerous areas that are potential wetlands or other jurisdictional waters in close proximity to the project, the DEIR/EIS does not analyze potential impacts because the features are beyond the 50-foot line. Even if the 50-foot study area could be justified for surface impacts (as explained above, it cannot) the underground (i.e. groundwater) impacts undeniably extend much further. Indeed, the maps in the DEIR/EIS show that the groundwater levels would decline by substantial amounts over the span of several miles—not just within the 50-foot study area. But there is no discussion regarding how changes in groundwater levels, or increases in salinity levels, could affect

overlying wetlands or other groundwater-dependent ecosystems. The DEIR/EIS must be revised to analyze these potential impacts and identify feasible mitigation measures that will reduce the impacts.

Moreover, as with other impacts in this section, the DEIR/EIS relies on mitigation measures that are woefully inadequate to support the conclusion that these impacts would be less than significant with mitigation. The reasons that these mitigation measures are inadequate are described above. Notably, the measure constitute improper deferral of mitigation, lack enforceable standards, and improperly rely on other agencies' regulatory programs without any explanation how the mitigation measures will reduce the impacts to a level of insignificance.

MCWD-141 cont.

q. ***The Discussion Regarding Consistency with an Adopted Habitat Conservation Plan (HCP), Natural Community Conservation Plan, or Other Approved Habitat Conservation Plan is Inadequate.***

As explained in the DEIR/EIS, the preparation of an HCP for the former Fort Ord military base, which will supersede the current Fort Ord Habitat Management Plan, was already underway when the DEIR/EIS was published and was expected to be complete in late 2016. (Draft EIR, p. 4.6-252.) Because the HCP was not yet adopted, the DEIR/EIS claimed that the requirements and mitigation measures cannot be known at this time. (*Id*.) Even if that was true then, the information is available now or should be before project approval is considered. Therefore, the Final EIR must analyze whether the project is consistent with the HCP for the former Fort Ord military base.

MCWD-142

This impact also relies on the same mitigation measures that are inadequate for numerous reasons described above. Mitigation Measure 4.6-8 fares no better. The mitigation requires only that CalAm implement certain vague measures, "unless otherwise negotiated between CalAm and FORA." As explained previously, CEQA does not allow for project proponents to "negotiate" mitigation measures after project approval. (*CBE v. City of Richmond, supra,* 184 Cal.App.4th at p. 93 ["Fundamentally, the development of mitigation measures, as envisioned by CEQA, is not meant to be a bilateral negotiation between a project proponent and the lead agency after project approval"].) Instead the measures must be fully enforceable at the time the project is approved and must identify specific performance criteria that ensure the impact will be less than significant. Mitigation Measure 4.6-8 does neither.

r. ***The Discussion of Cumulative Impacts is Inadequate.***

The cumulative impacts analysis is a mass of flaws. Foremost, the DEIR/EIS improperly relies on the significance conclusions for project-specific impacts to conclude that the cumulative impacts would not be cumulatively considerable. This approach has been rejected by the courts time and again. (See, e.g., *CBE v. Resources Agency* (2002) 103 Cal.App.4th 98,120; *Kings County Farm Bureau v. City of Hanford* (1990) 221 Cal.App.3d 692, 721.) Just because a project does not cause a significant impact by itself, does not mean

MCWD-143

that the project contribution to a cumulatively significant impact is not cumulatively considerable. Indeed, as recognized in the CEQA Guidelines, a project's incremental effects may be cumulatively considerable even when its individual effects are limited. (CEQA Guidelines, §§ 15130, 15064, subd. (h)(1), 15355, subd. (b).) (*Ibid*.; see also *Save Cuyama Valley v. County of Santa Barbara* (2013) 213 Cal.App.4th 1059, 1072 ["Under CEQA, a project having no significant effect on the environment when considered by itself may nonetheless have such an impact when considered in conjunction with-or cumulatively to-other past, existing or planned environmental influences. (CEQA Guidelines §§ 15130, subd. (a), 15064, subd. (h)(1))."].) But, here, the DEIR/EIS states that because certain project-specific impacts are mitigated to a less than significant level, the project's impact is not cumulatively considerable. This does not comply with CEQA's cumulative impact requirements.

For other cumulative impacts, the DEIR/EIS concludes that the project's contribution to a cumulative significant impact would not be cumulatively considerable because the project's contribution to the impact would be relatively small. For instance, the DEIR/EIS concludes that the project's contribution to cumulative impacts on wetlands or other waters would not be cumulatively considerable because, after mitigation, the MPWSP's residual effects "would be temporary and limited to a small percentage of wetlands habitat in the geographic scope of analysis." (DEIR/EIS, p. 4.6-260.) The courts have routinely rejected this type of "ratio" or "drop-in-the-bucket" methodology. (See *CBE v. Resources Agency* (2002) 103 Cal.App.4th 98,120; *Kings County Farm Bureau v. City of Hanford* (1990) 221 Cal.App.3d 692, 721.) Under this reasoning, each cumulative project could individually gobble-up only a small percentage of the available wetlands until all of the wetlands are gone, but none of the projects' impact would be considered cumulatively considerable. This is impermissible under CEQA.

MCWD-143 cont.

Moreover, even if the methodology used in the DEIR/EIS was appropriate under CEQA, the cumulative impacts analysis is tainted by the DEIR/EIS's failure to adequately fully analyze and disclose all of the project-specific impacts on terrestrial biological resources, as explained above. And the cumulative impacts analysis relies on the same mitigation measures that, as already explained, are inadequate under CEQA. The EIR also fails to consider how the habitat restoration required under the CEMEX reclamation plan will be affected by the project. In fact the DEIR/EIS fails disclose or acknowledge the existence of the reclamation plan and associated revegetation plan for the CEMEX site, which requires restoration or slopes and successful revegetation in the areas that will be affected by the project. (See RMC Lonestar, Reclamation Plan, Lapis Plant, City of Marina, County of Monterey: dated August, 1989; revised October 22, 1988 (Items Nos. 22, 27 and 29) and April 10, 1991 (Items Nos. 20, 22, 27 and 28); see also Burleson Consulting, Inc., 2016, 2016 Annual Revegetation Report, Lapis Sand Plant, Marina California, report prepared for CEMEX by Burleson Consulting, Inc., dated December 2016). Notably, no active mining is occurring in the area where the slant wells are proposed and "significant portions of the dune slopes previously mined in the southern portion of the property are considered to have met

MCWD-144

reclamation requirements." (see 2016 SMARA Mine Inspection Lapis Sand Plant, CA MINE ID No. 91-27-0006, City of Marina, California, December 9, 2016, available at ftp://ftp.consrv.ca.gov/pub/smgb/February-08-2017/19%20RBM%2002082017-12B-1%20Lapis%20Plant%20(91-27-0006).pdf.) The DEIR/EIS must be updated to disclose how the project will impact reclamation and revegetation requirements for the CEMEX site.

MCWD-144 cont.

Finally, the cumulative impacts analysis is woefully light on information. Although the discussion notes that cumulative impacts may occur, there is no quantification of impacts or other information or data that would allow the reader or the CPUC to understand the extent of those impacts. As explained previously, conclusory statements without explanation and evidentiary support do not suffice.

MCWD-145

4. The DEIR/EIS's Discussion of Coastal Erosion Impacts is Inadequate

The DEIR/EIS reveals that there is a likelihood coastal retreat could migrate the beach inland such that the subsurface slant well casings, concrete well head vaults, electrical panels, and certain sections of conveyance pipelines would become located on the beach within the project lifetime. (DEIR/EIS, pp. 4.2-48 through 4.2-52; 4.2-68 through 4.2-69.) The DEIR/EIS further acknowledges that the exposure of the project components to wave action, storm events, and rip embayments could alter the existing natural beach dynamics and the coastal environment, resulting in an increase in beach erosion and/or an interruption in the sand supply to other beaches along the Monterey Bay. The DEIR/EIS, however, fails to adequately analyze the potential for such impacts and fails to include adequate mitigation or alternatives to minimize or avoid those impacts.

The DEIR/EIS states the coastal retreat study (ESA, 2014 – Appendix C-2) anticipated that the subsurface slant wells in the CEMEX active mining area could become located on the beach within the project lifetime. It further states coastal retreat study assumes a worst case scenario for planning purposes; the actual amount or rate of coastal retreat could be less. (DEIR/EIS, pp. 4.2-69.) While perhaps this was accurate in 2014, the failure to update this study based more recent information violates the CEQA and NEPA. For example, we understand the annual erosion rate of 2014 at the CEMEX coastline nearly doubled from 220,000 to 380,000 cubic feet in 2016. Does the DEIR/EIS account for this? Moreover, the public cannot determine what annual erosion rate was used in the DEIR/EIS. What annual erosion rate was used in the DEIR/EIS and Appendix C-2? Is the 15 feet of scour that was observed around the exposed section of the outfall during the winter storm surge in early March 2016 that exposed the buried slant test well connection to the MRWPCA ocean outfall pipe (see DEIR/EIS, p. 4.2-22) consistent with the 2014 coastal retreat study projections? In addition, the DEIR/EIS's failure to use available computer-aided modeling as identified in Appendix C-2 is inconsistent with CEQA and NEPA's requirements.

MCWD-146

Figures 4.2-7 and 4.2-8 appear inaccurate and may mislead the public and decision makers. Is the current test well head 30 feet in elevation from the intertidal zone as shown in

MCWD-147

Figures 4.2-7? Does Figure 4.2-8 (which claims to be a representative image) representative of all each slant well location and the slant well that would most likely be impacted by coastal retreat?

MCWD-147 cont.

The DEIR/EIS states the final design locations for the slant wells were relocated approximately 400 feet further inland from the originally proposed locations to the locations shown on Figures 4.2-7, 4.2-8, and 3-3. (DEIR/EIS, p. 4.2-69.) Therefore, the DEIR/EIS concludes the proposed slant wells would not be exposed during the operational life of the slant production wells (anticipated to be 20 to 25 years) and would not contribute to further coastal erosion or changes in the beach environment. The use of the 20- to 25-year operational life for the slant wells to evaluate this impact is not consistent with the other sections of the DEIR/EIS, which never mention the potential for the slant wells being deconstructed (with the exception of the existing test well) or reconstructed over the 40 year life of the project. This inconsistency must be addressed in the revised DEIR/EIS.

MCWD-148

The DEIR/EIS states that the anticipated future presence of the test slant well on the beach due to coastal retreat would result in a significant impact, but that Mitigation Measure 4.2-9 (Slant Well Abandonment Plan) would reduce the impact to a less-than-significant level by requiring CalAm to monitor coastal retreat rates and initiate well decommissioning before the beach migrates inland to the location of the subsurface slant wells. (DEIR/EIS, pp. 4.2-71 through 4.2-72.) This conclusion is not supported by the DEIR/EIS's discussion. Moreover, the mitigation measure does not meet CEQA's requirements.

First, the Mitigation Measure 4.2-9 impermissibly delegates to CalAm the responsibility for annual monitoring of the rate of coastal retreat relative to the slant wells at the CEMEX site and the discretion to determine when the slant wells and associated pipelines have 5 years before exposure. (DEIR/EIS, p. 4.2-72.) There is not oversight or public reporting requirement. This violates CEQA requirements that "[m]itigation measures must be fully enforceable through permit conditions, agreements, or other legally-binding instruments." (*Center for Biological Diversity v. California Dept. of Fish and Wildlife* (2015) 62 Cal.4th 204, 237 [citing Guidelines § 15126.4, subd. (a)(2)].)

MCWD-149

Second, the mitigation measure states the sections of slant well casing and pipelines at risk of exposure shall be cut and removed to a depth of five feet below the 2060, 100-year lower profile envelope as determined by the 2014 Coastal Erosion Study (ESA, 2014) or as directed by any permit condition. (DEIR/EIS, p. 4.2-72.) This constitutes improper deferral of mitigation and fails to address that the Coastal Erosion Study concludes (albeit inadequately) that none of the slant wells casings or pipelines (with the exception of the test well) would be uncovered with the time period specified in the mitigation measure. Moreover, deconstruction of the test well and slant wells to a depth that they would not result in additional coastal erosion in the foreseeable future after the project is completed must also be addressed. What happens if the slant wells casings or pipelines are uncovered after 2060?

Finally, this high likelihood of exposure of the test well structures is enough reason to decommission the test well as required by the CCC in February 2018 or sooner. MCWD-149 cont.

5. The DEIR/EIS's Discussion of Land Use Impacts Fails to Disclose or Analyze the Numerous Land Use Conflicts

Under CEQA, an EIR must discuss any inconsistencies between a proposed project and applicable general plans, specific plans, and regional plans. (CEQA Guidelines, § 15125, subd. (d).) A project is consistent with a plan "if, considering all its aspects, it will further the objectives and policies of the . . . plan and not obstruct their obtainment." (*FUTURE v. Board of Supervisors* (1998) 62 Cal.App.4th 1332, 1336.) In *Napa Citizens for Honest Government v. Napa County Board of Supervisors* (2001) 91 Cal.App.4th 342, the court rejected the county's claim that a project was consistent with local plans because the EIR at issue did not "contain an adequate *discussion*" of local plan consistency. (*Id.* at p. 381, emphasis added.) The purpose of the required analysis is to identify any inconsistencies and to evaluate and consider ways to modify the project to avoid them. (*Orinda Assn. v. Board of Supervisors* (1986) 182 Cal.App.3d 1145, 1168-1169 [referencing EIR discussion of plan inconsistencies and mitigation measures to avoid them].)

Here, the DEIR/EIS's discussion regarding plan inconsistency and land use impacts does not satisfy CEQA. First, the land use section of the DEIR/EIS claims that all policies applicable to the project and relevant to land use are listed in Table 4.8-2. That is obviously not true. Table 4.8-2 includes only a tiny fraction of plans and policies that apply to the project. For example, in Section 4.4, Groundwater Resources, the DEIR/EIS notes that there are numerous state and local plans, policies, and laws that apply to the project. (DEIR/EIS, pp. 4.4-32 - 4.4-40.) But the Groundwater Resources section only includes a consistency determination for a few of these policies, and none are discussed in Section 4.8, despite the DEIR/EIS's promise that "a general overview of these policy documents is presented in Section 4.8, Land Use, Land Use Planning, and Recreation." (DEIR/EIS, p. 4.4-38.) MCWD-150

Worse yet, the land use section, including Table 4.8-2, does not even list all of the relevant plans and policies that were adopted specifically for the purpose of avoiding or mitigating an environmental effects – an identified threshold of significance for land use impacts. (DEIR/EIS, p. 4.8-34.) In fact, the table does not even include the policies and plans that are identified in other sections of the DEIR/EIS. For example, the Terrestrial Biological Resources section alone lists 30 pages of plans and policies related to protecting environmental resources and identifies copious inconsistencies or "potential inconsistencies." (DEIR/EIS, pp. 4.6-88 – 4.6-118 [Table 4.6-4].) Although numerous inconsistencies are identified, they are not analyzed or discussed anywhere in the DEIR/EIS. (See *Napa Citizens for Honest Government v. Napa County Board of Supervisors, supra,* 91 Cal.App.4th at p. 381 [EIR overturned because it did not include an adequate discussion regarding plan inconsistencies].) Instead, the DEIR/EIS simply lists the plans and policies and states in conclusory fashion that the proposed mitigation measures would bring the MPWSP into conformity with the plans and polices. (See, e.g., DEIR/EIS, pp. 4.6-162-164; 4.6-203-204;

4.6-219; 4.6-230; 4.6-232-233; 4.6-240-241; 4.6-245-246; 4.6-248-250.) There is no support for these conclusions and they are likely not accurate in most instances. Even if the DEIR/EIS could accurately conclude that an impact is less than significant after mitigation based on the thresholds of significance that does not mean the project would be consistent with all relevant plans and policies. For example, there are numerous local policies that prohibit development in protected habitat and ESHA, or otherwise seek to protect and conserve such habitat. (See DEIR/EIS, 4.6-88 – 4.6-118 [Table 4.6-4].) But the project is sited directly in ESHA and would adversely impact protected habitat. Given the project's inconsistency with the City of Marina's LCP and Coastal, it is remarkable those issues are not address in this Chapter. In fact, unless the City of Marina amends its LCP, it would appear the MPWSP cannot be approved. (Attached as Exhibit "5" are the Parties' briefs on the merits in *MCWD v. California Coastal Commission*, Santa Cruz Superior Court Case No. CV180839.) The DEIR/EIS failure to address this fundamental issue requires recirculation. In any event, even if the consistency determination could be justified, CEQA requires a much better explanation regarding *how* the project would be consistent with the plans or policies. The conclusory statements in the DEIR/EIS do not suffice.

MCWD-150 cont.

Further, because the land use section includes a threshold of significance that specifically states that a significant impact would occur the project would "conflict with any applicable land use plan, policy or regulation of an agency with jurisdiction over the project (including, but not limited to the general plan, specific plan, local coastal program, or zoning ordinance) adopted for the purpose of avoiding or mitigating an environmental effect, all of the inconsistencies and "potential inconsistencies" identified in other sections of the DEIR/EIS must be discussed in the land use section and analyzed against this threshold. The required analysis will likely uncover numerous significant environmental impacts that are currently not disclosed, including some that are likely unavoidable. The DEIR/EIS must also discuss ways the inconsistencies can be avoided and whether any of the inconsistencies are indicative of any other environmental impacts. Because the updated analysis will require adding significant new information to the DEIR/EIS, the documents must be recirculated for public review and comment.

6. The DEIR/EIS's Discussion of Hazards and Hazardous Materials Is Inadequate.

The DEIR/EIS reveals that there is a high likelihood that hazardous materials are present in the soil and groundwater in the project area, which pose significant health risks to workers and the public. (DEIR/EIS, pp. 4.7-2 through 4.7-12; 4.7-28 through 4.7-30.) Given the nature of the project, and particularly the fact that it involves significant disruption of soil and groundwater in the area, the project is likely to have significant impacts regarding hazards and hazardous materials. The DEIR/EIS, however, fails to adequately analyze the potential for such impacts and fails to include adequate mitigation measures to minimize or avoid those impacts.

MCWD-151

For Impact 4.7-2, for example, the DEIR/EIS explains that the potential for contaminated soil and groundwater to be released into the environment is considered

significant and proposes two mitigation measures. Neither the discussion of the impact or the proposed mitigation is adequate.

Although the DEIR/EIS discloses that a potential impact could occur including "health and safety risks" to workers and the public, it fails to describe the type of health risks that are present or the severity of the impact. (DEIR/EIS, p. 4.7-28.) Nevertheless, the DEIR/EIS states that implementation of Mitigation Measure 4.7-2a and Mitigation Measure 4.7-2b would reduce the impact to a less-than-significant level. There is, however, zero explanation of how the mitigation measures will operate and how they will reduce the impact to a less-than-significant level.

Further, the measures merely call for the preparation of various plans after the project is approved, which constitutes improper deferral of mitigation. (See *Preserve Wild Santee v. City of Santee* (2012) 210 Cal.App.4th 260, 280-281 ["impermissible deferral of mitigation measures occurs when an EIR puts off analysis or orders a report without either setting standards or demonstrating that the impact can be mitigated in the manner described in the EIR"].) Most glaringly, rather than including performance standards in the mitigation as CEQA requires, Mitigation 4.7-2b requires standards to be developed at some future time. For example, the measure states that "the plan must identify protocols for testing and disposal, identify the approved disposal site, and include written documentation that the disposal site will accept the waste." (DEIR/EIS, p. 4.7-30.) It also calls for the development of a groundwater dewatering and disposal plan that will "identify the locations at which groundwater dewatering is likely to be required, the method to analyze groundwater for hazardous materials, and appropriate treatment or disposal methods." (*Ibid*.) These are precisely the types of issues that must be resolved before the project is approved to demonstrate that the mitigation will be feasible and effective.

MCWD-151 cont.

The analysis under Impact 4.7-4 is similarly defective. The analysis simply states that hazardous materials storage and stormwater permitting requirements would ensure the risk of release of hazardous materials during construction would be low. There is no explanation how compliance with those requirements would reduce this particular impact to a less-than-significant level. Also, CEQA contains certain notice and consultation requirements for projects within a quarter-mile of a school site "that might reasonably be anticipated to emit hazardous air emissions, or that would handle an extremely hazardous substance or a mixture containing extremely hazardous substances in a quantity equal to or greater than the state threshold quantity specified pursuant to subdivision (j) of Section 25532 of the Health and Safety Code." (Pub. Resources Code, § 21151.4.) The DEIR/EIS does not discuss compliance with section 21151.4.

MCWD-152

Finally, the cumulative impacts analysis is also inadequate in that it relies on Mitigation Measures 4.7-2a and 4.7-2b to reduce the project's contribution to potential releases of or exposure to hazardous materials in soil or groundwater to a less-than-

MCWD-153

significant level. As set forth above, these measures improperly defer mitigation in violation of CEQA. MCWD-153 cont.

7. The DEIR/EIS's Discussion of Greenhouse Gas Emissions is Inadequate.

The DEIR/EIS's discussion of Greenhouse Gas Emissions (GHGs) is plagued by the inadequacies from Chapter 4.18, Energy Conservation, discussed below. Notably, the proposed mitigation does not satisfy CEQA.

The proposed mitigation in DEIR/EIS Section 4.11, Greenhouse Gas Emissions, is improperly deferred and inadequately discussed in violation of both CEQA and NEPA. All of the problems with Mitigation Measure 4.18-1, which is also relied on to mitigate GHG emissions, are described below under the discussion of the energy analysis.

CEQA permits deferral of mitigation only when: (1) an EIR contains criteria or performance standards to govern future actions; (2) practical considerations preclude the development of earlier measures; and (3) the lead agency has assurances that the future mitigation will be both "feasible and efficacious." (*Communities for a Better Environment v. City of Richmond* (2010) 184 Cal.App.4th 70 ("*CBE v. City of Richmond*"); see also *San Joaquin Raptor Rescue Center v. County of Merced* (2007) 149 Cal.App.4th 645, 669-71 [county improperly deferred mitigation when it allowed a land management plan for special status vernal pool species to be developed after certification of an EIR]; *Gentry v. City of Murietta* (1995) 36 Cal.App.4th 1359, 1396 [conditioning a permit on "recommendations of a report that had yet to be performed" constituted improper deferral of mitigation].) "A study conducted after approval of a project will inevitably have a diminished influence on decision-making. Even if the study is subject to administrative approval, it is analogous to the sort of post hoc rationalization of agency actions that has been repeatedly condemned in decisions construing CEQA." (*CBE v. City of Richmond, supra,* 184 Cal.App.4th at p. 92, quoting *Sundstrom, supra,* 202 Cal.App.3d at p. 307.) "Fundamentally, the development of mitigation measures as envisioned by CEQA, is not meant to be a bilateral negotiation between a project proponent and the lead agency after project approval; but rather, *an open process that also involves other interested agencies and the public*." (*Ibid.,* emphasis added.) MCWD-154

As an added consideration, NEPA requires that "an EIS contain a detailed discussion of possible mitigation measures." (*Robertson v. Methow Valley Citizens Council* (1989) 490 U.S. 332, 351.) "Mitigation must 'be discussed in sufficient detail to ensure that environmental consequences have been fairly evaluated.'" (*Carmel-By-the-Sea v. U.S. Dept. of Transportation* (9th Cir. 1997) 123 F.3d 1142, 1154.) "A mere listing of mitigation measures is insufficient to qualify as the reasoned discussion required by NEPA." (*Northwest Indian Cemetery Protective Assn. v. Peterson* (9th Cir. 1986) 795 F.2d 688, 697, *rev'd on other grounds, Lyng v. Northwest Indian Protective Assn.* (1988) 485 U.S. 439 ("*Northwest Indian Cemetery*").) A perfunctory description of mitigation measures is inconsistent with the "hard look" an agency is required to render under NEPA. (*Neighbors of Cuddy Mountain v. U.S. Forest Service* (9th Cir. 1998) 137 F.3d 1372, 1380-1381 ("*Cuddy Mountain*") [EIS

inadequate where agency did not provide an estimate of effectiveness of a mitigation measure, nor provide a reasoned explanation as to why such an estimate was not possible].)

Mitigation Measure 4.18-1 violates these basic requirements for the reasons set forth below in comments related to Section 4.18, Energy Conservation.

Mitigation Measure 4.11-1, subsection (b) suffers from similar fatal flaws. The qualifier that CalAm need only make a "good faith effort" (see DEIR/EIS, p. 4-11.21) to obtain renewable energy for operations of the project makes the mitigation unenforceable and a far cry from what CEQA and NEPA require. (See 95 *CBE v. City of Richmond, supra,* 184 Cal.App.4th at p. 95; CEQ Final Guidance for Federal Departments and Agencies on Consideration of Greenhouse Gas Emissions and the effects of Climate Change in NEPA Reviews, p. 19 ["agencies should carefully evaluate the quality of [potential] mitigation to ensure it is additional, verifiable, durable, enforceable, and will be implemented].) The DEIR/EIS provides no definition of what constitutes "good faith," making it appear as though the term was included merely to give CalAm an easy out.

In January 2017, California Air Resources Board (CARB) released the Draft 2017 Climate Change Scoping Plan Update—which identifies the overall strategy to reduce GHG emissions by 40 percent below 1990 levels by 2030. With respect to the water sector, the plan identifies reduction of energy intensity as the primary reduction strategy for the water sector. (2017 Scoping Plan Update, p. 126.) While the DEIR/EIS acknowledges that the vast majority of GHG emissions associated with long-term operation of the project would be due to the astronomical energy use in the desalination process, Mitigation 4.11-1 is hardly adequate to ensure any reduction in the project's electricity consumption. MCWD-154 cont.

The suggestion that CalAm is actually required to do anything under this mitigation measure is misleading. Rather, it amounts to a bald attempt to avoid performing all feasible mitigation measures. Moreover, as noted below, CEQA and Appendix F require that a discussion and analysis of renewable energy options must be included in the EIR. But instead, the DEIR/EIS defers this analysis and allows CalAm to proceed without implementing any feasible renewable energy options even though such options would reduce GHG emissions and conserve energy.

Worse yet, there are readily available mitigation measures that would reduce this significant and unavoidable impact (potentially even to a less-than-significant level). For example, GHG emissions associated with the project could be reduced by purchasing carbon offsets. Yet, the DEIR/EIS summarily dismisses the use of carbon offsets—concluding that the indirect GHG emissions are associated with electricity generation by fossil fuel plants, which are already subject to CARB's cap-and-trade program. However, under the cap-and-trade program carbon offsets are limited to eight percent of a covered entity's compliance obligation per compliance period. (Cal. Code Regs. tit. 17, § 95856, subd. (h)(A).) Mitigation for the project's GHG emissions should not rest solely on outside programs and regulations.

At a minimum, the CPUC should require CalAm to purchase carbon offsets sufficient to reduce the GHG emissions to a "net zero" level (i.e., sufficient to fully offset the emissions of the project). Carbon offsets are feasible and are frequently used to offset GHG emissions for projects, including desalination projects. (See *North Coast Rivers Alliance v. Marin Municipal Water District Bd. of Directors* (2013) 216 Cal.App.4th 614, 653 [in approving a desalination plant project, "the District's Board adopted a policy requiring offsets for all project-related GHG emissions"].) Further supporting the feasibility of carbon offsets, the analysis in the 2017 Draft Scoping Plan Update finds that cap-and-trade is the lowest cost, most policy efficient approach, and provides certainty that the 2030 goals will be met, even if other measures fall short. (2017 Draft Scoping Plan Update, pp. 69-72.) It should also be noted that the MBNMS Guidelines for Desalination Plants states that "Applicants should also identify measures available to reduce electricity use and related emissions (e.g., energy efficient pumps, low resistance pipes, ***use of sustainable electricity sources***, etc.) ***and to mitigate for all remaining emissions (e.g., purchase of offsets and/or credits that are consistent with the policies and guidelines of the California Global Warming Solutions Act of 2006 (AB 32), etc.***)." (see p. 7, emphasis added, available at http://montereybay.noaa.gov/resourcepro/resmanissues/pdf/050610desal.pdf)

MCWD-154 cont.

It is important to emphasize that simply because the DEIR/EIS concludes that all GHG emissions impacts are significant and unavoidable does not absolve the CPUC or Sanctuary of its obligation under CEQA to mitigate potential environmental impacts to the fullest extent feasible. In other words, finding GHG emissions significant and unavoidable cannot save the DEIR/EIS from its inadequacies. (See e.g., *California Clean Energy Committee v. City of Woodland* (2014) 225 Cal.App.4th 173 ("*California Clean Energy Committee*") [mitigation measure in EIR requiring further study of potential urban decay impacts was improper, despite EIR's conclusion that the impact was significant and unavoidable].) The DEIR/EIS must be revised to include fully enforceable mitigation measures that are supported by substantial evidence.

8. The DEIR/EIS's Discussion of Public Services and Utilities Is Inadequate.

The DEIR/EIS discussion of Public Utilities fails to discuss the MPWSP's potential impacts on MCWD's service area and water supplies, including the Regional Urban Water Augmentation Project ("RUWAP") Desalination Element. As addressed above, updated modeling based on the best available information is needed to ensure the MPWSP will not impact MCWD's wells, which serve as the sole source of supply for the Marina/Ord Community. The DEIR/EIS also needs to address here, or at minimum in the cumulative impacts analysis, how the MPWSP would affect the salinity levels of the proposed source wells for the RUWAP Desalination Element, either in this section or in its cumulative impacts analysis. The discussion must disclose whether increased salinity levels at the proposed RUWAP source well locations due to the MPWSP would require MCWD to install additional infrastructure for the treatment of source water or increase energy requirements (as well as the associated air quality/GHG emissions and impacts associated with any increased energy requirements).

MCWD-155

The DEIR/EIS should also confirm that MRWPCA's ocean outfall has capacity to handle both MPWSP discharges and MCWD's vested rights to the facility, including discharges from the RUWAP Desalination Element, as well as MRWPCA's ordinary use. To the extent MCWD's ability to use the outfall would be affected or additional requirements would be imposed on MCWD, this information should be disclosed in the revised and re-circulated DEIR/EIS. MCWD-156

Finally, under the DEIR, MCWD's 30" pipeline in General Jim Moore Blvd. has been made a critical component of the MPWSP delivery system. The New 36" Transmission Main from the MPWSP desalination plant terminates into MCWD's pipeline. From there, the water is carried through MCWD's water system, and then back to the Cal Am system to deliver its water to its proposed Terminal Reservoir and to the Monterey Peninsula. This is not clearly described nor discussed in the DEIR/EIS and is shown as a pipeline "gap" between the proposed Terminal Reservoir and the end of the New Transmission Main in many of the Figures in the DEIR/EIS. The DEIR/EIS does not address the capacity limitations in MCWD's pipeline that may be exceeded by adding additional water from the MPWSP to flow through this pipeline in addition to the capacity needed by MCWD to serve the South Ord portion of its Ord Community service area when those areas develop and the capacity needed by MRWPCA to convey GWR water.

Further, the DEIR/EIS does not explain how MCWD's pipeline is to be operated with the new supply to allow it to adequately serve both CalAm's and MCWD's water systems. MCWD currently allows Cal Am to use the pipeline for Carmel River water injection into the Seaside Basin (Phase 1 and Phase 2 ASR) under an Agreement between the two parties (2007 Wheeling Agreement). However, subject to operational studies, the pipeline may not be able to be used simultaneously to convey (1) MCWD's water south to meet service area demands, (2) Carmel River water north for ASR injection, (3) GWR water south to the Peninsula, (4) extracted ASR water south to the Peninsula, and (5) direct distribution of CalAm's desalination water south to the Peninsula. For example, during January, how will the MCWD pipeline be operated if Carmel River is available to convey north in the MCWD pipeline for ASR injection while at the same time CalAm wants to convey GWR water and desalination water south in the same pipeline? There are significant complexities to overcome in operating the pipeline in this manner, which may cause the need for additional booster pumps, reservoirs, a completely separate pipeline to convey all or some of the desal water, and/or a reduction in pipeline life through intensified use, all of which have not been adequately addressed in the DEIR/EIS. This is another example of the failure of the DEIR/EIS to perform an integrated total water system analysis of CalAm's system. MCWD-157

In order to explore whether MCWD's pipeline can accommodate both MCWD's needs and CalAm's needs, the DEIR/EIS must provide CalAm's average, max day, and peak hour demands for the use of the pipeline and a projected use of the pipeline broken down for

each calendar month of the year, including proposed injection and extraction into and from the Seaside basin, for both the 9.6 MGD plant and the 6.4 MGD plant. MCWD-157 cont.

Additionally, MCWD identified significant conflicts between the planned MPWSP New Transmission Main and the existing/planned MCWD utilities in Light Fighter Drive and General Jim Moore Blvd. From DEIR/EIS figures 3-8 and 3-9, the MPWSP Transmission Main conflicts with the existing and planned MCWD facilities and possibly conflicts with other utilities as well (e.g. PG&E). The DEIR/EIS does not adequately address the conflicts in the alignment of the utilities and how those are to be mitigated. MCWD-158

9. The DEIR/EIS's Discussion of Energy Consumption and Mitigation is Inadequate.

The DEIR/EIS's discussion of energy conservation and proposed mitigation in Section 4.18, Energy Conservation, is inadequate under CEQA and NEPA.

CEQA Guidelines Appendix F provides that the "[p]otentially significant energy implications of a project shall be considered in an EIR." As recently explained in *California Clean Energy Committee, supra,* 225 Cal.App.4th at p. 203, "an EIR is 'fatally defective' when it fails to include a detailed statement setting forth the mitigation measures proposed to reduce wasteful, inefficient, and unnecessary consumption of energy." The court in that case was emphatic that the provisions set forth in Appendix F are mandatory, and failure to include the items listed under Appendix F, Section II (EIR Content) renders an EIR inadequate. (*Id*., at pp. 209-213.) The energy discussion in the DEIR/EIS does not address all of the items in Appendix F and is inadequate in numerous other respects. MCWD-159

s. ***The DEIR/EIS fails to analyze renewable energy options.***

In direct contravention of Appendix F and the court's holding in *California Clean Energy Committee, supra,* 225 Cal.App.4th 173, the DEIR/EIS fails to analyze renewable energy options. The introduction to Appendix F states that its goals include "increasing reliance on renewable energy sources." (CEQA Guidelines, Appendix F, § I, subd. 3.) Appendix F further states that "[m]itigation measures may include: [¶] … [¶] 4. Alternate fuels (particularly renewable ones) or energy systems." (*Id*., § II, subd. D.4.) The DEIR/EIS barely pays lip service to a single option for renewable energy—the Landfill-Gas-to-Energy Option. (DEIR/EIS, p. 4.18-13.) Despite the fact that it would substantially reduce energy consumption, the DEIR/EIS provides no analysis of this option. (*Ibid*.) Instead, the DEIR/EIS states that "[i]mplementation of this option and the construction of associated interconnected improvements would require separate environmental review and are not evaluated in this EIR/EIS." (*Ibid*.) MCWD-160

This is not appropriate. To comply with CEQA, this feasible renewable energy option is required to be included and analyzed in the DEIR/EIS, and discussed as mitigation in accordance with Appendix F. (See also *California Clean Energy Committee, supra,* 225 Cal.App.4th at p. 213 [holding EIR "failed to comply with the requirements of Appendix F to the Guidelines by not discussing or analyzing renewable energy options"]; *Id*. at p. 213, ["the

requirement to adopt energy impact mitigation measures 'is substantive and not procedural in nature and was enacted for the purpose of requiring the lead agencies to focus upon the energy problem in the preparation of the final EIR.' [Citation.]"].)

Moreover, any future review and approval of this project component in a separate environmental document would, as contemplated in the DEIR/EIS, constitute improper piecemealing under CEQA. CEQA requires that all project components and all reasonably foreseeable project activities must be analyzed together in a single EIR. (See *Laurel Heights Improvement Assn. v. Regents of University of California* (1988) 47 Cal.3d 376, 396; CEQA Guidelines, § 15378, subd. (a) [the term "project" under CEQA is defined as the "whole of an action"].) Similarly, federal regulations implementing NEPA prohibit the "segmentation" of environmental analysis by mandating that "[p]roposals or parts of proposals which are related to each other closely enough to be, in effect, a single course of action shall be evaluated in a single impact statement." (40 C.F.R., § 1502(a).) Therefore, the feasible option that would mitigate energy impacts must be analyzed now as part of the DEIR/EIS. MCWD-160 cont.

t. ***The DEIR/EIS ignores indirect energy consumption associated with construction of the Project.***

The DEIR/EIS completely ignores the massive amount of electricity and energy that would be indirectly consumed during construction of the project. To skirt the disclosure of indirect energy consumption and to avoid any analysis, the DEIR/EIS states that the amount of electricity and indirect energy consumption that would be associated with the project is unknown and cannot be estimated, but is not expected to be substantial. (DEIR, p. 4.18-14.) This is inconsistent with the previous statement in the DEIR/EIS that "indirect energy use typically represents three-quarters of the total construction energy consumed, while direct energy use represents about one-quarter." (*Ibid*.) In other words, based on that statement, it is reasonable to assume that at least three times the amount of energy use disclosed and analyzed in the DEIR/EIS would be consumed by activities that, although indirect, are attributable to the project. But the DEIR/EIS fails to even attempt to quantify the amount of electricity and indirect energy consumption or discuss ways to reduce the consumption. Without full disclosure of energy consumption and a complete analysis, it is impossible for the reader (and the decisionmakers) to understand the full construction impacts of the project, as they relate to energy. MCWD-161

u. ***The analysis of energy consumption during Project operations is conclusory and not supported by substantial evidence.***

As an initial matter, the DEIR/EIS fails to provide adequate explanation to support the assumptions upon which the project's energy consumption is based. The DEIR/EIS states that CalAm's operational electrical power demand for the proposed project is estimated to be approximately 63,164 MWh per year, which would result in a net increase in CalAm's annual electrical power demand for water production of approximately 51,698 MWh per year. (DEIR, p. 4.18-16.) But there is no explanation how the 63,164 MWh per year figure was derived—making it impossible for the reader to assess the veracity of that number. The MCWD-162

document cited to support this number ("CalAm 2016") provides little help.[24] The document is a one page table that provides very little by way of explanation for how the energy demand was calculated. In fact, the amount of energy consumption for the MPWSP Desalination Plant appears to be based entirely on an email from CDM Smith, the contents of which are not described in the EIR itself[25] (CalAm 2016). This table also provides zero information regarding the project's energy peak demands, costs, fluctuations in energy use due to intake salinity and water temperature, power supply availability in the Monterey region during peak periods, or electric line upgrade requirements. Please explain how these numbers changed so dramatically from prior estimates.

MCWD-162 cont.

Furthermore, the analysis of energy consumption during project operations (Impact 4.18-2) is conclusory and unsupported by substantial evidence. After disclosing the energy consumption during operations would be astronomical (63,164 MWh of electricity and 26,000 gallons of fuel annually), the DEIR/EIS provides very little discussion regarding how energy use could be reduced. There is no discussion as to the effectiveness of the energy efficient design elements, which are proposed to be incorporated into the project. Nor is there any discussion of accessing available sustainable electricity sources. Instead, the discussion purports to justify the enormous energy consumption on the basis that the project will help CalAm provide water to its customers.

That is not the purpose of energy analysis (or an EIR for that matter). If the CPUC determines that the project's benefits outweigh its significant impacts, and that determination is supported by substantial evidence, it can make such findings in a statement of overriding considerations if and when it approves the project. (See CEQA Guidelines, § 15093.) But that does not excuse the CPUC from proposing mitigation that could reduce significant energy impacts.

MCWD-163

Notably, the DEIR/EIS itself mentions at least one feasible way to mitigate this impact—implementation of the Landfill-Gas-to-Energy Option, which would provide an alternative source of power for the project. But the DEIR/EIS does not consider this mitigation measure or any others. The Section 4.11, Greenhouse Gas Emissions, of the DEIR/EIS even acknowledges, although without much elaboration, that "there may be

[24] / In any event, the data relied on to support this determination must be presented and explained in the draft EIR itself, and not buried in an incompressible report that is merely cited by the DEIR/EIS. (*Vineyard Area Citizens for Responsible Growth, Inc. v. City of Rancho Cordova* (2007) 40 Cal.4th 412, 422 (*"Vineyard"*) ["The data in an EIR must not only be sufficient in quantity, it must be presented in a manner calculated to adequately inform the public and decision makers, who may not be previously familiar with the details of the project. Information 'scattered here and there in EIR appendices or a report 'buried in an appendix,' is not a substitute for 'a good faith reasoned analysis.' [Citations.]"].)

[25] / It is impossible to verify the numerical figures set forth in the DEIR/EIS for the MWSP Desalination Plant, itself.

additional feasible energy reducing features available to reduce the electrical consumption associated with the project." (DEIR/EIS, p. 4.11-22.)

MCWD-163 cont.

v. ***The DEIR/EIS improperly defers mitigation for Impact 4.18-1.***

Mitigation Measure 4.18-1 is improper and cannot support a less-than-significant impact determination. This measure constitutes improper deferral of mitigation because it merely requires CalAm to prepare a plan that will identify mitigation measures *after* project approval. (DEIR/EIS, p. 4.18-15.) A fundamental requirement of CEQA is that the formulation of mitigation cannot be deferred until after project approval except in limited circumstances, as set forth above. Mitigation Measure 4.18-1 provides no performance criteria; there is no explanation (or reason) why mitigation cannot be developed now; and there is no assurance the mitigation will be both feasible and efficacious. In fact, the measure only requires the yet-to-be determined mitigation measures "where feasible" or "to the maximum extent feasible." (DEIR/EIS, p. 4.18-15.) Thus, in addition to being improperly deferred, the measure has absolutely no teeth. There is no support for the conclusion that the mitigation measures would reduce the impact to a less-than-significant level.

MCWD-164

Mitigation Measure 4.18-1 also falls far short of federal standards, which are set forth in the above, in that there is an utter lack of discussion or quantification of the estimated effectiveness of energy efficiency measures with respect to construction impacts. The DEIR/EIS instead merely provides the conclusory statement that with mitigation (the substance of which is to be determined at a later date), the significant energy impact would somehow be reduced to a less-than-significant level. This cursory and unsupported discussion does not satisfy NEPA requirements. (See *Northwest Indian Cemetery, supra*, 795 F.2d, at p. 697; *Cuddy Mountain, supra,* 137 F.3d at pp. 1380-1381.)

Moreover, there are numerous additional mitigation measures that would reduce this impact that are both feasible and widely accepted, but are not considered in the DEIR/EIS. For example, the CPUC could require that CalAm use only the most efficient off-road equipment and vehicles to reduce the amount of fuel consumed by project activities or include other mechanisms to ensure greater fuel efficiency for equipment and vehicles. Further, as explained in CEQA Guidelines, Appendix F, "the discussion should explain why certain measures were incorporated into the project and why other measures were dismissed." (§ II, subd. D.1.) The DEIR/EIS fails to do this.

w. ***The DEIR/EIS fails to adequately address transportation energy impacts.***

Appendix F states that the environmental impacts subject to the EIR process include "[t]he project's projected transportation energy use requirements and its overall use of efficient transportation alternatives. (§ II, subd. C.6.) Here the project would result in an additional 60 commuter vehicle trips per day. (DEIR/EIS, p. 4.18-16.) Yet, the DEIR/EIS concludes that the energy impacts from operation of the project would be less than significant—and therefore fails to consider mitigation for transportation energy impacts. (See *California Clean Energy Committee, supra,* 225 Cal.App.4th at p. 210 [EIR analysis

MCWD-165

deficient where it did not assess or consider mitigation for transportation energy impacts of the project].) The CPUC should consider mitigation measures that would reduce the amount of fuel consumption from vehicle trips such as a ride-share or electric vehicle program or offer alternative modes of transportation if the amount of trips required cannot be reduced by other means. (See CEQA Guidelines, Appendix F, § C.6 [discussion must include the project's "overall use of efficient transportation alternatives"].)

MCWD-165 cont.

x. ***The DEIR/EIS conclusion as to Impact 4.18-3 is unsupported by substantial evidence.***

The conclusion under Impact 4.18-3 that the project would not constrain local or regional energy supplies, require additional capacity, or affect peak and base periods of electrical demand during operations is conclusory and not supported by substantial evidence. There is no discussion of peak or base period electrical demand or any other facts or evidence in the DEIR/EIS to support the conclusion that impacts would be less than significant.

For example, just based upon the statement that the proposed project would result in a net increase of electrical demand of 51,698 MWh per year, would mean that if you assume that the project is in constant 24/7 electrical use, the new electric generating capacity required to supply that new energy demand would be 5.90 Mwh per hour or 141.6 Mwh per day. The actual peak energy demands could be higher and coincide with the existing peak energy demands for this area, which would result in even greater environmental impacts.

MCWD-166

Given that Moss Landing is PG&E's transmission hub for this area, it would not be unreasonable to assume that this additional energy use would be supplied at times during peak periods from the Moss Landing Power Plant, resulting in increases in power plant cooling water demands from Monterey Bay and increased amounts of air pollutants generated by burning GHG-intensive fuel in this very region.

The DEIR/EIS lacks area-specific analysis of whether the PG&E sub-transmission electric lines from Moss Landing to the proposed project site are sufficient to meet this new electricity demand or whether those lines will need to be upgraded resulting in additional indirect project impacts.

In fact, the conclusion appears to be based entirely on a personal communication with PG&E via email, the contents of which are not described in the EIR itself. This total lack of a specific discussion as to the new significant electric generation and sub-transmission requirements and their impacts on the environment in a DEIR/EIS by the CPUC—which directly regulates PG&E—is highly unusual and emphasizes the sweeping inadequacy of the DEIR/EIS's discussion on energy impacts. The facts and evidence that support the conclusions must be included in the DEIR/EIS itself so the public and decisionmakers can readily evaluate the information and determine whether the conclusions are accurate. (See e.g., *Vineyard, supra,* 40 Cal.4th at p. 422.)

y. ***The DEIR/EIS's discussion of cumulative impacts related to energy conservation is inadequate.***

An EIR must discuss cumulative impacts when they are significant and the project's incremental contribution is "cumulatively considerable." (CEQA Guidelines, § 15130, subd. (a). A project's incremental contribution is cumulatively considerable if "the incremental effects of an individual project are significant when viewed in connection with the effects of past projects, the effects of other current projects, and the effects of probable future projects." (CEQA Guidelines, § 15065, subd. (a)(3).) The DEIR/EIS plainly fails to comply with CEQA with respect to the cumulative energy impacts of the project.

The DEIR/EIS incorrectly relies on Mitigation Measure 4.18-1 to conclude that project construction would not have a cumulatively considerable contribution to a significant cumulative impact on the availability of fuel sources. As set forth above, Mitigation Measure 4.18-1 improperly defers mitigation and cannot serve as the basis of support for such a conclusion. MCWD-167

Additionally, statements regarding the cumulative impacts of project operation on energy conservation are conclusory and unsupported by substantial evidence. The DEIR/EIS acknowledges that many of the other cumulative projects would be high demand users and that upgrades to the existing distribution system may be required. (DEIR/EIS, pp. 4.18-18 through 4.18-19.) Yet, without any further explanation, the DEIR/EIS simply concludes that the project would not have a cumulatively considerable contribution associated with energy use. (See CEQA Guidelines, § 15130, subd. (a)(2) [If a lead agency concludes that a cumulative impact is not significant, the EIR must provide a brief explanation of the basis of the finding and identify the facts and analysis supporting it]; *Klamath-Siskiyou Wildlands Center v. U.S. Bureau of Land Management* (9th Cir. 2004) 387 F.3d 989, 993 ["proper consideration of the cumulative impacts of a project requires some quantified or detailed information; … [g]eneral statements about the possible effects and some risk do not constitute the hard look absent a justification regarding why more definitive information could not be provided" (internal quotations omitted)].) The cumulative impacts discussion related to energy conservation falls short of both CEQA and NEPA standards.

D. THE DEIR/EIS FAILS TO INCLUDE A REASONABLE RANGE OF POTENTIALLY FEASIBLE ALTERNATIVES AND THE ALTERNATIVES ANALYSIS IS NOT SUPPORTED BY SUBSTANTIAL EVIDENCE.

As the DEIR/EIS acknowledges CEQA requires an EIR to "describe a range of reasonable alternatives to the project … which would feasibly attain most of the basic objectives of the project but would avoid or substantially lessen any of the significant effects … and evaluate the comparative merits of the alternatives." (Guidelines, §§ 15126.6, subd. (a), 15002, subd. (a)(3); see also 42 U.S.C. 4332(C)(iii) [NEPA requiring same].) The DEIR/EIS, however, fails to meet this fundamental requirement. MCWD-168

The fundamental problem with the DEIR/EIS's alternatives analysis is that it only considers alternatives to CalAm's originally proposed 9.6 MGD desalination plant that is no longer necessary in light the approval of the GWR project. Confusingly, the DEIR/EIS states that "the GWR Project would not be relevant in the context of the proposed project *or any alternative that includes a 9.6 mgd desalination plant* built and operated by CalAm (i.e., Alternatives 1 and 2) because, if the GWR project is implemented, CalAm would not need to construct a 9.6 mgd desalination plant (the proposed project); instead, it would construct the 6.4 mgd plant as described in Alternatives 5a and 5b." (DEIR/EIS, pp. 5.2-6 and 5.2-7.) Inexplicably, the DEIR/EIS, however, ignores the reality that GWR Project has been approved and evaluates the comparatives merits of alternatives to the originally proposed 9.6 MGD desalination plant.[26] In doing so the DEIR/EIS sets up a strawman analysis and concludes the 6.4 MGD plant with GWR is the environmentally superior alternative. The DEIR/EIS, however, fails to consider alternatives to the 6.4 MGD plant (with GWR) that would feasibly attain most of the basic objectives of the project but would avoid or substantially lessen any of the significant impacts.[27] As discussed below, the DEIR/EIS only considers alternatives that would meet all (rather than most) of the Primary Project Objectives and with either a 6.4 MGD or 9.6 MGD plant provide vastly more water supplies than are necessary. It does not consider alternatives that could feasibly attain most of the Primary Project Objectives (with the GWR Project and without either the 6.4 MGD or 9.6 MGD plant), but would avoid or substantially lessen any of the significant effects. As a result, not only does the DEIR/EIS fail to consider a reasonable range of alternatives, it also fails to meet the EIR's major function "to ensure that ***all reasonable alternatives to proposed projects are thoroughly assessed by the responsible official***." (*Laurel Heights Improvement Assn. v. Regents of University of California* (1988) 47 Cal.3d 376, 400 [emphasis added].**)**

MCWD-168 cont.

10. Comments on Alternatives Not Evaluated in Detail

An "EIR 'is required to make an in-depth discussion of those alternatives identified as at least *potentially feasible*.' [Citation.]" (*Preservation Action Council v. City of San Jose* (2006) 141 Cal.App.4th 1336, 1354, italics added.) "While the lead agency may ultimately determine that the potentially feasible alternatives are not actually feasible due to other considerations, the actual infeasibility of a potential alternative does not preclude the

MCWD-170

[26] / In fact, the originally proposed 9.6 MGD desalination plant is no longer feasible given CalAm commitment to the GWR project under the July 30, 2013 Settlement Agreement on Plant Size, etc., wherein it agreed to pursue the 6.4 MGD plant with implementation of GWR. (Sett. Agr., p. 4 at § 3(c).) The CPUC approved CalAm's entry into an agreement to purchase GWR water from MRWPCA in D.16-09-021.

[27] / The DEIR/EIS's identification of the project's significant environmental impacts in the Alternatives chapter (Section 5.1.1.2) must be revised to the extent additional significant and unavoidable impacts are identified in the revised DEIR/EIS. As explained in the comments above and the expert comments attached to this letter, the proposed project will result in significant and unavoidable impacts to the SVGB among others.

MCWD-169

inclusion of that alternative among the reasonable range of alternatives." (*Watsonville Pilots Assn. v. City of Watsonville* (2010) 183 Cal.App.4th 1059, 1087.)

The DEIR/EIS states that the alternatives listed in Section 5.2 and Appendix I1 were either "considered and rejected in earlier environmental review documents because the projects were determined to be politically, legally, economically, or technically infeasible" or "are concepts that were speculative or technically or economically infeasible." (DEIR/EIS, p. 5.2-7.) When an agency uses the scoping process to narrow the range of potential alternatives to be analyzed in detail in an EIR, the EIR must describe the facts and rationale by which rejected alternatives were deemed infeasible. (*Laurel Heights Improvement Association v. Regents of the University of California* (1988) 47 Cal.3d 376, 404–405 ["An EIR's discussion of alternatives must contain analysis sufficient to allow informed decision making"; CEQA Guidelines, § 15126.6, subd. (c).) Here, the DEIR/EIS erroneously excludes several *potentially* feasible alternatives that could feasibly attain most of the basic objectives of the project and would avoid or substantially lessen the proposed project's significant impacts without any factual basis. In fact, as discussed below, the rationale for excluding several alternatives is demonstrably false. Therefore, the DEIR/EIS must be revised and recirculated so the public, responsible public agencies, and decisionmakers can consider and comment on these potentially feasible alternatives.

MCWD-170 cont.

z. ***Comments on Alternatives Rejected and Not Mentioned in DEIR/EIS***

ix. The use of Horizontal Wells for MPWSP intakes is potentially feasible and would eliminate or reduce several of the project's significant and unavoidable environmental impacts.

The DEIR/EIS dismisses the feasibility of horizontal wells without adequately describing the technology, its advantages over the project's proposed slant wells intakes, or its appropriateness for the Monterey Bay coastal environment. (See Intake Works Comments, p. 7.) Instead, the DEIR/EIS summarily rejects horizontal (or "HDD") wells as a potentially feasible alternative intake technology in Appendix I1, stating: "Horizontal wells are not evaluated further for the following reasons: (1) the amount of pipeline that would be pushed under the sea floor (upwards of 2,500 feet) would be challenging in terms of construction time, physical limitations and the disposal of drilling sludge (and consequently much more expensive than other options); (2) installing artificial filter packs to stabilize unconsolidated formations like those found in the project area has yet to be demonstrated successfully and on a consistent basis, and; (3) HDD would not avoid or minimize any of the impacts associated with the proposed action." (Appendix I1, p I1-5) There is no evidence or citations to evidence that provide support for any of these conclusions. As explained below and in the attached Intake Works Comments, all three conclusions are inaccurate.

MCWD-171

Horizontal wells could be constructed faster than the proposed MPWSP slant wells, have fewer physical limitations, and are potentially less expensive than the proposed slant wells.

Contrary to the DEIR/EIS's conclusion in Appendix I1 that HDD would be challenging in terms of construction time, the construction time for developing Horizontal Wells would likely be considerable shorter than the construction time needed to develop the MPWSP's proposed slant wells. As described in the attached Intake Works Comments, eight horizontal wells were drilled using one HDD drilling rig in approximately four (4) months along the Spanish Mediterranean Coast. Moreover, unlike the proposed slant wells, additional HDD drilling rigs could be used to ensure all required horizontal wells could be drilled within a timeframe that would avoid Snowy Plover breeding season. Additionally, unlike slant wells, HDD wells can curve to avoid unfavorable subsurface conditions. Finally, contrary the DEIR/EIS's suggestion the disposal of drilling sludge would be similar to, or less of an issue, than for the MPWSP's proposed slant wells. (See Intake Works Comments, p. 8.)

Importantly, Horizontal Wells can extend much further than the 2,500-foot mentioned in the Appendix I1 description of Horizontal Wells. (See Intake Works Comments, pp. 11-12.) As a result, the well heads can be located further from the beach than the MPWSP's proposed slant wells to avoid ESHA.

Thus, there is no support for the DEIR/EIS rejecting Horizontal Wells on this basis.

MCWD-171 cont.

Horizontal wells, unlike slant wells, have been employed successfully as a desalinization intake.

The DEIR/EIS states, without any supporting citations, that installing artificial filter packs to stabilize unconsolidated formations like those found in the project area has yet to be demonstrated successfully and on a consistent basis. (Appendix I1, p I1-5.) Initially, this rationale provides no basis for rejecting Horizontal Wells here, whether the proposed intake technology has never been demonstrated successfully. As discussed below, the only operation slant well designed to extract ocean water, other the MPWSP test slant well (which has been started and stopped on countless occasions over its short duration), is Dana Point that under recent longer term testing dramatically declined in efficiency. Even if this was a potential basis for rejecting Horizontal Wells, the DEIR/EIS's conclusion is unsupportable. Artificial gravel-pack filters have been installed and are successfully operating around horizontal well screens within the range of depositional environments in and around the Monterey Bay area that would be encountered at potential sites for horizontal wells. Moreover, artificial filter packs have not been required when utilizing the Neodren® technology in horizontal wells. (See Intake Works Comments, pp. 13-14.)

Thus, there is no support for the DEIR/EIS rejecting Horizontal Wells on this basis.

Horizontal wells would avoid or minimize many of the significant impacts associated with the proposed project and would reduce the amount of source water needed for the MPWSP.

The DEIR/EIS's conclusion that HDD would not avoid or minimize any of the impacts associated with the proposed action is untenable, and appears to demonstrate a significant lack of independent judgment on the part of the DEIR/EIS preparers. (See discussion in Part II.A, above). While HDD could potentially be employed at numerous locations along the Monterey Coast, including but not limited to locations within CalAm's service area, it has the potential to avoid many of the projects' significant impacts at both locations identified in the DEIR/EIS.

For example, if horizontal wells were properly designed at or near the CEMEX site, they would likely avoid or reduce many of the proposed project's significant impacts:

1. Because Horizontal Wells can extend thousands of feet more than the proposed slant wells, they could be located further onshore and outside of ESHA, which would avoid the proposed project's impacts to endangered species as wells as the project's inconsistencies with the City of Marina's LCP and Coastal Act. (See Intake Works Comments, pp. 11-12, 14.)
2. Because Horizontal Wells can extend thousands of feet more than the proposed slant wells and at a curve, they can actually be screened underneath the ocean floor to avoid drawing in groundwater from the SVGB basin, which would avoid the project's impacts to groundwater levels and quality. This in turn would avoid potential significant impacts groundwater dependent ecosystems that the DEIR/EIS fails to evaluate. (See Intake Works Comments, pp. 14.)
3. Because Horizontal Wells could avoid drawing in groundwater from the SVGB there would be no need to return water to the SVGB, which would reduce all the impacts associated with return water pipeline. (See Intake Works Comments, p. 14.)
4. Because Horizontal Wells could avoid the need for any return water to the SVGB, they would reduce the amount of supply water and desalinated water needed for the MPWSP, which would reduce energy impacts and GHG emissions. (See Intake Works Comments, p. 14.)

MCWD-171 cont.

Similarly, if horizontal wells were properly designed at or near the Potrero Road site they would likely avoid or reduce many of the potentially significant impacts identified at this location:

- Because Horizontal Wells can extend thousands of feet more than the proposed slant wells, they can actually be screened underneath the ocean floor to avoid drawing in groundwater from the SVGB basin, which would avoid drawdown impacts to groundwater basin water levels and therefore would

eliminate any potential impacts to Elkhorn Slough (which the DEIR/EIS speculates may be significant). (See Intake Works Comments, p. 14.)

- Similar to the CEMEX site, Horizontal Wells would not take in groundwater from SVGB there would be no return water obligation, which would reduce all impacts associated with return water pipeline. (See Intake Works Comments, p. 14.)
- Similar to the CEMEX site, Horizontal Wells could avoid the need for any return water to the SVGB, they would reduce the amount of supply water and desalinated water needed for the MPWSP, which would reduce energy impacts and GHG emissions. (See Intake Works Comments, p. 14.)

Moreover, additional locations closer to or in CalAm's service area may be feasible, which in turn could substantially reduce the length of the pipelines proposed for the project and impacts associated with those pipelines. (See Intake Works Comments, p. 14.)

Finally, the DEIR/EIS's suggestion that Horizontal Wells may be more expensive is impossible to evaluate given the information provided in the DEIR/EIS. While drilling the Horizontal Wells could be more expensive than the proposed slant wells, such a comparison does not address the potential cost savings from water and pipeline savings. Moreover, potential alternatives cannot be excluded from consideration because it 'would impede to some degree the attainment of the project objectives, or would be more costly.'" (*Preservation Action Council*, *supra*, (2006) 141 Cal.App.4th at p. 1354; CEQA Guidelines, § 15126.6, subd. (b); *Habitat and Watershed Caretakers*, *supra*, 213 Cal.App.4th at pp. 1303-1304; *Goleta I*, supra, 197 Cal.App.3d at pp. 1180–1183.) Similarly, the fact that CalAm has constructed a slant test well at the CEMEX site does not make slant wells more viable than Horizontal Wells. This is especially true given the Coastal Commission's failed to consider alternative technologies prior to approving the test slant well.[28] As discussed below, if CalAm desires to test a Horizontal Well before considering this alternative, CalAm has sufficient water supplies with GWR to evaluate this technology prior to seeking approval of the MPWSP.

MCWD-171 cont.

In summary, Horizontal Wells are, at minimum, potentially feasible and would avoid or substantially lessen many of the proposed project's significant environmental impacts. Therefore, the DEIR/EIS's alternatives analysis must be revised and recirculated to evaluate Horizontal Wells to comply with CEQA and NEPA. This analysis should consider the number of Horizontal Wells necessary to meet most of the project objectives (including the reduction in supply needed for the proposed slant wells return water) rather than the amount

[28] / CalAm and the Coastal Commission have argued the test well is not part of the MPWSP and will not prejudice the environmental review or consideration of alternatives for the larger MPWSP. (Attached as Exhibit "5" are the Parties' briefs on the merits in MCWD v. California Coastal Commission, Santa Cruz Superior Court Case No. CV180839.)

of feedwater required for the proposed 9.6 MGD desalination plant that provides an oversupply of water. MCWD-171 cont.

x. Vertical wells

The DEIR/EIS's rejection of vertical wells for the alleged reason that the number of "vertical wells that would be needed to provide a reliable source water flow to the desalination plant is considered infeasible, both from a construction and operational perspective and in terms of economic, legal (permitting) and environmental factors" is again not supported by any facts. (DEIR/EIS Appendix I1, p. I1-4 and I1-5.) As noted above, a potential alternative cannot be excluded from consideration because it 'would impede to some degree the attainment of the project objectives, or would be more costly.'" (*Preservation Action Council*, *supra*, (2006) 141 Cal.App.4th at p. 1354; CEQA Guidelines, § 15126.6, subd. (b); *Habitat and Watershed Caretakers*, *supra*, 213 Cal.App.4th at pp. 1303-1304; *Goleta I*, supra, 197 Cal.App.3d at pp. 1180–1183.) Moreover, given the CPUC approved vertical wells as part of the Regional Project, the argument that this alternative source is not potentially feasible actually conflicts with the record. As noted above, there is no reason why the legal permitting factors would be more onerous than for the slant wells proposed by the MPWSP. In fact, the fact vertical wells can be construct outside ESHA and other environmentally sensitive habitat likely makes permitting vertical wells more feasible. The DEIR/EIS suggestion that undisclosed environmental factors make vertical wells infeasible without any analysis cannot be supported under CEQA. MCWD-172

Finally, the DEIR/EIS only considers vertical wells without GWR and, therefore, improperly estimates that at least 24 vertical wells would be required. As discussed above, the DEIR/EIS must address whether the use of vertical wells (with GWR) could meet most of the project objectives, rather than the amount of feedwater required for the proposed 9.6 MGD desalination plant that provides an oversupply of water. As noted in the attached Intake Works Comments, using vertical wells with pre-engineered, so called "packaged" desalination systems, could result in avoiding or substantially lessening the proposed project's significant impacts and may be more economical because package solutions are available for desalination plants that are up to 5 MGD. (See Intake Works Comments, pp. 4-5.)

xi. Infiltration Galleries

The DEIR/EIS's rejection of infiltration galleries without analysis is similarly not supported by substantial evidence and would appear to conflict with available data on the feasibility of this option provided in the CCC's "Final Report: Technical Feasibility of Subsurface Intake Designs for the Proposed Poseidon Water Desalination Facility at Huntington Beach, dated October 9, 2014, available at http://www.coastal.ca.gov/pdf/ISTAP_Final_Phase1_Report_10-9-14.pdf. That report concluded that infiltration galleries were the only potentially feasible options for subsurface intakes for the proposed Poseidon Water Desalination Facility, which proposes producing 50 MCWD-173

Million Gallons per Day (MGD) of potable water, five times as much as the current project. The CCC's Report notes that:

> ***A key aspect of a beach gallery system is that it underlies the surf zone of the beach, fully or in part. This means that the active infiltration face of the filter is continuously cleaned by the mechanical energy of the breaking waves and is therefore self-cleaning*** (Maliva and Missimer, 2010). ***Also, the location within the intertidal zone allows the gallery to be continuously recharged with no impact on the inland shallow aquifer system. The vertical flow of water from the sea assures that the inorganic chemistry is not significantly altered over time***… The gallery system is unaffected by variations in the deeper groundwater, which could be fresh or brackish in nature at the shoreline. The uppermost natural sand layer is the primary treatment zone within the filter and will likely allow the removal of all algae and a high percentage of bacteria and naturally occurring organic compounds (e.g., natural organic matter). The long-term data collected at the seabed gallery in Japan shows that the SDI was reduced below two, which is at the approximate level produced by conventional SWRO pretreatment systems (Shimokawa, 2012).
>
> ***The beach gallery would reduce or eliminate the impingement and entrainment of marine fauna. Also, upon completion of construction, the gallery would be located below the surface and could not be observed by beach users***

MCWD-173 cont.

(Id. at p. 40, emphasis added.)

The DEIR/EIS's determination that infiltration galleries result in permanent disturbance to habitat does not appear to be consistent with the CCC's report. (*Ibid.*; see also *id.*, Figure 3.6 on p. 41.) Unlike the Fukuora location (on the semi-protected coast of the Sea of Genkai), it may be possible to limit the amount of excavation and lay out sections of filter pipe on the sandy seabed and allow natural forces to bury the system at the CEMEX site. The sandy bottom biological community is adapted to moving sands, which could reduce potential significant impacts. In addition, contrary to the DEIR/EIS's suggestion the sediment or filtration bed is unlikely to need much maintenance work given the turbulent forces near the seafloor would keep the upper most layer of the filter bed active. See Intake Works Comments, pp. 5-6.)

Notably, as with Horizontal Wells, infiltration galleries would eliminate impacts to the SVGB, which would eliminate the need for return water and the proposed return pipeline thereby avoiding those impacts as discussed above. As infiltration galleries are at least potentially feasible and would eliminate the project's significant impacts to the SVGB, including the Marina Subarea, the alternative must

actually be discussed in the DEIR/EIS before the CPUC can determine it is not feasible due to environmental impacts. Again, the size of the infiltration gallery should be based on need to meet most of the project objectives (including the reduction in supply needed for the proposed slant wells return water) rather than the amount of feedwater required for the proposed 9.6 MGD desalination plant that is provides an oversupply of water

MCWD-173 cont.

xii. EIR/EIS Fails to acknowledge, disclose, analyze the uncertainty regarding the long-term operational efficiencies of slant wells

Finally, the DEIR/EIS's discussion of slant wells ignore the fact that slant wells are unproven technology. As addressed in the CCC's "Final Report: Technical Feasibility of Subsurface Intake Designs for the Proposed Poseidon Water Desalination Facility at Huntington Beach, California:

> Only one slant well has been successfully constructed to date, although a major installation to provide 20 MGD of feedwater capacity is under consideration in the Monterey Bay area [this project]. The successfully completed well is at Dana Point. When it was built and tested in 2006, it was test pumped at 2000 gpm and displayed a well efficiency of 95%. ***Recent longer term testing of the completed test well in 2012 documents the reduction in well efficiency from the original value of 95% in 2006 to 52% in 2012*** (GeoScience 2012). ***Given this observed reduction in efficiency over a short period, the long-term performance of the technology has yet to be confirmed.***
> … Slant wells completed in the Talbert aquifer would draw large volumes of water from the Orange County Groundwater Basin, which in itself is considered a fatal flaw. Recent public comments have suggested that pumping seawards of the Talbert Salinity Barrier could have beneficial impacts in managing seawater intrusion. In the Panel's opinion, however, this benefit is too uncertain to overcome the ISTAP conclusion about the fatal flaw of this technology as applied to the proposed Huntington Beach site. ***The advantage of having a subsea completion is largely lost in confined aquifers.*** The performance risk is considered medium, as the dual-rotary drilling method used to construct the wells is a long-established technology, but ***there is very little data on the long-term reliability of the wells. Maintainability is also a critical unknown issue.***
> … Slant wells tapping the Talbert aquifer would interfere with the management of the salinity barrier and the management of the freshwater basin, and further, would likely have geochemical issues with the water produced from the aquifer (e.g., oxidation states of mixing waters).

MCWD-174

(CCC's "Final Report: Technical Feasibility of Subsurface Intake Designs for the Proposed Poseidon Water Desalination Facility at Huntington Beach, dated October 9, 2014, pp. 37, 56, 64, available at http://www.coastal.ca.gov/pdf/ISTAP_Final_Phase1_Report_10-9-14.pdf, emphasis added.)

In addition, the DEIR/EIS's failure to disclose and discuss the reduced efficiency of the Dana Point slant well is surprising given CPUC's representative on the HWG authored the report on this decline. (See GeoScience's Aquifer Pumping Test Analysis and Evaluation of Specific Capacity and Well Efficiency Relationships SL-1 Test Slant Well, Doheny Beach, Dana Point, California, dated September 7, 2012, available at http://www.mwdoc.com/filesgallery/SL_1_Step_Test_Comp._FINAL_TM_Geoscience_12_09_2012.pdf.) Notably, information from data responses and public records act requests reveal that Mr. Williams and Geoscience were involved in the selection process for alternatives despite the potential conflict of interests identified above. The DEIR/EIS's failure to disclose and address the findings in both reports require recirculation so the public can is aware of the project's risks and can comment on them. The risk that the project may not succeed is not born solely by the applicant, or CalAm ratepayers, here.

MCWD-174 cont.

As explained in the Intake Works and HGC Comments, while the efficiency problems from the Dana Point may not manifest themselves at the CEMEX site, there is a considerable risk they could based on the previous study and unproven track record for this technology. Therefore, the DEIR/EIS must discuss mitigation in the event there is a considerable drop in efficiency as it would likely eliminate the MPWSP's ability to provide return water. Specifically, the DEIR/EIS must evaluate the how many slant wells will likely need to be replaced over foreseeable life of the project, where the replacement wells would be located, and the potential impacts of replacing the slant wells. The DEIR/EIS must also evaluate potential alternatives to slant wells if efficiency drops to the point that alternative feed water sources are required.

aa. ***Comments on Alternatives Rejected and Not Evaluated in Detail in DEIR/EIS***

Section 5.2.1 states that is summarizes the previous proposals and projects, and the environmental documentation prepared for them (as relevant), and discusses why each of these alternatives is not addressed in detail in this EIR/EIS. The DEIR/EIS further states that no viable alternatives have been identified that would supply water without a desalination plant being included. This conclusion, however, is improperly based on the assumption that any feasible alternative must meet all of the project's objectives. As discussed in Part I of these comments and below, at minimum the Coastal Water Project/Regional Project remains potentially feasible. The DEIR/EIS, however, must evaluate whether the other alternatives in this section could meet most of the project objectives, including the already approved GWR as a component or on stand-alone basis.

MCWD-175

xiii. i. The Coastal Water Project/Regional Desalination Project Remains Potentially Feasible.

First, the DEIR/EIS' suggestion that Coastal Water Project/Regional Desalination Project (or "Regional Project") approved by the CPUC in 2010 is "no longer feasible for economic, social and legal reasons" is not supported by facts. The DEIR/EIS fails to provide any explanation or facts supporting its assertion that the Regional Project is not feasible. "A

MCWD-176

potential alternative should not be excluded from consideration merely because it 'would impede to some degree the attainment of the project objectives, or would be more costly.'" (*Preservation Action Council v. City of San Jose* (2006) 141 Cal.App.4th 1336, 1354; CEQA Guidelines, § 15126.6, subd. (b); *Habitat and Watershed Caretakers v. City of Santa Cruz* (2013) 213 Cal.App.4th 1277, 1303-1304.) As explained in *Citizens of Goleta Valley v. Board of Supervisors* (1988) 197 Cal.App.3d 1167, 1180–1183 (*Goleta I*) assertions that a particular alternative is economically infeasible simply because it would be more expensive or less profitable to the private applicant are not adequate. "In the absence of comparative data and analysis, no meaningful conclusions regarding the feasibility of the alternative could have been reached." (*Id.* at pp. 1180–1181.) The Court of Appeal added that:

> The fact that an alternative may be more expensive or less profitable is not sufficient to show that the alternative is financially infeasible. What is required is evidence that the additional costs or lost profitability are sufficiently severe as to render it impractical to proceed with the project.

(*Ibid.*) Because the DEIR/EIS fails support its conclusion that the Regional Project is infeasible and rejects it out of hand, additional analysis is required before the CPUC may approve the project. (Pub. Resources Code, § 21002; *Sierra Club v. Gilroy City Council* (1990) 220 Cal.App.3d 30, 31.) Similarly there is no discussion, and MCWD is unaware of any reasons why the Regional Project is infeasible. The fact that CalAm would like to proceed with MPWSP without the involvement of MCWD or another public agency, does not render such alternatives infeasible. (See *Save Round Valley Alliance v. County of Inyo* (2007) 157 Cal.App.4th 1437, 1462 [An agency may not simply accept the project proponent's assertions about an alternative; rather, the agency "must independently participate, review, analyze and discuss the alternatives in good faith"], quoting *Kings Cnty. Farm Bureau v. City of Hanford*, 221 Cal.App.3d 692, 736 (1990).) MCWD is willing to work through any issues relating to Regional Project. The fact that CalAm would prefer to go it alone does not make the Regional Project infeasible.

MCWD-176 cont.

Notably, the Regional Project configuration approved in 2010 with Marina Coast's participation is likely more feasible than the currently proposed project for the reasons explained in Part I above, including:

- The Regional Project addresses CalAm's lack of water rights that likely make the MPWSP infeasible.
- The Regional Project addresses the MPWSP's inability to comply with the Agency Act, which likely makes the MPWSP infeasible.
- The Regional Project's approval of vertical wells addressed high risks associated with slant wells that could make the MPWSP infeasible.

- The Regional Project Well included testing and comprehensive groundwater modeling to ensure groundwater impacts remained less-than significant unlike the MPWSP.
- The Regional Project, unlike the MPWSP, satisfies the Monterey County Desal Ordinance, which requires public ownership of desalination plants constructed within the County.

MCWD-176 cont.

In sum, it is likely the Regional Project remains feasible provided that the project would be within the confines of the SGMA and the greatly-expanded availability of data concerning the state of the basin and pertinent sub-basin, as well as current drought and climate-change related conditions. Again, it is certainly more feasible the project, as proposed.

xiv. The GWR Project Meets Most of the Project Objectives.

The DEIR/EIS states that the "GWR Project is not considered in this DEIR/EIS as a stand-alone alternative to the MPWSP because it would not provide enough water to meet the basic project objectives of the MPWSP; ***it would be about 6,250 afy short***." (DEIR/EIS, p. 5.2-6.) Again, this conclusion is improperly based on the assumption that feasible alternatives must meet all the project objectives as incorrectly construed by the DEIR/EIS. For example, Primary Project Objective #4 states, "Develop a reliable water supply for the CalAm's Monterey District service area, accounting for the peak month demand of existing customers." "Existing customers' demand is reflected in the 2016 actual demand of 9,285 AF, not the 2016 demand plus the future water needed to meet Pebble Beach water entitlements, legal lots of record, and the hospitality industry rebound. As discussed above, in Part III.A.1 of these comments and below, it appears GWR Project, which would include additional sources of water not currently projected to be used for Phases 1 and 2, would meet most of the Primary Project Objectives under Scenario A and Scenario B, if not all of the Primary Project Objectives. The DEIR/EIS, however, fails to disclose this fact.

MCWD-177

Rather, the DEIR/EIS states the GWR Project is included in the No Project/No Action alternative and "would not be relevant in the context of the proposed project or any alternative that includes a 9.6 mgd desalination plant built and operated by CalAm," because CalAm would instead construct the 6.4 MGD plant, which would have production capacity substantially in excess of any demand in 2022 and beyond. (DEIR/EIS, pp. 5.2-6 and 5.2-7.) Why does the DEIR/EIS assume that the GWR Project under the No Project/No Action alternative, but fail to consider it in evaluating the feasibility of alternatives that do not include slant well intakes.

bb. ***Comments on Alternatives Intake Options not carried forward for analysis in the DEIR/EIS***

MCWD-178

DEIR/EIS Section 5.3.3.11 states that Intake Option 11 (Ranney Wells in Seaside/Sand City) was not carried forward in the alternatives analysis stating:

> As described in Appendix I2, Intake Option 11 would involve the installation of three Ranney wells at two sites in the former Fort Ord coastal area in Seaside and Sand City. However, the former ***Fort Ord Wastewater Treatment Plant site and former Stillwell Hall sites faced political challenges*** …

(DEIR/EIS, p. 5.3-17, emphasis added.) The DEIR/EIS rejection of this alternative on the grounds it would could face political challenges is not grounds to reject this alternative under CEQA. Notably, the CEMEX site faces major political challenges also. Unlike the CEMEX site, however, the Seaside/Sand City Intake Option draw water from within CalAm's service area. So the affected municipalities and residents would at least ostensibly receive benefits from the project, unlike the citizens of Marina. In sum, potential political challenges is not grounds for failing to consider this alternative that would likely reduce the project's significant impacts. Therefore, the revised DEIR/EIS must include this alternative.

MCWD-178 cont.

Even more egregious, the DEIR/EIS decision not to include Ranney Wells at the CEMEX site based on speculation that this option would have similar impacts to the MPWSP's proposed slant wells and is not supported. As discussed in the attached Intake Works Comments (see pp. 14-15), the DEIR/EIS's analysis makes several incorrect assumptions about the technology and fails to provide meaningful analysis of this option. Most critically, the DEIR/EIS description of the option proposes to construct the Ranney Wells so they would extract groundwater from the deeper aquifers. If the Ranney Wells were properly designed to tap the shallow marine aquifer, this alternative would likely significantly reduce the project's groundwater impacts (and potentially other impacts). Given the DEIR/EIS concludes that Ranney Wells at the CEMEX site are at least potentially feasible, the DEIR/EIS must be revised to evaluate whether they would potentially reduce the project's significant impacts at the CEMEX site. As explained in the attached Intake Works Comments, available information indicates they could, if properly designed. Given the project's significant groundwater impacts to the Marina Subarea, including the 180-foot aquifer, the DEIR/EIS must evaluate Ranney Wells at the CEMEX site to meet its obligation under CEQA and NEPA.

11. Comments on Analysis of CEQA Alternatives (Section 5.4).

cc. ***Comments on the No Project Alternative***

Initially, the DEIR/EIS discussion of the no project alternatives fails to address what is reasonably expected to occur in the foreseeable future at the CEMEX project site (i.e., any reclamation that would occur, decommissioning of test well, restoration of ESHA, etc.) if the project if is not approved. Instead, the DEIR/EIS only discusses the effect that the No Project Alternative would have on water supplies and impacts associated with those supplies. The DEIR/EIS's summary on water supplies appears to ring a false alarm stating:

MCWD-179

> Impacts related to a No Project Alternative could result in severely supply-constrained conditions in CalAm's Monterey

> District. Existing conservation programs would continue to be implemented and new conservation and rationing measures would be required in an attempt to balance out the severe supply shortfall following Carmel River diversion curtailments under the Revised CDO in 2018 through 2021. Given the limited water supplies, it is assumed this alternative would trigger Stage 3, Conservation Rates, and very possibly Stage 4, Rationing Measures, of the Monterey Peninsula Water Conservation and Rationing Plan.

(DEIR/EIS, p. 5.4-10.) The DEIR/EIS then states the No Project Alternative with the (already approved) GWR Project:

> The GWR Project, when constructed, would provide 3,500 of potable supply for the CalAm service area. ***With the GWR Project supply, total supplies available to CalAm at the end of the Revised CDO extension period would total about 9,880 afy, which is about*** 81 percent of 2010 demand and approximately ***89 percent of estimated demand after implementation of foreseeable demand management and offset programs and other planned projects described in Section 5.4.2.3.*** Although this volume of supply would be much closer to the existing demand, the No Project Alternative in combination with the GWR Project would fail to meet most project objectives. While this scenario would achieve compliance with the Revised CDO and the Seaside Groundwater Basin Adjudication, even in combination with the GWR Project, the No Project Alternative would not provide supply to allow for replenishment of water that CalAm previously pumped from the Seaside Basin in excess of CalAm's adjudicated right; would not provide water supply reliability; and would not provide supply for Pebble Beach water entitlement-holders, for the development of vacant legal lots of record, or supply to meet demand resulting from economic recovery and rebound of the hospitality industry. In addition to failing to provide sufficient supply to meet the average annual demand assumed in MPWSP planning, the No Project Alternative combined with a GWR Project water purchase agreement would not provide sufficient supply flexibility to meet most peak demands

MCWD-179 cont.

(DEIR/EIS, p. 5.4-11, emphasis added.) Despite the fact that even by CalAm's own estimation (without independent modeling verification) that the No Project alternative with the GWR would meet 89 percent of its 2010 demand and exceed its 2016 demand of 9,285

AFY, the DEIR/EIS remarkably did not revise its conclusion that the no project alternative would likely trigger Stage 4, Rationing Measures, of the Monterey Peninsula Water Conservation and Rationing Plan. What is the rationale for not revising the conclusion?

The DEIR/EIS also appears to miscalculate the amount of water that would be available under the No Project Alternative with GWR. As discussed in Part III.A.1 above, if the 3,700 AFY GWR water is added to the 6,380 AFY identified in the No Project Alternative (on p. 5.4-9), the total becomes 10,080 AFY, not 9,880 AFY. Why does the DEIR/EIS use 9,880 AFY as that total amount water available? If this was a mathematical error, and assuming 10,080 AFY provides 795 AFY more than CalAm's 2016 demand of 9,285 AFY, what is the basis for concluding the No Project Alternative with GWR does not meet <u>most</u> of the project objectives? Assuming all the non-water supply objectives (i.e., Primary Objectives 8 and 9, and CalAm's secondary objective can be met by an alternative), what is the minimum amount of water supplies are needed to meet most of the project objectives? This number must be disclosed and its method of calculation for the public and decisionmakers to evaluate the potential feasibility of alternatives, including the No Project Alternative.

MCWD-179 cont.

dd. ***Comments on the Alternative 1 – Slant Wells at Potrero Road***

Regarding Alternative 1, the DEIR/EIS states:

> Alternative 1 would contain the same elements as the proposed project and would produce the same volume of product water. However, because of the hydrogeology of the Potrero Road area, Alternative 1 would draw a greater volume of water from the Salinas Valley Groundwater Basin than the proposed project. In the event the Salinas Valley Return Water obligation is determined to be 12 percent (the highest return value simulated), Alternative 1 would meet the need for replacement supplies and meeting peak month demand, but limited supply would be available for other uses, including accommodating tourism demand under recovered economic conditions. Alternative 1 would not provide sufficient supplies to serve existing vacant legal lots of record and would therefore, not meet the project objective/need for water, some of which was to support limited growth (e.g., Objective 6)..

MCWD-180

(DEIR/EIS, p. 5.4-15.) How does the DEIR/EIS determine that Alternative 1 would not provide sufficient supplies to meet Objective 6? How much water would Alternative 1 produce? How much water does the DEIR/EIS estimate would be needed to meet Salinas Valley Return Water obligations? How was this estimate calculated? What assumptions were used in the calculation?

After determining Alternative 1 would result in a reduced impact conclusion on groundwater quality compared to the proposed project, the DEIR/EIS states:

> Unlike the proposed project, groundwater modeling (see Appendix E2) indicates pumping from the slant wells at Potrero Road would result in a cone of depression in the underlying groundwater aquifers that would draw or divert water from Elkhorn Slough. This drawdown impact is discussed in Section 5.5.4, Groundwater Resources, and presented in Figure 5.5-2. ***The modeling cannot predict the amount of water diverted from Elkhorn Slough although it must be conservatively assumed, based on the predicted areal extent of the drawdown, that operations could potentially adversely affect aquatic habitat in Elkhorn Slough due to reduced surface water flow and volumes.*** This would be an increased level of impact compared to the proposed project and because there is no method to mitigate for impacts on surface water flow and volumes in Elkhorn Slough, ***Alternative 1 would result in an increased impact conclusion on marine species, natural communities or habitat, protected wetlands or waters, and critical habitats compared to the proposed project, significant and unavoidable.***

MCWD-180 cont.

(DEIR/EIS, pp. 5.5-114, emphasis added; see also 5.5-128 [reaching same conclusion as to Alternative 5A].) As explained in the HGC Comments, this conclusion is based on the NMGWM^{2016} model, which is poorly calibrated and does not reliably predict potential drawdown, especially for the Potrero Road site, which the modeling uses untested and not substantiated vertical hydraulic conductivity values that are 2 orders of magnitude less than the CEMEX site. As explained in HGC's comment, the assessment of the impact of surface water losses from Elkhorn Slough due to pumping is general and compared to annual conditions that don't consider low-flow or no-flow conditions resulting from seasonal or climatic dry periods. (HGC Comments, p. 61, 78.) Thus, without improved modeling, it impossible for the DEIR/EIS to assess whether this this impact is significant and therefore, what the environmentally superior alternative is.

While MCWD does not fault the DEIR/EIS for conservatively determining this impact is significant due to the lack reliable modeling information, MCWD notes this this conservative conclusion is inconsistent with the DEIR/EIS's conclusion regarding the potential impacts to the Salinas River and the Tembladero Slough. However, the fact that the DEIR/EIS's modeling cannot predict the amount of water diverted from Elkhorn Slough and conservatively assumes operations could potentially adversely affect aquatic habitat in Elkhorn Slough due to reduced surface water flow and volumes does not excuse the DEIR/EIS from qualitatively evaluating the potential impacts. What are the potential impacts to aquatic habitat in Elkhorn Slough that could result from Alternative 1 and Alternative 5A? Without this information is impossible to determine whether any

potential impacts could be mitigated. Moreover, these potential impacts must compared with the projects potential impacts to groundwater dependent ecosystems (that are not evaluated in the DEIR/EIS) and ESHA so the public and decisionmakers can weigh the environmental consequences of these alternatives with those of the proposed project. MCWD-180 cont.

12. Comments on Environmentally Superior Alternative/Preferred Alternative (Section 5.6.)

The DEIR/EIS discussion of the Environmentally Superior Alternative/Preferred Alternative states:

> While CalAm is seeking approval of the 9.6 mgd project (proposed project), CalAm proposes to move forward with a 6.4 mgd desalination plant (Alternative 5a and 5b) if the GWR project is successfully implemented to help meet the SWRCB's CDO. In case the GWR project faces hurdles that would impair its ability to supply the additional 3.2 mgd of water for CalAm's customers in a timely manner, CalAm also seeks contingency approval for the 9.6 mgd desalination plant.

MCWD-181

(DEIR/EIS, p. 5.6-2) The DEIR/EIS's decision to speculate that approved GWR project may not be fully implemented, without any explanation as why, in order to provide CalAm with an apparent contingency plan (which could allow CalAm abandon the GWR Project like the Regional Project for purely financial reasons) fatally undermines the DEIR/EIS's Alternatives Analysis and the CEQA and NEPA processes. As noted above, using this dual-track approach is inconsistent with CEQA and NEPA and this sets up a strawman alternative that ignores the fact the GWR Project is approved and moving forward.

Based on the DEIR/EIS's decision to compare all the alternatives to the vastly oversized and unnecessary 9.6 MGD project originally proposed by CalAm (prior to the approval of GWR), the DEIR/EIS determines that Alternative 5a paired with the GWR project, is the environmentally superior/environmentally preferred alternative. (DEIR/EIS, p. 5.6-7.) This conclusion, however, is fundamentally flawed because the DEIR/EIS fails to evaluate multiple potentially feasible alternatives that would eliminate or reduce the project significant and unavoidable impacts. As explained above, both Horizontal Wells and Ranney Wells are potentially feasible alternatives that would eliminate or reduce the project's significant and unavoidable impacts. MCWD-182

Setting aside these errors, the DEIR/EIS's conclusion that Alternative 5b (Reduced Desal with Slant Wells at Potrero Road) is environmentally inferior to Alternative 1A appears indefensible. The DEIR/EIS acknowledges that Alternative 5b would have similar but reduced groundwater level impacts at Elkhorn Slough in the Dune Sands aquifer. But concludes that "Although it would avoid impacts on marine and terrestrial biological resources at the proposed CEMEX site, the impacts on Elkhorn Slough biological resources were determined to be of greater magnitude. Therefore, Alternative 5b would not offer overall environmental advantages over the proposed project or Alternative 5a." The MCWD-183

DEIR/EIS provides no explanation for its determination that Alternative 5b's potential impacts on Elkhorn Slough biological resources are of greater magnitude than avoid Alternative 5b's impacts on marine and terrestrial biological resources at the proposed CEMEX site. As noted above, there is explanation in the DEIR/EIS of the Alternative 5b's potential impacts on Elkhorn Slough biological resources. Again, with any explanation, it is impossible for the public or decisionmakers to comment on or evaluate the DEIR/EIS's conclusion.

MCWD-183 cont.

Finally, based on its comments above, MCWD offers the following comments regarding alternatives that must be considered in a revised DEIR/EIS, given the project significant impacts on the Marina Subarea, CalAm lack of water rights, and the Agency Act's prohibition of exports from the SVGB, before the CPCU or Sanctuary can determine the Environmentally Superior Alternative/Preferred Alternative.

- Horizontal Wells at CEMEX site. (See Intake Works Comments, p. 20.)
- Horizontal Wells at the Potrero site and/or other sites closer to CalAm's service area. (See Intake Works Comments, p. 20.)
- Ranney wells at CEMEX and Potrero Road sites. (See Intake Works Comments, p. 20.)
- Ranney wells at sites along Carmel Beach or other suitable locations closer to CalAm's service area. (See Intake Works Comments, p. 16.)
- In addition, the DEIR/EIS must consider alternative locations for a permanent wells on CEMEX site other than the slant well site. The CCC has determined that the existing slant test well is located in "primary habitat" (CCC Findings (analysis limited to temporary impacts to ESHA) – and MPWSP propose to make this location permanent. As this is inconsistent with City of Marina's LCP, the current test well location cannot be permitted by the City of Marina without an amendment to the City's LCP. Moreover, even under the CCC's current findings relating to the test well, a slant well at this location can only be approved if there are not feasible alternative locations on the CEMEX site. (*Ibid.*) Given the DEIR/EIS's suggestion the other proposed slant well locations are not within primary habitat – removal of the test well to one of these locations is required.

MCWD-184

In sum, the DEIR/EIS must be revised and recirculated to consider these alternatives. As explained in *Citizens of Goleta Valley v. Board of Supervisors* (1988) 197 Cal.App.3d 1167, 1180–1183 (*Goleta I*) assertions that a particular alternative is economically infeasible simply because it would be more expensive or less profitable to the private applicant are not adequate. "In the absence of comparative data and analysis, no meaningful conclusions Because the DEIR/EIS fails to provide substantial evidence supporting a finding of infeasibility for any suggested alternatives above and rejects them out of hand, additional analysis is required before the CPUC or Sanctuary can consider approval of the project.

(Pub. Resources Code, § 21002; *Sierra Club v. Gilroy City Council* (1990) 220 Cal.App.3d 30, 31.) MCWD-184 cont.

Given these serious flaws in the DEIR/EIS analysis, the only Alternatives that MCWD can support is a test well for any of the above alternatives. This assumes any approved test well's impacts will adequately mitigated, unlike the CEMEX slant well, to ensure no harm to the SVGB. We further note that the Potrero Road site appears to be a superior site for subsurface seawater intake facilities for the reasons explained in the HGC Comments. Therefore, MCWD requests CPUC move forward with a test well alternative at the Potrero Road site. MCWD-185

E. Other Considerations.

13. Comments on Growth-Inducing Impacts (Section 6.3)

As explained in above in Part III.A.1, the proposed project provides substantially more water than is needed to meet the peak month demand of existing 2016 customers. Contrary to the DEIR/EIS's conclusion CalAm's requested contingency approval for the 9.6 MDG desalination plant would likely induce growth within the coastal areas substantially in manner that would be inconsistent with Sanctuary's Management Plan requirements. Unless the DEIR/EIS is revised to either eliminate the 9.6 MDG desalination plant from consideration, this section of the DEIR/EIS must be revised to evaluate the possibility of both the 6 MDG desalination plant and the GWR Project (potentially without CalAm's participation). Moreover, this Section must be revised based an independently reviewed assessment (preferably a computer model of its existing water supply sources and demands as they vary by water year type and by month and how it will change come 2022) of CalAm's future water supplies and demands. MCWD-186

14. Project Consistency with Monterey Bay National Marine Sanctuary Desalination Guidelines (Section 6.4)

The DEIR/EIS states the project is consistent with Sanctuary Desalination Guideline that "The implementation of subsurface intakes ***s<u>hould not cause saltwater intrusion to aquifers or adversely affect coastal wetlands that may be connected to the same aquifer</u>*** being used by the intake, and the intake proposal must address the likelihood of increased coastal erosion in the future." (Compare Monterey Bay National Marine Sanctuary Desalination Guidelines, p. 6 to DEIR, p. 6-48.) As discussed, above the DEIR/EIS modeling cannot and does not evaluate the project's potential to cause saltwater intrusion to aquifers or adversely affect coastal wetlands that may be connected to the same aquifer. Moreover, as explained in the attached HGC and EKI Comments, the project by design will cause seawater intrusion to Marina Subarea aquifers and adversely affect coastal wetlands that may be connected to the Marina Subarea. Therefore, this DEIR/EIS must be revised to disclose the project is not consistent with the Guideline. This Section should also be revised to consider the issue surrounding public versus private ownership based on the Sanctuary's MCWD-187 MCWD-188

Management Plan. It should also address the project's consistency with the NOAA Guideline: "Desalination plant proponents should pursue collaborations with other water suppliers and agencies currently considering water supply options in the area to evaluate the potential for an integrated regional water supply project." (Monterey Bay National Marine Sanctuary Desalination Guidelines, p. 4.) Given these policies, MCWD fails to understand why the DEIR/EIS is only considering CalAm's go-it-alone approach or open water intakes. MCWD-188 cont.

***

MCWD requests that The Figure 5.1 from appendix E2 be revised to show the areas impacted on a topographical map or other map were locations or landmarks are visible. The current figure does not allow the public to understand the extent of potential impacts. MCWD-189

F. Recirculation of the Revised DEIR/EIS with Project or Programmatic Analysis of MPWSP Source Water Is Required.

State CEQA Guidelines Section 15088.5 provides for recirculation of an EIR prior to certification when significant new information is added to the EIR after public notice is given of the availability of the draft EIR for public review but before certification. The term "information" can include changes in the project or environmental setting as well as additional data or other information. New information added to an EIR is not "significant" unless the EIR is changed in a way that deprives the public of a meaningful opportunity to comment upon a substantial adverse environmental effect of the project or a feasible way to mitigate or avoid such an effect (including a feasible project alternative) that the project's proponents have declined to implement.

The number one concern of MCWD and many other interested parties has been whether and to what extent the MPWSP will impact existing groundwater resources in the SVGB and Marina Subarea. As explained above, the DEIR/EIS groundwater analysis is fundamental flawed and fails to disclose adequate information regarding the Marina Subarea aquifer that will be impacted by the proposed MPWSP slant wells. This violates CEQA fundamental principles. *Cadiz Land Co., Inc., supra*, is on point. In that case the petitioner's comments on a draft EIR and a supplement to the draft EIR, including the consultant's report, proved that the EIR could have included an estimate of the groundwater volume in the aquifer. According to the court, upon receipt of these comments, "the County should have revised the EIR to include such information, along with a discussion of the estimated date of depletion of the aquifer water." (83 Cal.App.4th at p. 95.) Acknowledging that the county's decisionmakers considered this information before approving the project, the court nevertheless held that the consultant's report constituted "significant new information" within the meaning of Public Resources Code section 21092.1, and that "the EIR should have been revised and recirculated for purposes of informing the public and governmental agencies of the volume of groundwater at risk and to allow the public and governmental agencies to respond to such information." (*Ibid*.) As in *Cadiz*, recirculation is required here. MCWD-190

IV. CONCLUSION.

MCWD requests the DEIR/EIS be revised as detailed in the comments above. Due to the significant nature of the revisions that will be required, MCWD believes that the DEIR/EIS is plainly deficient. After the Commission and Sanctuary make the recommended revisions, the DEIR/EIS must be re-circulated for further comment.

In addition, due to the seeming infeasibility of the proposed project based on both legal and physical considerations related to likely significant adverse impacts on the groundwater environment, MCWD recommends that the Commission and CalAm consider the full range of feasible alternative configurations and feasible alternatives (including the no project alternative) that are not presently or sufficiently addressed in the DEIR/EIS.

MCWD-191

CalAm and other project proponents have been using the "Cliff" argument to scare people into supporting the MPWSP. The argument is that if Cal-Am does not get a 9.6 MGD desalination plant built by 2021, then come January 1, 2022, when the final diversion reduction under the Carmel River Cease and Desist Order kicks in, there will be severe rationing. The DEIR/EIS's no project alternative analysis improperly adopts this scare technique. As MCWD has explained to the State Water Resources Control Board and explained above—there is no cliff. As MCWD has shown, Scenario A meets seven of nine Primary Project Objectives without the need to construct the MPWSP. Consequently, there is additional time to properly evaluate feasible alternatives, including intake technologies and locations, which would result in significantly less impacts to the environment and groundwater and lower capital costs by properly sizing the project. In fact, given the proposed project's risks and significant impacts, this evaluation is required for all the reasons explained above.

Sincerely,

Keith Van Der Maaten

Attention: Mr. Keith Van Der Maaten
General Manager

Subject: CalAm Monterey Peninsula Water Supply Project, Draft Environmental Impact Report/Environmental Impact Statement, Prepared for California Public Utilities Commission and Monterey Bay National Marine Sanctuary, January 2017.

Dear Mr. Keith Van Der Maaten:

As requested, Hopkins Groundwater Consultants, Inc. (HGC) has reviewed the hydrogeology-related and alternatives portions of the Cal-Am Monterey Peninsula Water Supply Project (MPWSP or the "project") Draft Environmental Impact Report/ Environmental Impact Statement (DEIR/EIS) prepared for the California Public Utilities Commission, dated January 2017, and is providing these comments for Marina Coast Water District's (MCWD) consideration and use. In preparing these comments, we have reviewed the relevant portions of: (1) the DEIR/EIS; (2) the DEIR/EIS appendices; (3) references cited in the DEIR/EIS and DEIR/EIS appendices; (4) the calibrated model developed for the MPWSP and the application of the superposition model scenario constructed to evaluate the project; (5) the documents provided to HGC in response to MCWD's data and public records act requests that were made available before March 27, 2017; and (6) publicly available information referenced at the end of our comments.[1]

Preliminary Statement on DEIR/EIS's Analysis of MPWSP's Hydrogeological Analysis.

The DEIR/EIS frames the MPWSP and the project area hydrogeology in a manner that would lead anyone to believe the MPWSP can cause no harm and will ultimately be of benefit to the entire Salinas Valley Groundwater Basin (SVGB) as well as all groundwater users in the project area. In painting this picture, however, the DEIR/EIS mischaracterizes the project and the complex hydrogeological conditions in the project area by incorrectly suggesting, without any supporting evidence in many cases, that:

[1] / As you are aware, our review of the DEIR/EIS was hampered by the extensive delays in receiving requested information relied on in the DEIR/EIS's groundwater analysis and modeling. In addition, we still have not received some of the information we requested through MCWD's data and public records act requests that would further inform our comments and analysis.

1. The intake system will induce seawater flow vertically through the ocean floor by using facilities that extend beyond the coastline at sufficiently shallow depths to virtually eliminate the production of groundwater from the overdrafted SVGB, and in particular the Marina Subarea[2]. As explained in Comment Nos. 2, 6, 9, 11, 14, 22, and 23 below, this assertion is not accurate.

2. The shallow aquifers along the coastline around the CEMEX site are fully intruded by seawater and the groundwater in the project area of SVGB consists almost entirely of highly saline seawater that extends up to 8 miles inland. As explained in Comment Nos. 3, 7, 9, 15, 16, 17, 19, 20, 21, 22, 24, 29, 33, 36, and 37 below, this characterization ignores contrary information, is a gross misrepresentation of the aquifers in the Marina Subarea, and is simply not accurate.

3. The groundwater gradient (flow) in all aquifer zones produced by the project is onshore (inland or away from the coast) in the entire area that is potentially impacted by the MPWSP and efforts to abate seawater intrusion (prohibition of groundwater production in coastal areas of SVGB Pressure Area, etc.) have had little to no effect on restoring coastal conditions and are not expected to over the entire life of the project. As explained in Comment Nos. 2, 3, 6, 11, 15, 16, 19, 23, 26, and 37 below, this is also not accurate.

4. Historical studies are sufficiently complete and comprehensive in nature to document conditions in the vicinity of the project using existing wells (or without wells) and that baseline conditions inland of the project area, within the area the model shows will become completely intruded by seawater, do not need to be investigated prior to designing the project and modeling its impacts. As explained in Comment Nos. 3, 7, 9, 15, 16, 17, 18, 19, 20, 22, 24, 26, 27, 28, 29, 30, 33, 34, 36, 37, 38, 39, 42, and 43 below, this is not accurate.

---

[2] / The "Marina Subarea" is used in these comments to refer to the combination of (1) that portion of the 180/400 Foot Aquifer Subbasin of the SVGB located south of the Salinas River plus (2) the northwest portion of the Monterey Subbasin that would be impacted by the proposed slant well pumping on the CEMEX property. While the Marina Subarea is not a formally DWR-recognized subarea, it contains highly complex hydrogeological conditions that are very different from the portion of the 180/400 Foot Aquifer Subbasin north of the Salinas River as explained herein. The Marina Subarea is the coastal subarea of the overdrafted SVGB and is the area that would be directly impacted by the proposed project feed water pumping of 27,000 AFY. The Monterey County Water Resources Agency has defined the "Pressure Area" as a combination of the DWR-designated 180/400 Foot Aquifer Subbasin and the former Seaside Area and Corral De Tierra Subbasins (now the new Seaside and Monterey Subbasins). The Pressure Area is not a formally DWR-recognized subarea either, but that term is used throughout the DEIR/EIS.

5. The limited exploration and testing to date sufficiently validates the assumptions in the DEIR/EIS's groundwater model(s) used to simulate impacts of the proposed project and additional modeling based on actual conditions identified through recent fieldwork and laboratory testing is not necessary to disclosure of the project's potential groundwater impacts or evaluate of project alternatives. As explained in Comment Nos. 2, 4, 5, 6, 15, 18, 25, 26, 27, 28, 29, 31, 32, 33, 38, and 39 below, this is not accurate.
6. The DEIR/EIS's superposition model is reliable and demonstrates that the project's potential impacts on groundwater levels and groundwater quality in the Marina Subarea will be less than significant. As explained in Comment Nos. 4, 5, 8, 15, 25, 26, 27, 28, 30, 31, 32, 35, 37, and 39 below, this is not accurate.
7. Mitigation of the project's impacts can be accomplished through multiple methods and means. As explained in Comment Nos. 1, 4, 6, 8, 9, 10, 11, 12, 13, 21, 22, 23, 24, 25, 29, 30, 34, 35, 36, and 40 below, this is not accurate.

With these factors and hydrogeological conditions in mind, HGC has reviewed pertinent sections of the DEIR/EIS, calibrated model and superposition model numerical files that were made publicly available, numerous historical reports, and the baseline hydrogeological data that have been generated prior to February 2017 near the CEMEX site and south of the Salinas River (and is still being generated at the time of this review), and we offer the following comments for your consideration. Following our detailed comments on the DEIR/EIS, we also provide a summary of our conclusions and recommendations at end of the document.

Prior to turning to our specific comments, we note that our review of the documentation of the groundwater models that were constructed to simulate surface water and groundwater in the SVGB indicates there is a fundamental problem with the modeling utilized for the DEIR/EIS. Namely, the calibrated North Marina Groundwater Model ($NMGWM^{2016}$) was abandoned and replaced with the inferior superposition model because of technical problems. While not explained in the DEIR/EIS, based on our review, the problems appear to originate with the Salinas Valley Integrated Ground and Surface Water Model (SVIGSM) where all wells used to calibrate the model are located north of the Salinas River outside of the Marina Subarea/project area (LSCE, 2015).[3] The problems, however, carry over to the $NMGWM^{2016}$ and CEMEX Model (CM), which were used to create the DEIR/EIS's superposition model as explained below.

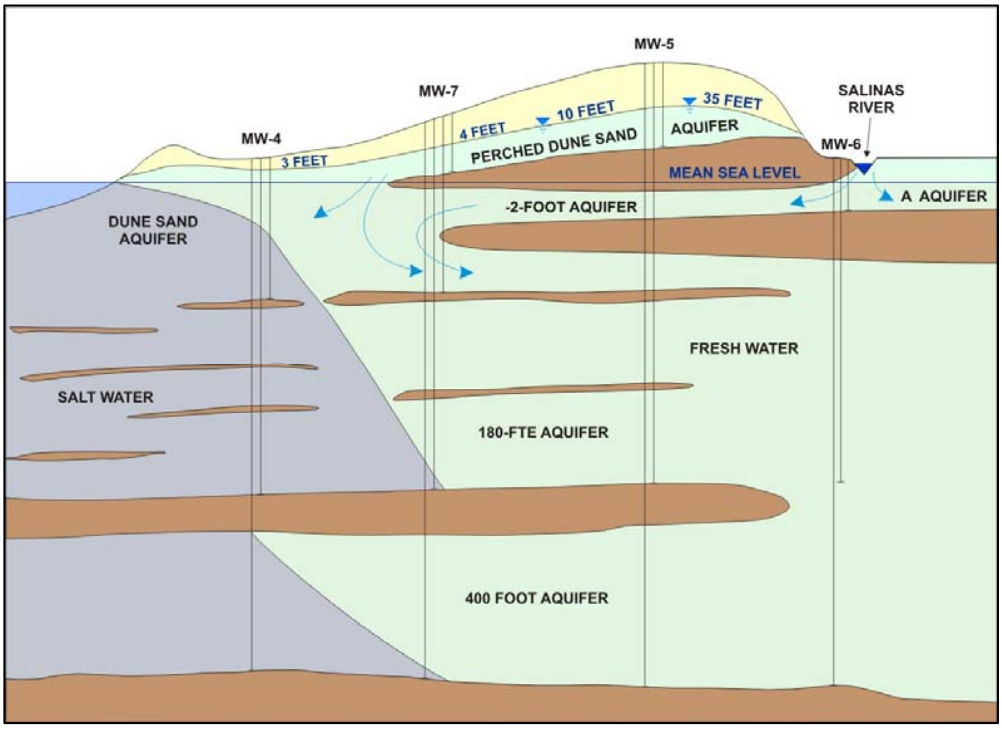
[3] / The Marina Subarea/project area as defined by available studies (KJC, 2004, Geoscience, 2014) as being separated from the main portion of the Pressure Area north of the Salinas River by a geologic facies change (the depositional environment) creating differences in the strata that formed as the 180-Foot Aquifer and 180-Foot Equivalent Aquifer (180-FTE), and the shallower Dune Sand and A-Aquifer zones.

The NMGWM^{2016} domain covers the coastal area northwest of Salinas and uses input from the SVIGSM for its simulations. The NMGWM^{2016}, however, largely uses wells north of the Salinas River as target wells for model calibration while incorporating only a few wells from the Fort Ord area south of the river along with abbreviated data sets from the TSW monitoring wells. The results of the NMGWM^{2016} simulations were used as input to the CM, which has a domain that covers a smaller area centered around the CEMEX active mining area and was used to simulate effects of production proposed for the TSW project. The NMGWM^{2016} was then initially used to evaluate the effects of the proposed MPWSP, but later abandoned because of the inability to complete satisfactory model calibration in the Dune Sand and 180-FTE Aquifers south of the river.

It appears the NMGWM^{2016} modeling was abandoned due to the difficulty with model calibration in the modelers attempts to add hydrogeologic information that was not included in the SVIGSM. This additional information generated by the pre-project studies indicates a semi-perched groundwater condition within the Dune Sand Aquifer that is also documented by other studies. This condition is of particular importance because it has resulted in Dune Sand Aquifer groundwater elevations in the Fort Ord area of 70 to 90 feet above mean sea level (amsl) (Ahtna, 2015), which decline to approximately 35 feet amsl at MW-5S. The presence and effects of this perched layer of fresh water was attempted to be incorporated in the NMGWM^{2016}, but was unsuccessful. The wells located south of the Salinas River in the project area that were used for calibration to compare simulated results with observed groundwater level elevations produced model error in the Dune Sand Aquifer (model layer 2) on the order of 30%. Consequently, there was not a high level of confidence in the accuracy of model predictions in the project area. Nonetheless, the hydraulic conductivity values used unsuccessfully in the NMGWM^{2016} were subsequently used to create the superposition model. As a result, the superposition model uses all the aquifer parameters of the poorly calibrated NMGWM^{2016} and assigns new boundary conditions and starting heads of zero. This maneuver, however, does not fix or improve the problems with the DEIR/EIS's modeling or its reliability. In fact, instead of improving on the poorly calibrated model, the maneuver removes all other stresses and recharge conditions in the basin and fails to address the project's impacts on the beneficial groundwater conditions that have developed in the Marina Subarea. Not only does this make the DEIR/EIS's assessment of groundwater even more unreliable, as a result the DEIR/EIS is incapable and therefore fails to evaluate the project's impacts on semi-perched groundwater conditions within the Dune Sand Aquifer and the semi-confined -2-Foot Dune Sand Aquifer conditions. This failure is fatal to the DEIR/EIS's ability to reliably analyze the project's potential groundwater impacts.

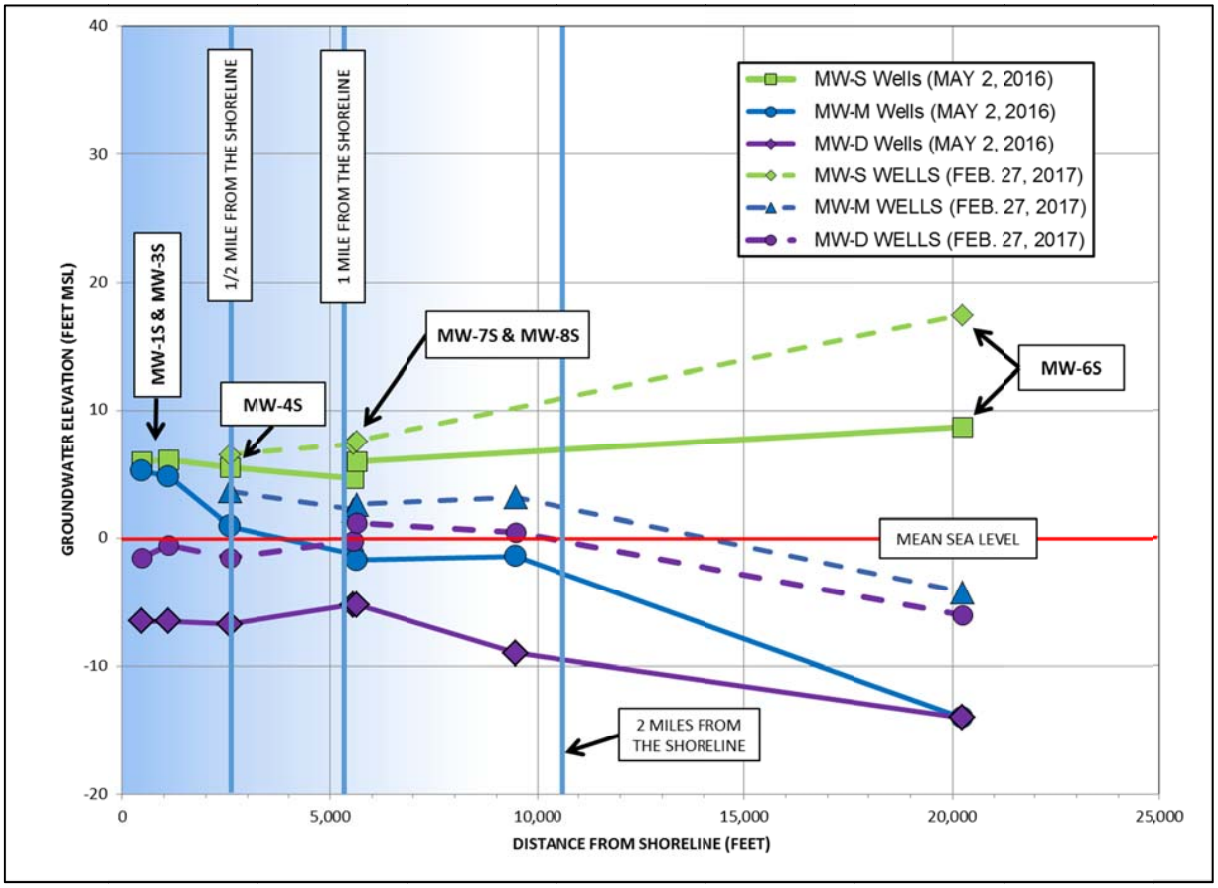
As discussed in detail below, the pre-project studies indicate that MW-1S, MW-3S, MW-4S, and MW-7S likely are connected to the Dune Sand Aquifer zone recognized as the -2-Foot Aquifer that is identified beneath the County landfill site (Geoscience, 2016). The elevation and thickness of this zone indicates it likely has a hydraulic continuity to the A-Aquifer zone in the main portion of the SVGB located north of the river. The concept demonstrated by these data is further illustrated on Diagram 1 – Conceptual Hydrogeology of Marina Subarea along with the perched Dune Sand Aquifer condition.

Diagram 1 – Conceptual Hydrogeology of Marina Subarea



Also discussed below, recent data obtained regarding the gradient beneath the landfill (near MW-5) shows recharge from the river that creates a groundwater gradient toward the coastline. Importantly, this is consistent with the elevated heads in MW-6S where it also receives recharge from the river. Diagram 2 – Water Level Elevation and Shoreline Proximity compares available data that were collected just prior to restarting the long term pumping test on May 2, 2016, and the high water level conditions observed on February 27, 2017. This diagram shows the wells that are constructed in the Dune Sand Aquifer zone that is equivalent to the -2-Foot Aquifer zone along with MW-6S, which is in the A Aquifer zone (Geoscience, 2016). As shown by these data, there is a groundwater gradient that moves water from the river area of recharge toward the coastline in the Marina Subarea of the SVGB. Monitoring Well MW-5S data with water levels in excess of 35 feet amsl were not included in Diagram 2 because it is now recognized to be screened in a semi-perched dune sand layer on top of the aquitard layer identified as the Fort Ord Salinas Valley Aquitard (FO-SVA). The FO-SVA layer overlies the -2-Foot Aquifer/Dune Sand Aquifer, which is reportedly 30 to 40 feet thick and rests on the Salinas Valley Aquitard near the river in the Marina Subarea northeast of the project site (Geoscience, 2016).

Diagram 2 – Water Level Elevation and Shoreline Proximity



The significance of this condition south of the Salinas River is illustrated by Diagram 3 – Particle Tracking With No Background Gradient, and Diagram 4 – Particle Tracking With 8-Foot Gradient Across Model Domain. The DEIR/EIS, however, does not recognize this condition due to the poor model calibration.

Turning back to the modeling used in the DEIR/EIS, the NMGWM^{2016} was constructed with a landward gradient in the 180-Foot Aquifer and does not simulate the -2-Foot-Aquifer beneath the confining layer that underlies the perched portion of the Dune Sand Aquifer. Initial head conditions create a constant landward flow of seawater beneath the perched layer. The particle tracking results during operation of wells for the MPWSP were not presented for either the calibrated NMGWM^{2016} or the superposition model, however particle movement would be similar to Diagram 3, which has a flat gradient prior to pumping, like the superposition model. As shown in Diagram 4, an 8-foot gradient across the entire model toward the coastline results in a different flow pattern and the capture of groundwater that is flowing toward the shoreline like the groundwater in the semi-perched Dune Sand Aquifer above the confining layer and groundwater in the -2-Foot Dune Sand Aquifer below the confining layer (see Diagram 2).

Diagram 3 – Particle Tracking With No Background Gradient

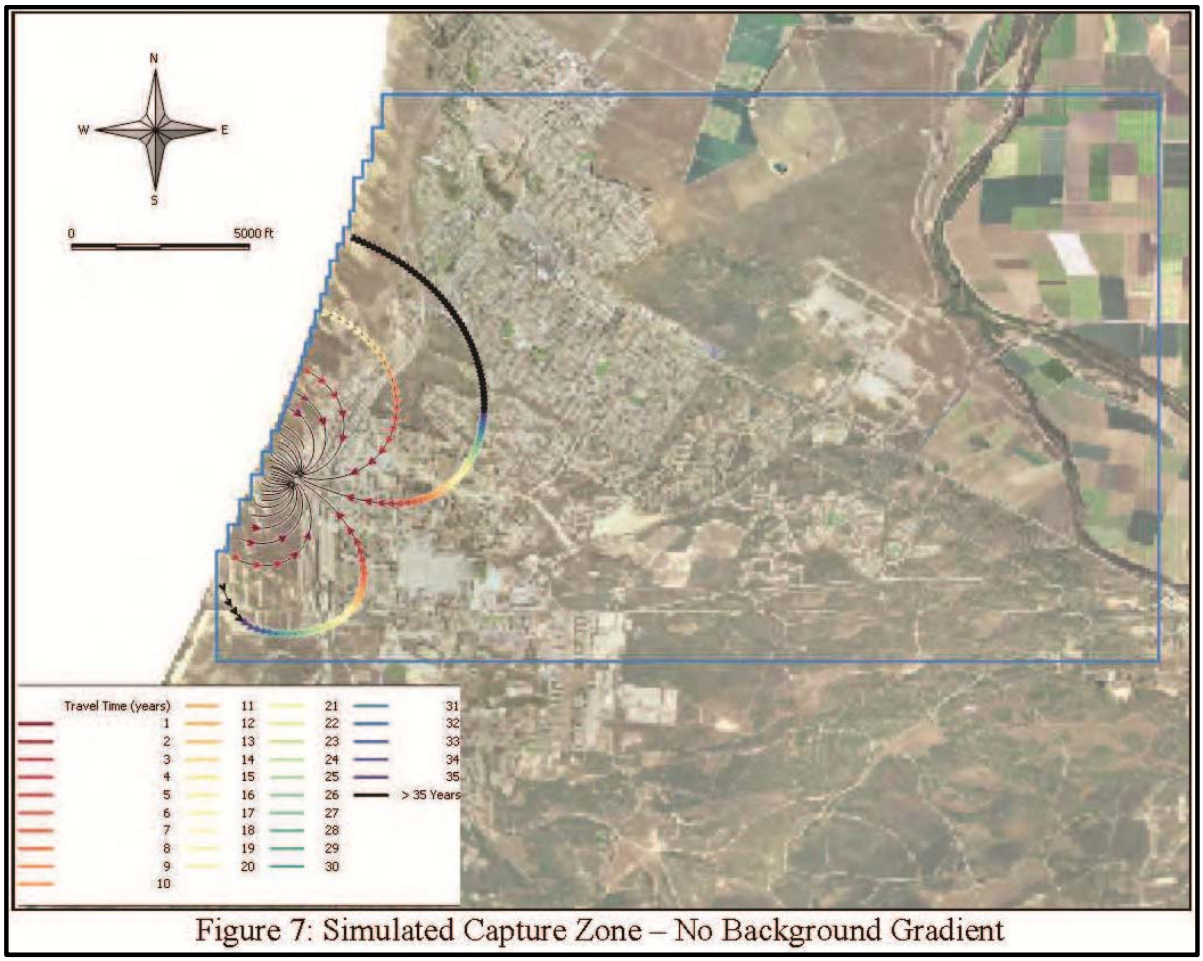


Figure 7: Simulated Capture Zone – No Background Gradient

FROM (HYDROMETRICS, 2006)

Again, this failure is fatal to the DEIR/EIS's ability to reliably analyze the project's potential groundwater impacts. Given the potential magnitude of the increased groundwater production, the impacts to the SVGB, in particular the Marina Subarea, the project's potential impact on the Marina Subarea are very likely grossly understated by the superposition model. Therefore, a well calibrated model is needed to quantify the project's potential impacts with a reasonable scientific basis. Specifically, a model that utilizes all the recharge and discharge components included in the older SVIGSM, and constructed with a level of detail reflecting our present understanding and knowledge of the hydrogeological system in the Marina Subarea is needed. Moreover, because seawater is an issue, a dual density model should be used to allow calculation of the head differences between the ocean water offshore and onshore, and freshwater in the aquifer zones inland and to allow prediction of water quality changes and the concentrations of feedwater that would be produced by the proposed project.

FROM (HYDROMETRICS, 2006)

With this understanding of perched groundwater conditions within the Dune Sand Aquifer in the Marina Subarea and with the fundamental flaws in the DEIR/EIS's modeling, we offer the following specific comments on the DER/EIS. To simplify the presentation of our comments and assist your review of these pertinent issues, we have excerpted or summarized the sections of the DEIR/EIS that we address and subsequently provide our comments or concerns of the hydrogeological issues that are crucial to understanding the potential project impacts. Please note that while we have selected certain sections of the DEIR/EIS to comment upon, our comments apply to similar statements that are repeated in other sections of the DEIR/EIS.

Comments on DEIR/EIS Chapter 2 (Water Demand, Supplies, and Water Rights).

DEIR/EIS's water rights discussion fails to estimate the amount of return water required for the project and may have insufficient supply to meet all return water requirements:

On **Page 2-22 of the DEIR/EIS** states:

> MPWSP source water would include some brackish groundwater from the SVGB. As part of the proposed project, CalAm would return to the SVGB a volume of desalinated product water equal to the amount of SVGB groundwater included in the source water. While CalAm's SVGB return water obligation will be based on the amount of fresh water in the source water, in order to consider the effect of the return water for this EIR/EIS, groundwater modeling simulated scenarios with return water obligations representing 0, 3, 6, and 12 percent of the source water (see Section 4.4, Groundwater Resources). The amount of SVGB groundwater included in the source water is expected to decrease over time (CalAm et al., 2016b).

Then on **Page 2-35 of the DEIR/EIS** states:

> CalAm proposes as part of the MPWSP to return to the Basin (in the manner further described below) the fresh water portion of the brackish source water. In other words, although the groundwater modeling indicates that the Basin water that could be withdrawn by the supply wells would be brackish and thus not fresh, potable water, the MPWSP would return to the Basin desalinated product water in the amount of the fresh water molecules that make up the withdrawn brackish Basin water. In that the quantity of such fresh water component of the supply water is not currently known, the modeling and the EIR/EIS analysis assess a range of return water between 0 and 12 percent of the source water.

HGC Comment No. 1:

The DEIR/EIS fails to disclose the amount of return water that would be necessary to replace the groundwater drawn from the SVGB as proposed in the Project Description.[4] Nor does the DEIR/EIS provide any discussion or information to support bracketing the return water percentage between 0% to 12%. In fact, it is likely that the return water obligation would be more than 12%, especially in the initial years of operation. Even the $NMGWM^{2016}$ calibrated model, which likely underestimates the slant wells production of groundwater as discussed in

[4] / As discussed below and in Comment No. 4 below, the return water proposal in the DEIR/EIS does not address the amount return water that is needed to mitigate the project's cumulative impacts on groundwater quality that would be required to comply with the SWRCB's report, the SGMA, and CEQA.

Comment No. 5 below, predicts up to 22% of groundwater will be produced from the Dune Sand Aquifer and another 3.5% of groundwater will be produced from the 180-FTE Aquifer during the initial time step.[5]

While it is not stated exactly how the range of 0 to 12 percent estimates were determined in the DEIR/EIS, an analysis of the salinity of the feedwater using ocean water with a total dissolved solids (TDS) concentration of 33,500 milligrams per liter (mg/l) and groundwater with an average TDS concentration of 440 mg/l can yield an estimate. Using these values and the laboratory test results obtained during the MPWSP's Test Slant Well (TSW) production period and included in the water quality report to the Hydrogeologic Working Group (HWG) (Geoscience, 2015p, Table 2), the TSW produced water with an average TDS concentration of 25,033 mg/l and was comprised of 25.6 percent groundwater and 74.4 percent ocean water.

Over the initial period of the long-term pumping test, the TDS concentration had reached approximately 29,100 mg/l prior to cessation of the test in early June 2015. Subsequent laboratory test results indicate that on December 12, 2016, and January 19, 2017 the TDS concentration had reached approximately 30,200 mg/l and 31,700 mg/l, respectively. Using these values along with the average February 2017 value of 29,900 mg/l, we can estimate a range of return water quantities by considering the groundwater component produced if a groundwater TDS concentration of 1,000 mg/l (State Drinking Water secondary standard) or 3,000 mg/l (Regional Water Quality Control Board [RWQCB] Water Quality Control Plan (WQCP) for the Central Coast Basin, water quality defined for beneficial uses) were used compared to the reported 440 mg/l average groundwater TDS concentration. Table 1 – Feedwater Composition Based on TDS Concentrations shows a comparison of the results using these values.

As shown, approximately 13.3 to 14.4 percent of the feedwater was groundwater when pumping was initiated. While higher salinity feedwater was produced by the TSW in December 2016 and January 2017, the concentration declined by February 2017 where approximately 11 to 12 percent of the groundwater produced would need to be returned. As explained below (see Comment No. 33), the water quality bias of the TSW to be more saline than other comparable

---

[5] / Modeling summarized in Appendix E1 of the **April 30, 2015 MPWSP Draft EIR** (Geoscience, 2014a, Figure 20) indicates that the initial groundwater production would be much greater during the initial production period (50 to 40 percent during the first year) and would decrease over a 4-year period to an estimated 4 percent after 4 years of production. Our review of the NMGWM^{2016} calibrated model results indicates that initially over 25 percent of the production will come from groundwater and that after 5 years, the component predicted to come from the SVGB is approximately 10 percent. The NMGWM^{2016} calibrated model, like the prior modeling, likely underestimates the slant wells production of groundwater (See Comment Nos. 3 and 9 below) and should not be considered to represent maximum amount of groundwater that may need to be returned to comply with the Agency Act.

wells located away from the CEMEX operations is a result of the dredge pond location and the salt water discharges that occur inland of the TSW location.

Notably, if a greater percentage of groundwater is produced than presently estimated by the DEIR/EIS, which is likely, or if usable groundwater salinity increases, the annual amount of return water to the SVGB would increase accordingly. The higher return water volumes required during the initial production period when a greater component of groundwater is pumped is not addressed in the DEIR/EIS. Please note that our comment here should not be interpreted to suggest the return of all groundwater to the SVGB as proposed MPWSP's return water proposal would mitigate the project's impacts to the Marina Subarea. The inadequacy of the DEIR/EIS's analysis of the MPWSP's return water proposal and DEIR/EIS's failure to mitigate the project's cumulative impacts on groundwater is discussed in HGC Comment No. 4.

Table 1 – Feedwater Composition Based on TDS Concentrations

OCEAN WATER SALINITY (MG/L)	GROUNDWATER SALINITY (MG/L)	FEEDWATER SALINITY (MG/L)	GROUNDWATER PERCENTAGE	OCEAN WATER PERCENTAGE
33,500	440	29,085	13.3	86.7
33,500	1,000	29,085	13.5	86.5
33,500	3,000	29,085	14.4	85.6
33,500	440	30,200	10.0	90.0
33,500	1,000	30,200	10.2	89.8
33,500	3,000	30,200	10.8	89.2
33,500	440	31,700	5.4	94.6
33,500	1,000	31,700	5.5	94.5
33,500	3,000	31,700	5.9	94.1
33,500	440	29,900	10.9	89.1
33,500	1,000	29,900	11.1	88.9
33,500	3,000	29,900	11.8	88.2

Finally, the DEIR/EIS cites to the settlement agreement regarding return water as support for the assumption that the amount of SVGB groundwater included in the source water is expected to decrease over time. This assumption appears to be based on the belief that the project's cumulative impacts will make the entire Marina Subarea hypersaline and therefore less

groundwater will be available to pump. Under the proposed return water agreement and project description, the greater the project's cumulative impacts to the Marina Subarea water quality, the less mitigation Cal-Am is required to provide. Not only is this inconsistent mitigation requirements under the California Environmental Quality Act (CEQA), it ignores the Sustainable Groundwater Management Act's (SGMA) mandates as discussed below. As shown in Diagram 4, when efforts under SGMA increase inland groundwater levels to further abate seawater intrusion, a greater amount of groundwater will be captured by the slant well intake system.

DEIR/EIS's water rights discussion presents misleading picture of where slant wells will draw water:

One such example is on **Page 2-30,** where the DEIR/EIS states, "The proposed project (MPSWP) and Alternative 5a are designed to take supply water from the ocean via underground slant wells that draw water from the earth underneath the ocean … b***ecause the project supply wells could draw some water from the Basin***, concerns have been expressed as to whether CalAm does or will hold legal rights to use the water that would be taken by the slant wells, treated at the desalination plant and supplied to CalAm customers located outside the Basin." (emphasis added)

HGC Comment No. 2:

The above statements are likely to mislead the public and the Commissioners. While it may be accurate to state that the proposed slant wells will pump most of the water from underneath the ocean, to state that the project supply wells "could draw some water from the Basin," using the term "could" inaccurately suggests there is some doubt that groundwater would be drawn from the SVGB.

While the amount of groundwater that would be drawn from the SVGB cannot be accurately determined based on available information or DEIR/EIS modeling to date, there is no question a substantial amount of groundwater will be drawn from the SVGB – and based on currently available information, a much greater quantity than indicated in the DEIR/EIS as discussed in Comment No. 1 and explained later in these comments.

DEIR/EIS's water rights discussion inaccurately suggests the MPWSP will create "developed water" because all the aquifers in the Marina Subarea of the SVGB are contaminated by seawater and will not support beneficial uses; this conflicts with available data from the TSW's monitoring wells:

Specifically, **Pages 2-32 and 33** of the DEIR/EIS state:

> Essentially, if the extraction of otherwise unusable Basin groundwater will not harm lawful water users and any fresh water extracted can be returned to the Basin without injury to existing legal water users, then CalAm would have rights to the portion of feedwater that comes from the Basin because the MPWSP product water that contains such Basin water would be "developed water."

Developed water is water that was not previously available to other legal users and that is added to the supply by the developer through artificial means as a new water source. "The key principle of developed water is if no lawful water user is injured, the effort of an individual to capture water that would otherwise be unused should be legally recognized." Report at 37. Due to long-term seawater intrusion (where the seawater has moved inland) in the Basin, large areas of the Basin groundwater are impaired as to drinking and agricultural uses. The geographic areas from which the project supply wells could draw water inland of the sea are indeed intruded by seawater. (See Section 4.4, Groundwater Resources) "Since this groundwater is reportedly impaired, it is unlikely that this water is, or will be put to beneficial use." Report at 15. In fact, in response to concerns over seawater intrusion and historic overdraft in the Basin, the County adopted Ordinance No. 3709, which precludes the installation of new groundwater wells and prohibits groundwater pumping between mean sea level and 250 feet below mean sea level in certain areas.

HGC Comment No. 3:

Contrary to the DEIR/EIS suggestion, "developed water" is not being created by the MPWSP, but is already there because of the restriction on pumping from Monterey County adopted Ordinance No. 3709 (and conservation efforts in the area) and it would otherwise be available to existing overliers and appropriators if it were not for the Ordinance restrictions. As shown in Table 2 – Groundwater Composition Based on TDS Concentrations – the salinity of groundwater in the Marina Subarea affected by the project is not largely intruded by seawater as claimed in the DEIR/EIS. Using the TDS concentration of 33,500 mg/l for ocean water and the TDS concentration of native groundwater 440 mg/l,[6] we analyzed the composition of the local groundwater in the aquifer zones that will be produced by the MPWSP slant wells by using the following equation:

$$OWP = (GS-IS) / (OWS - IS) \times 100.$$

OWP = Ocean Water Percentage, (%)
GS = Groundwater Salinity, (mg/l)
IS = Inland Water Salinity (TDS = 440 mg/l)
OWS = Ocean Water Salinity (TDS = 33,500 mg/l)

[6] / Our use of 440 mg/l here is based upon the TDS concentration provided by Geoscience as the SVGB average concentration. It should not be used to infer that groundwater that exceeds 440 mg/l has no beneficial uses. As discussed in Comment No. 21, the DEIR/EIS assumption that groundwater that exceeds 500 mg/l has no beneficial uses is wrong and inconsistent with the Basin Plan.

The analysis of available data shows that the percentage of ocean water decreases significantly within a short distance from the coastline. It also shows that within the area affected by the project, the groundwater is not the salinity of seawater as claimed in above passage – or intruded for up to 8 miles inland as stated in the DEIR/EIS on page 4.4-31. A visual presentation of these data is shown in Diagram 5 – Percent Groundwater and Ocean Water with Distance from the Shoreline.

Table 2 – Groundwater Composition Based on TDS Concentrations

GROUND-WATER SAMPLE LOCATION	OCEAN WATER SALINITY/TDS (MG/L)	GROUND-WATER SALINITY/TDS (MG/L)[1]	GROUND-WATER SAMPLE SALINITY/TDS (MG/L)	PERCENT GROUND-WATER	PERCENT OCEAN WATER	DISTANCE FROM THE COASTLINE (FEET)
DUNE SAND AQUIFER OR A-AQUIFER						
MW-1S	33,500	440	27,050[2]	19.5 %	80.5 %	480
MW-3S	33,500	440	23,350[2]	30.7 %	69.3 %	1,100
MW-4S	33,500	440	12,350[2]	64.0 %	36.0 %	2,590
MW-5S	33,500	440	1,141[2]	97.9 %	2.1 %	9,450
MW-6S	33,500	440	608	99.5 %	0.5 %	20,240

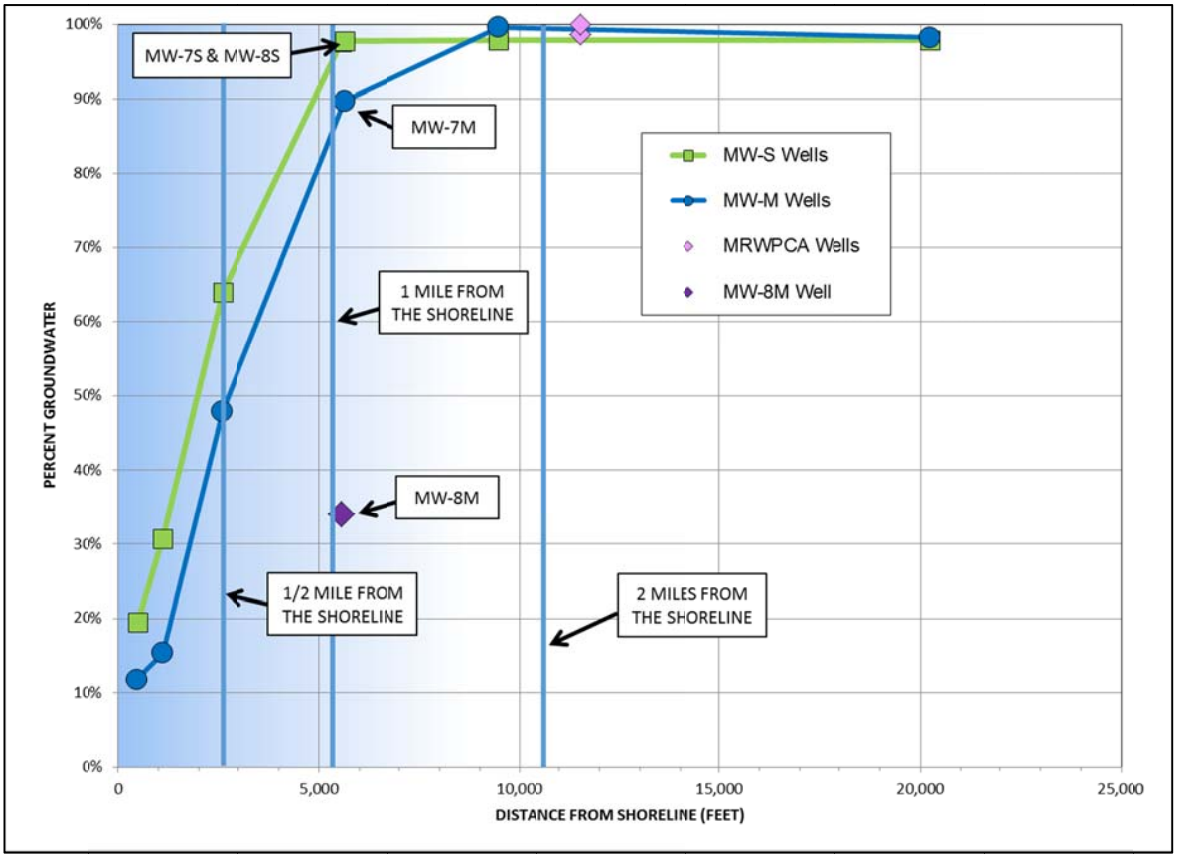
1 – AVERAGE INLAND WATER SALINITY FROM (GEOSCIENCE, 2015a)
2 – AVERAGED FROM DATA IN (GEOSCIENCE, 2015p) TABLE 2
3 – DATA FROM (GEOSCIENCE, 2015p) FIGURE 3-5
4 – WATER QUALITY BETTER THAN INLAND WATER SALINITY

Figure 1 – Average Chloride Concentrations, Dune Sand and 180-Foot Aquifer (attached to these comments) shows the location of the wells being monitored for the TSW project. As shown, the chloride concentrations in the 180-Foot Aquifer decrease from 9,664 mg/l in MW-4M to 105 mg/l in MW-5M, which is in the middle of the reported zone of seawater intrusion that is defined by a chloride concentration of 500 mg/l (B&C, 2015). Figure 2 – Average Total Dissolved Solids Concentrations, Dune Sand and 180-Foot Aquifer (attached to these comments) shows this same trend in the average TDS values obtained from available laboratory data (Geoscience, 2015p) and unpublished data provided by the CPUC in response to an MCWD data request, which we understand MCWD will include with its comments.

Diagram 5 – Percent Groundwater and Ocean Water with Distance from the Shoreline



The Monterey Regional Water Pollution Control Agency (MRWPCA) well locations are indicated on Figures 1, and 2, for reference, however, available data are provided on Figure 3 – MRWPCA Wells in 400-Foot Aquifer (attached to these comments), which shows the delineation of the seawater intrusion front(s) estimated by previous study (B&C, 2015) for water

quality in the 400-Foot Aquifer at the MRWPCA site. As shown on Figure 3, the MRWPCA Wells are within the seawater intruded portion of the SVGB but have a fresh water quality.

To assist in reviewing the chemical character of the fresh water contained in the 180-FTE and Dune Sand Aquifers Figures 4 - and 5 – Stiff Diagrams Dune Sand and A Aquifer, and 180-Foot Aquifer (attached to these comments), respectively, visually show the dominant cations and anions for available groundwater data. As shown in Figure 4, monitoring wells MW-5S, MW-6S, MW-7S, and MW-8S have a distinctly different chemistry than the cluster of wells located at the CEMEX site. First, there are a number of overlying land uses in that area including agricultural, waste disposal, composting, and sewage treatment that commonly contribute salts and nutrients to groundwater. For instance, MW-5S has a water surface of approximately 35 feet above sea level. It is not possible for seawater intrusion to flow uphill to this location. The chemical character of MW-5S groundwater is a calcium chloride with a nitrate concentration of approximately 235 mg/l (nitrate as NO_3). Seawater does not have a high concentration of nitrate, which clearly shows this freshwater source has received about 25% of its existing dissolved mineralogy as a nutrient from overlying land uses. Both MW-7S and MW-8S have high nitrate concentrations of 198 mg/l and 123 mg/l, respectively, which appear to be flowing from the semi-perched water source at MW-5S and dilute on its way westward. Both MW-7S and MW-7M have a calcium chloride chemical character consistent with recharge from the semi-perched layer and not seawater with a sodium chloride chemical character.

These data appear to indicate that cessation of pumping along the coast in combination with natural recharge mechanisms, only now being discussed, has resulted in favorable groundwater conditions that appear to be protecting the shallow aquifers in an area of the SVGB located inland of the project and south (or in the vicinity) of the Salinas River. The DEIR/EIS does not acknowledge these water quality data as significant and insists that the groundwater is impaired to an extent that it is unlikely that this water is suitable for, or can be put to beneficial use. Available data do not support the DEIR/EIS's conclusion and in fact indicate additional study of existing conditions should be conducted to further understand sources of groundwater recharge and its movement within the aquifers of the Marina Subarea of the SVGB Pressure Area.

DEIR/EIS's water rights discussion incorrectly assumes that the proposed return water agreement or other alternatives will mitigate the project's groundwater impacts in the Marina Subarea as required by the State Water Resources Control Board's (SWRCB's) advisory opinion and CEQA:

On **Page 2-34 and 35**, the DEIR/EIS quotes the SWRCB report stating:

> Cal-Am could use one of several possible options to replace any fresh water it extracts from the Basin. Cal-Am could return the water to the aquifer through injection wells, percolation basins, or through the CSIP. Cal-Am would need to determine which of these methods would be the most feasible, and would in fact, ensure no

> harm to existing legal users. The feasibility analysis would depend on site-specific geologic conditions at reinjection well locations and at the percolation areas. These studies need to be described and supported in detail before Cal-Am can claim an appropriative right to export surplus developed water from the Basin.

Report at 39. The Report emphasizes more than once that any injection wells or percolation basins for the purpose of returning fresh water to the Basin would need to be located where the underlying aquifer does not contain degraded water so as to avoid a waste of beneficial water.

> In summary, to appropriate groundwater from the Basin, the burden is on Cal-Am to show no injury to other users. Key factors will be the following: (1) how much fresh water Cal-Am is extracting as a proportion of the total pumped amount and how much desalinated water is thus available for export as developed water; (2) whether pumping affects the water table level in existing users' wells and whether Cal-Am can avoid injury that would otherwise result from any lowering of water levels through monetary compensation or paying for upgraded wells; (3) whether pumping affects water quality to users' wells within the capture zone and whether Cal-Am can avoid or compensate for water quality impacts; (4) how Cal-Am should return any fresh water it extracts to the Basin to prevent injury to others; and (5) how groundwater rights might be affected in the future if the proportion of fresh and seawater changes, both in the larger Basin area and the immediate area around Cal-Am's wells.

Report at 46. The Report concluded that further data were needed in order to apply the facts and evidence to the criteria set forth in the Report for determining CalAm's water rights. The Report noted that information was needed pertaining to the depth of the project supply slant wells, the hydrogeologic conditions of the site and the area, updated modeling to evaluate the impacts of the project, aquifer testing, and studies to help determine how extracted fresh water would be replaced. Most of these studies and activities have been undertaken and the results are described and reflected in Section 4.4, Groundwater Resources. CalAm has supplied details about its proposed supply wells and return water proposal. Test borings have helped to characterize the hydrogeologic framework within which the project would operate. Groundwater modeling has been conducted. CalAm also obtained approval to construct a test well on the CEMEX site. That well is in place (and core samples taken during the drilling of the well confirmed the assumptions about hydrogeologic conditions) and test pumping is occurring. Test slant well pumping and monitoring data was used to refine the aquifer properties

represented in the revised version of the groundwater model to test the model's reliability for simulating drawdown from slant well pumping. Once the test well results are complete, the modeling will be verified and will be re-run as warranted. Thus, the full panoply of evidence concerning the project's relationship to groundwater (and thus water rights) may continue to evolve and be refined throughout the CPUC proceeding. This preliminary analysis of water rights is based upon detailed and extensive groundwater aquifer characterization and groundwater modeling that has been undertaken by the EIR/EIS preparers to assess the effects of the project on Basin groundwater users.

HGC Comment No. 4:

The DEIR/EIS incorrectly assumes the "Settlement Agreement on MPWSP Desalination Plant Return Water," will mitigate all the project's groundwater impacts. The proposal, however, would return groundwater to the SVGB and provide benefit to well operators located north of the Salinas River, which is outside of the area that will experience the greatest impact from the project (i.e. Marina Subarea) which is located south of the river. See HGC Comments 9 and 10 for further discussion.

Regional data available for model construction south of the Salinas River in the vicinity of the CEMEX site are limited. The initial field work and aquifer testing conducted for the TSW project has provided hydrogeological data indicating conditions that were not anticipated during construction of the model (i.e., 180-FTE Aquifer semi-confinement, mounded water in the Dune Sand Aquifer, a portion of the Dune Sand Aquifer being confined along the river, freshwater present in the 180-FTE Aquifer at MW-5, etc.). The Lawrence Berkeley National Laboratories Peer Review contained in DEIR/EIS as Appendix E1 reviewed the hydrogeologic conditions incorporated and omitted from NMGWM ^{2015} and indicated on page 26 that,

> "In this case, the input of areal recharge to the 180-FTE at the edge of the FO-SVA will not increase in response to extractions, and so the area of capture zone in the 180-FTE aquifer will increase. Consequently the distribution of water level drawdowns due to the proposed extraction will be different than those predicted by the model. The portion of the total volume of water extracted that is from beneath the onshore is also likely to be different."

To proceed with any level of confidence with the water rights analysis and the amount of return water that will be required of the project, it is imperative that aquifer test results from the TSW and monitoring well information be used along with historical data available from Fort Ord Wells and the landfill monitoring wells to update and calibrate the NMGWM^{2016} in order to simulate MPWSP impacts. Incorporation of these data will require successful model modification and recalibration of the area south of the river to an acceptable standard. The failure to achieve successful modification and calibration is reportedly why the calibrated model (NMGWM^{2016}) was abandoned and the superposition model approach adopted. Without successful model revision and recalibration based on the newly acquired data, it will be

impossible for experts, much less the public, to understand the potential impacts of the TSW and the MPWSP production as explained in our comments.

DEIR/EIS's water rights discussion of potential harm fails to provide any estimate of groundwater pumped from slant wells and thus cannot assess the feasibility of the project or potential impacts to the groundwater basin or potential harm to users:

On **Page 2-35**, the DEIR/EIS states:

> The extensive groundwater modeling conducted for this EIR/EIS and discussed in detail in the Groundwater Resources section and in Appendix E2 is different from that conducted for the 2015 Draft EIR on the MPWSP. As explained in Chapter 4.4, Groundwater Resources, the modeling is specifically targeted to isolating the change in groundwater levels that would be generated by the MPWSP. **This modeling, however, cannot project the amount of Basin water that is expected to be drawn into the supply wells** [emphasis added]. Due to decades of seawater intrusion in the area, any Basin water extracted by the supply wells would be brackish water, which is a combination of ocean water and water that originated from the inland aquifers of the Basin. CalAm proposes as part of the MPWSP to return to the Basin (in the manner further described below) the fresh water portion of the brackish source water. In other words, although the groundwater modeling indicates that the **Basin water that could be withdrawn by the supply wells would be brackish and thus not fresh, potable water** [emphasis added], the MPWSP would return to the Basin desalinated product water in the amount of the fresh water molecules that make up the withdrawn brackish Basin water. In that the quantity of such fresh water component of the supply water is not currently known, the modeling and the EIR/EIS analysis assess a range of return water between 0 and 12 percent of the source water.
>
> The concept of significant effect under CEQA is not necessarily synonymous with harm or injury to water rights holders. In other words, physical change caused by the project might not rise to the level of a significant environmental impact under CEQA, but could still cause some harm or injury to a Basin water user (for instance, if the cost to a Basin water rights holder of withdrawing water were to rise even though the environment would not suffer significant impacts). Here, though, the Groundwater Resources section of this EIR/EIS strives to and does in fact effectively and meaningfully analyze two of the three precise concepts of "harm" or "injury" set forth in the Report. **These two criteria are reduction in the availability of fresh water and reduction of water quality** [emphasis added]. In addition, the analysis in the Groundwater Resources section (based upon the groundwater modeling) provides an answer to the third concept of injury

> set forth in the Report, that of a reduction in groundwater levels that requires users to spend additional funds to extract water.

HGC Comment No. 5:

This section appropriately states that "This modeling, however, cannot project the amount of Basin water that is expected to be drawn into the supply wells." Then it concludes "Due to decades of seawater intrusion in the area, any Basin water extracted by the supply wells would be brackish water." This statement is contradicted by the freshwater quality observed in wells constructed and/or sampled for the observation of test slant well pumping. The blanket statement of seawater intrusion in the area ignores the conditions that have protected this specific section of coastline in the Marina Subarea and result in fresh water located in both the Dune Sand and 180-FTE Aquifers. When fresh quality groundwater is drawn from these inland areas and mixed with seawater produced by the MPWSP, a brackish source water at the project intake facilities will be the result.

Groundwater modeling conducted using the NMGWM^{2016} or the superposition model does not indicate that the "Basin water that could be withdrawn by the supply wells would be brackish and thus not fresh, potable water…". Neither of these models are a dual density model that can track and predict water quality changes. The MPWSP brackish source water is a result of mixing seawater and fresh potable groundwater drawn into the slant well facilities from the SVGB. It is only a matter of inference to conclude that the contamination of the freshwater with seawater will result in a brackish water supply, even without the modeling capabilities.

The analysis conducted for the DEIR/EIS cannot and does not effectively or meaningfully analyze the reduction in the availability of fresh water or reduction of water quality as stated in the above passage. Rather, because the models constructed for the DEIR/EIS are not capable of this analysis, the DEIR/EIS's discussion of these issues amounts to pure speculation. Importantly, the DEIR/EIS conclusions are not consistent with the limited data that is available, which indicate a substantial area of fresh water that is contained in the 180-FTE and Dune Sand Aquifers directly inland of the CEMEX site. As this groundwater is removed by the project and replaced with seawater, the project will effectively reduce fresh water in the Marina Subarea for the duration of the project and the induced concentrated flow of seawater will reduce the water quality and render the area unsuitable for freshwater projects for the foreseeable future.

DEIR/EIS's water rights discussion conclusion that the MPWSP will not significantly impact groundwater resources is not supported by the MPWSP modeling to date or other evidence:

On **Page 2-36**, the DEIR/EIS after addressing the significance thresholds further goes on to state:

> Applying the thresholds stated above, the analysis concludes that the MPWSP would not result in a significant impact to groundwater resources. It would not reduce, or affect at all, the availability of fresh water (only brackish water from the Basin is projected to be drawn into the MPWSP supply); would not lower groundwater levels in the Basin so as to affect the water supply of any

groundwater users or substantially deplete aquifer volume; and would not alter or reduce groundwater quality.

HGC Comment No. 6:

The DEIR/EIS's conclusions are not supported by the information presented in the DEIR/EIS or any other evidence and must be revised.

First, the suggestion that the project "would not affect at all" the availability of fresh water because only brackish water is projected to be drawn into the MPWSP supply is misleading and conflicts with other sections of the DEIR/EIS. As discussed in Comment No. 5 above, the DEIR/EIS's speculation that only brackish water would be extracted by the project's slant wells is not supported by the models used to analyze the project impacts. It would appear beyond dispute that the project will replace freshwater and slightly brackish water with highly saline seawater and, therefore, alter and reduce the groundwater quality. Nor is this impact limited to the upper aquifers in the Marina area, the water budget obtained from our independent operation of the calibrated NMGWM^{2016} shows that the project will effectively cause up to 235 acre-feet per year to seep upward out of the 900 Foot-Deep Aquifer. This quantity could be significant on a cumulative basis and could adversely affect the main source of groundwater presently used by the MCWD - the deep aquifer. Therefore, the DEIR/EIS must be revised based on reliable modeling to disclose that the project will reduce the availability of fresh water in the Marina Subarea, including the Deep 900-Foot Aquifer.

Second, the DEIR/EIS's statement that the project would not lower groundwater levels in the SVGM so as to affect the water supply of any groundwater users or substantially deplete aquifer volume is similarly unsupportable. The DEIR/EIS incorrectly assumes that unless the project is directly/solely responsible for causing water levels in an existing well to drop below the wells' screened intervals, the project would not substantially deplete aquifer volume. Despite the fact that it is undisputed that the project will deplete aquifer volumes, the DEIR/EIS fails to consider what amount of depletion would constitute a substantial impact. As explained further below, assuming that lowering groundwater levels in the Marina Subarea would not substantially deplete aquifer volume unless an existing well goes dry is not a meaningful analysis, especially in this portion of the SVGB where pumping is restricted to support basin water level recovery.

Third, the DEIR/EIS's statement that the project would not alter or reduce groundwater quality is demonstrably false. The project, by design, will significantly reduce groundwater quality within the Marina Subarea. Moreover, this statement fails to consider how dropping groundwater heads along the coast has the potential to significantly induce greater seawater intrusion and interfere with future Sustainable Groundwater Management Agency activities.

DEIR/EIS's water rights discussion conclusion that the SVGB and Basin users will not be harmed fails to consider the project's water quality impacts on the Marina Subarea:

On **Page 2-36 and 37**, the DEIR/EIS states:

> Due to the long-degraded condition of water in the Basin within the radius of influence (the area within which the project could affect groundwater levels), there are few active wells that could potentially be affected by the project. As discussed in detail in the Section 4.4, Groundwater Resources, there are only three active supply wells with well screens across the Dune Sand Aquifer or 180-Foot Equivalent Aquifer within the area where the project may cause groundwater levels to decrease by more than 1 foot but no more than 5 feet.3 These three wells are located at the Monterey Peninsula Landfill and are used for dust control. Given that the well pumps and the screens are set at least tens of feet below the existing groundwater level, a decrease in the levels of less than 5 feet would not cause injury to this overlying user. There are four active wells with well screens in the 400-Foot Aquifer. These include the South Well on the CEMEX property, a well on land owned by Ag Land Trust that is used to supply water for dust control, and two private wells with unknown owners. Due to the brackish to saline quality of the groundwater within the 400-Foot Aquifer, these wells would not be expected to supply drinking water. The Groundwater Resources section concludes as to all active wells that a water level decline between 1 and 5 feet would not expose well screens, cause damage, or reduce yield in the groundwater supply wells that could be influenced by the MPWSP. All in all, the project was determined not to result in a significant impact in terms of groundwater supplies either quantitatively or qualitatively. Thus, it appears reasonable to conclude that the MPWSP would not result in harm or injury to the water rights of legal users of water in the Basin in terms of fresh water supply or water quality, two of the Report's three injury criteria relative to the development of legal water rights.

HGC Comment No. 7:

As noted above, this is not a meaningful analysis of the project's potential to substantially deplete aquifer volumes or impact current water users within the Marina Subarea. More importantly, it does not assess or analyze the project's potential cumulative water quality impacts on existing users, in and outside the potential drawdown area, or reasonably foreseeable groundwater projects that may be conducted under the SGMA. These projects include, but are not limited to, the use of the MCWD's Armstrong Ranch property for storage and recovery of river diversions.

DEIR/EIS's water rights discussion conclusion that the SVGB and Basin users will not be harmed fails to consider the project's water quality impacts on the Marina Subarea water rights holders:

On **Page 2-37**, the DEIR/EIS states:

> Turning to the third of the three injury criteria set forth in the Report – increased pumping costs – as noted above, the water levels in seven potentially active wells could drop by somewhere between 1 and 5 feet, thus requiring marginally more

energy to extract the water from those wells. As a physical solution to ensure that those well owners continue to enjoy the same measure of water rights as they do prior to MPWSP implementation and thus are not injured, CalAm could compensate the well owners for any increased pumping costs causally tied to the MPWSP. Assuming that CalAm were to compensate the owner of these wells for any increased pumping costs sustained due to the MPWSP, the slant wells' operation would not cause injury under the Report's third injury criteria.

Furthermore, CalAm has proposed a mitigation measure (set forth in Section 4.4, Groundwater Resources as Mitigation Measure 4.4-3) to further ensure that Basin groundwater users are not injured. Working with the Monterey County Water Resources Agency, CalAm would fund the installation of monitoring wells to expand the County's network of groundwater monitoring wells so as to be better able to monitor on an on-going basis the effect of the project slant wells on groundwater within the radius of influence. If the monitoring efforts were to demonstrate that the project were affecting any existing neighboring active wells, CalAm would coordinate with the affected well owner and take both interim and long-term steps to avoid harm (possibly including improving well efficiency, providing a replacement water supply and/or compensating the well owner for increased costs).

In light of the foregoing, it seems reasonable to conclude that the MPWSP would not cause harm or injury to Basin water rights holders such that CalAm would possess the right to withdraw water from the Basin to produce "developed water" for beneficial use and under the physical solution doctrine.

HGC Comment No. 8:

Groundwater Resources Mitigation Measure 4.4-3, which is voluntary and appears unenforceable, fails to ensure the project will not result in significant groundwater impacts to the Marina Subarea or its groundwater users. Given the DEIR/EIS's use of the superposition model, which fails to evaluate potential future cumulative conditions, it would be impossible for anyone to assess whether impacts to a well are directly tied to the MPWSP. As well, the use of this model cannot determine the impact of the project on future basin management efforts planned to improve the groundwater conditions in the SVGB.

Again, the DEIR/EIS does not assess or analyze the project's potential water quality impacts on existing users, in and outside the potential drawdown area, or with any reasonably foreseeable groundwater projects under the SGMA.

DEIR/EIS's water rights discussion estimates regarding feedwater composition are not supported by evidence and conflict with the SWRCB RWQCB WQCP:

On **Pages 2-37 and 38**, the DEIR/EIS states:

> The entirety of the geographical area of the Basin that would be affected by the project contains brackish water rather than fresh water. Based on the groundwater modeling and as discussed in the Groundwater Resources section, while the project may actually improve the Basin's seawater intrusion issue by slowing the seawater interface line from advancing more inland, the project is not forecasted to draw any fresh water through the MPWSP source water supply wells over the life of the project. If indeed no fresh water is withdrawn by the project, then no physical solution in the form of return to the Basin of fresh water (or other off-setting mechanism to alleviate the harm) would be required in order for CalAm to secure and maintain water rights for the project feedwater. If the water in the Basin were to become fresher in the future such that the MPWSP supply wells were drawing fresh water from the Basin, then a physical solution (such as the proposed return component of the project, discussed below) would be needed in order for CalAm to maintain rights to the Basin water for the project.
>
> In any event, the proposed project does include a return water component. CalAm proposes to return to the Basin the percentage of supply water that is determined to have originated from the inland aquifers of the Basin, i.e., the fresh water component of the water that is extracted by the slant wells as if the brackish water could be segregated between its ocean (seawater) and inland (fresh water) elements. Not only would this plan further ensure that there is no injury to Basin groundwater users, but the Basin and its groundwater users could be benefitted by the return of fresh water to the seawater-intruded Basin.

HGC Comment No. 9:

First, data developed for the TSW project indicate that the blanket statement "The entirety of the geographical area of the Basin that would be affected by the project contains brackish water rather than fresh water" is false as discussed above. Wells MW-5, MW-6, MW-7, and MW-8 shallow and middle wells are located within the geographical area that would be affected by the project and the measured TDS concentrations for samples from the Dune Sand Aquifer wells ranges from approximately 608 to 1,237 mg/l and is considered fresh water under the Basin Plan. Table 3 – Dune Sand and 180-FTE Aquifers Water Quality Data summarizes the existing freshwater quality in these 4 shallow wells. Moreover, salts impacting these wells are derived from overlying land uses and not seawater intrusion. See HGC Comment No. 3. As well, the 180-FTE Aquifer zone was found to be saline at MW-8M, but brackish at MW-7M and fresh at MW-5M and MW-6M. These new data indicate the statement that the project "may actually improve the Basin's seawater intrusion issue" is not accurate for this area of the SVGB.

Other than the more coastal wells MW-7M and MW-8M, these wells do not contain chloride concentrations above the 500 mg/l indicator of seawater intrusion (see Table 3).

Table 3 – Dune Sand and 180-FTE Aquifers
Water Quality Data

WATER QUALITY SOURCE	SAMPLE DATES[1]	TDS (MG/L)	CHLORIDE (MG/L)	NITRATE-NO3 (MG/L)[3]
MW-5S	3/10/15 4/02/15	1,142	272	235
MW-5M	3/03/15 4/02/15	559	105	67
MW-6S	4/05/15	608	57	ND
MW-6M	4/04/15	966	167	ND
MW-7S	8/03/15	1,200	387	198
MW-7M	8/02/15	3,832	1,739	15
MW-8S	5/28/15 6/23/15	1,237	256	119
MW-8M	5/27/15 6/23/15	22,250	11,463	6

[1] – IF MORE THAN ONE SAMPLE DATE IS SHOWN SAMPLE RESULTS WERE AVERAGED

Second, the determination method for calculating brackish groundwater produced is not clearly identified in the DEIR/EIS. Brackish groundwater proximate to the CEMEX site has been identified through initial water quality testing of monitoring well samples for the TSW project. The results of a feedwater blend using these brackish groundwater data for comparison are presented in Table 4 – Feedwater Composition Based on Brackish Groundwater TDS Concentrations.

These estimates indicate the range of fresh and brackish groundwater percentages that would be required to be returned to the SVGB given present water quality conditions in shallow and middle aquifers at MW-4. Brackish groundwater samples proximate to the TSW indicates the average TDS concentration is between 12,350 and 17,700 mg/l. Based on these brackish groundwater concentrations and using the present average feedwater salinity (29,900 mg/l) previously estimated from the February 2017 samples (Geoscience, 2017), the amount of

groundwater produced by the MPWSP from the SVGB would range between 4,596 and 6,152 afy (17 to 22.8 percent).

Table 4 – Feedwater Composition Based on Brackish Groundwater TDS Concentrations

WATER QUALITY SOURCE	OCEAN WATER SALINITY (MG/L)	GROUND-WATER SALINITY (MG/L)	FEED-WATER SALINITY (MG/L)[3]	GROUND-WATER (%)	OCEAN WATER (%)	ESTIMATED ANNUAL QUANTITY RETURNED (AFY)
BASIN AVE.	33,500	440[1]	29,900	10.9	89.1	2,943
WQCP	33,500	3,000	29,900	11.8	88.2	3,187
MW-4S	33,500	12,350[2]	29,900	17.0	83.0	4,596
MW-4M	33,500	17,700[2]	29,900	22.8	77.2	6,152
MW-5S	33,500	1,142	29,900	11.1	88.9	3,004
MW-5M	33,500	559	29,900	10.9	89.1	2,951
MW-6S	33,500	608	29,900	10.9	89.1	2,955
MW-6M	33,500	966	29,900	11.1	88.9	2,988
MW-7S	33,500	1,200	29,900	11.1	88.9	3,009
MW-7M	33,500	3,832	29,900	12.1	87.9	3,276

1 – AVERAGE INLAND WATER SALINITY FROM (GEOSCIENCE, 2015a)
2 – AVERAGED FROM DATA IN (GEOSCIENCE, 2015p) TABLE 2
3 – AVERAGED FROM TSW LABORATORY TESTS IN FEBRUARY 2017 (GEOSCIENCE, 2017)

For comparison, the present feedwater concentration would require 2,943 afy be returned to the SVGB as groundwater produced with an average TDS concentration of 440 mg/l. Using the RWQCB WQCP TDS concentration of 3,000 mg/l as usable groundwater indicates over 3,187 afy would need to be returned to the SVGB to mitigate groundwater pumped as a feedwater supply. These estimates ignore the salt water recharged to the aquifer inland of the TSW by the CEMEX operations.

Moreover, the project return water proposed would not ensure that there is no injury to SVGB groundwater users. While the return water proposal would likely increase groundwater levels in other areas of the SVGB around Castroville, it would not address potential harms to present and future legal users in the Marina Subarea.

DEIR/EIS's assumption that the "Settlement Agreement on MPWSP Desalination Plant Return Water" will mitigate the project's groundwater impacts to the SVGB and the Marina Subarea is not supportable:

On **Page 2-38 and 39**, the DEIR/EIS states:

> CalAm has worked with other stake-holders to develop its current proposal for returning water to the Basin. The construct proposed was not an identified option at the time that the SWRCB Report was prepared and thus was not specifically addressed therein, but appears to advance the goals stated in the Report for returning water to the Basin. CalAm proposes to deliver fully desalinated water to end users for use in lieu of existing groundwater production from the SVGB.
>
> The two points of delivery would be (i) to the Castroville Community Services District (CCSD) to supply water for municipal purposes (e.g., typical drinking, bathing, sewer, watering and other non-agricultural water uses) and (ii) to the Castroville Seawater Intrusion Project (CSIP) pond or directly into the reclaimed water CSIP pipe for use by the agricultural users that obtain water through CSIP. Under these return water locales, the clean desalinated water would be provided for municipal or agricultural use (respectively) in lieu of pumping Basin water in an amount equal to the quantity of return water. The return water would be supplied as follows:
>
> 1. At the start-up of the MPWSP, 175 acre feet of return water would be provided to CSIP.
>
> 2. Each year, 805 acre feet of return water will be provided to CCSD, even if the calculated amount of Basin water withdrawn by MPWSP is less than that amount.
>
> 3. To the extent that the calculated amount of Basin water withdrawn by MPWSP exceeds 805 acre feet, that excess amount will be provided to CSIP.
>
> Water is expected to be returned between May and November of the same calendar year as it is withdrawn (see Chapter 3, operating table) such that the senior overlying and prescriptive users would not suffer harm from loss of water. As examined by the groundwater modeling and explained in the Groundwater Resources section, this proposed return water plan would improve groundwater conditions in the 400-Foot Aquifer underlying the CSIP, CCSD and adjacent areas because water levels would increase as a result of in-lieu groundwater recharge, and would benefit each of the aquifers by either reducing the area of influence of the MPWSP or by increasing groundwater levels in other areas. Since this return option would essentially put the Basin in a "no net loss" position in terms of fresh water quantity and would benefit legal water users by providing fresh water for beneficial use in lieu of Basin pumping, it appears consistent with the Report and enhances the preliminary conclusion that CalAm would likely possess water rights for the project.

HGC Comment No. 10:

First, the 175-acre feet of return water would be provided to CSIP at the start-up of the MPWSP grossly underestimates the amount of groundwater that modeling shows will be pumped during the initial start-up period. See HGC Comment Nos. 1 and 5.

Second, the statement that the project would benefit each of the aquifers by either reducing the area of influence of the MPWSP or by increasing groundwater levels in other areas is misleading. While the proposed return water agreement would likely increase groundwater levels in other areas, it would not reduce the area of influence within the Marina Subarea. Moreover, the DEIR/EIS suggestion that the project would benefit legal water users is only a half-truth as it fails to acknowledge that it does not address potential harms to present and future legal users in the Marina Subarea.

For this mitigation measure to be effective, the water user receiving the offset supply to reduce pumping must be located in the Marina Subarea of the SVGB affected by the project (i.e., south of the Salinas River). To avoid potential injury to the Marina Subarea, the DEIR/EIS should also analyze potential mitigation through injection well sites to ensure they will mitigate the projects impacts on the SVGB to a less-than significant level (i.e., no degradation of water quality in the Marina Subarea). We note that placing the wells in the wrong location could actually push groundwater impacted by seawater into aquifer areas that are currently fresh to slightly brackish in quality, but usable.

DEIR/EIS's discussion of the project's consistency with Monterey County Water Resources Agency (MCWRA) Agency Act is misleading and inaccurate.

On **Pages 2-39 and 40**, the DEIR/EIS states:

> … the State Water Resources Control Board Report, discussed in detail above, raises the question as to whether the Agency Act would apply to all of the proposed project groundwater extractions given the location of some screens of the slant wells outside the jurisdictional boundaries of the County:
>
> > The applicability of the Agency Act to the MPWSP is unclear. As currently proposed, the project would use slanted wells and have screened intervals located seaward of the beach. Although the project would serve areas within the territory of the MPWSP, the points of diversion for these proposed wells may be located outside the territory of MCWRA as defined by the Agency Act.
>
> Report at 39. The Agency Act's effect on project feasibility may be minimized by virtue of its application only to water drawn through well screens located within County jurisdiction.
>
> Assuming, however, that the Agency Act would apply to the entire project, the Report (while acknowledging that the SWRCB is not the body charged with interpreting the Agency Act) opines that the project would appear consistent with

the Agency Act and the Ordinance given that the project would return to the Basin any quantity of fresh water withdrawn from the Basin. The Report states:

> Based on the State Water Board's analysis, as reflected in the Report, the Project as proposed would return any incidentally extracted usable groundwater to the Basin. The only water that would be available for export is a new supply, or developed water. Accordingly, it does not appear that the Agency Act or the Ordinance operate to prohibit the Project. The State Water Board is not the agency responsible for interpreting the Agency Act or MRWCA's ordinances. It should be recognized, however, that to the extent the language of the Agency Act and ordinance permit, they should be interpreted consistent with policy of article X, section 2 of the California Constitution [declaring that the waters of the state shall be put to maximum beneficial use], including the physical solution doctrine . . .

Report at 40. Therefore, it appears at least preliminary reasonable to conclude that the project would be consistent with the Agency Act and the Ordinance such that those laws would not impair project feasibility.

HGC Comment No. 11:

First, the DEIR/EIS presents inconsistent and misleading language regarding the location of the well screens. As the DEIR/EIS preparers are aware, the project's slant well locations have moved significantly landward when compared to the originally proposed project intake location evaluated by the SWRCB (see Figure 4, SWRCB, 2013). The conceptual location and design of the original slant well seawater intake system array is shown in Diagram 6 – Original Test Slant Well Design Evaluated by SWRCB. Contrary to this original design, the proposed slant well designs and locations disclosed in the DEIR/EIS indicate a majority of the well screen sections are now located landward of the shoreline. In addition, only the deepest portions of the well screens would potentially be located beneath the ocean floor with the shallower well screen intervals producing from the Dune Sand Aquifer and located onshore (see DEIR/EIS, Chapter 3, Figures 3-3a and 3-3b, and Table 3-2). Thus, the project does not appear to comply with the MCWRA Agency Act (also see details on, Geoscience, 2015a, Figures 47, 48, and 51 to 69) as the DEIR/EIS suggests. The DEIR/EIS must be revised to address consistency with the Agency Act based on the percentage of the well screens for each test well that has screened intervals located landward of the beach mean high water line to assess consistency with the MCWRA Agency Act. It is also not clear if the SWRCB would have arrived at the same conclusions if it had been reviewing the presently proposed intake design.

Diagram 6 – Original Test Slant Well Design Evaluated by SWRCB

Second, it is unclear as to what is considered "usable groundwater." To be consistent with the RWQCB WQCP, all water under 3,000 mg/l TDS would need to be returned (RWQCB, 2011). See HGC Comment No. 21.

Finally, we note that the Agency Act further empowers the MCWRA to prevent extraction of groundwater from particular areas of the SVGB if needed to protect groundwater supplies. As discussed in these comments, the project will adversely impact groundwater supplies. Therefore, the DEIR/EIS must address compliance with this mandate also.

DEIR/EIS's discussion of the project's consistency with the Annexation Agreement is not supported by the evidence.

On **Page 2-42**, the DEIR/EIS states:

> Moreover, even if annexation of the CEMEX property to MCWD's benefit assessment zones were to take place in the future, triggering the 500 afy groundwater withdrawal limitation, it appears that operation of the MPWSP could still be feasible. CalAm could conceivably construct and employ an injection well on the CEMEX property to return 500 afy to that property such that the MPWSP would have a net-zero effect on groundwater from the CEMEX land and conceivably could operate regardless of whether the 500 afy groundwater withdrawal limitation were imposed at some point in the future.

HGC Comment No. 12:

There is no evidence to support the conclusion that returning 500 afy to the CEMEX property would ensure that no more than 500 afy groundwater was withdrawn from the project as limited by the Annexation Agreement. In fact, the evidence indicates substantially more groundwater would need to be injected to demonstrate consistency with the agreement.

Comments on DEIR/EIS Chapter 3 (Project Description).

DEIR/EIS's project description inaccurately suggests the TSW's groundwater impacts were fully evaluated by the California Coastal Commission:

The DEIR/EIS at **Page 3-2** states:

> To inform the final design of the subsurface slant wells and the MPWSP Desalination Plant treatment system, and to collect geologic and hydrogeologic data needed for Federal, state, regional, and local permits for the full-scale project, CalAm built a test slant well at the same location as the seawater intake system for the proposed Project. CalAm currently is operating the test slant well as a pilot program to collect data. Construction of the test slant well and operation of the pilot program was covered under separate environmental review. The test slant well is permitted to operate until February 2018 and it is not part of the proposed Project being evaluated in this EIR/EIS. If the MPWSP with subsurface slant wells at CEMEX is not approved and implemented, the test well would be removed. However, if the proposed subsurface slant wells at CEMEX are ultimately approved as part of the proposed Project, CalAm would convert the test slant well into a permanent well and operate it as part of the seawater intake system. The conversion and long-term operation of the well has not been covered under previous approvals and is evaluated in this EIR/EIS as part of the proposed project.

HGC Comment No. 13:

I have previously provided comments on the California Coastal Commission's analysis of the TSW in the *MCWD v. California Coastal Commission* litigation. Please refer to my comments addressing the inadequacies in the Coastal Commission environmental review of the TSW. I further note the project should return the groundwater that has been pumped to date by the TSW as mitigation for the project's cumulative impacts to groundwater.

DEIR/EIS's project description inaccurately suggests all slant wells would extend offshore:

On **Pages 3-15 through 17**, the DEIR/EIS states:

> The nine new permanent slant wells would be approximately 900 to 1,000 feet long and drilled at approximately 14 degrees below horizontal to extend offshore

> to a distance of 161 to 356 feet seaward of the MHW line (except #8, which would not extend past the MHW line) and to a depth of 190 to 210 feet beneath the seafloor. This means that although all construction activities and ground disturbance would occur above mean sea level and landward of the MHW line, the well casings would extend subsurface and seaward of the MHW line and below the seafloor within MBNMS. Each well would be screened for approximately 400 to 800 linear feet at depths corresponding to both the Dune Sand Aquifer and the underlying 180-Foot-Equivalent Aquifer of the Salinas Valley Groundwater Basin. CalAm would operate eight wells at a time at approximately 2,100 gallons per minute (gpm) per well and maintain the other two wells on standby.
>
> Table 3-2 presents the total length of each slant well extending seaward of the MHW line. Because the slant wells would be drilled at a 14-degree angle, the horizontal distance to which the wells would extend seaward of the MHW line would be slightly shorter than the length of the well casing. This is illustrated in Figure 3-3b, Illustrative Cross-Sectional View of Subsurface Slant Wells.
>
> The 10 slant wells would be located at six sites along the back of the dunes: four sites (the test slant well site and three new sites) would each have one slant well, and two sites would have three slant wells (see Figure 3-3a). The well sites are numbered sequentially, with Site 1 being the northernmost site and Site 6 the southernmost site. The test slant well would be converted into a permanent well at Site 1. The nine new permanent wells would be drilled over a total distance of about 900 feet at Sites 2 through 6. The wellheads of the three new permanent wells at Site 2 would be located about 300 feet south of Site 1. Sites 3, 4, and 5 would be spaced approximately 250 feet apart and would have one slant well each. Site 6 would have three wells.

HGC Comment No. 14:

Again, we note that as designed, most of the slant well screen sections are not below the ocean floor and "seaward of the Mean High Water (MHW) line." See HGC Comment No. 11. We further note that the drilling technology utilized by the project has physical limitations. To the extent the drag (friction) on the drill casing exceeds the ability of the drill rig or the strength of the drill casing material being used, the length of the wellbore could be shortened and the well screen production sections would be that much more short of being offshore. In fact, it is our understanding the TSW is significantly shorter than designed due to drilling problems. The DEIR/EIS has not disclosed these problems or described how they will be resolved for new slant wells. If the seawater intake facilities were actually located at a shallow depth and a sufficient distance offshore, the problems with SVGB groundwater production would be mitigated.

Comments on DEIR/EIS Chapter 4.4 (Groundwater Resources).

DEIR/EIS's analysis of groundwater impacts fails to consider or disclose best available information in evaluating potential impacts to the SVGB and the Marina Subarea:

On **Page 4.4-4**, the DEIR/EIS states:

> This chapter's description of the groundwater system underlying the project area reflects the scientific community's current understanding of the subsurface geologic units and the depth and extent of the aquifers and aquitards …This comprehensive description of the groundwater system was developed through the collaborative efforts of recognized experts in Monterey Bay coastal geology and groundwater, as well as stakeholders in the groundwater use and management process who are familiar with this region. This body of expertise is the Hydrogeology Working Group (HWG), with members that represent the Salinas Valley Water Coalition, the Monterey County Farm Bureau, California American Water Company (CalAm); the CPUC/MBNMS CEQA/NEPA team members attend the meetings.[1] To identify the area's hydrology, the HWG relied on previous groundwater studies, published geologic maps, observation of well performance, water quality data, and findings from site-specific subsurface investigations and modeling. The data review and eventual formulation of an evidence- and science-based understanding of the local and regional hydrogeology required several years. So, to enable analysis of the impacts of the proposed project, this EIR/EIS presents the best information available for describing the hydrogeologic setting of the study area.
>
> [1] The HWG developed a collaborative plan of investigation to assess the hydrogeologic conditions in the project area. The draft work plan provided a phased approach to progressively investigate the hydrogeology and the potential effects of the project on aquifers from the use of subsurface slant wells for obtaining feedwater supply. The final work plan incorporated comments and recommendations by members of the HWG, and covered the investigative steps needed to evaluate the project impacts (Geoscience, 2013c). The final work plan became the hydrogeology investigation roadmap and resulted in the implementation of the fieldwork and modeling efforts described in the approach to analysis, Section 4.4.3.2.

HGC Comment No. 15:

As discussed herein, there are major holes in the project data set, analysis, and modeling. Initially, the TSW was installed along with the project monitoring wells during an extended drought period. Therefore, the conclusions reached from evaluation of these data are limited to these dry climatic conditions and cannot represent wet or average water year conditions within the Salinas Valley that affect the Marina Subarea. Recently during the 2016-2017 water year, abundant rainfall has ended the drought conditions and for the first time in the project 1 ½-year-baseline data set that is presently being established, the shallow monitoring wells MW-6S, MW-8S, and MW-9S show the result of significant recharge from the river (see Diagram 2). This recharge resulted in water level elevations ranging from approximately 7.5 feet amsl in MW-8S

to 17.5 feet amsl in MW-6S. These observations show that the river recharges the Dune Sand Aquifer in the vicinity of the Marina Subarea. However, it is not clear if the high water levels were purely a result of excess river flows, or a result of inflation of the rubber dam located downstream of MW-6. This occurrence is not discussed in the DEIR/EIS, nor was it recognized or discussed in the TSW Long Term Monitoring Report No. 96 and HWG Monthly Monitoring Report No. 16 where it is plainly visible (see Geoscience, 2017, Figure 2-5). This additional recharge mechanism substantiates the inference that protective groundwater levels in the Marina Subarea are maintained under average climatic conditions and have prevented saltwater intrusion into the Dune Sand Aquifer. This condition has likely protected the 180-FTE Aquifer and preserved the freshwater condition observed in MW-5M and MW-6M. Without a data set from a sufficiently long baseline period, the analysis that forms the "evidence- and science-based understanding of the local and regional hydrogeology" is biased by the limited baseline period observed along with the conclusions that are derived from it.

Next, the field work plan discussed in footnote 1 developed by the HWG also included a monitoring well (MW-2) which was to be located away from the CEMEX site and parallel to the coastline. Because MW-2 was never drilled, data are not available to evaluate the shallow coastal conditions in the Dune Sand Aquifer at a location removed from the influence of the CEMEX operations. These plant operations routinely discharge seawater into the dune sands landward of the TSW. The saline water originates from the dredge pond operations and from up to 500 afy produced from the CEMEX wells that draw from the seawater intruded 400-Foot Aquifer. Without MW-2, the effect of the CEMEX discharges on the TSW water quality cannot be determined. This artificial saltwater influence is not evaluated and will not be present further south along the coast where the remaining intake wells will be located. See HGC Comment No. 33 and Diagram 7.

The difficulty with model calibration in the Dune Sand and 180-FTE Aquifers south of the river is believed to largely result from a lack of data that developed the understanding of the hydrogeology and the aquifers recharge mechanisms that were used by the United States Geological Survey (USGS) in the SVIGSM. When this was discovered, the DEIR/EIS modeling effort abandoned the poorly calibrated NMGWM and switched to the superposition model, which still used the same aquifer parameters. Any error that was in the poorly calibrated area of the NMGWM south of the Salinas River, was brought into the superposition model and subjected to a new set of model boundary conditions. As such, the use of the inferior superposition model approach cannot show cumulative effects. Also, because the model is not a dual density model, it cannot be used to show effects of the CEMEX operation on the water quality produced by the TSW and ultimately the water quality changes in the Marina Subarea aquifers.

In summary, the DEIR/EIS's statement that its evaluation of groundwater impacts is based on an evidence- and science-based understanding of the local and regional hydrogeology and the best information available for describing the hydrogeologic setting of the study area, in fact, is not supportable. Importantly, the DEIR/EIS does not discuss how the project will affect

protective groundwater levels necessary to abate seawater intrusion in the SVGB and subsequently affect future sustainable conditions as discussed above and further below.

DEIR/EIS's analysis of groundwater impacts misrepresents baseline conditions in the Dune Sand Aquifer:

On **Pages 4.4-6 through 4.4-8**, the DEIR/EIS states:

> The Older Dune Sand, referred to as the Dune Sand Aquifer, extends to 85 to 95 feet below the ground surface beneath the CEMEX site and is about 60 feet thick at the locations of the proposed slant wells. The shallow aquifer underlying the Moss Landing Area is referred to as the Perched A Aquifer and differs from the Dune Sand Aquifer in that it is underlain by a defined layer of less permeable, fine-grained sediments known as the Salinas Valley Aquitard. Water quality of the Perched A Aquifer and Dune Sand Aquifer is directly influenced and controlled by seawater. Because of the aquifer's proximity to the ocean, most of the water in the Dune Sand Aquifer has been intruded by seawater and is considered saline to brackish (Kennedy/Jenks, 2004). This influence decreases inland where the infiltration of precipitation and applied agricultural water has more of an influence. Figure 4.4-3 presents a west to east geologic cross section that illustrates the relationship of the aquifers and geologic units from the CEMEX area to east of Highway 1 and Del Monte Boulevard. The upper portions of the proposed slant wells at the CEMEX of the proposed slant wells at the CEMEX site would have well screens installed across them, and would draw water from these deposits.

HGC Comment No. 16:

Based on data provided by the TSW investigation, the DEIR/EIS's statement that "Dune Sand Aquifer is directly influenced and controlled by seawater" is inaccurate. More importantly, the DEIR/EIS fails to quantify the fresh water held in storage in the Dune Sand Aquifer between the Salinas River and Fort Ord. It also does not estimate the amount of recharge the aquifer receives annually and the direction of flow in the the Dune Sand Aquifer beneath the confining layer (-2-Foot Aquifer). Without this information, it is impossible for experts, much less the public, to understand the project's potential impacts.

In Table 4.4-1 on page 4.4-6, the DEIR/EIS states: "shallow groundwater is not expected within the elevated dune deposits, except in localized low-lying areas along the coastline." This conclusion fails to recognize the protective head that is provided by this layer of the Dune Sand Aquifer along the coastline and, therefore, further undermines the project's evaluation of potential impacts to the groundwater system. We further note that relying on broad statements about the occurrence of seawater intrusion from a 2004 study (KGC, 2004) that did not have the benefit of the data being generated by the TSW project is not scientifically supportable because it inappropriately ignores the data that has been developed for project analysis. The DEIR/EIS's conceptual description of seawater in the Dune Sand Aquifer, which is being inferred from "the

aquifers proximity to the ocean" is then offset by the statement that "this influence decreases inland where the infiltration of precipitation and applied agricultural water has more of an influence" does not remedy this problem. Without any attempt to quantify the fresh water held in storage in the Dune Sand Aquifer between the Salinas River and Fort Ord, neither experts nor the public can assess the project's potential impacts as noted above. Also, see Comment No. 3.

DEIR/EIS's analysis of groundwater impacts ignores available information demonstrating 180-Foot Aquifer is not unconfined rendering its analysis and modeling inadequate:

On **Page 4.4-11**, the DEIR/EIS states:

> At the CEMEX site, the Dune Sand Aquifer and the 180-FTE Aquifer are unconfined, as there are no extensive overlying low-permeability clay units.
>
> The Terrace Deposits of the 180-FTE Aquifer are composed of former alluvial fan and river floodplain deposits, possibly with some marine terrace deposits that contain sand, silt, and gravel now buried under the coastal dunes. There is groundwater within the Terrace Deposits, which extend to 240 to 255 feet below the ground surface beneath the CEMEX site, and are about 135 feet thick at the proposed slant well locations, thinning seaward. Based on the recent groundwater testing data discussed in the Groundwater Quality subsection below, the quality of water in the 180-FTE Aquifer is directly influenced by seawater; this influence extends for miles inland, as discussed below in the Seawater Intrusion section. The lower portion of the proposed slant wells at the CEMEX site would have well screens installed across and would draw water from these deposits.

HGC Comment No. 17:

Initially the DEIR's statements that Dune Sand Aquifer and the 180-FTE Aquifer are unconfined at the CEMEX site appear to conflict with the previous acknowledgement that the 180-FTE is semi-confined (Geoscience, 2015r, page 5), which indicate that the originally unconfined nature of the aquifer and its communication with the overlying Dune Sand Aquifer is overstated. This is not insignificant as the higher degree of confinement in the 180-FTE Aquifer will likely result in a greater radius of influence and more drawdown at further distances than the DEIR/EIS model presently predicts. Moreover, the presence of an aquitard layer just inland of the project area is documented by other studies including (Harding ESE, 2001, Plates 1 through 6, and Ahtna, 2015).

The DEIR's statement that recent groundwater testing shows the quality of water in the 180-FTE Aquifer is directly influenced by seawater is misleading. As discussed in Comment No. 3, data obtained from the TSW phase of work indicate that the blanket concept that all groundwater in the 180-FTE Aquifer is saline for miles inland is inaccurate. (See also Figures 1, 2, and 5).

DEIR/EIS's analysis of groundwater impacts inaccurately describes groundwater flow in the Dune Sand Aquifer:

On **Page 4.4-14**, the DEIR/EIS states:

> The MCWRA conducts a groundwater monitoring program throughout the Salinas Valley that for the fall 2013 monitoring event included 61 wells in the 180-Foot Aquifer and 103 wells in the 400-Foot Aquifer (Brown and Caldwell, 2015). Water-level data collected from wells in the study area indicate that the direction of groundwater flow is from the ocean to inland, as shown on Figures 4.4-5 and 4.4-6.
>
> In the Pressure and East Side Areas, groundwater flows northwest from the upper reaches of the SVGB until it reaches the city of Salinas, at which point groundwater in both the 180-Foot and 400-Foot Aquifers flows towards a groundwater depression north of the city (MCWRA, 2014b). Along the coast, flow in both the 180-Foot and 400-Foot Aquifers is towards the east, or landward, and has resulted in seawater intrusion. At the proposed slant well locations, the Dune Sand and 180-FTE Aquifers along the coast are hydraulically connected to the Pacific Ocean, as verified by the saline chemistry of the groundwater samples collected from borings drilled along the coast. The groundwater flow patterns within the Dune Sand Aquifer are not known but, based on the aquifer depth and geologic structure, it is reasonable to expect that they would be tidally controlled, with little to no net horizontal flow in any particular direction.
>
> There is a groundwater divide along the north side of the SGB separating groundwater flow paths between the SGB and the SVGB in both the shallow and deep aquifers, as illustrated on Figures 4.4-7 and 4.4-8. The SGB has been divided into four subareas, with the northern two composing the Northern Subbasin and the southern two composing the Southern Subbasin. The proposed ASR injection/extraction wells would be located near the northern border of the Northern Subbasin. There is a groundwater depression in both the shallow and deep aquifers in the Northern Subbasin, resulting in some landward flow along the coast (HydroMetrics, 2015).

HGC Comment No. 18:

The DEIR/EIS's description of the groundwater flow pattern in the Dune Sand Aquifer is inaccurate and based on available data (Harding ESE, 2001, Ahtna, 2015) it likely affects the ability to calibrate the model in the area south of the river. The conceptual complexity of the groundwater flow in the project area is shown in Diagrams 1 and 2 above. Most critically, without using available information and filling data gaps, the DEIR/EIS's description of baseline coastal aquifer flow conditions makes it impossible to quantitatively analyze the project's potential impacts on water quality. As explained in Comment No. 3, the project inland

monitoring wells discovered a significant amount of freshwater and brackish groundwater within the Marina Subarea of the project area of influence.

One such discovery was well MW-5S, which was constructed in the Dune Sand Aquifer that is perched on top of a regional clay layer. Adjacent the Salinas River at the Monterey Peninsula Landfill, this aquifer zone is designated as the 35-Foot Aquifer. This same Dune Sand Aquifer layer was also identified to the south in the Fort Ord cleanup site where it was designated as being perched/semi perched on top of the FO-SVA. Available groundwater elevation data from the Dune Sand Aquifer wells constructed for the TSW project were combined with data from the regional landfill, Fort Ord cleanup, and Beacon Gas Station cleanup sites to construct Figure 6 – Dune Sand Aquifer Groundwater Elevation Contour Map (attached to these comments). As shown, groundwater is flowing into the Marina Subarea on top of the FO-SVA layer from the area of aquifer recharge to the south. Data for the Dune Sand Aquifer used to construct this figure were obtained from readily available consultant reports and are shown in Figure 7 – Fort Ord Cleanup Site Groundwater Elevation Data, Figure 8 – Monterey Peninsula Landfill Groundwater Elevation Data, and Figure 9 – Beacon Gas Station Groundwater Elevation Data (attached to these comments). The most important aspect of these data is that perched groundwater is flowing toward the coast and infiltrating into the underlying -2-Foot Dune Sand Aquifer and the underlying semi-confined 180-FTE Aquifer. This source of recharge is unique to the Marina Subarea portion of the SVGB and is believed to contribute to protective groundwater conditions.

DEIR/EIS's investigation of the project area is inadequate to support the DEIR/EIS's groundwater impacts analysis:

On **Pages 4.4-21 and 22**, the DEIR/EIS states:

> CalAm commissioned a subsurface soil and groundwater investigation to further understand the existing subsurface geologic units, aquifers, and water quality of the proposed slant well locations on the CEMEX site. The investigation included the installation of nested monitoring wells and the test slant well, subsurface lithologic logging, soil and groundwater sample analysis, aquifer testing, and aquifer conditions modeling (Geoscience, 2013c, 2016a, 2016b). Figure 4.4-9 shows the locations of the nested monitoring wells. The nested wells have screen intervals to discretely sample the Dune Sand Aquifer, 180-FTE Aquifer, and the 400-Foot Aquifer depth intervals. The subsurface investigation provided information and data to better characterize the subsurface stratigraphy, aquifer conditions, how the aquifer responds to pumping, and groundwater chemistry at various depth intervals. Updated information on subsurface materials informed the design of the proposed slant wells, and data on groundwater flow characteristics and water chemistry facilitated further refinement of the groundwater models used to analyze project impacts.

> The proposed slant wells would draw water from the Dune Sand Aquifer and the 180-FTE Aquifer from about 30 feet below msl to 200 feet below mean sea level (Geosciences, 2016b). As discussed above in Section 4.2, the Dune Sand Aquifer overlies the 180-FTE Aquifer with no aquitard /between the units. The test slant well is screened across both units and has been sampled on a weekly basis when operational. Table 4.4-4 summarizes water quality results from the May 19, 2016, sampling event. The table also provides the chemical composition of seawater; as the comparison shows, the water quality from the test slant well closely resembles the average seawater TDS concentration found along the central coast of California.

HGC Comment No. 19:

We note that the boreholes referenced by this discussion are all close to the ocean and not representative of background data at inland locations that will be affected by the MPWSP. These data show only near shoreline conditions. As shown by the water composition in MW-4 (see Table 2, Diagram 5 above, and Figure 1 attached to these comments), the water quality begins to change significantly within a short distance of the coastline. Also, there is no discussion about the CEMEX operations that discharge saline water inland of the TSW which serves to create a saline mound of groundwater and bias the produced TSW water quality. See HGC Comment No. 33.

Because there is a lack of discussion of the groundwater quality in SVGB Pressure Area south of the Salinas River, the discussion of borehole data improperly implies water quality is the same throughout the project area of influence. It is reasonable to assume that the water quality at the CEMEX site would be worse than quality further inland where recharge from the Dune Sand Aquifer is likely occurring along with recharge from the Salinas River. The interconnectivity of the -2-Foot Aquifer beneath the Monterey County Landfill and the shallow Dune Sand Aquifer screened by MW-1, MW-3, MW-4, MW-7, and MW-8 is indicated by the study (Geoscience, 2016). This aquifer is also recognized as being recharged by the Salinas River in this area of the Marina Subarea (Geoscience, 2016). The recent water level rise in MW-6, MW-8, and MW-9 (Geoscience, 2017, Figures 2-5, 2-7, and 2-8) when winter rains resulted in significant river flows shows the likely hydraulic connectivity between the river and these wells and that this inland freshwater recharge keeps the saline groundwater close to the coast in the Dune Sand Aquifer (see Diagrams 1, 2, 5 above, and Figure 1 attached).

DEIR/EIS's groundwater impacts analysis baseline description of seawater intrusion in the SVGB, particular the Marina Subarea, is misleading and conflicts with available information:

On **Page 4.4-28 through 4.4-32**, the DEIR/EIS states:

> Figures 4.4-10 and 4.4-11 illustrate the seawater intrusion areas as of 2013 within the 180-Foot and 400-Foot Aquifers, respectively (MCWRA, 2015). Seawater intrusion occurs when ocean water enters fresh groundwater aquifers at the coast and migrates inland. The salty seawater combines with the fresh groundwater to

create a mixture referred to as brackish. Brackish groundwater can contain Total Dissolved Solids (TDS) concentrations ranging from that of seawater (about 35,000 mg/L) down to 500 mg/L near the leading edge of the inland seawater intrusion front. Brackish water in the 180-foot aquifer near the proposed project ranges from about 5,000 mg/L to 29,000 mg/L. The California Secondary Drinking Water Standard was amended in 2006 to include a Maximum Recommended Level for TDS in drinking water of 250 mg/L (Cal. Code Regs., tit. 22, § 64449). The MCWRA define the leading edge of inland seawater intrusion as groundwater containing TDS at 500mg/L or more.

The current, standard practice for monitoring the inland advance of seawater intrusion involves TDS analysis of groundwater from a select group of monitoring wells that intersect the seawater-intruded aquifers. The TDS concentration data are used to identify the areas of the aquifer intruded by seawater and to plot the leading edge of the inland seawater intrusion front. The more groundwater wells available in the monitoring program, the better regional seawater intrusion is represented. Regular annual monitoring data can be used to estimate the rate at which seawater is migrating inland. The MCWRA has been conducting seawater intrusion monitoring for many years using several groundwater wells in the western end of the Salinas Valley.

Geophysics are giving researchers the opportunity to study seawater intrusion using high-resolution, regional scale imaging. The technique, sometimes referred to as Electrical Resistivity Tomography (ERT), can be used to differentiate salty water from fresh water hundreds of feet beneath the ground. Electrical resistivity imaging uses a series of sensors placed along a transect line on the ground surface. An electrical current is applied and the sensors measure the electrical resistance the current encounters as it travels at depth between the sensors. Salty water has a lower resistance than freshwater, due to the higher TDS. The high and low resistivity zones in the subsurface are displayed as a series of colors in a cross section that indicate areas of fresh water, brackish water and seawater. Over the past few years, Stanford environmental geophysics researcher Rosemary Knight has conducted a study to determine the viability of using electrical resistivity techniques to study seawater intrusion along the coast of the Monterey Bay. Professor Knight's initial survey was conducted along a 4-mile segment parallel to the beach between the cities of Seaside and Marina. The study found that the electrical resistivity readings positively correlated with measured TDS concentrations to a depth of 500 feet in four area groundwater wells.

Salinas Valley Groundwater Basin

…. The 2013 estimates of seawater intrusion within the 180-Foot and 400-Foot Aquifers indicate that seawater has intruded to a maximum of approximately 8 miles and 3.5 miles inland, respectively, as inferred from chloride concentrations greater than 500 mg/L. The

seawater intrusion degraded groundwater supplies, requiring urban and agricultural supply wells within the affected area to be abandoned or destroyed (MCWRA, 2001). Increased degradation of coastal groundwater aquifers led to restrictions on drilling groundwater wells and extracting groundwater from areas affected by seawater intrusion, as discussed in Section 4.4.2, Regulatory Framework. Such restrictions are intended to reduce further inland migration of seawater and reduce the landward advance of the seawater/freshwater interface.

Seaside Groundwater Basin

Groundwater pumping from aquifers in the SGB has exceeded recharge and freshwater inflows that caused pumping depressions near the coast, as shown on the groundwater flow maps for both the shallow aquifer zone (see Figure 4.4-7) and the deep aquifer zone (see Figure 4.4-8) (HydroMetrics, 2015). In addition, seawater intrusion has occurred just north of the SGB in the adjacent 180/400 Foot Aquifer Subbasin of the SVGB, as discussed above. The boundary between these two basins is a groundwater divide that migrates in response to variations in natural recharge and pumping on either side of the divide. HydroMetrics noted increased chloride concentrations in two wells along the coast, although the concentrations have not yet exceeded drinking water standards. These conditions all suggest that the SGB could be vulnerable to seawater intrusion.

HGC Comment No. 20:

Data developed by the TSW project indicates the DEIR/EIS's baseline description is inaccurate. While effects of seawater intrusion are evident significant distances inland, the entire area between the seawater intrusion front defined by ongoing study (MCWRA, 2014) and the coastline where the MPWSP intake system is proposed is not all intruded by seawater. Since the cessation of pumping in restricted areas along the coast, the hydrologic balance in the groundwater system has changed. Additional field data must be obtained in the area directly affected by the project to define the pre-project baseline conditions that have developed over the last two decades (see attached Figures 1 and 2). As the DEIR/EIS recognizes, the more groundwater wells available in the monitoring program, the better regional seawater intrusion is represented. South of the Salinas River, the MCWRA program lacks sufficient monitoring wells within the Marina Subarea. Moreover, there is no monitoring or mapping for the Dune Sand Aquifer. The seawater intrusion section incorrectly states that "the MCWRA define the leading edge of inland **seawater intrusion as groundwater containing TDS at 500 mg/L or more**." [emphasis added] The MCWRA study tracks the concentration of chloride and defines seawater intrusion as groundwater containing 500 mg/l or more of chloride, not TDS. The discussion interjects a reference to the highest drinking water standard for TDS of 250 mg/l without mentioning that municipalities can serve a municipal drinking water supply that occasionally exceeds 1,000 mg/l TDS concentration. The discussion continues to indicate low TDS concentrations are used as the basis for seawater intrusion. This whole section is misleading and misinforms the public and the Commissioners.

This discussion is also in direct conflict with the groundwater quality objectives shown in Table 4.4-6 where the 180-Foot Aquifer objective is 1,500 mg/l TDS concentration. This does not indicate that the aquifer objective promotes a component of seawater intrusion as implied by the previous discussion.

DEIR/EIS's groundwater impacts analysis fails to address conflicts with the SWRCB's WQCP; MPWSP would likely violate WQCP's anti-degradation policy:

On **Page 4.4-35** , the DEIR/EIS states:

> The RWQCB has established water quality objectives for selected groundwater resources; these objectives serve as a basis for evaluating water quality management in the basin. Specific water quality objectives have been defined for the 180-Foot Aquifer and 400-Foot Aquifer for the SVGB, as listed in Table 4.4-6 below.

TABLE 4.4-6 - GROUNDWATER QUALITY OBJECTIVES

AQUIFER	TDS	CHLORIDE	SULFATE	BORON	SODIUM	NITRATE AS NITROGEN
180-FOOT	1,500	250	600	0.5	250	1
400-FOOT	400	50	100	0.2	50	1

NOTES: All concentration are in milligrams per liter (mg/L) SOURCE: RWQCB, 2011b.

> The Basin Plan would apply to the treated water to be injected into the proposed ASR injection/extraction wells because it could affect the quality and beneficial uses of the Basin's groundwater. Accordingly, these project elements would be subject to regular water quality monitoring by the RWQCB. This water quality monitoring would ensure that any deviation from the established objectives is identified and corrected pursuant to Basin Plan requirements.

HGC Comment No. 21:

The DEIR/EIS only addresses whether the project "operational discharges" of the MPWSP would be consistent with the provisions of the SWRCB Anti-Degradation Policy (Chapter 4.3) and the project's ASR injection wells. The DEIR/EIS must be revised to also address whether the extraction proposed by the project is consistent with the SWRCB's Anti-Degradation Policy. As discussed herein, it appears the project will violate the RWQCB WQCP objectives by degrading the water quality within the SVGB over a significant area. The model results indicate that areas of the Pressure Area that range from brackish to fresh will be degraded and will become hypersaline as a result of project pumping. Drawdown effectuated in the onshore portion of the aquifer system that is beyond the capture zone of the slant wells is a

cumulative effect that will contribute to a greater onshore gradient and proportionally increase the rate of seawater intrusion into those portions of the SVGB.

This section of the DEIR/EIS also fails to discuss the regulatory guidance in the 2011 WQCP for the Central Coast Basin where Resolution No. 88-63 is incorporated by reference and applies to the proposed project. The WQCP may be found at http://www.waterboards.ca.gov/rwqcb3/publications_forms/publications/basin_plan/docs/basin_plan_2011.pdf, and Resolution No. 88-63 is Appendix A-9 of the WQCP. Resolution No. 88-63 sets forth the following policy regarding surface and ground water within the project area and indicates that all surface and ground waters of the State are considered suitable, or potentially suitable, for municipal or domestic water supply with the exception of:

a. The TDS exceeds 3,000 mg/l (5,000 µmhos/cm, electrical conductivity);

b. Contamination exists, that cannot reasonably be treated for domestic use;

c. The source is not sufficient to supply an average sustained yield of 200 gallons per day;

This indicates that based upon Resolution No. 88-63, the feedwater, which includes "developed water" that is not suitable or potentially suitable for municipal or domestic water supply purposes, is water that exceeds 3,000 mg/l TDS, in order to be eligible as "developed water." The DEIR/EIS's focus on the groundwater quality objectives and failure to discuss this standard does not sufficiently inform the public or the decision makers of the potential impacts of producing groundwater for the project that is potentially suitable for municipal or domestic uses either through treatment or blending. This reference indicates that at least the 3,000 mg/l TDS concentration should be utilized in determining the production of usable groundwater from the SVGB and not the inland average of 440 mg/l. It should also be recognized that MW-5S, MW-5M, MW-6S, MW-6M, MW-7S, MW-8S all contain groundwater that meets the WQCP objective of 1,500 mg/l TDS concentration. See HGC Comment Nos. 1, 3, and 10 to understand the significance of this issue.

DEIR/EIS fails to address Sustainable Groundwater Management Act and the MPWSP likely conflicts with the Act:

On **Page 4.4-37**, the DEIR/EIS states:

> Adopted in 2014, the Sustainable Groundwater Management Act (SGMA) provides local agencies the capability to customize groundwater sustainability plans to their regional economic and environmental needs. SGMA creates a framework for sustainable, local groundwater management in California. The DWR and the SWRCB are the lead state agencies responsible for developing regulations and reporting requirements necessary to carry out SGMA. DWR sets basin prioritization, basin boundaries, and develops regulations for groundwater sustainability. The SWRCB is responsible for fee schedules, data reporting, probationary designations and interim sustainability plans (DWR, 2016a). The

State of California has designated the Salinas Valley as a priority basin and stakeholders have been working since 2015 to form a Groundwater Sustainability Agency for the Salinas Valley. The MPWMD applied to alter the boundaries of the Seaside/Corral de Tierra areas so they are similar to the adjudicated boundaries of the Seaside Basin. While the SGMA does not have a direct impact on the MPWSP, it is included here as it is new legislation affecting both the Salinas Valley Groundwater Basin and the boundaries of the adjudicated Seaside Basin. The proposed project would not adversely affect groundwater management in the Basin, because it would be extracting groundwater that is not presently being used as a potable or an irrigation supply. Rather, when considering seawater intrusion and water surface elevations in the 400-Foot Aquifer, the proposed project may have a positive contribution to the sustainable management of groundwater. Regarding the former, groundwater modeling shows that the proposed project would retard the advance and limit the ultimate inland extent of seawater intrusion. With respect to the latter, by returning in-lieu desalinated water to the CCSD, the proposed project would provide recharge benefits to groundwater levels in the 400-Foot Aquifer. For these reasons, the proposed project would not conflict with the SGMA.

HGC Comment No. 22:

The DEIR/EIS discussion of the MPWSP's consistency with the Sustainable Groundwater Management Act (SGMA), which became effective January 1, 2015, is grossly inadequate. The SGMA defines "basin" as either a subbasin or a basin. (Water Code, § 10721, subd. (b).) The California Department of Water Resources had previously classified the 180/400 Foot Aquifer Subbasin as a high-priority subbasin and in January 2016, the Subbasin was designated as a Critically Overdrafted Basin. (http://www.water.ca.gov/groundwater/sgm/pdfs/COD_BasinsTable.pdf) Both the MPWSP's slant wells and desalination plant are located within the 180/400 Foot Aquifer Subbasin.

Because of the Critically Overdrafted Basin classification, the 180/400 Foot Aquifer Subbasin is required to adopt a State-approved groundwater sustainability plan (GSP) or coordinated GSPs by January 31, 2020. The GSP must include measurable objectives and milestones in increments of five years to achieve sustainability within 20 years of the GSP adoption, which would be no later than January 31, 2040, in the case of the 180/400 Foot Aquifer Subbasin. Because of these existing conditions, it is false to state "the proposed project would not adversely affect groundwater management in the Basin, because it would be extracting groundwater that is not presently being used as a potable or an irrigation supply". Ultimately, the stakeholders forming the sustainable Groundwater Management Agency (GMA) will be responsible to deal with any adverse impacts that result from the project.

While the DEIR/EIS focuses on whether the MPWSP pumping will injure any legal user of the groundwater, it fails to address whether MPWSP pumping will further injure the overdrafted, seawater-intruded groundwater subbasin and prevent the subbasin from full

groundwater sustainability within the Marina Subarea. (Water Code, § 10727.2, subd. (b)(1)). Given the MCWD's and other concerted efforts to address seawater intrusion and over-pumping, the DEIR/EIS's failure to address this issue should be considered a serious flaw.

The Marina Subarea of the SVGB must be included in an adopted groundwater sustainability plan due to its designation as a priority subbasin. The Act requires "the existence and implementation of one or more groundwater sustainability plans that achieve sustainable groundwater management by identifying and causing implementation of measures targeted to ensure that the applicable basin [or subbasin] is operated within its sustainable yield." (Water Code, § 10721, subd. (t).) The sustainability goal must be achieved in the subbasin or basin within 20 years of the implementation of the groundwater sustainability plan. (Water Code, § 10727.2, subd. (b).) **"Sustainable yield"** is defined as **"the maximum quantity of water,** calculated over a base period representative of long-term conditions in the basin and including any temporary surplus, **that can be withdrawn annually from a groundwater supply without causing an undesirable result."** (Water Code, § 10721, subd. (v), emphasis added.) The DEIR/EIS does not address the MPWSP's potential impacts on sustainable yields in the Marina Subarea or the SVGB. Nor does it address reasonably foreseeable projects that must be proposed to bring the Marina Subarea of the SVGB into compliance with SGMA.

Instead, the DEIR/EIS assumes there is no benefit to the local development and use of the brackish or fresh quality groundwater contained within the coastal portion of the SVGB Pressure Area. It fails to consider the use of treatment or blending of this groundwater for future sustainable uses within the basin. The MPWSP as proposed, however, will remove freshwater and the brackish groundwater influenced by seawater and replace it with highly saline groundwater (pure seawater) by inducing seawater intrusion. The DEIR/EIS ignores the potential for local SVGB users to use the brackish groundwater supply as a beneficial use for sustainable basin management efforts and that seawater intrusion is identified as an undesirable result. It also fails to address how the MPWSP will impact potable water within the Marina Subarea as noted above and discussed below.

While the DEIR/EIS references the recent State of the Salinas River Groundwater Basin Report, dated January 16, 2015, from the Monterey County Water Resources Agency, the DEIR/EIS fails to discuss or heed its recommendation. The Report notes that based on the continued large storage declines in the East Side and Pressure Areas (and resulting groundwater head declines and seawater intrusion), the current distribution of groundwater extractions is not sustainable. Seawater intrusion can account for up to 18,000 afy of the total storage loss of 24,000 afy. Sustainable use of groundwater will only be achieved by aggressive and cooperative water resources planning to mitigate seawater intrusion and groundwater head declines. As the Salinas River Groundwater Basin Report concluded:

> The consequences of no-action under continued drought conditions will be the imminent advancement of seawater intrusion within the next few years and the continued decline of groundwater head. Both of these conditions would necessitate the drilling of deeper groundwater wells to produce the quantity and

> quality of water needed for consumptive use and irrigation. The installation of deeper wells may not be feasible in some areas because of lower groundwater yield and water quality in the Pressure Deep Aquifer. A more sustainable and long term management practice would encourage a Basin-wide redistribution and reduction of groundwater pumping, which would require cooperative and aggressive resource management. The unsustainability of the current distribution of groundwater extractions has long been recognized by various investigators, and Basin- wide redistribution and reduction of pumping have been recommended previously (e.g. DWR, 1946).

(Report at p. ES-12; see also p. 6-3.) Based on this conclusion, the Salinas River Groundwater Basin Report provided several options for reducing storage losses in the SVGB. One option was to reduce pumping in the Pressure and East Side to assist in mitigating some of the anticipated effects of the extended drought on groundwater storage and water quality. **The report noted that shifting of pumping to areas further away from the coast would also be helpful,** as long as it is shifted south of the current head trough in the East Side Subarea. **A second alternative was shifting of some pumping from the P-180 and P-400 Aquifers to the Pressure Deep Aquifer to reduce the storage deficit in the shallower aquifers.** The MPWSP's proposed slant wells are inconsistent with the Report's recommendations for addressing continued declining aquifer heads, water storage losses, and seawater intrusion in the Basin. The slant wells represent a significant increase in pumping from the Dune Sand Aquifer and 180-foot Aquifers in the Marina Subarea over existing conditions and will reverse the cumulative efforts of MCWD and others to shift production to other aquifer zones and reduce pumping in the 180-foot aquifer in order to reduce seawater intrusion. The DEIR/EIS also does not consider cumulative impacts on future plans to expand these groundwater management efforts.

Notably, the DEIR/EIS, also fails to discuss historical studies that have indicated there are 2 locations at the shoreline where seawater inflow preferentially follows the paths of greatest hydraulic conductance (least impedance to flow) when onshore gradients induce landward flow of groundwater (KJC, 2004, Page ES-15, Figure 3). The main pathway identified is located north of the Salinas River where the greatest amount of seawater has intruded into the heavily used portion of the Pressure Area. The second preferential pathway for flow is located south of Marina and allows seawater to flow into the aquifers beneath the Fort Ord Area. This area is south of the boundary defined as the Pressure Area by some studies, but within the Pressure Area defined by other studies. The CEMEX site lies midway between these 2 areas of preferential seawater intrusion and does not directly intercept either of these main areas of onshore flow. The potential impact of this condition, or the relocation of the project further north or south to better benefit the coastal conditions is not discussed in the DEIR/EIS.

As previously discussed, the project will contribute to the present overdraft of the SVGB and effectively induce the SGMA identified undesirable result of seawater intrusion. While the DEIR/EIS indicates the project would not conflict with the SGMA, the study does not mention groundwater dependent ecosystems and the potential undesirable result that may occur within the

coastal dunes when water levels are lowered to levels below the root zones of groundwater dependent plants. The study also does not address how the replacement of a floating freshwater lens along the shoreline with seawater could potentially impact salt sensitive plants within the area of project influence.

In summary, the DEIR/EIS provides insufficient discussion of the effect and application of the most notable development in California water law in the past century, the enactment of the SGMA and the proposed slant wells are inconsistent with the Salinas River Groundwater Basin Report recommendations to shift pumping away from the coast and into deeper aquifers.

The DEIR/EIS's discussion of the project's consistency with MCWRA Agency Act and MCWRA Ordinance 3709 is misleading and inaccurate.

On **Page 4.4-38**, the DEIR/EIS states:

> As discussed more fully in Section 2.7, Water Rights, given the locations of the slant well screens beyond the jurisdictional boundaries of the County, it is not clear whether the Agency Act applies to the proposed project. However, as further discussed in that section, were the Agency Act to apply, it is preliminarily reasonable to conclude that the proposed project would be consistent. This is because the proposed project would return to the SVGB any incidentally extracted useable groundwater. The water available for export would be new supply, or developed water, not extracted from the SVGB.
>
> MCWRA Ordinance 3709 prohibits drilling into and pumping groundwater from the 180-Foot Aquifer within specific onshore areas, designated as Territories A and B (MCWRA, 1993). The proposed seawater intake system would be located at the westernmost edge of Territory B. Although the wells would be drilled within Territory B, the source water for the proposed project would be extracted from beneath the ocean floor, an area not located within the restrictive territories identified by Ordinance 3709. As with the Agency Act, it is not clear that the MCWRA Ordinance 3709 applies to the proposed project. However, for the same reasons presented above, if it were to apply, it is preliminarily reasonable to conclude that the proposed project would be consistent. This issue is discussed further in Section 2.7, Water Rights.

HGC Comment No. 23:

As noted above, the DEIR/EIS's statement that the locations of the slant well screens are "beyond the jurisdictional boundaries of the County" is inconsistent with the DEIR/EIS's project description. As addressed above in HGC Comment No. 12, only the deepest portions of the well screens would potentially be located at a depth of a couple hundred feet beneath the ocean floor with the shallower well screen intervals producing from the Dune Sand and 180-FTE Aquifers and located onshore and within the jurisdictional boundaries of the County. (see DEIR/EIS,

Chapter 3, Figures 3-3a and 3-3b, and Table 3-2). The DEIR/EIS must be revised to address the percentage of the well screens for each test well that has screened intervals located landward of the beach to assess consistency with the MCWRA Agency Act.

Second, it is unclear as to what is considered "any incidentally extracted useable groundwater." As noted above, to be consistent with the RWQCB WQCP all water with TDS levels under 3,000 mg/l would need to be returned (RWQCB, 2011). See also HGC Comment No. 3, explaining that the MPWSP slant wells will likely extract significant amounts of groundwater from the Marina Subarea because the area is not completely filled with seawater.

As discussed above, many of the MPWSP's proposed slant wells will not actually extend beneath the ocean floor and a large section of the well screens that produce groundwater is onshore within the restrictive territory identified by Ordinance 3709. The well designs shown in the DEIR/EIS indicate the onshore sections of the well screens that will contribute groundwater to the slant well facilities and are not "beneath the ocean floor." The DEIR/EIS does not demonstrate through use of a territorial boundary map that the slant well configurations and designs are located outside Territory B and comply with the ordinance.

While the DEIR discusses the Agency Act and recognizes the provisions in Ordinance 3709, it has not demonstrated that operation of the proposed MPWSP well facilities as designed will not violate both regulations.

The DEIR/EIS's modeling relies on the Geosciences 2016 CEMEX Model Update, which makes a number of unsupported assumptions based on the lack of available data.

On **Page 4.4-42 and 4.4-43**, the DEIR/EIS states:

> CalAm installed the test slant well to further evaluate subsurface conditions and to test the response of the Dune Sand Aquifer, the 180-FTE Aquifer, and the 400-Foot Aquifer to pumping. The results have been used to refine the groundwater models and inform the analysis of the proposed project. The first phase of the test slant well investigation began with the construction of a 724-foot long test well drilled at an angle of 19 degrees below horizontal at the CEMEX site. Special Condition 11 of the Coastal Development Permit, "Protection of Nearby Wells," requires the MPWSP HWG to establish baseline water and TDS levels prior to commencing the long term pumping tests (Geoscience 2015b). The long-term pumping test began in mid-April 2015, and results are available at http://www.watersupplyproject.org/#!test-well/c1f1l.
>
> **Monitoring Wells Installation and Testing**
>
> To monitor the response of the aquifers to pumping from the test slant well and verify that the aquifers would respond as simulated by the groundwater modeling discussed below, CalAm installed a network of monitoring well clusters at the locations shown on Figure 4.4-9, along with a water level data logger in the pond that CEMEX uses to dredge sand (Geoscience, 2016b). The details of the

subsurface exploration including boring logs, well construction details, field screening tests results, and laboratory analytical results are presented in a report titled: Monterey Peninsula Water Supply Project, Hydrogeologic Investigation, Technical Memorandum (TM2) Monitoring Well Completion Report and CEMEX Model Update (Geosciences, 2016b). The Hydrogeological Working Group peer reviewed TM2 before the final document was released; that document is also discussed in Section 4.2, Geology, Soils, and Seismicity. Four of the monitoring well clusters are located west to east along the CEMEX access road, from near the proposed slant wells to near the CEMEX facility entrance. Monitoring well clusters were also installed at the proposed desalination plant site on Charles Benson Road, at the intersection of Lapis Road and Del Monte Road, and along West Blanco Road about 4 miles southeast of the CEMEX site. The clusters monitor water levels and chemistry in the Dune Sand, 180-FTE, and 400-Foot Aquifers. Groundwater elevation and water quality data developed from monitoring the cluster wells are presented in the impact analysis, below.

HGC Comment No. 24:

First, my comments and testimony in the *MCWD v. Coastal Commission* case addressed Technical Memorandum No. 1 that did not establish baseline conditions at MW-4 or any of the other required monitoring wells. Rather, the memorandum included a cursory discussion of water levels at some of the monitoring wells over a period of weeks (or a couple months depending on the date of their construction) and then provides a Section 7.0 entitled "Recommended Monitoring of Baseline and TDS Levels," which suggests a method for evaluating impacts without actually establishing baseline water levels. (See Geoscience 2015p, Technical Memorandum, p. 14.) There was no information regarding tidal, seasonal, or climatic variations in the memorandum. In fact, it was even unclear what was being considered as pre-pumping conditions.

With its predecessor (TM1), TM2 (Geoscience, 2016) provides information on all the wells constructed to date, and attempts to summarize baseline conditions, the TSW and monitoring wells were installed during a drought. The single season groundwater contour maps for the fall of 2015 inadequately show the coastal conditions in the Marina Subarea of the SVGB. Notable, until the spring of 2017, the river and its reservoir system have been stressed by reduced rainfall. Showing seasonal low water levels during an extended dry period does not sufficiently portray the dynamic system that has largely been undocumented. For instance, the entire record of MW-6S shows a relatively constant level for the A Aquifer with the seasonal variation of approximately 1 to 1.5 feet between April 2015 and December 2016. With the end of the drought, we see an entirely new dynamic. The water level in the fall of 2015 was 7.8 feet (see TM2, Figure 10) and only changed when storm flows resumed in the river. As winter rains filled reservoirs and caused tributary runoff, the Salinas River flows began to show a huge source of recharge to the A Aquifer zone. MW-6S rose from its steady trend approximately 10 feet resulting in shallow groundwater levels of over 17 feet amsl. The TSW project may be

developing baseline data, but this source of recharge to the shallow A Aquifer, -2-Foot Aquifer, and Dune Sand Aquifer was not apparent in previous data. The 2015 fall season water level in MW-7S used for contouring was 3.9 feet amsl. The level was observed to rise to about 6 feet amsl after the winter rains of 2015, and it remained above 5.5 feet amsl throughout 2016. These are all protective water levels for the Dune Sand Aquifer. But now the coastal water levels are at approximately 8 feet amsl and rising. This protective head condition could only be speculated, prior to this year's observations and was based on the fresh water quality present in the aquifer instead of seawater. There were no baseline data available in this central area of the Marina Subarea prior to TSW project monitoring.

Furthermore, as actual field data are being developed, the adequacy of the originally proposed work plan for field investigations must be reviewed and revised. Recent findings indicate that Monitoring Well No. 2 should provide valuable information for understanding the changes in the hydrogeology that occur south of the CEMEX site where the intake wells are proposed and project impacts would occur. This monitoring well has not yet been constructed. Recent information indicates that the complexities of the hydrogeology in the Marina Subarea are not well understood and should be further investigated to fully define the potential MPWSP impacts.

The degree of uncertainty in the DEIR/EIS's groundwater modeling is intolerable due to its failure to utilize the best available information:

On **Pages 4.4-43 through 4.4-51,** the DEIR/EIS describes the investigation of groundwater conditions and modeling, and provides the following assessment of the "Limitations of Groundwater Models" at Page **4.4-44:**

> Groundwater models simulate aquifer conditions based on a specific set of data that describes parameters such the subsurface characteristics, groundwater flow, and land use. The more robust the data set, the more capable the model will be to accurately simulate subsurface conditions. Most groundwater models use conservative input parameters so that the output overstates the actual aquifer response. Nevertheless, groundwater models are mathematical-based computer programs that rely on input parameters and, consequently, there is a degree of uncertainty. However, the models used to analyze the proposed project have been used previously and have benefited from input data derived from site-specific subsurface information. Given that, and given the fact that these models were calibrated with known data, the level of degree of uncertainty for this analysis is considered tolerable.

On Page **4.4-47**, however, the DEIR/EIS further reveals it did not use the prior models:

> For this project, the NMGWM is converted to a superposition model and only solves for the groundwater changes due solely to the proposed project. These changes are independent of the effects from the other stresses on the basin such as

seasonal climate and agricultural pumping trends, other pumping wells, injection wells, land use, or contributions from rivers. By using superposition, the actual effects of only the proposed project can be isolated from the combined effects of all other basin activity. For example, when the NMGWM reports a 1-foot drawdown in a well, it is understood that the one foot of drawdown would be the effect on the basin of the proposed project only. That well may experience greater drawdown due to other stresses, such as drought or other nearby pumping wells, or may experience increases in water levels due to reduced regional pumping or an extremely wet year. But the proposed project's contribution to that drawdown in the well would remain only 1-foot. Superposition is described in Appendix E2, Section 5.2.

Then on Page **4.4-49**, however, the DEIR/EIS further reveals it did not determine return water that would be required or address cumulative impacts (other than sea level rise):

Return Water Considerations

The MPWSP proposes to return a certain fraction of water (referred to here as return water) extracted by the slant wells to water users in SVGB as desalinated product water … The exact quantity of water to be returned annually would vary and would be determined each year using a mathematical formula. However, for groundwater modeling and impact analysis purposes in this EIR/EIS, it is estimated that somewhere between 0 and 12 percent of the source water withdrawn for the project would comprise water originating from the inland aquifers, and thus would be returned to the basin. The water would be returned to the SVGB through deliveries of up to 800 afy of desalinated product water to the Castroville Community Services District (CCSD). This water would be piped to the CCSD and the CSIP and provided to water customers instead of their pumping an equal amount from the ground. This method of returning water is referred to as in-lieu recharge because the delivered water would reduce the need to pump groundwater in corresponding quantities. The NMGWM accounts for the 0 to 12 percent range by simulating the aquifer response in the various scenarios with a 0, 3, 6, and 12 percent returned product water.

Model Period

The model period for the NMGWM is 63 years. The model scenarios are run over a set time period, beginning with the baseline conditions and extending out to a future point in time, typically set as the life span of a given project. Over this time period, land use, climate conditions, and, if located along the coast, sea level rise would be expected to change. ***However, as discussed above, superposition modeling does not account for other stresses on the basin except for the effects***

on groundwater flow from projected sea level rise over the 63 years of modeled operations. (emphasis added)

HGC Comment No. 25:

As discussed in HGC Comment No. 5, the level of degree of uncertainty in the DEIR/EIS's modeling is intolerable given its failure to utilize the best available information.

As previously discussed, ***the recalibrated NMGWM^{2016} was not successful*** at providing shallow groundwater responses to project pumping and in fact may be less representative of real world conditions than the predecessor model NMGWM^{2015}. The CEMEX model is too small to be used to project aquifer parameters across the NMGWM domain. The SVIGSM is inappropriately constructed in the project area and did not include boundary recharge into the Dune Sand Aquifer or the existence of the FO-SVA and cannot be used to feed realistic input into the NMGWM^{2016}. The unsuccessful calibration attempts prevented using data developed from the site specific study unless a new model was constructed. ***Instead and because of these failings, the effort to use a calibrated model was aborted and the superposition model was constructed.*** The superposition, however, uses the hydraulic conductivity values for aquifers in the Marina Subarea from the ***recalibrated NMGWM^{2016}***, which did not predict water levels within an acceptable error range, and therefore its results are similarly unreliable, if not worse. Moreover, while the superposition model can simulate drawdowns, it can't be used to evaluate the project's impacts on water quality or the project's potential cumulative impacts. It is also incapable of showing the water budget (from different sources) and boundary conditions dictate results by limiting drawdown effects. As a result, it cannot be used to estimate the amount of return water or evaluate whether the project is performing as expected in the future. Finally, the DEIR's reliance on the modeling to date to evaluate the project's potential impacts on groundwater in the Marina Subarea is not tolerable based on the DEIR/EIS's own evaluation criteria.

DEIR/EIS's analysis of potential impacts to the Salinas Valley Groundwater Basin is based on an inadequate investigation of baseline conditions in the Marina Subarea and fatally flawed modeling that does not utilize the best available information:

On **Page 4.4-57,** the DEIR/EIS provides the following threshold of significance for Impact 4.4-3:

> Deplete groundwater supplies or interfere substantially with groundwater recharge such that there would be a net deficit in aquifer volume or a lowering of the local groundwater table level during operations. (Less than Significant)

HGC Comment No. 26:

Given the DEIR/EIS's inadequate investigation of baseline conditions in the Marina Subarea and flaws in its modeling, there is no way for the public or Commission to make an informed decision on the project's potential groundwater impacts for the reasons discussed in HGC Comment Nos. 5 and 25 above and further below. We note that the threshold includes "interfering substantially with groundwater recharge," which would include the interception of

recharge before it reaches its area of replenishment and/or beneficial use. Notable, groundwater recharge can serve many purposes including replenishing groundwater being removed, diluting groundwater as it is flowing through an area, and/or maintaining a sufficient head to prevent the movement of poor quality water in an undesirable direction. As discussed above, the superposition groundwater model constructed and utilized to assess impacts in the DEIR/EIS is incapable of predicting the impact of the project on any of these groundwater recharge benefits. As a result, the DEIR/EIS's less than significant determination is speculation at best.

The DEIR/EIS's analysis of potential impacts to the Salinas Valley Groundwater Basin groundwater supply is based on an inadequate investigation of baseline conditions in the Marina Subarea and fatally flawed modeling that does not utilize the best available information:

On **Page 4.4-57,** the DEIR/EIS states:

> The first step in this analysis was to determine the pumping scenario that would have the most profound aquifer response surrounding the slant wells at the CEMEX site in order to conservatively judge potential impacts. Extracting groundwater from slant wells at the CEMEX site could cause an aquifer response up to 4 miles inland. Figure 4.4-13 shows the cone of depression with -1, -5, -10, and -20-foot drawdown contours and the extent of pumping influence in the 180-FTE Aquifer; these drawdowns would stabilize within five years after pumping begins, and would remain stable as long as the MPWSP is pumping. For purposes of this impact analysis, this model scenario assumes that no water would be returned to the SVGB and the sea level would be consistent with current levels. This scenario generates the most pronounced cone of depression with the largest area of influence because groundwater would not be returned to the basin, and because current sea level would not increase groundwater levels and gradients at the coast as it is expected to do in the next 63-years. This scenario is used to represent the maximum area of pumping influence. In other words, Figure 4.4-13 depicts the improbable worst case aquifer response from the proposed project.

HGC Comment No. 27:

The DEIR/EIS representation that Figure 4.4-13 depicts the improbable worst case aquifer response from the proposed project is simplistic and the discussion should actually clarify it is the worst case that the superposition model can simulate. This error is significant and results in the DEIR/EIS failing to evaluate potential impacts on future inland water quality degradation, on depletion of storage, on Groundwater-Dependent Ecosystems, and the project's consistency with the requirements under the SGMA.

The DEIR/EIS's analysis of potential impacts to the Salinas Valley Groundwater Basin groundwater supply is based on an inadequate investigation of baseline conditions in the Marina Subarea and fatally flawed modeling that does not utilize the best available information:

On **Page 4.4-57 through 4.4-59,** the DEIR/EIS states:

> The second step in this analysis was to use the drawdown contour map on Figure 4.4-13 to determine the area of influence and maximum drawdown caused by the slant well pumping. As shown by modeling results depicted on Figure 4.4-13 the center of the cone of depression and thus, the capture zone for the slant wells show that the majority of the groundwater drawn into the proposed MPWSP slant wells would originate in the aquifer zones located at and offshore of the coast and would be composed primarily of seawater. This is illustrated by the configuration of the cone of depression shown in Figure 4.4-13. The western extent of the cone of depression is just offshore and in close proximity to the slant wells where the drawdown is deepest and contours are steeper, indicating more flow to the slant wells and higher yield near the coast. At the coast, seawater entering the slant wells would have the shortest and least restricted pathway through the overlying sea floor deposits. The drawdown contours extend inland but at considerably shallower gradients, between -1 and -5 feet, indicating that the inland basin is less permeable, and that groundwater must flow through thicker sediments to reach the slant wells. This additional resistance to flow reduces the volume of water available to the slant wells and flattens the gradient. The cone of depression shown on Figure 4.4-13 illustrates that the majority of the water pumped at the slant wells would originate at the coast and just offshore, where the drawdown is most pronounced while a smaller volume of groundwater would be extracted from the inland portion of the 180-Foot Aquifer.

HGC Comment No. 28:

While the superposition model results can illustrate the concept of groundwater flow direction, it cannot quantify the amount of seawater or fresh groundwater that will be produced. The discussion about the apparent resistance to flow from the landward side of the project and that the inland basin is less permeable is merely an observation of the lower hydraulic conductivity values assigned in the model domain inland of the CEMEX site. As discussed above, hydraulic conductivity values assigned in the superposition model are based on the ***recalibrated NMGWM^{2016}*** model and therefore are not reliable.

DEIR/EIS's analysis of potential impacts to the Salinas Valley Groundwater Basin groundwater supplies is based on an inadequate investigation of baseline conditions in the Marina Subarea and fatally flawed modeling that does not utilize the best available information:

On **Page 4.4-59,** the DEIR/EIS states:

> The third step in this analysis was to assess the quality and current use of the groundwater that would be extracted by the slant wells. The MPWSP slant wells would not extract potable groundwater. The groundwater in the 180-foot Aquifer that is underlying the area influenced by the MPWSP pumping, up to about 4 miles inland, has been intruded with seawater for decades, and far exceeds the State Drinking Water Standard of 500 mg/L of total dissolved solids (TDS).23 The inland groundwater has been degraded by legacy and ongoing seawater intrusion and is not being produced for beneficial potable uses. Figure 4.4-10, above, shows the areas of groundwater in the 180-Foot Aquifer degraded by seawater intrusion over time. The CEMEX site and the area of influence from slant well pumping in the 180-FTE are well within the area degraded by historical sea water intrusion.
>
> Recent testing for TDS in groundwater within the area of influence of the proposed MPWSP slant well pumping verifies the degree of seawater intrusion. Water samples from Monitoring Well MW7M (180-FTE Aquifer) and MW-7D (400-Foot Aquifer), located just over a mile southeast from the proposed slant well location, contained TDS concentrations at 3,832 mg/L and 26,700 mg/L, respectively. Samples from Monitoring Well MW-8M and MW8D, located 1.5 miles to the northeast, had TDS concentrations of 24,000 mg/L and 583 mg/L, respectively. Monitoring Well MW-9S (Dune Sand Aquifer) and MW-9M (180-FTE Aquifer), located 2 miles to the northeast, had TDS concentrations of 3,204 mg/L and 29,000 mg/L, respectively. These data show that groundwater within the inland area of influence of the proposed MWSP slant wells is brackish with elevated TDS attributable to seawater intrusion; the groundwater in the Dune Sand, 180-FTE and 400-foot Aquifer is therefore unsuitable for potable supply.
>
> Current groundwater production in the Dune Sand Aquifer, the 180-FTE Aquifer, and the 400-Foot Aquifer, which are projected to exhibit a response to MPWSP slant well pumping, is limited to minor irrigation and dust control. There are no water supply wells pumping potable water. Most of the wells in this area are no longer active because of seawater intrusion. Furthermore, groundwater production is restricted within the seawater intruded coastal areas in the vicinity of the CEMEX site through MCWRA Ordinance 3709, which prohibits drilling wells and pumping groundwater from the 180-FTE Aquifer in order to protect groundwater resources. The slant wells at CEMEX and the area of pumping

influence east of CEMEX are within the jurisdictional boundary of Ordinance 3709.

HGC Comment No. 29:

First, while the statement that "the MPWSP slant wells would not extract potable groundwater" may be accurate, it is also misleading. While it is true that once the freshwater produced from the inland side of the intake wells is mixed with ocean water, it will no longer be "potable," the statement is misleading to the lay reader because it incorrectly suggests/implies that no potable groundwater would be drawn into the slant wells. Therefore, the DEIR/EIS should clarify this statement and recognize that the project's slant wells would extract both seawater and freshwater and/or brackish groundwater suitable for beneficial uses.

Second, the DEIR/EIS only discusses the groundwater that would be extracted from 180-FTE Aquifer and provides a broad sweeping statement that 180-FTE Aquifer: a) is seawater up to about 4 miles inland, b) has been intruded for decades, and c) far exceeds the State Drinking Water Standard of 500 mg/L Critically, the DEIR/EIS fails to address the Dune Sand Aquifer implying there is no beneficial uses for the water that the aquifer contains. As explained in HGC Comment No. 3, the water quality data developed by the project show fresh water within 2 miles of the coast in the 180-FTE and 400 Foot Aquifers (see Diagram 5 above). The Dune Sand Aquifer contains fresh water within 1 mile of the coast and is believed to be contributing to protective conditions in the underlying 180-FTE Aquifer through recharge along the coast (see attached Figures 1 and 4).

The statements regarding seawater intrusion into the 180-FTE Aquifer are only partially correct and thus misleading. The DEIR/EIS's statement that the 180-FTE Aquifer groundwater has been degraded (a relative term) by legacy and ongoing seawater intrusion is accurate, but the suggestions that it is completely intruded to about 4 miles inland is false. As previously explained, the TSW findings show that inland of the project location this aquifer has fresh water at MW-5 and MW-6 (see attached Figures 1 and 2).

The DEIR/EIS's claim that recent testing for TDS in groundwater within the area of influence of the proposed MPWSP slant well pumping verifies the degree of seawater intrusion but it shows significant amounts of brackish and fresh groundwater in areas where the aquifers where inferred to be completely filled with seawater (see attached Figures 4 and 5).

Finally, using the DEIR/EIS's statement that characterizes the groundwater in the 180-FTE Aquifer as far exceeding the State Drinking Water Standard of 500 mg/L, the DEIR/EIS improperly limits its analysis to whether the project will directly impact "potable" uses. The DEIR/EIS fails to address whether the project will have a direct, indirect, or cumulative impacts on all types of beneficial uses of groundwater in Marina Subarea aquifers. The DEIR/EIS is careful not to say "**all uses,**" it merely concludes that "groundwater in the Dune Sand, 180-FTE and 400-foot Aquifer is therefore unsuitable for potable supply", which again is extremely misleading. This approach implies that if groundwater is not suitable to meet the highest drinking water standards without blending or treatment, it has no beneficial use. This is

distracting from the reason why decades of seawater intrusion (which is not a linear process) has not rendered the entire coastal area completely full of salt water and how recent management efforts have abated intrusion to its current position and slowed its rate of advancement.

Coastal farming has been impacted by saltwater intrusion for over 70 years and yet it continues to produce groundwater inland. Initially, dilution of minor seawater incursions with freshwater sources onshore could make the salinity of the groundwater supply tolerable. Dilution of legacy saline water along the coast and further inland is visible from both water quality measurements taken by the TSW program and by the lack of advancement of the 500 mg/l chloride front observed between 2011 and 2013. While greater management efforts are planned to further reduce pumping along the coastal portion of the SVGB, natural and artificial replenishment of freshwater to the coastal portion of the basin serves to dilute and make the originally unsuitable quality of groundwater acceptable for beneficial uses decades later and miles inland.

At the time of the TSW investigation, the groundwater within a half mile of the coast shows significant dilution in certain areas of certain aquifer zones (see Diagram 5 above) and within a mile of the coast, fresh water is present that could be used for irrigation of several types of crops and for potable consumption (with nitrate removal). The key issues are really that the TSW project findings are helping to develop our understanding of the natural groundwater recharge and flow conditions in the Marina Subarea and that management strategies are beginning to manifest visible beneficial results.

A better understanding of the present condition would be that the effects of seawater intrusion since 1944 extends significant distances inland, but the extent of intrusion varies along the coast (particularly in the Marina Subarea) and accurate maps of this intrusion do not currently exist. Notably, as shown by the TSW project data (Geoscience, 2015p, Table 2), and contrary to the implication of statements elsewhere in the DEIR/EIS, seawater does not occupy the 180-Foot/180 FTE Aquifer or the 400-Foot Aquifer between the CEMEX site and 8 miles inland or 3.5 miles inland, respectively (See HGC Comment No. 4, Table 2, Diagram 4 above, and Figures 1 through 5 attached to this letter). These statements and similar statements throughout the DEIR/EIS must be revised so the public and decision makers are not led to believe all the groundwater in the Marina Subarea is contaminated by seawater and that all management efforts have failed.

Furthermore, the concept that wells that are located within the radius of influence and screened in the 180-Foot and 400-Foot Aquifers have been brackish-to-saline for years, and are no longer serving irrigation or potable uses is also misleading given the well production prohibition zone along the coast has stopped well production in these affected aquifer zones. The prohibition of pumping along the coastal portion of the SVGB, including the Marina Subarea, as a management effort has almost entirely removed active wells in the Dune Sand Aquifer and the 180-Foot/180-FTE Aquifer from operation (except the CEMEX wells). As discussed above, this lack of pumping (and other conservation efforts) has resulted in restoring groundwater quality and improved protective heads from seawater intrusion in the Marina

Subarea even during the current extended drought period. The DEIR/EIS's discussion of the lack of facilities that would be directly impacted by the MPWSP's operational drawdown is not surprising nor particularly relevant to whether the MPWSP would result in adverse impacts to the Marina Subarea and the SVGB as a whole. The bigger question is whether the project would result in a "net deficit in aquifer volume" as it relates to long-term water quality impacts and basin management efforts, not drawdown impacts on proximal well facilities operations. For these reasons and those discussed above, the DEIR/EIS analysis of MPWPS potential to cause a "net deficit in aquifer volume" (loss of storage) as it relates to long-term water quality impacts and basin management efforts is woefully inadequate.

The DEIR/EIS's conclusion that the project impacts to Salinas Valley Groundwater Basin groundwater supplies is less than significant must be updated based on new modeling results that address cumulative impacts and disclose the amount groundwater supplies within the Marina Subarea that will be depleted:

On **Page 4.4-60**, the DEIR/EIS states:

> The proposed project would not deplete groundwater supplies; it would extract primarily seawater and a smaller volume of brackish inland groundwater from a localized area with only minor localized groundwater drawdown. The area influenced by the MPWSP groundwater pumping is within a zone that is degraded by seawater intrusion and therefore unusable for potable water supply due to its high salinity. When desalinated water is returned to the basin as part of the MPWSP, groundwater conditions in the 400-Foot Aquifer underlying the CSIP, CCSD, and adjacent areas would improve as water levels increase as a result of in-lieu groundwater recharge. The return water component of the MPWSP would benefit each of the aquifers by either reducing the area of influence or by increasing groundwater levels in other areas. The effects of return water on the basin water levels are discussed below and shown on Figures 4.4-14 through 4.4-16. If the proposed project did not return any water, localized depressed groundwater levels would persist in the three affected aquifers throughout the life of the project. However, the area affected by groundwater pumping would remain localized and the proposed project would continue to extract only brackish, degraded groundwater from the coast and, to a lesser extent, the inland portion of the aquifer. Based on the conclusions of this analysis, this impact would be less than significant.

HGC Comment No. 30:

The statement that "The area influenced by the MPWSP groundwater pumping is within a zone that is degraded by seawater intrusion and therefore unusable for potable water supply due to its high salinity" assumes there is no way to pump brackish groundwater and clean it up for beneficial potable uses. This is false. As discussed above, the shallow aquifers in the coastal

area are not presently pumped because of a management strategy that has been employed to abate seawater intrusion and not solely because it has a component of seawater present.

Again, the DEIR/EIS's statement that the "proposed project would not deplete groundwater supplies" is misleading to the public and the Commissioners. With only a month to review the ***recalibrated NMGWM^{2016}*** and superposition model due to the CPUC's failure to make this information available until February 16, 2017, we have worked with GeoHydros to analyze groundwater depletion from the proposed production of 27,000 afy. Based on this review of ***recalibrated NMGWM^{2016}***, which likely understates the project's impacts as discussed above, the MPWSP would initially produce approximately 30 percent of its supply from groundwater. Again, if the model was properly calibrated, this number could be higher. Nonetheless, the water budget clearly shows the project will draw a substantial portion of groundwater during the initial year at minimum. Moreover, the water budget also show that project would significantly reduce groundwater storage within the Marina Subarea. The DEIR/EIS must be revised to disclose the amount of Marina Subarea groundwater supplies that would be depleted by the project. Without this information, it is impossible for the public and Commissioners to propose or evaluate potential mitigation measures. While the CPUC may determine that the impacts to groundwater supplies in the Marina Subarea are significant and unavoidable, it cannot approve the project without disclosing this condition and allowing public comment on this impact.

In addition, the DEIR/EIS's characterization of the project as creating only a "minor localized groundwater drawdown" is misleading and fails to acknowledge the magnitude of the groundwater extraction proposed. As designed, a single well would produce 2,100 gpm and the operation of 8 wells would total 16,800 gpm. That rate of groundwater extraction would fill an average size swimming pool in 1.5 to 2 minutes. Different than other municipal wells that cycle to meet day time demands and then rest at night, the MPWSP intake wells would pump constantly. Similarly, the suggestion that the project would only draw a small amount of brackish groundwater from the inland side of the project is significantly downplaying the quantity to be produced. Annually, the project production of groundwater would fill a 2,700-acre reservoir with water to a depth of 10 feet. After 10 years, the reservoir would be one hundred feet deep.

Finally, the return water component of the MPWSP would benefit each of the aquifers "by either reducing the area of influence **or** by increasing groundwater levels in other areas" does not address or mitigate impacts to the Marina Subarea aquifers directly impacted by the project.

Again, groundwater production should be calculated to include the 3,000 mg/l beneficial use standard provided in the WQCP. The amount of groundwater return to the basin needs to be specifically indicated and analyzed to determine the effectiveness of its implied mitigation of the potential project impacts.

The DEIR/EIS's conclusion that the project impacts to the existing wells is less than significant must be updated based on new modeling results that address cumulative drawdown levels:

On **Page 4.4-68**, the DEIR/EIS states:

> The nearby groundwater production wells affected by the change in groundwater levels are built in the Dune Sand Aquifer, 180-FTE Aquifer, or the 400-Foot Aquifer and thus have casings, pumps, and screens at depths considerably deeper than the depths at which MPWSP pumping could affect the water levels. A water level decline between 1 and 5 feet would not expose screens, cause damage, or reduce yield in the groundwater supply wells influenced by MPWSP pumping. Based on the modeled response of the 24.1-mgd extraction rate at the CEMEX site, the impact on nearby water supply wells would be less than significant.

HGC Comment No. 31:

As discussed above, the superposition model does not address cumulative drawdown and therefore does not address the project's potential to impact existing wells under cumulative conditions, which could include extended drought periods.

The DEIR/EIS's conclusion that the impacts of the project on the surface water-groundwater interaction at the Salinas River and Tembladero Slough is inconsistent with the conclusions in the Alternatives Section regarding Elkhorn Slough:

On **Page 4.4-70**, the DEIR/EIS states:

> The NMGWM can estimate the loss of groundwater outflow to a surface water feature such as the Salinas River. Based on the modeling, the estimated volume of groundwater removed from the river recharge system would be approximately 400 afy. A similar condition exists for Tembladero Slough, where the volume of groundwater removed by the slant well pumping from that system would be about 65 afy. The volume of water flowing to the ocean through the Salinas River in 2012 was about 250,000 afy, so the reduction of 400 afy is about 0.16 percent of the total flow. From a surface water supply standpoint, this magnitude of groundwater diversion from the Salinas River would be a minor, if not immeasurable, reduction in surface water supply. The same conclusion is applied to the Tembladero Slough, where the removal of 65 afy of groundwater discharge would not constitute a recognizable loss in supply for that system. The reduction of surface water attributable to slant well pumping is not a substantial reduction of water supply and thus this impact would be a less than significant impact.

On **Page 5.5-114**, the DEIR/EIS states:

> Unlike the proposed project, groundwater modeling (see Appendix E2) indicates pumping from the slant wells at Potrero Road would result in a cone of depression in the underlying groundwater aquifers that would draw or divert water from

Elkhorn Slough. This drawdown impact is discussed in Section 5.5.4, Groundwater Resources, and presented in Figure 5.5-2. The modeling cannot predict the amount of water diverted from Elkhorn Slough although it must be conservatively assumed, based on the predicted areal extent of the drawdown, that operations could potentially adversely affect aquatic habitat in Elkhorn Slough due to reduced surface water flow and volumes. This would be an increased level of impact compared to the proposed project and because there is no method to mitigate for impacts on surface water flow and volumes in Elkhorn Slough, Alternative 1 would result in an increased impact conclusion on marine species, natural communities or habitat, protected wetlands or waters, and critical habitats compared to the proposed project, significant and unavoidable.

HGC Comment No. 32:

The assessment of the impact of surface water losses from these features due to the project pumping is general and compared to annual conditions that don't consider low-flow or no-flow conditions resulting from seasonal or climatic dry periods. This may be largely a result of the inadequacy of the NMGWM^{2016} prior to switching to use of the superposition model. In addition, the DEIR's conclusion regarding the potential impacts to the Salinas River and the Tembladero Slough are inconsistent with its treatment of Elkhorn Slough in the Alternatives Chapter.

The DEIR/EIS's discussion of the surface water-groundwater interaction at CEMEX fails to analyze or disclose how the TSW's impacts were effected by CEMEX operations making the revised modeling subject to untolerable uncertainty.

On **Page 4.4-70 through 4.4-72**, the DEIR/EIS states:

The CEMEX facility has several ponds on its property. The largest pond, located to the north of the slant wells, is the source of the sand mined by CEMEX. The impact analysis of MPWSP pumping effects on recharge considered the largest pond to determine whether the proposed project would have an adverse impact on its recharge or on the current sand mining operations. A significant impact would occur if the proposed pumping at CEMEX reduced recharge to the Dune Sand Aquifer or interfered with or otherwise limited the ability of CEMEX to operate due to intolerable draw down in its main sand mining pond.

Pond Operation

The bottom of the large CEMEX dredge pond is assumed to be at about 10 to 20 feet below the surface water level in the pond (Geoscience, 2015b). The water level in the pond is in hydraulic connection with the ocean, receiving ocean water as seepage through the beach sand and occasional storm surges over the beach and into the pond. Winter storm surges push sand with very little silt or clay particles over the beach and into the largest pond, and the sand settles to the bottom of the pond. CEMEX then dredges the sand from the pond, sorts the sand

into different grain sizes depending on the desired end product, and washes the sand to remove residual salts from seawater. The wash water is routed to the smaller ponds located north and east of the location of the proposed slant wells, where the seawater seeps into the sand and migrates back to the ocean. The larger, deeper sand source pond is in an area composed entirely of sand. The water level in the largest pond is controlled by the ocean tides (Geoscience, 2015b). Occasionally, storm surges remove the sand barrier between the larger dredge pond and the ocean and the pond temporarily becomes a small bay, as occurred in March 2016. The smaller, shallower wash water ponds are fed entirely by the wash water and are not directly connected to either to the ocean or the underlying groundwater; wash water either evaporates or infiltrates into the shallow sand and migrates to the ocean.

A water level transducer was installed in the large dredge pond on the CEMEX property to monitor changes in water elevations. The most recent monitoring report indicates that the pond is tidally influenced (Geoscience, 2015a, b) due to the proximity of the pond to the ocean (within 200 feet). In addition, the pond water level monitoring indicates that the sand mining operations conducted on Monday through Friday also affect pond water levels. Pond water levels fluctuate and decrease during the week as sand and water is pumped out of the pond and then stabilize on Saturday and Sunday when the sand mining operations are closed.

Impact Analysis for CEMEX Dredging Pond Drawdown

This impact analysis is based on the analysis completed for the test slant well, which was completed in September 2014, and is also informed by data that was generated in April 2015 after a five-day constant discharge pump test of the test slant well.

In the September 2014 analysis, the localized CEMEX model was used to determine whether the dredge pond would be influenced by pumping at the proposed test well operating at 2,500 gallons per minute (gpm) (Geoscience, 2014a). The localized CEMEX model simulates the response of the Dune Sand Aquifer in its second, third, and fourth vertical layers. The depth of the large dredge pond falls within the second and part of the third model layer so the response in the dredge pond would be captured as a response in the upper portion of the Dune Sand Aquifer. The CEMEX model simulated the test well pumping for 8 months at 2,500 gpm. The results of the model run showed a drawdown at the dredge pond of about 1 foot. If a drawdown of 1 foot occurred for a pumping rate of 2,500 gpm from one well (the test slant well), there is a possibility that additional drawdown would occur in the pond during operation of the all of the proposed slant wells, which would operate at the combined pumping rate of 24.1 mgd or about 16,736 gpm. However, when compared to the daily tidal

fluctuations in the dredge pond water levels of up to eight feet throughout the year, the decline in the water surface of any depth would be masked by the consistent recharge and tidal influence from the ocean.

On March 8, 2015, a water-level transducer was installed in the dredge pond, and it has been collecting data ever since. In April 2015, a five-day constant-discharge pumping test was conducted (Geoscience, 2015b). The transducer showed a series of cyclical fluctuations from March 8 through March 21, followed by relatively flat levels through April 2, followed by similar pattern of cyclical fluctuations at similar elevations through April 11. The cyclical fluctuations are due to a combination of tidal influence and the routine dredging of the pond for sand. The early March fluctuations, which occurred before the pumping test, and the early April fluctuations, which occurred during the pumping test, show a similar pattern at about the same water level, indicating that the water level in the dredge pond was not being influenced by the pumping of the test slant well. This also indicates that as the pond is dredged, the water levels quickly recover, with seawater seeping through the loose sand on the beach.

While pumping at the slant wells could elicit a drawdown response in the large dredge pond over periods of extended pumping, the magnitude of that response would not interfere with recharge to the Dune Sand Aquifer, nor would it inhibit sand mining operations by depleting available water supplies to the pond. This impact is less than significant.

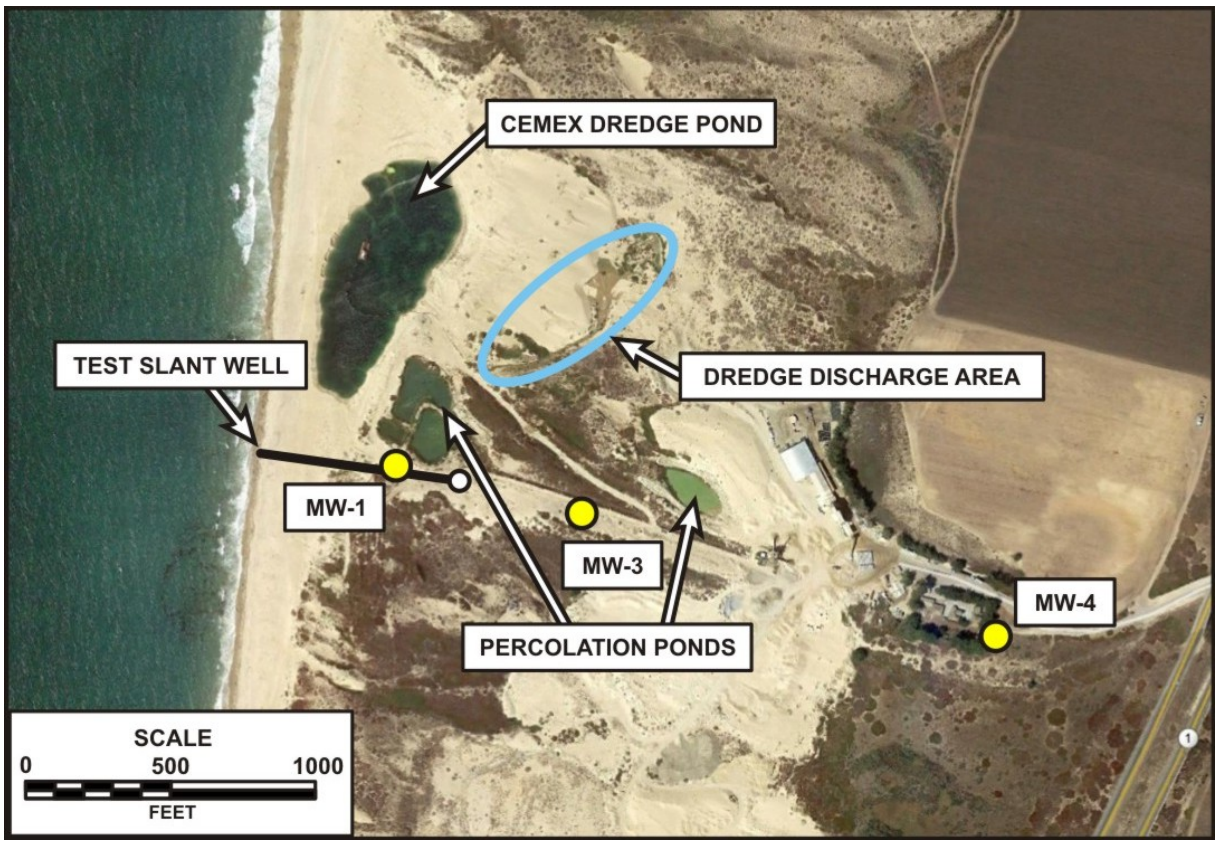
HGC Comment No. 33:

While the project may not significantly impact CEMEX's dredge pond operations, the DEIR/EIS fails to disclose how CEMEX's operations affected the test slant well discharge water quality and whether they would have similar effects on the 9 additional slant wells proposed further south and away from the dredge pond, the dredge pond discharges, and wash water containment ponds infiltration. Notably, due to CEMEX operation, the measured values relevant to salinity (specific conductivity, TDS, and practical salinity units (PSU)) provided by the TSW laboratory results and field measurements are not representative of what is expected from the larger MPWSP source wells array. At the time the higher salinity water quality samples were taken, the CEMEX dredge pond, which is in close proximity to the test well and inland of the shoreline, was breached for a significant period of time and directly filled by ocean water. It is likely the significant increase in salinity readings in the TSW during and following this period of time. The result was a large surge of ocean water into the dredge pond area overlying the inland portion of the beach adjacent to the test well. This condition will not persist throughout the year and is not present at the other proposed MPWSP source well locations.

Additionally, the CEMEX plant operations have influenced shallow groundwater quality in this reach of the shoreline for decades. As shown on Diagram 7 – CEMEX Surface Water Features August 2013, the test slant well is located adjacent to numerous sources of saline water

that are not present at other locations along the coast in particular where the other source water wells are proposed.

Diagram 7 – CEMEX Surface Water Features August 2013



These localized sources of salt water shown in Diagram 7 significantly influence the quality of the shallow groundwater that is observed in MW-1, MW-3, MW-4 and produced by the test slant well. The results in an overestimation of the seawater component flowing landward from the shoreline and an under estimation of the return water that will be required for mitigation.

The depletion of these landward sources of seawater is evident in the declining specific conductance trend for the TSW since November of 2016 (see Figure 3-12, Geoscience, 2017) and the overall decline in specific conductance trend in MW-4S since operation of TSW (see Figure 3-3, Geoscience, 2017).

Finally, I would note that this comment was provided to the CPUC in my testimony regarding the return water proposal, but the DEIR/EIS still does not address this issue.

The DEIR/EIS's conclusion that Impact 4.4-3 is less than significant is not supported by the best available scientific evidence and must be updated based on new modeling:

On **Page 4.4-73 through 4.4-74**, the DEIR/EIS concludes:

> The proposed project would extract mostly seawater and some brackish groundwater from a localized area; no fresh water supplies would be removed from the basin. When water is returned to the basin, groundwater conditions in the 400-Foot Aquifer underlying the CSIP and CCSD and adjacent areas would improve. Water levels in nearby wells may decline in the 180-FTE Aquifer between 1 and 5 feet, but that would not expose screens, cause damage, or reduce yield in the groundwater supply wells. Injection and extraction through the ASR well system would be managed so that the water provided from the desalination plant would not constitute a net change in storage. The reduction of surface water from the Salinas River attributable to slant well pumping would not be a substantial loss to water supply, nor would it constitute a substantial interference to surface water recharge. Pumping at the slant wells could cause drawdown in the large dredge pond over periods of extended pumping, but the magnitude of that response would not interfere with recharge. The MPWSP may slightly increase the area of impervious surface in the project area, but it would not reduce the potential for surface water to recharge the underlying aquifers. Impacts associated with changes to groundwater recharge during the operation of all project facilities would be less than significant.

HGC Comment No. 34:

As explained above, the DEIR/EIS's conclusion regarding Impact 4.4-3 are based on assumptions that conflict with the best available evidence and groundwater modeling that fails to assess cumulative conditions. The DEIR/EIS's conclusion that no fresh water supplies would be removed from the basin is not based on modeling capable of evaluating this criteria or other scientifically acceptable criteria. As a result the DEIR/EIS's conclusion the impact is less than significant is pure speculation. More importantly, it conflicts with available information regarding the groundwater conditions in the Marina Subarea and ignore the project's impacts on water quality.

The DEIR/EIS's conclusion that Applicant Proposed Measure 4.4-3 is not necessary to avoid impacts to the groundwater aquifers in the Marina Subarea is unsupportable; the measure, however, is inadequate to ensure the project would not result in significant impact:

On **Page 4.4-68**, the DEIR/EIS states:

> CalAm recognizes the long-term nature of the proposed project and the need to provide continued verification that the project would not contribute to lower groundwater levels in nearby wells within the SVGB. So, as part of the project, CalAm proposes to expand the existing regional groundwater monitoring program to include the area where groundwater elevations are anticipated to decrease by one foot or more in the Dune Sand

Aquifer and the 180-FTE Aquifer. This constitutes an Applicant-Proposed mitigation measure that is presented and evaluated at the end of Impact 4.4-3.

On **Page 4.4-74 and 75**, the DEIR/EIS further provides:

The project applicant has proposed to expand the existing regional groundwater monitoring program to include the area where groundwater elevations are anticipated to decrease in the Dune Sand Aquifer and the 180-FTE Aquifer. ***This Applicant Proposed Measure is not required to reduce a potential impact to less than significant. [emphasis added]***

… Applicant Proposed Measure 4.4-3: Groundwater Monitoring and Avoidance of Well Damage.

Prior to the start of MPWSP construction, the project applicant, working with the MCWRA, shall fund and develop a groundwater monitoring and reporting program that expands the current regional groundwater monitoring network to include the area near the proposed slant wells. Once expanded, the program will monitor groundwater levels and water quality within the area where groundwater elevations are anticipated to decrease in the Dune Sand Aquifer and the 180-FTE Aquifer and within at least one mile outside of the predicted radius of influence. The area of groundwater monitoring shall be determined by MCWRA and the MPWSP HWG. The elements of the groundwater monitoring program proposed under this measure are described below.

• Using a current survey of wells within the pumping influence of the slant wells, CalAm will offer to private and public well owners the opportunity to participate in a voluntary groundwater monitoring program to conduct groundwater elevation and quality monitoring. The voluntary groundwater monitoring program shall include retaining an independent hydrogeologist to evaluate the conditions and characteristics (e.g., well depth, well screen interval, pump depth and condition, and flow rate) of participating wells prior to the start of slant well pumping. Water elevation and quality monitoring shall begin following initial groundwater well assessment.

• Based on a review of the well network of voluntary well owners, CalAm will identify areas lacking adequate groundwater data and if deemed necessary, install new monitoring wells. These new wells would be in the 180-Foot Aquifer.

• Seven clusters of monitoring wells were recently completed on and near the CEMEX property. These well clusters monitor various depths within the Dune Sand Aquifer, the 180-Foot Aquifer, and the 400-Foot Aquifer and shall be included in the monitoring network.

• Using the groundwater data developed through the voluntary well monitoring program and data gathered at the new monitoring wells, ***CalAm will evaluate***

whether project pumping is causing a measurable and consistent drawdown of local groundwater levels in nearby wells that is distinguishable from seasonal groundwater level fluctuations. In the event that a consistent and measurable drawdown is identified, CalAm will determine if the observed degree of drawdown would damage or otherwise adversely affect active water supply wells. ***[emphasis added.]*** Adverse effects from lowered groundwater levels in existing active groundwater supply wells can include cavitation due to exposure of the well screen, water elevation declines that draw water below pump intakes, reduced well yields and pumping rates, and changes in groundwater quality indicating that project pumping is drawing lower quality water toward the well. Adverse effects would only occur in active wells; inactive wells would not be considered for mitigation.

• If it is determined that a nearby active groundwater well has been damaged or otherwise negatively affected by the project pumping of the slant wells, the project applicant shall coordinate with the well owner to arrange for an interim water supply and begin developing a mutually agreed upon course of action to repair or deepen the existing well, restore groundwater yield by improving well efficiency, provide long term replacement of water supply, or construct a new well.

Applicant Proposed Measure 4.4-3 would monitor changes in the groundwater surface elevations caused by the proposed pumping at the slant wells through a voluntary program and use of new groundwater monitoring wells. If it is determined that the project is causing groundwater levels to damage local active wells, this measure would ensure that active wells are repaired or replaced. Implementation of Applicant Proposed Mitigation Measure 4.4-3 is not necessary to address any significant project effect.

HGC Comment No. 35:

The fact that "CalAm recognizes the long-term nature of the proposed project and the need to provide continued verification that the project would not contribute to lower groundwater levels in nearby wells within the SVGB," but the CPUC and Monterey Bay National Marine Sanctuary (MBNMS) do not recognize the need for continued monitoring is troubling. As explained above, the DEIR/EIS's conclusion regarding Impact 4.4-3 are based on assumptions that conflict with the best available evidence and groundwater modeling that fails to assess cumulative conditions. The superposition model cannot assess water quality impacts or cumulative conditions. The DEIR/EIS itself acknowledges the "Limitations of Groundwater Models" at Page 4.4-44. As noted above, there are no borehole results or monitoring wells located in the project coastal area south of the test slant well or in the area between the project and Dune Sand Aquifer within the Fort Ord area. Thus, the DEIR/EIS's conclusion that

additional monitoring is not required to ensure the project's impacts are less than significant is unsupportable.

Moreover, the Applicant Proposed Measure 4.4-3 even if adopted as mandatory mitigation would not reduce the project's potential groundwater impacts to a less-than-significant level. First, the measure fails to identify where additional monitoring wells will be located. In addition, leaving this decision to CalAm as well as the responsibility to evaluate whether project pumping is causing a measurable and consistent drawdown of local groundwater levels in nearby wells that is distinguishable from seasonal groundwater level fluctuations is problematic given CalAm's advocacy positions regarding the test slant well to date. Rather, another public agency with the expertise and jurisdiction to enforce the mitigation measure and be responsible for implementing the corrective action measures must be identified. The mitigation measure also needs to be expanded to ensure that the project does not directly, indirectly or cumulatively cause undesirable results as defined under the SGMA. It should also require a pumping curtailment or other measures to address the potential undesirable impacts that could result from the project. As discussed above, without modeling or other scientifically supported estimates of future groundwater levels and groundwater quality impacts, it will be impossible to determine whether the project pumping is causing a measurable or consistent drawdown in the affected aquifers.

The DEIR/EIS's conclusion that the project impacts to groundwater quality within the slant well pumping area of influence is less than significant, is inadequate and must be updated based on new modeling results:

On **Page 4.4-76**, the DEIR/EIS states:

> From the time the slant wells begin pumping, and throughout the life of the project, local groundwater quality around the slant wells and within the cone of depression could change from the brackish quality it is now to higher salinity groundwater. The degradation in water quality (measured as an increase in TDS) would occur because the slant wells would draw in the brackish water that is currently in the aquifer formation and seawater would flow in to replace it. This effect would be most detectable near the coast at the CEMEX site and less pronounced inland because seawater would enter the slant wells more readily closer to the Monterey Bay compared to farther east where a smaller fraction of brackish groundwater would be drawn from the inland portion of the aquifers.
>
> This impact analysis considers whether this projected degradation in localized water quality would constitute a significant impact. A significant impact would occur if the proposed project violated water quality standards or degraded a groundwater source such that it would interrupt or eliminate the available potable groundwater for other users in the basin. Groundwater in the Dune Sand and the 180-FTE Aquifers within the area projected to be affected by slant well pumping is not used for potable supply or irrigation. As stated in Impact 4.4-3, the use of

> the current groundwater production in this area is limited to minor irrigation and dust control. There are no water supply wells pumping potable water, and most of the wells in this area are no longer active because of seawater intrusion. Furthermore, groundwater production is restricted in the vicinity of the CEMEX site through MCWRA Ordinance 3709, which prohibits drilling wells and pumping groundwater from the 180-FTE Aquifer in order to protect groundwater resources.
>
> Based on current groundwater quality and the minimal groundwater use within the area affected by slant well pumping, the localized change in groundwater quality that could occur as a result of slant well pumping is not expected to violate water quality standards or interrupt or eliminate the potable or irrigation groundwater supply available to other basin users. Therefore, this impact is considered less than significant.

HGC Comment No. 36:

The DEIR/EIS limits its analysis to whether the project would violate water quality standards or degrade the groundwater source such that it would interrupt or eliminate "the available potable groundwater for other users in the basin." As noted above, the DEIR/EIS's assumption that any water that does not meet the most stringent potable water standards has no beneficial uses and can be degraded without causing any significant impact is inconsistent with the SWRCB Basin Plan and SWRCB Anti-Degradation Policy. Moreover, also explained above, the TSW monitoring results show there are significant areas of freshwater within within the cone of depression. Finally, we note that changing fresh quality and slightly brackish groundwater within the Marina Subarea to hypersaline water will impact the ability to meet the SGMA's mandates. The statement that "the ***localized change in groundwater quality that could occur (emphasis added)*** as a result of slant well pumping is not expected to violate water quality standards" is misleading and inaccurate. The suggestion that water quality changes could occur indicates that they also could not. The DEIR should identify under what scenarios the project would not change the water quality in the Marina Subarea. As discussed above, causing any area of the basin that is fresh in quality or slightly brackish to become hypersaline will violate the basin WQCP objectives of 1,500 mg/l TDS. Therefore, the DEIR/EIS must be revised to disclose this impact is significant. If feasible mitigation is not identified that would reduce this impact to a less than significant level, which may be the case, the DEIR/EIS must disclose the impact would remain significant and unavoidable AFTER all feasible mitigation is adopted.

The DEIR/EIS's conclusion that the project impacts to groundwater quality within the slant well pumping area of influence is less than significant, is inadequate and must be updated based on new modeling results:

On **Page 4.4-77**, the DEIR/EIS states:

> As shown on Figures 4.4-10 and 4.4-11, the current location of the seawater/freshwater interface is about 8 miles inland in the 180-Foot Aquifer and

3.5 miles inland in the 400-Foot Aquifer. Once operational, the proposed slant wells would extract 24.1 mgd from the subsurface. A significant impact would occur if the proposed project caused the seawater/freshwater interface to migrate further inland, thereby exacerbating the seawater intrusion condition in the SVGB.

The effects on seawater intrusion were evaluated using the NMGWM with particle tracking (described in the Approach to Analysis section, above). Figure 4.4-17 shows the coastal seawater intrusion in the SVGB using the seawater/freshwater interface location estimated by the MCWRA and shown in Figures 4.4-10 and 4.4-11. Before running the model to simulate the 63 years of operation, individual water "particles" were placed along the leading edge of the mapped seawater intrusion front. Without the project, these particles are expected to continue to migrate inland with the movement of the seawater/freshwater interface. The NMGWM is a superposition model, meaning that modeled project effects are isolated from all other stresses in the basin, such as the effects from other groundwater pumpers, inland pressure gradients, injection systems, and recharge. In superposition, the NMGWM output is therefore the change attributable solely to the slant well pumping. Figure 4.4-17 depicts the resulting particle-tracking outputs, showing that a number of particles radiate away from the seawater/freshwater front back towards the coast. In Figure 4.4-17, some particle locations change substantially, whereas others do not. As to those that do change, the change in particle location shows where the seawater front would be after 63 years of MPWSP pumping if that was the only factor affecting groundwater movement in the basin (no recharge, no groundwater pumping, no pressure gradients, etc.). Therefore, Figure 4.4-17 illustrates the MPWSP's contribution to redirecting or reversing the inland advance of seawater intrusion. Because there are many stresses in the basin, the MPWSP project would not necessarily draw the leading edge of the seawater intrusion line back towards the coast to the extent shown by the particle-tracking output, but it does indicate that the MPWSP provides a benefit for the basin. Based on the particle-tracking results, the MPWSP would not exacerbate seawater intrusion, and groundwater extraction from the coast, as part of project operations, would be expected to retard future inland migration of the seawater/freshwater interface. The proposed project would facilitate the reduction of seawater intrusion in the long term, and the impacts of the proposed project are considered less than significant.

HGC Comment No. 37:

As noted above, the MCWRA maps used to justify the DEIR/EIS position are included with this response letter and include recent data from the TSW project that contradict the blanket statement that the freshwater/seawater interface is 8 miles inland (see attached Figures 1 through 5 and Diagram 5). Moreover, MCWRA does not have any maps for the extent of seawater

intrusion into the Dune Sand Aquifer. In fact, the DEIR/EIS does not address or evaluate potential impact to the Dune Sand Aquifer. As discussed above, the Dune Sand Aquifer water elevations indicate it flows toward the ocean (see Diagram 2 above and Figure 6 attached). Therefore, the project's impact on lowering heads within the Dune Sand Aquifer will induce seawater intrusion where it presently does not exist. The DEIR/EIS's failure to analyze or disclose this impact lacks any support and conflicts with the best available information. Moreover, increasing seawater intrusion into the Dune Sand Aquifer will in turn likely increase seawater intrusion into the lower aquifers that currently are recharged by freshwater from the Dune Sand Aquifer. Therefore, the DEIR/EIS must be revised to disclose this impact is significant. If feasible mitigation is not identified that would reduce this impact to a less than significant level, which may be the case, the DEIR/EIS must disclose the impact would remain significant and unavoidable AFTER all feasible mitigation is adopted.

The DEIR/EIS's conclusion that the project impacts to groundwater quality associated with existing groundwater remediation systems is less than significant, as mitigated, is inadequate and must be updated based on new modeling results that address cumulative impacts:

On **Page 4.4-86**, the DEIR/EIS concludes:

> **Impact Conclusion Groundwater Quality**
>
> For the slant wells, the seawater/freshwater interface would migrate back toward the ocean, which would be a less-than-significant impact. For the slant wells, the potential impact of interference with existing remediation systems would be reduced to less than significant with the implementation of Mitigation Measure 4.4-4. For the ASR injection/extraction wells, the net addition of injection water is considered a less than significant impact. For the ASR injection/extraction wells, the potential impact of interference with existing remediation systems would be less than significant. The operation of all other project facilities would have no impact on groundwater quality.
>
> Therefore, for the proposed project as a whole, the potential operations impacts would be less than significant with mitigation, relative to groundwater quality.

HGC Comment No. 38:

As discussed above, the presence of the FO-SVA and the groundwater gradient in the perched Dune Sand Aquifer control the present migration of contamination beneath the Fort Ord remediation site. As previously indicated, the project's increased production from the Dune Sand Aquifer could result in significantly more drawdown than previously anticipated which could accelerate or even change the direction of the contaminant plumes. This should be re-evaluated when the NMGWM^{2016} is appropriately revised and calibrated or a new dual density model is constructed. Mitigation Measure 4.4-4 is problematic and unlikely to ensure the project's impacts are mitigated for the same reasons identified in my comments about Mitigation

Measure 4.4-3 – namely the mitigation is delegated to Cal-Am without any meaningful performance standards.

The DEIR/EIS's conclusion that the project cumulative groundwater impacts is less than significant is inadequate and must be updated based on new modeling results that includes cumulative impacts:

On **Page 4.4-90**, the DEIR/EIS concludes:

> Because the MPWSP combined with the possible RUWAP desalination element would not result in a significant adverse cumulative impact and may have beneficial consequences, and the Salinas Valley Water Project Phase II and the Interlake Tunnel would have beneficial effects, the cumulative effect of these four possible projects on groundwater resources would be less than significant. Therefore, the proposed project would not have a cumulatively considerable contribution to a significant cumulative impact during operations (less than significant).

HGC Comment No. 39:

The DEIR/EIS's analysis of cumulative impacts fails to account for how groundwater conditions have changed over time and how they are likely to change in the future without the project. In fact, the DEIR/EIS acknowledges its modeling "only solves for the groundwater changes due solely to the proposed project." It goes on to expressly state:

> These changes are independent of the effects from the other stresses on the basin such as seasonal climate and agricultural pumping trends, other pumping wells, injection wells, land use, or contributions from rivers. By using superposition, the actual effects of only the proposed project can be isolated from the combined effects of all other basin activity. For example, when the NMGWM reports a 1-foot drawdown in a well, it is understood that the one foot of drawdown would be the effect on the basin of the proposed project only. That well may experience greater drawdown due to other stresses, such as drought or other nearby pumping wells, or may experience increases in water levels due to reduced regional pumping or an extremely wet year. But the proposed project's contribution to that drawdown in the well would remain only 1-foot. Superposition is described in Appendix E2, Section 5.2.

The DEIR/EIS suggests this limited approach to figuratively assessing the project's potential cumulative impacts to groundwater is permissible because baseline conditions reflect the contributions of past actions on groundwater resources within the geographic scope. This approach ignores that groundwater conditions have changed over time under baseline conditions and will continue to change in the future from other stressors. As noted above, the DEIR/EIS acknowledges this possibility. The fact that the modeling exists and has been run for the project (but the results not disclosed) and that it address these additional stressors is inexplicable. Even if the DEIR/EIS preparers believe

this modeling provides flawed results, the information must be disclosed (with an explanation regarding the flawed results) so the public can comment on the information and the decision makers can take it into account.

Finally, the cumulative impacts analysis must be revised to consider reasonably foreseeable projects that will be necessary under the SGMA. See discussion of no project alternative (DEIR/EIS, p. 5.5-84 ["Existing, ongoing regional groundwater pumping would continue throughout the Salinas Valley, as would efforts to develop a sustainable groundwater management plan."]).

DEIR/EIS Chapter 7 (Alternatives).

DEIR's discussion of slant wells ignores the fact that slant wells are an unproven technology.

Other than the recently completed TSW, there is only one slant well that has been successfully constructed to date in Dana Point, California. As addressed in the CCC's "Final Report: Technical Feasibility of Subsurface Intake Designs for the Proposed Poseidon Water Desalination Facility at Huntington Beach, California:

> When it was built and tested in 2006, it was test pumped at 2,000 gpm and displayed a well efficiency of 95%. Recent longer term testing of the completed test well in 2012 documents the reduction in well efficiency from the original value of 95% in 2006 to 52% in 2012 (GeoScience, 2012). Given this observed reduction in efficiency over a short period, the long-term performance of the technology has yet to be confirmed.
>
> … Slant wells completed in the Talbert aquifer would draw large volumes of water from the Orange County Groundwater Basin, which in itself is considered a fatal flaw. Recent public comments have suggested that pumping seawards of the Talbert Salinity Barrier could have beneficial impacts in managing seawater intrusion. In the Panel's opinion, however, this benefit is too uncertain to overcome the ISTAP conclusion about the fatal flaw of this technology as applied to the proposed Huntington Beach site. **The advantage of having a subsea completion is largely lost in confined aquifers *(emphasis added)*.** The performance risk is considered medium, as the dual-rotary drilling method used to construct the wells is a long-established technology, but there is very little data on the long-term reliability of the wells. Maintainability is also a critical unknown issue.
>
> … Slant wells tapping the Talbert aquifer would interfere with the management of the salinity barrier and the management of the freshwater basin, and further, would likely have geochemical issues with the water produced from the aquifer (e.g., oxidation states of mixing waters).

(CCC's "Final Report: Technical Feasibility of Subsurface Intake Designs for the Proposed Poseidon Water Desalination Facility at Huntington Beach, dated October 9, 2014, pp. 37, 56, 64, available at http://www.coastal.ca.gov/pdf/ISTAP_Final_Phase1_Report_10-9-14.pdf.)

HGC Comment No. 40:

We were surprised the DEIR/EIS does not discuss the CCC's Report or efficiency issues raised in the report (although it is referenced on 5.3-57) given that Martin Feeney, a Hydrogeologic Working Group member, was one of the Report's authors and Geoscience was involved in the well construction and testing. While the efficiency problems from the Dana Point may not manifest themselves at the CEMEX site, there is a considerable risk that has been identified by previous study. Therefore, the DEIR/EIS should discuss mitigation in the event there is a considerable drop in efficiency as it would likely eliminate the MPWSP's ability to provide return water. Alternatively, this could be considered a fatal flaw for the project.

The Potrero Road site appears to be a superior site for subsurface seawater intake facilities. Given aquifer parameter estimations and hydraulic boundary condition assumptions made in the model, a test well at the Potrero Road site is necessary to determine the accuracy of the aquifer parameter estimations and assumptions.

The DEIR/EIS on **p. 5.4-15** states:

> Alternative 1 would contain the same elements as the proposed project and would produce the same volume of product water. However, because of the hydrogeology of the Potrero Road area, Alternative 1 would draw a greater volume of water from the Salinas Valley Groundwater Basin than the proposed project. In the event the Salinas Valley Return Water obligation is determined to be 12 percent (the highest return value simulated), Alternative 1 would meet the need for replacement supplies and meeting peak month demand, but limited supply would be available for other uses, including accommodating tourism demand under recovered economic conditions. Alternative 1 would not provide sufficient supplies to serve existing vacant legal lots of record and would therefore, not meet the project objective/need for water, some of which was to support limited growth (e.g., Objective 6).

The DEIR/EIS then further states on **p. 5.5-86 through 5.5-90**:

> **Effects on the Perched-A Aquifer**
>
> Slant well pumping at Potrero Road would create a cone of depression in the Perched-A Aquifer that would extend up to 5 miles inland, as shown in Figure 5.5-2.4 The extent of modeled drawdown in the Perched-A Aquifer is almost twice the inland distance modeled at CEMEX for the proposed project because: 1) the Perched-A Aquifer is not as thick as the Dune Sand Aquifer underlying the CEMEX site, and 2) the ocean water capture zone is restricted at Potrero Road to the Perched-A Aquifer (the wells would not also be screened in the 180/180-FTE

Aquifers) because the underlying Salinas Valley Aquitard separates the Perched-A Aquifer from the 180-Foot Aquifer. The 1-foot drawdown response would be similar in the Perched-A Aquifer with and without modeled return water scenarios (0, 3, 6, and 12 percent), because the resulting in-lieu recharge in the 400-Foot Aquifer would have a negligible effect on recharge in the Perched-A Aquifer. Modeling indicates that pumping under Alternative 1 would influence the Perched-A Aquifer north of Potrero Road and the cone of depression would encompass the mouth of the Elkhorn Slough and about 1 mile inland up the slough (a portion of which is within MBNMS). This effect is shown by the 1-foot drawdown contour lines on Figures 5.5-2 and 5.5-3 and these results suggest a direct or indirect effect of project pumping at Potrero Road on the surface water-groundwater interaction in the Elkhorn Slough. For example, the slant well pumping at Potrero Road could draw in groundwater that would otherwise flow to recharge the Slough, or draw surface water directly from the Slough that would not occur under the proposed project. However, quantification of such an effect is not feasible within the context of the model given the location of Elkhorn Slough relative to the northern boundary of the NMGWM.

Effects on the 180-Foot Aquifer

Figure 5.5-3 shows the effects on the 180-Foot Aquifer from slant well pumping for Alternative 1, for varying percentages of Salinas Valley return water (0, 3, 6 and 12 percent return water). The modeled aquifer response shows a cone of depression that extends a maximum of about 4 miles inland with 0 percent return water, and the maximum extent of the cone is reduced by about 2 miles with increased percentages of return water. The modeled drawdown in the 180-Foot Aquifer is not directly due to project pumping because the slant wells at Potrero Road would not be screened in the 180-Foot Aquifer; rather, the water lost through extraction from the Perched-A Aquifer that would have otherwise infiltrated to and recharged the 180-Foot Aquifer may have been interpreted by the model as drawdown due to pumping. Similar to the effects on the Perched-A Aquifer, the response from slant well pumping (1-foot contour line at 0 percent and 3 percent return water) extends north to partially encompass the mouth of the Elkhorn Slough, indicating a possible surface water-groundwater interaction with the Slough. However, quantification of such an effect is not feasible within the context of the model given the location of Elkhorn Slough relative to the northern boundary of the NMGWM.

Pumping Response on 400-Foot Aquifer

Figure 5.5-4 shows the effects of the slant well pumping at Potrero Road on the 400-Foot Aquifer. The 1-foot drawdown contour, representing 0 percent return water, shows the largest area of drawdown extending about 2 miles inland and offshore about 0.75 mile. The 1-foot drawdown contour with 3 percent return

water extends inland only about 1.5 miles and offshore about 0.5 mile. There is also a localized groundwater level increase in Castroville with 3 percent return water. The 1-foot contour resulting from 6 percent return water shows a groundwater level rise in Castroville, as does the 12 percent return water contour that is almost 5 miles in diameter. The response from slant well pumping, as shown by the 1-foot drawdown contour at 0 percent and 3 percent return water, extends north to partially encompass the mouth of the Elkhorn Slough. Given the depth of the 400-Foot Aquifer and the presence of the Salinas Valley Aquitard, it is unlikely that there would be a direct surface water-groundwater interaction between the Elkhorn Slough and the 400-Foot Aquifer. The water lost through extraction from the Perched-A Aquifer that would have otherwise infiltrated to and recharged the 400-Foot Aquifer was likely interpreted by the model as drawdown in the 400-Foot Aquifer and given the location of Elkhorn Slough relative to the northern boundary of the NMGWM, quantification is not feasible within the context of the model.

Analysis and Conclusion of Operational Impacts

Pumping of slant wells at Potrero Road under Alternative 1 would extract mostly seawater and inland brackish water from an area where groundwater is not extracted for beneficial uses by others. There would be some degree of water level increase in areas of the 400-Foot Aquifer as a result of the Salinas Valley return water. No groundwater supply wells are currently pumping within the area of influence of the affected aquifers; therefore, Alternative 1 would have a reduced potential for impact on supply at nearby wells compared to the proposed project. However, like the proposed project, and would result in the same impact conclusion as the proposed project, less than significant. However, like the proposed project, Applicant-Proposed Mitigation Measure 4.4-3 (Groundwater Monitoring and Avoidance of Well Damage) would be implemented under Alternative 1, in recognition of the need to provide continued verification that project pumping from Alternative 1 would not impact groundwater levels in neighboring wells or contribute to seawater intrusion within the SVGB.

Regarding Water Quality Impacts, the DEIR/EIS states on p. **5.5-90**:

Similar to the proposed project, Alternative 1 would gradually and locally degrade groundwater quality from brackish to more saline as project pumping continues. However, this degradation would not violate water quality standards or interrupt or eliminate groundwater supply for other users. Groundwater modeling results show that Alternative 1 slant well pumping would hold back inland migration of the seawater intrusion front similar to the proposed project. However, because the effects of slant well pumping at Potrero Road would extend farther north than the proposed project, it would have a greater positive influence on the northern half of the seawater intrusion front compared to the proposed project.

> Unlike the proposed project, Alternative 1 groundwater extraction would occur too far north to interfere with groundwater remediation systems currently operating at the former Fort Ord Army base. Therefore, the Alternative 1 intake system would not interfere with active remediation systems or contaminant plumes, the impact would be decreased compared to the proposed project and Mitigation Measure 4.4-4 (Groundwater Monitoring and Avoidance of Impacts on Groundwater Remediation Plumes) would not have to be implemented. Like the proposed project, operation of the ASR system would have a less-than-significant impact related to groundwater quality.
>
> In summary, project pumping at Potrero Road, like the proposed project at CEMEX, would cause the brackish groundwater to locally turn more saline, but not in violation of water quality standards; it would hold back seawater intrusion similar to the proposed project but would have a greater positive effect on the northern portion of the intrusion front; and it would eliminate the potential interference with existing contaminant plumes and remediation systems at the former Fort Ord military base as a result of slant well operation, eliminating the need for mitigation. Therefore, Alternative 1 would result in a reduced impact conclusion on groundwater quality compared to the proposed project, less than significant.

Regarding operational impacts on marine biological resources, the DEIR/EIS states on p. **5.5-114**:

> Unlike the proposed project, groundwater modeling (see Appendix E2) indicates pumping from the slant wells at Potrero Road would result in a cone of depression in the underlying groundwater aquifers that would draw or divert water from Elkhorn Slough. This drawdown impact is discussed in Section 5.5.4, Groundwater Resources, and presented in Figure 5.5-2. The modeling cannot predict the amount of water diverted from Elkhorn Slough although it must be conservatively assumed, based on the predicted areal extent of the drawdown, that operations could potentially adversely affect aquatic habitat in Elkhorn Slough due to reduced surface water flow and volumes. This would be an increased level of impact compared to the proposed project and because there is no method to mitigate for impacts on surface water flow and volumes in Elkhorn Slough, Alternative 1 would result in an increased impact conclusion on marine species, natural communities or habitat, protected wetlands or waters, and critical habitats compared to the proposed project, significant and unavoidable.

HGC Comment No. 41:

Our review of the project field investigations study indicate that the Potrero Road site hydrogeology and aquifer property estimations were defined by 5 formation samples collected

from a single borehole (Geoscience, 2014). The hydraulic conductivity values estimated from the grain-size analyses of those samples show a highly permeable aquifer that would yield water to well facilities with up to 3 times the performance of wells at the CEMEX site. Compared to the 6 boreholes drilled at the CEMEX site during the initial study, there are limited data from which to build a high level of confidence in the model input parameters and subsequent model results and DEIR/EIS conclusions about the viability of the Potrero Road site. Similarly, the NMGWM used substantial water level data from the 180-Foot Aquifer for model calibration, but no well data from the Dune Sand/A Aquifer zone that is the target for production by the Potrero Road alternative.

The vertical hydraulic conductivity used in the model (0.16 feet/day) at the Potrero Road site is not only untested and not substantiated by production test data, it is 2 orders of magnitude less than the CEMEX site estimate (15 feet/day). While the horizontal hydraulic conductivity value was estimated at 2 times greater than the modeled value at the CEMEX site, the reduced vertical hydraulic conductivity indicates a confined/semi-confined condition. The simulated impact of these aquifer parameter estimations results in a significant impedance to vertical flow from the ocean floor and a reduced amount of seawater infiltration estimated by the model. The greater horizontal hydraulic conductivity combined with reduced vertical flow results in a greater amount of groundwater production estimated. Should the actual aquifer conditions allow greater vertical flow from the ocean floor, the model simulations would indicate a significantly greater production of seawater and far lower production of groundwater.

The designs of slant well facilities at the Potrero Road site extend significantly further offshore with a majority of the well screen sections beneath the ocean floor (Geoscience, 2014, Figures 49, 50, and 68 to 84). The wells are significantly shallower in depth and located above SVA only in the Dune Sand/A Aquifer. This design and configuration would result in little impact on the 180-Foot Aquifer, below the SVA, and is closer to the ocean floor, which is better positioned for inducing seawater infiltration. Water quality test data indicate the salinity of the groundwater in the Dune Sand/A Aquifer at Potrero Road is virtually seawater (34,000 to 34,853 mg/l TDS).

Aside from the aquifer parameter estimations and hydraulic boundary condition assumptions made by the study, the Potrero Road site appears to be a superior site for subsurface seawater intake facilities. For this reason, we recommend the MPWSP construct a TSW at the Potrero Road Site to determine the accuracy of the aquifer hydraulic conductivity estimations that were derived from an empirical estimation method. If the assumed conditions that are simulated in the model are biased by the lack of data, the model results are overstating the groundwater that will be produced from the Dune Sand/A Aquifer zone and underestimating the amount of seawater that would be produced by an intake system at the Potrero Road site.

The DEIR/EIS should consider relocation of the MPWSP's subsurface intake wells either further north or south to better benefit the coastal conditions in the Pressure Area where seawater inflow preferentially follows the paths of greatest hydraulic conductance

HGC Comment No. 41:

Historical studies have indicated that there are 2 locations along the coastal portion of the Pressure Area where seawater inflow preferentially follows the paths of greatest hydraulic conductance (least impedance to flow) and where onshore gradients induce landward flow of groundwater (KJC, 2004, Page ES-15, Figure 3). The main pathway is located north of the Salinas River where the greatest amount of seawater has intruded into the heavily used portion of the Pressure Area. The second preferential pathway for flow is located south of Marina and allows seawater to flow into the aquifers beneath the Fort Ord Area. This area is south of the boundary defined as the Pressure Area by some studies, but within the Pressure Area defined by other studies. The CEMEX site lies midway between these 2 areas of preferential seawater intrusion and does not directly intercept either of these main areas of onshore flow. The potential impact of this condition, or the relocation of the project further north or south to better benefit the coastal conditions is not discussed in the DEIR/EIS.

DEIR/EIS Chapter 4.6 (Terrestrial Biological Resources).

On p. 4.6-3, the DEIR/EIS defines the area studied for potential impacts to terrestrial biological resources:

> Study area encompasses a 50-foot buffer around the project area. A 50-foot buffer around the project area was established as the survey area to ensure biological resources within the project area and immediate adjacent vicinity were assessed for potential direct and indirect project impacts.

HGC Comment No. 42:

The study area fails to account for potential operation impacts from the slant well drawdown and water quality impacts on groundwater-dependent ecosystems. The significant drawdown and changes to water quality have the potential to impact wetlands and other biological resources that rely on the groundwater resources within the project area of influence. The DEIR/EIS must be revised to disclose, analyze, and mitigate potential impacts on groundwater-dependent ecosystems within the operational area of influence. A cursory review of the Figure showing "Vegetation Communities and Potential Wetlands and Waters in the Terrestrial Biological Resources Study Area" shows resources both within and outside the areas evaluated by the study that are within the drawdown contours of the project and could be adversely impacted by the project's reduction of water levels and water quality. The SGMA defines adverse impacts to groundwater dependent ecosystems as an undesirable result and further supports the need for additional analysis that extends beyond construction related impacts.

Conclusion

Based on the findings of our review, HGC concludes that at a minimum the DEIR/EIS needs revision to include an adequate description of baseline conditions as they are presently being observed and the unique hydrogeology of the Marina Subarea portion of the SVGB. The DEIR/EIS must also utilize the information developed from the TSW field investigations and available from other studies in the Marina Subarea to refine and fully calibrate the NMGWM^{2016} or preferably construct a dual density model that would generate a reasonable level of confidence in the simulated effects of the MPWSP. Without this information, it is impossible to determine whether the project's significant impacts on groundwater levels (storage) and water quality can be mitigated to a less than significant level.

The revised DEIR/EIS must also provide analysis of alternatives that could satisfy the project's water demand requirements. That discussion must compare the impacts of each alternatives water intake sources (e.g. slant wells, Ranney collectors, beach infiltration galleries, horizontal directional drilling, etc.) with real data, not conjecture. Without a revised DEIR/EIS that provides this information, it is impossible to make an informed decision regarding the potential impacts of the project on the SVGB, particularly the aquifers in the Marina Subarea, and whether feasible alternatives to the project would reduce the project's significant impacts. We also conclude that if the seawater intake facilities were located a sufficient distance offshore beneath the ocean floor and effectively inducing seawater infiltration, the groundwater impacts from the MPWSP to the SVGB could be mitigated.

Sincerely,

March 27, 2017

Keith Van Der Maaten
General Manager
Marina Coast Water District

Subject: Review of the 2016 North Marina Groundwater Model

Dear Mr Van Der Maaten,

Please find attached our report summarizing our review and findings regarding the 2016 North Marina Groundwater Model.

In summary, we believe our report sufficiently demonstrates why the Draft EIR/EIS's conclusions regarding the MPWSP's groundwater impacts are not scientifically supportable and conflict with available information. Please note that given the problems with the model calibration identified above, we do not recommend additional scenario analysis using the 2016 NMGWM because it would not provide scientifically supportable results.

Please contact us is you have any questions or would like us to perform additional analyses. We have also attached our firm CV and individual CVs, as you requested.

Sincerely,

Todd R Kincaid, Ph.D.
President, Principal Hydrogeologist

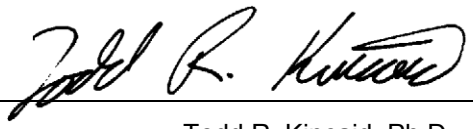
Review of the 2016 Version of the North Marina Groundwater Model Marina Coast California

March 27, 2017

Prepared for:

Marina Coast Water District
11 Reservation Road
Marina, California 93933

Prepared by:



Todd R. Kincaid, Ph.D.
President / Principal Hydrogeologist

I, Kevin E. Day, P.G., no. 8034, have read and agree with the findings in this report titled *2016 Version of the North Marina Groundwater Model Marina Coast, California dated March 27, 2017* and do hereby certify that I currently hold an active professional geology license in the state of California. The report on the status of tasks, including the evaluation of the updated North Marina Groundwater Model prepared by Dr. Todd R. Kincaid of GeoHydros, LLC, has been reviewed by me and found to be in conformance with currently accepted geologic practices, pursuant to Title 16, Division 29 of the California Code of Regulations.

1 BACKGROUND

GeoHydros, LLC was contracted by the Marina Coast Water District to review the 2016 version of the North Marina Groundwater Model (NMGWM) with specific regard to the findings derived from that model and reported in Section 4.4[1] and Appendix E2[2] of the CalAm Monterey Peninsula Water Supply Project Draft EIR/EIS dated January 2017 and used as the basis for the determinations of impact from proposed slant well pumping near the city of Marina, California. Our work included a review of the documents listed above and the 2015 version of Appendix E2; and obtaining, running, and performing scenario analyses with the calibrated version of the 2016 NMGWM and the associated "superposition" models that were created from it for the 2016 EIR/EIS.

2 NMGWM

The 2016 NMGWM is a finite difference numerical groundwater flow model constructed with the MODFLOW groundwater modeling software[3] using a uniform grid of 200 x 200 foot cells. The model simulates flow from the Pacific Ocean into and through four aquifers separated by aquitards that inhibit but do not prevent vertical flow between the aquifers. The model is a modification of the 2015 version[4] to include and address more site specific hydrostratigraphic units, namely the Dune Sand Aquifer and the Salinas Valley aquitard, groundwater elevations in the vicinity of the proposed wells, and structural changes that favored the conceptualized flow from the Pacific Ocean into the aquifers[5].

Table 1. Hydrostratigraphic Units in the 2016 NMGWM

Layer	Type	Name
1	N/A	Ocean
2	Aquifer	Dune Sand Aquifer
3	Aquitard	Salinas Valley Aquitard
4	Aquifer	180-ft Aquifer
5	Aquitard	180/400-ft Aquitard
6	Aquifer	400-ft Aquifer
7	Aquitard	400/900-ft Aquitard
8	Aquifer	900-ft Aquifer

MCWD-GH-01

The model has been used directly or indirectly to predict the impacts to groundwater resources of various possible configurations of a proposed project to withdraw groundwater from the Dune Sand and 180-FT aquifers adjacent to the coast of the Pacific Ocean at the CEMEX site (Figure 1). Predictions stemming from the model include: 1) delineation of cones of depression in the Dune Sand, 180-FT, 400-FT, and 900-FT aquifers associated with different pumping, return flow, and sea level scenarios; 2) quantification of the sources of water that will supply the proposed extractions, namely the ocean versus groundwater; and 3) the effect of the proposed pumping scenarios on the transition zone between freshwater and salt water in the aquifers.

[5] Table 3.1, Appendix E2, Ibid

The model domain encompasses a nearly square area rotated 16 degrees clockwise, approximately 13 miles northwest-southeast by 11.4 miles northeast-southwest, approximately 40% of which extends into the Pacific Ocean (Figure 1). The model boundaries are arbitrary and do not represent natural hydrologic divides therefore the model simulates flow across the external boundaries that cannot be verified from data. MCWD-GH-02

General head boundary conditions were assigned to the inland portions of the external model boundaries meaning that the groundwater elevations were inferred by the model from nearby wells or sources at some distance from the boundary. In these cells, flow across the boundaries was determined by the simulated hydraulic gradient and the specified hydraulic conductivities. Constant head boundary conditions were assigned to the outer boundaries of the offshore portions of the external model boundaries as well as all offshore cells in the uppermost model layer and a portion of the offshore cells in Layers 2-6 (Figures 2 and 3). The constant head boundary assignments differed from the 2015 version of the NMGWM in that the 2016 version prescribed equivalent freshwater heads to the offshore cells that account for the depth of the ocean water over the respective model layers and the density difference between saltwater and freshwater[6] whereas the 2015 version assigned constant heads only in layer 1 (ocean) and set the values to sea level[7]. Figures 4 and 5 show perspective cross-sections through the model domain that depict the effect of the equivalent freshwater head assignments in the ocean on the hydraulic gradient (slope) of the groundwater surfaces in the Dune Sand Aquifer (model layer 2) and the 180-FT Aquifer (model layer 4). MCWD-GH-03

By limiting the use of equivalent freshwater heads to the ocean side of the model layers, HydroFocus did not account for the effect of varying salinities in the groundwater inland from the coast and therefore over-predicted the west-east hydraulic gradient. This results in a failure to reasonably simulate saltwater intrusion as it appears was the intent. The appropriate way to simulate saltwater intrusion is with the use of a dual-density model such as could have been constructed with the SEAWAT or FEFLOW groundwater modeling software. In its present form, the NMGWM should not be used to infer how the proposed project or any other stresses would likely affect saltwater intrusion or the position of the saltwater/freshwater interface in any of the simulated aquifers. Use of a dual-density simulation software would also allow for model calibration to salinities observed in onshore wells. MCWD-GH-04

External head-dependent boundary conditions (aquifer water levels), pumping rates, recharge rates, and stream losses and gains were derived from the Salinas Valley Integrated Ground and Surface Water Model (SVIGSM),[8] which is a considerably larger and coarser model encompassing the Salinas River watershed that does not simulate the added hydrostratigraphic units (Dune Sand Aquifer or Salinas Valley Aquitard). The interconnectivity between these two models is problematic because they simulate different conceptual hydrostratigraphic frameworks. In particular, the initial heads and boundary conditions pertaining to the Dune Sand Aquifer and Salinas Valley Aquitard are likely not appropriate resulting in a poor simulation of MCWD-GH-05

[8] Montgomery Watson, 1997, "Salinas Valley Integrated Ground Water and Surface Model Update, Final Report," May 1997.

groundwater levels and horizontal and vertical hydraulic gradients in these units. HydroFocus identified this problem as a likely source of the large calibration errors in the Dune Sand Aquifer monitoring wells. MCWD-GH-05 cont.

Due in part to the constant head boundary assignments and relationship to the SVIGSM, the design of the 2016 NMGWM yields implausible hydraulic conditions in all four of the simulated aquifers. Figures 6-9 depict the simulated groundwater surfaces for each of the four aquifers at the first and last timestep in the 32-year simulation period. MCWD-GH-06

Figure 6 reveals that the Dune Sand Aquifer is essentially not present at the first timestep and that there is little to no northward flow across the model boundary in the aquifer in the last timestep though the aquifer is reported to continue southward into the Fort Ord region. Appendix 1 provides groundwater surfaces exported after each year of the simulation period, which reveal that the Dune Sand Aquifer doesn't fully evolve until approximately year 20. Though fluctuations in recharge and pumping incorporated into the transient simulation contribute to the simulated variation through time, the difference between the hydrostratigraphic frameworks represented in the SVIGSM and the NMGWM is most likely the dominant cause. MCWD-GH-07

The simulated groundwater surface in the Dune Sand Aquifer is inconsistent with the majority of the surfaces simulated by the 2015 version of the model. Specifically, the 2015 version of the model depicted northward flow into the model domain in the Dune Sand Aquifer for multiple of the simulated scenarios, whereas the 2016 version represents the Dune Sand Aquifer as a mound that doesn't extend to the south, which differs from the conceptual model that reflects hydraulic continuity into the Fort Ord area. These differences indicate that the changes made in the 2016 version of the NMGWM also contributed to the problems with the Dune Sand Aquifer simulation and calibration. MCWD-GH-08

Figures 8-9 show nearly consistent west-to-east hydraulic gradients across the model domain in the 400-FT and 900-FT aquifers indicating that the ocean is the primary source of water flowing across the model. Based on these maps, we would infer that nearly all of the volume of these two aquifers throughout the model domain should be substantially impacted by saltwater intrusion. The occurrence and use of freshwater from these lower aquifers indicates that model is over-estimating the gradient and/or not adequately simulating the sources of fresh groundwater inflow to the aquifers within the model domain. MCWD-GH-09

The calibration criteria used to define model acceptability addressed only the difference between simulated and observed groundwater levels at the calibration wells wherein the definition of acceptable was achieving a root mean square error (RMSE) of 10% - 15% of the range in observed groundwater elevations within the model domain. This criteria was more permissive than the 10% value described in the 2015 version of the model documentation and the RMSE for the whole model increased from the 2015 version (10.5 feet)[9] to the 2016 version (12.4 feet)[10]. MCWD-GH-10

[9] Figure 37, Appendix E2 of the 2015 Draft EIR/EIS entitled: Monterey Peninsula Water Supply Project Groundwater Modeling and Analysis, April 17, 2015, prepared by GeoScience, Inc.

[10] Figure 4.3a, Appendix E2 of the 2017 Draft EIR/EIS entitled: North Marina Groundwater Model Review, Revision, and Implementation for Slant Well Pumping Scenarios, November 23, 2016, prepared by HydroFocus, Inc.

Inspection of the calibration plots presented by HydroFocus[11] indicates that the range in groundwater elevations for all simulated aquifers is approximately 200 feet. For the individual aquifers, the ranges are approximately 100 feet, 50 feet, 110 feet, and 80 feet for the Dune Sand, 180-FT, 400-FT, and 900-FT aquifers respectively. The HydroFocus calibration criteria would therefore be 20-30 feet for the whole model, and 10-15 feet, 5-7.5 feet, 11-16.5 feet, and 8-12 feet for the Dune Sand, 180-FT, 400-FT, and 900-FT aquifers respectively. Within this context, the model fails the stated calibration test in the Dune Sand Aquifer (RMSE=30.2). Using the stricter 2015 version of the criteria, the model also fails the calibration test for the 180-FT Aquifer (RMSE=7.2) and the 900-FT Aquifer (RMSE=11.3). In general, we have inferred from the data and results available that the quality of the model calibration declined between the 2015 and the 2016 versions, which further indicates that the changes made during the 2016 revisions have resulted in diminished reliability and contribute to the calibration problems cited by HydroFocus and attributed to the SVIGSM. Moreover, guidelines for model calibration also include ensuring the appropriateness of the model boundary conditions, the conceptual model, and the initial conditions for transient models[12], all of which are problematic in the 2016 NMGWM. MCWD-GH-11

For the reasons described above, the NMGWM predictions of impacts to groundwater resources due to the proposed pumping are not reliable particularly in the Dune Sand Aquifer. The calibration problems in the Dune Sand Aquifer undermine confidence in the hydraulic conductivity assignments in Layer 2 and Layer 3 and therefore the predicted magnitude and spatial extent of the cones of depression in those layers. MCWD-GH-12

HydroFocus performed sensitivity analyses to address uncertainty with respect to hydraulic conductivity assignments by varying the ratio between horizontal and vertical hydraulic conductivity by a factor of five to create scenarios for higher and lower vertical anisotropy[13]. Their results indicate that a five-fold increase in horizontal hydraulic conductivity coupled with a five-fold decrease in vertical hydraulic conductivity can substantially increase the predicted size of the cone-of-depression, nearly doubling the size in the Dune Sand Aquifer. Their findings emphasize the importance of achieving better calibration in the Dune Sand Aquifer to the reliability of the impact predictions. MCWD-GH-13

The boundary conditions problems, particularly the southern boundary in Layer 2, prevents the simulation of inflow to the model domain from the southern boundary and undermines confidence in the predicted contributions to the proposed pumping from the Dune Sand Aquifer. MCWD-GH-14

Finally, the model cannot simulate saltwater intrusion nor the effect of pumping on the position of the transition zone between freshwater and salt water conditions in the aquifers due to the proposed pumping scenarios because it is not a dual-density model. The use of equivalent freshwater heads does not overcome this limitation. MCWD-GH-15

3 SUPERPOSITION MODEL

Superposition modeling is a method used to simulate the effects of some specific and singular form of aquifer stress (including pumping) on groundwater levels that can be used only when the effects of the active aquifer stresses are related linearly, i.e. simply additive. The method is typically used when the totality of aquifer stresses is too complicated to be pragmatically simulated or when there is insufficient data to develop a comprehensive simulation. The superposition method does not add to the confidence in the predictions, it merely simplifies the process of rendering a prediction in exchange for reduced ability to evaluate the condition of the hydrologic system. Such conditions would include groundwater surface elevations, water budget impacts, and/or impacts to existing actions such as other pumping, groundwater/surface water exchange, or cross-boundary flows.

In the case of the NMGWM, superposition models were generated for each pumping scenario by removing all other simulated stresses from the model and adjusting initial and boundary condition heads to 0.0 feet thereby providing a convenient datum for the simulation of cones of depression. In doing this, the models use the same distribution of horizontal and vertical hydraulic conductivities that were derived through model calibration and limited impacts assessments to a prediction of the cone-of-depression associated with each pumping scenario.

MCWD-GH-16

Though superposition modeling is a valid technique, it isn't necessary or appropriate for these evaluations because:

1) superposition modeling precludes evaluation of impacts to the water budget associated with the proposed pumping, i.e. defining the source of water to be extracted, which is a critical and central point of concern for stakeholders regarding the proposed project;
2) superposition modeling precludes prediction of measurable changes associated with the proposed pumping (i.e. predicted groundwater elevations and gradients), which would provide the only means for stakeholders to validate the model predictions and potential project impacts;
3) a comprehensive numerical model that includes other active stresses had been developed and calibrated that could be used to render those assessments;
4) GeoScience had previously developed impact assessments using the calibrated model directly and thus the groundwork for repeating that process had presumably been laid; and
5) a comparison of the cones of depression predicted by the superposition model and those we developed using the calibrated version of the 2016 NMGWM reveal that the prescription of the 0.0 datum to initial and boundary heads constrained their size and thus likely under-estimates the spatial extent of drawdown associated with the proposed pumping (Figures 10-13).

MCWD-GH-17

4 EVALUATION OF POTENTIAL IMPACTS

Though the calibration and boundary condition problems described in Section 2 render predictions derived from the NMGWM unreliable particularly with respect to the Dune Sand Aquifer, we performed one of the scenario analyses using the calibrated NMGWM to expand on the depiction of potential impacts described in the Draft EIR/EIS. To do this, we modified the calibrated model to include the proposed pumping, ran the

MCWD-GH-18

modified model, and compared the results to the calibrated version to evaluate and report impacts to groundwater surfaces and the water budget. We chose scenario DD1-44/56, which assumes a project pumping rate of 24.1 million gallons per day (mgd), no return flows, and 2012 sea level conditions[14].

The associated pumping assignments were copied from the wells file associated with the DD1-44/56 superposition model and inserted into the assignments into the wells file associated with the calibrated model. The model was then rerun to produce results that include the proposed project pumping. This approach effectively assumes that the proposed pumping described by the DD1-44/56 scenario began at the beginning of the transient simulation period wherein all other aquifer stresses remained identical to those prescribed for the calibrated scenario. Water budget and heads were then extracted and used in conjunction with the same output exported from the calibrated scenario as the basis for the impact assessments presented below.

MCWD-GH-18 cont.

4.1 Impact to Groundwater Surfaces

Figures 14-17 depict the simulated groundwater surfaces for the Dune Sand, 180-FT, 400-FT, and 900-FT aquifers exported from the calibrated and DD1-44/56 scenarios after the final timestep in the calibrated model's simulation period. The maps show obvious cones of depression surrounding the proposed pumping wells at the CMEX Site but no obvious perturbations to the groundwater surfaces in the lower 400-FT and 900-FT aquifers.

MCWD-GH-19

Figures 18-21 depict the simulated impacts to the groundwater surfaces (cones-of-depression) in the four aquifers after the first and last timestep in the calibrated model's simulation period that were created by subtracting the calibrated groundwater surface from the DD1-44/56 scenario surface for each aquifer and each timestep. The Dune Sand, 180-FT, and 400-FT aquifers all show obvious impacts that significantly expand over the course of the simulation period where as no impacts greater than or equal to 0.5 feet are predicted to occur in the lowest 900-FT Aquifer. For both the Dune Sand and 180-FT aquifers, reductions in the groundwater surface of more than 1 foot are predicted to extend for considerable distances (>3 miles) to the east, north, and south from the proposed wells and be slightly more extensive in the 180-FT aquifer than in the Dune Sand Aquifer. Reductions of between 0.5 and 1 foot are predicted to extend for more than 6 miles to the northeastern boundary of the Dune Sand Aquifer and more than 4 miles to the northeast in the 180-FT aquifer. Reductions in the groundwater surface of between 5 and 10 feet in both aquifers are predicted to occur to within ~1 mile of the wells (reaching across Cabrillo Highway).

MCWD-GH-20

Appendix 2 provides simplified drawdown maps for each of the four aquifers computed for the last timestep in each year of the 32-year simulation period. These maps show that drawdown in the 180-FT, 400-FT, and 900-FT (shown in these figures as between 0.25 and 0.5 feet) aquifers is predicted to stabilize after approximately 5 years of continuous pumping meaning that the full impact to groundwater surface elevations can be expected to occur within five years after the beginning of pumping. Drawdown maps for the Dune Sand Aquifer reveal a substantially different response over time wherein the cone-of-depression is predicted to continue to expand over the course of ~25 years after the beginning of pumping. Most of the change

[14] *Scenarios_Matrix.xlsx, provided to GeoHydros from the applicant.*

however is isolated to the same teardrop-shaped region where the model must first create the aquifer due to its probable absence in the initial and boundary condition heads derived from the SVIGSM.

Drawdowns created under other of the proposed project scenarios would be proportionally different as defined by the magnitude of pumping and returns. The relative differences between the predictions for the Dune Sand and lower aquifers will however be similar because these are driven by the model configuration more so than the scenario characteristics such as the magnitude of the proposed pumping and/or proposed return flows.

MCWD-GH-20 cont.

4.2 Water Budget Impacts

One of the fundamental capabilities of the numerical groundwater flow model is the water budget analysis, which quantifies all flows into and out of the model through all of the source sink terms incorporated in the model design. The impact of any action or stress to the aquifer can then be evaluated in much the same way as drawdown maps are calculated, by running the water budget report for both the scenario being evaluated and the calibrated scenario and comparing the results. Tables 2 and 3 and Figures 22-24 provide summaries of the water budget analysis conducted from reports extracted and compared in the manner described above for five timesteps in the calibrated and DD1-44/56 scenarios of the 2016 NMGWM. Appendix 3 provides the water budget reports from which these analyses were derived.

Table 2. Summary of water budget analyses performed using reports generated from the calibrated and DD1-44/56 scenarios of the 2016 NMGWM.

MCWD-GH-21

Table 3. Evolution of source water for the proposed extractions as defined by water budget reports exported from five timesteps of the calibrated and DD1-44/56 scenarios of the 2016 NMGWM.

Days after Start	Ocean	DSA	SVA	180-ft	400-ft	900-ft	*Total*	Total GW
30	69.1%	22.3%	4.2%	3.5%	0.6%	0.3%	*100%*	30.9%
365	89.0%	3.6%	0.1%	4.9%	1.6%	0.8%	*100%*	11.0%
730	89.7%	2.4%	0.0%	5.2%	1.8%	0.8%	*100%*	10.3%
3,650	90.0%	1.9%	0.0%	5.3%	1.9%	0.9%	*100%*	10.0%
11,680	90.0%	1.8%	0.0%	5.3%	1.9%	0.9%	*100%*	9.9%

The water budget data indicates that the proposed pumping will initially derive more than 30% of the water from groundwater, predominantly the Dune Sand Aquifer (>22%) and to a smaller extent the 180-FT, 400-FT, and 900-FT aquifers. The groundwater contribution is predicted to decline to approximately 10% within 1-2 years and stabilize at that level of contribution after approximately 5 years throughout the remainder of the 32-year simulation period. Approximately 2.8% of the proposed extractions is predicted to come from the deeper 400-Ft and 900-FT aquifers, which equates to approximately 756 acre-feet per year. This water will come from cross-boundary flows into the respective aquifers and then via upward flow into the overlying 180-FT and Dune Sand Aquifers. Increased cross-boundary flows indicate that the cones of depression created by the existing wells will expand into the adjacent areas outside of the NMGWM domain.

The magnitudes of the water budget impacts described above will differ proportionally with the pumping magnitudes and return flows defined by the different project scenarios. The percentages described in Table 3 will likely be similar owing to the linearity in the groundwater flow and drawdown calculations.

MCWD-GH-21 cont.

5 CONCLUSIONS

- The 2016 NMGWM is poorly calibrated in the Dune Sand Aquifer likely due to incongruity between the NMGWM and the SVIGSM and to the assignment of large constant head elevations offshore in the ocean, Dune Sand Aquifer, Salinas Valley Aquitard, 180-FT Aquifer, 180/400-FT Aquitard, and 400-FT Aquifers.

MCWD-GH-22

- Using the stricter 2015 version of the calibration criteria (10% of observed head variation), the model fails calibration in the 180-FT Aquifer and the 900-FT Aquifer in addition to the Dune Sand Aquifer. In general, we have inferred from the data and results available that the quality of the model calibration declined between the 2015 and the 2016 versions, which indicates that the changes made during the 2016 revisions have resulted in diminished reliability.

MCWD-GH-23

- The poor calibration in the Dune Sand Aquifer undermines confidence in the magnitude and distribution of the assigned horizontal and vertical conductivities, and thus the predicted impact to groundwater elevations and predicted percentage of aquifer water that will be extracted by the proposed project because both of these impacts are largely predicated on the magnitude and distribution of hydraulic conductivities.

MCWD-GH-24

- The steep eastward hydraulic gradient from the ocean across the model domain in the 400-FT and 900-FT aquifers is improbable and inconsistent with the extraction of freshwater from these aquifers from within the model domain, and the groundwater surfaces simulated by all but the driest condition scenarios reported for the 2015 version of the NMGWM.

MCWD-GH-25

- The 2016 NMGWM cannot simulate saltwater intrusion to any of the simulated aquifers nor can it be used to predict how the proposed pumping might affect the position of the transition zone between freshwater and saltwater conditions in the aquifers. MCWD-GH-26
- The use of equivalent freshwater heads does not provide any meaningful simulation of landward saltwater migration and their assignments likely contributes to the calibration problems. MCWD-GH-27
- A dual-density model should be constructed if saltwater intrusion and/or the impact of the proposed project on groundwater salinities is to be evaluated. MCWD-GH-28
- It is unlikely that the incongruity between the NMGWM and SVIGSM hydrostratigraphies can be overcome through model calibration owing to the degree to which initial and boundary heads in the NMGWM are dependent on SVIGSM output, and this limitation undermines confidence in NMGWM predictions. MCWD-GH-29
- Superposition modeling is inappropriate for this evaluation because: MCWD-GH-30
    - it precludes the identification of source water contributions to the proposed extractions, which is a key issue with the application;
    - it precludes prediction of measurable groundwater elevations associated with the proposed pumping, which would provide the only means for stakeholders to validate the model predictions and potential project impacts;
    - it is unnecessary because it provides no benefit in terms of reliability over the use of the calibrated version of the model for impact assessment, which allows for the assessments described above; and
    - the prescription of the 0.0 datum to initial and boundary heads has been shown to constrain the spatial extent of the simulated cones of depression in the aquifers created by the proposed pumping.
- Notwithstanding the limitations of the model described above, the model reveals potential impacts that were not fully described in the Draft EIR/EIS. The most relevant of these are: MCWD-GH-31
    - the proposed pumping will initially derive more than 30% of the water from groundwater, predominantly the Dune Sand Aquifer (>22%) and to a smaller extent the 180-FT, 400-FT, and 900-FT aquifers.
    - Within 1-2 years, the groundwater contribution to the proposed extractions is predicted to decline to approximately 10% and stabilize at that level of contribution throughout the life of the proposed project.
    - A small but relevant portion of the proposed extraction (2.8% or 756 acre-feet for scenario DD1-44/56) is predicted to come from the deeper 400-Ft and 900-FT aquifers indicating that the proposed extractions will contribute to any overdraft problems in those aquifers.
    - For both the Dune Sand and 180-FT aquifers reductions in the groundwater surface of more than 1 foot are predicted to extend for considerable distances (>3 miles) to the east, north, and south from the proposed wells within five years after the start of pumping under the DD1-44/56 scenario. MCWD-GH-32

- The predicted cone-of-depression will be slightly more extensive in the 180-FT aquifer than in the Dune Sand Aquifer.
- Reductions of between 0.5 and 1 foot are predicted to extend for more than 6 miles to the northeastern boundary of the Dune Sand Aquifer and more than 4 miles to the northeast in the 180-FT aquifer within five years of the start of pumping under the DD1-44/56 scenario.
- Reductions in the groundwater surface of between 5 and 10 feet in both aquifers are predicted to occur to within ~1 mile of the wells (reaching across Cabrillo Highway) within five years of the start of pumping under the DD1-44/56 scenario.

MCWD-GH-32 cont.

- The sensitivity analyses performed by HydroFocus with respect to hydraulic conductivity indicate that the predicted impacts could be substantially understated, which demonstrates the importance of achieving better calibration.

MCWD-GH-33

- Reconstructing the model using a dual-density program, extending the model boundaries to natural divides or to a sufficiently distant point that boundary effects on the predicted impacts of the proposed project are eliminated or marginalized, and calibrating the model to groundwater salinities as well as heads would substantially increase the reliability of the predicted impacts.

MCWD-GH-34

- Based on the findings presented in this report, we believe that the Draft EIR/EIS's conclusions regarding the MPWSP's groundwater impacts are not scientifically supportable and that they conflict with available information.
- Given the problems with the model calibration identified above, we do not recommend additional scenario analysis using the 2016 NMGWM because it would not provide scientifically supportable results.
