MEMORANDUM

To: Keith Van Der Maaten, P.E., Marina Coast Water District
Michael Wegley, P.E., Marina Coast Water District

From: Vera Nelson, P.E., Erler & Kalinowski, Inc.
Anona Dutton, P.G., C.Hg, Erler & Kalinowski, Inc.

Subject: Comments Regarding California America Water Monterey Peninsula Water Supply Project Draft Environmental Impact Report/Environmental Impact Statement, Released 13 January 2017
Marina Coast Water District, California
(EKI B60094.01)

On behalf of the Marina Coast Water District ("MCWD" or "District"), Erler & Kalinowski, Inc. ("EKI") has reviewed and prepared comments on the California America Water ("CalAm") Monterey Peninsula Water Supply Project ("MPWSP" or "Project") Draft Environmental Impact Report/Environmental Impact Statement, released 13 January 2017 ("DEIR/EIS"). The DEIR/EIS was prepared on behalf of the California Public Utilities Commission ("CPUC") and the Monterey Bay National Marine Sanctuary ("MBNMS"). The DEIR/EIS analyzes the potential environmental impacts of the proposed CalAm Project which includes an intake system consisting of 10 subsurface slant wells at the CEMEX sand mining site near the City of Marina; a desalination plant; a brine discharge system; product water conveyance pipelines; one pump station; storage facilities; and improvements to the existing Seaside Groundwater Basin's aquifer storage and recovery ("ASR") system. The proposed intake system lies immediately northwest of MCWD's Service Area, which includes the Central Marina Service Area, the MCWD Sphere of Influence ("SOI"), and the Ord Community Service Area, see Figure 1 (Shaaf & Wheeler, 2016).

A central issue addressed in the DEIR/EIS relates to CalAm's legal right to extract source water for the Project from offshore aquifers of the Salinas Valley Groundwater Basin ("SVGB"). This issue is addressed by the State Water Resources Control Board ("SWRCB") in its 2013 letter included in Appendix B2 of the DEIR/EIS, which states that in order for CalAm to appropriate groundwater from the SVGB, the DEIR/EIS must demonstrate that the proposed Project "*will not*

harm or cause injury to other basin users". The SWRCB (2013) makes specific recommendations regarding additional studies and analyses required to make such a demonstration.

EKI's comments on the DEIR/EIS evaluate: (1) the adequacy of information presented in the DEIR/EIS to meet the SWRCB's requirement that the proposed Project "*will not harm or cause injury to other basin users*", and (2) whether the Project specifically has the potential to harm or cause injury to MCWD interests in the local subbasins. Where information is found to be inadequate, additional studies, demonstrations, and/or mitigation measures are identified. Specific issues discussed in this comment letter are summarized below.

- **The DEIR/EIS does not incorporate water quality from the Dune Sand Aquifer and 180-Foot Aquifer from nearby Fort Ord where over 300 monitoring wells have been installed.** The omission of these data leads to an incomplete understanding of hydrogeologic conditions and the importance of the Dune Sand Aquifer in limiting saltwater intrusion and providing fresh water recharge to the 180-Foot Aquifer within MCWD's service area. Fort Ord water quality data and water quality data collected from Cal Am monitoring wells show that fresh water exists in both the Dune Sand Aquifer and the upper 180-Foot Aquifer outside of the immediate area of the CEMEX site. This information is critical to the evaluation of the Project which will influence groundwater flow in these zones and disrupt the current system equilibrium.

- **The DEIR/EIS dismisses the potential beneficial use of groundwater within the Dune Sand and 180-Foot Aquifers.** Their characterization is based on assumed "poor water quality" and the current absence of groundwater production wells. This characterization is inconsistent with available monitoring well data, the Water Quality Control Plan for the Central Coastal Basin "Basin Plan" (RWQCB, 2016), and the remedial action objectives applied to these aquifer zones at Fort Ord, where millions of dollars have been spent restoring groundwater to drinking water standards. The DEIR/EIS also fails to consider the Project's impact on potential beneficial use of these aquifer zones for storage or augmentation of groundwater supplies through applied recharge. Multiple studies and field investigations have been conducted by MCWD since 2008 to assess such groundwater recharge options at the nearby Armstrong Ranch, many of which would be precluded by the Project.

- **The DEIR/EIS provides inadequate documentation of groundwater modeling inputs and outputs to facilitate transparency, public review, and future verification of results**. The DEIR/EIS does not include figures identifying assumed baseline water levels

in each aquifer zone so hydraulic gradients can be verified. This issue is of particular concern for the Dune Sand Aquifer where model calibration results for Fort Ord wells are extremely poor. The DEIR/EIS also does not identify groundwater flow paths prior to and after Project implementation so changes to salt water migration patterns can be assessed and effects of boundary conditions can be evaluated. The use of superposition also precludes verification of modeling results through future monitoring. Most importantly, the modeling does not assess potential water quality changes to the Dune Sand Aquifer and the upper 180-Foot Aquifer that will occur as a result of reduced recharge from the Dune Sand Aquifer and induced saltwater migration inland of the Project's slant wells.

- **Groundwater modeling presented in the DEIR/EIS predicts that extraction from the slant wells will create significant water level declines within in the Dune Sand and 180-Foot Aquifers.** Although it is impossible to accurately assess the impacts of the Project on groundwater levels within MCWD's service area, given the poor model calibration for the Dune Sand and 180-Foot Aquifers south of the Salinas River, the model does predict that drawdowns will extend between 1.5 and 4.5 miles inland into MCWD's service area. Nonetheless, the DEIR/EIS does not acknowledge that any negative impacts to water quality will occur as a result. Cal Am proposes to replace groundwater withdrawn from these aquifer zones by in-lieu recharge in the 400-Foot Aquifer outside of MCWD's service area. This proposed in-lieu recharge, however, will not mitigate the Project's adverse impacts to Dune Sand and 180-Foot Aquifers or avoid harm to MCWD water rights. Nor does it recognize that the Project will preclude MCWD from utilizing the Dune Sand Aquifer for storage and/or augmentation of groundwater supplies through surface water recharge at Armstrong Ranch.

Further information in support each of these comments is provided below.

1. THE PROJECT DOES NOT DEMONSTRATE COMPLIANCE WITH SWRCB REQUIREMENTS FOR APPROPRIATION OF GROUNDWATER FROM THE SVGB

The SWRCB 2013 letter included in Appendix B2 of the DEIR/EIS (SWRCB, 2013) states: MCWD-EKI-1

> *To appropriate groundwater from the Basin, the burden is on Cal-Am to show their project will not cause injury to other users… The groundwater quality in the Basin will be a key factor in determining the effects of extraction on groundwater users in the Basin, assessing*

> *any potential injury that may occur, and measures that would be necessary to compensate for it…*
>
> *Additional information is needed to accurately determine MPWSP impacts on current and future conditions of the Basin regardless of whether the extraction occurs from pumped or gravity wells. First, specific information is needed on the depth of the wells and aquifer conditions. Studies are needed to determine the extent of the Dune Sand Aquifer, the water quality and water quantity of the Dune Sand Aquifer, the extent and thickness of the Salinas Valley Aquitard, and the extent of the 180-Foot Aquifer.*

As described in detail in the following comments, the DEIR/EIS does not meet the SWRCB criteria for demonstrating that the Project *will not cause injury*. In particular, through omission of publicly available data, the DEIR/EIS does not accurately characterize water quality and hydrogeologic conditions within the Dune Sand Aquifer and 180-Foot Aquifer in the vicinity of Project which includes the northern portion of MCWD's Service Area (i.e., including the Ford Ord portion of the Monterey Subbasin) (see Figure 2). As shown in Figures 3 and 4, water quality data, specifically Total Dissolved Solids ("TDS") and chloride data, have been collected over the years in the vicinity of the Project and south into Fort Ord. These data show that groundwater with TDS concentrations of less than 3,000 milligrams per liter ("mg/L"), which is the SWRCB Resolution No. 88-63 criteria *potentially suitable, for municipal or domestic water supply*[1] standard for drinking water, is present in the Dune Sand Aquifer and the 180-Foot Aquifer in the vicinity of the Project site and south into Fort Ord. These data show that the Dune Sand Aquifer and upper 180-Foot Aquifer are an important source of water in the region. As a result of this failure, the DEIR/EIS fails to analyze or disclose that increased groundwater extraction from Project wells

MCWD-EKI-1 cont.

[1] SWRCB Resolution No. 88-63 states:

All surface and ground waters of the state are considered to be suitable, or potentially suitable, for municipal or domestic water supply and should be designated by the Regional Boards with the exception of surface and ground waters where:

a. *The total dissolved solids (TDS) exceed 3,000 mg/L (5,000 us/cm, electrical conductivity) and it is not reasonably expected by Regional Boards to supply a public water system, or*
b. *there is contamination, either by natural processes or by human activity (unrelated to a specific pollution incident), that cannot reasonably be treated for domestic use using either Best Management Practices or best economically achievable treatment practices, or*
c. *The water source does not provide sufficient water to supply a single well capable of producing an average, sustained yield of 200 gallons per day.*

would impact the equilibrium of that system and the local and regional groundwater quality. Therefore, the DEIR/EIS does not demonstrate compliance with the SWRCB requirements for appropriation of groundwater from the SVGB

MCWD-EKI-1 cont.

2. PROJECTED IMPACTS FROM THE PROJECT ARE INCONSISTENT WITH THE BASIN PLAN

Potential degradation of groundwater water quality in the Dune Sand Aquifer and the 180-Foot Aquifer by the Project violates the Water Quality Control Plan for the Central Coastal Basin "Basin Plan" (RWQCB, 2016), which designates all groundwater within the SVGB as potential drinking water source[2]. As shown in Figures 3 and 4, groundwater in the Dune Sand Aquifer and upper 180-Foot Aquifer inland of the Project site meets the SWRCB Resolution No. 88-63 criteria for *potentially suitable, for municipal or domestic water supply*. This beneficial use designation within the Basin Plan is articulated as an applicable or relevant and appropriate requirement ("ARAR") within the Fort Ord Basin Wide Record of Decision (U.S. Department of the Army, 1997). As such, national and state primary drinking water standards are identified as ARARs and established as remedial action objectives for groundwater in the Dune Sand Aquifer and 180-Foot Aquifer at chemically impacted sites at Fort Ord. Millions of dollars have been, and continue to be spent, to remediate groundwater to meet these remedial action objectives within these aquifer zones. Therefore, statements made within the DEIR/EIS that imply that these aquifer zones have poor water quality and therefore have limited or no beneficial use, are inconsistent with the Basin Plan and any potential degradation of groundwater within these aquifers must be addressed within the DEIR/EIS.

MCWD-EKI-2

The Basin Plan further states that:

> *Controllable water quality shall conform to the water quality objectives contained herein. When other conditions cause degradation of water quality beyond the levels or limits established as water quality objectives, controllable conditions shall not cause further degradation of water quality*[3].

Therefore, further degradation of existing water quality even within brackish areas of the aquifers is also precluded under the Basin Plan.

[2] Basin Plan *Chapter 2.I. Present and Potential Beneficial Uses*. States: "Ground water throughout the Central Coastal Basin, except for that found in the Soda Lake Sub-basin, is suitable for agricultural water supply, municipal and domestic water supply, and industrial use."
[3] RWQCB,2016. Chapter 3. Section II Water Quality Objectives. Page 3-1

3. HYDROGEOLOGIC CONDITIONS AND WATER QUALITY IN DUNE SAND AQUIFER AND UPPER 180-FOOT AQUIFER ARE INCOMPLETELY CHARACTERIZED IN THE DEIR/EIS

The Project slant wells at the CEMEX Site will be screened through the Dune Sand Aquifer and into the 180-Foot Aquifer. These wells will draw groundwater from these zones and potentially underlying aquifer zones. Therefore, characterization of groundwater quality and flow conditions within these aquifer zones is critical to understanding Project impacts. Cal Am recently installed eight groundwater monitoring well clusters (MW-1, MW-3, MW-4, MW-5, MW-6, MW-7, MW-8, and MW-9) to further assess baseline groundwater conditions and monitor the response to extraction at the test slant well installed at the CEMEX Site. When information from these wells is combined with data from Fort Ord, a basic understanding of groundwater flow and quality conditions in the Project vicinity and within the northern portion of MCWD's Service Area can be inferred with reasonable confidence; such work or understanding is not reflected in the DEIR/EIS.

MCWD-EKI-3

Specifically, the baseline water level data and water quality information presented in the DEIR/EIS for the adjacent MCWD Service Area is incomplete. No water level maps for the Dune Sand Aquifer are included, although, as described below, water level data have been collected from local and CalAm monitoring wells that, when plotted, show a Bay-ward gradient and an apparent connection between the Dune Sand Aquifer and the 180-Foot Aquifer in the vicinity of the Project site. In addition, publicly-available water quality data from Fort Ord, where over 300 monitoring wells in the Dune Sand Aquifer and 180-Foot Aquifer have been installed, are not presented or analyzed.

Further, although the DEIR/EIS estimates projected drawdown within the Dune Sand Aquifer and 180-Foot Aquifer, the DEIR/EIS does not address the impacts of the Project on freshwater recharge from the Dune Sand Aquifer into the 180-Foot Aquifer. It is apparent that the modeling does not accurately characterize baseline water level conditions in these aquifer zones based on the limited information included in the DEIR/EIS for this area and extremely poor model calibration results are reported for the Dune Sand Aquifer (i.e., the root mean square error between modeled and observed water levels for the Dune Sand Aquifer is 30.2 feet).

3.1 The DEIR/EIS Does Not Adequately Characterize or Address Project Impacts to Groundwater Flow Within and Between the Dune Sand and 180-Foot Aquifers

The DEIR/EIS provides limited information regarding groundwater levels and hydraulic gradients in the Dune Sand Aquifer and 180-Foot Aquifer in the northern portion of MCWD's Service Area although over 300 monitoring wells have been installed at Fort Ord in these aquifer zones. For example, DEIR/EIS Figures 4.4-5 and 4.4-7 only present baseline water level data for the 180-Foot Aquifer in the 180/400 Foot Subbasin north of the Salinas River and in the Seaside Subbasin, respectively – no data are presented for the Monterey Subbasin, which lies between those two subbasins and includes the MCWD Service Area. Selected Fort Ord wells have been incorporated into the numerical model, however calibration results for the Dune Sand Aquifer are poor and do not accurately reflect baseline conditions[4]. The DEIR/EIS's failure to adequately characterize baseline conditions in the Dune Sand Aquifer is exemplified in its statement: MCWD-EKI-3.1

> *The groundwater flow patterns within the Dune Sand Aquifer are not known but, based on the aquifer depth and geologic structure, it is reasonable to expect that they would be tidally controlled, with little to no net horizontal flow in any particular direction*[5].

Draft Technical Memorandum No.2 ("TM2") referenced in the DEIR/EIS (Geosciences, 2016), includes water level maps for the Dune Sand Aquifer and 180-Foot Aquifer[6]. However, these maps further complicate and obscure the continuity of groundwater flow within the Dune Sand Aquifer, by separating this aquifer into a "perched zone" and "-2 foot aquifer zone", and incorrectly imply that groundwater flow is discontinuous between Fort Ord and the northern portion of MCWD service area in both the Dune Sand and 180-Foot Aquifers. Copies of these maps are presented in Appendix B hereto.

[4] The root mean square error between modeled and observed water levels for the Dune Sand Aquifer was 30.2 feet.
[5] DEIR/EIS Section 4.4.1.3 Groundwater Flow and Occurrence; Groundwater Elevations and Flow Directions page 4.4-14
[6] TM2 Figure 9- Groundwater Elevations – "Perched Aquifer" (Using Fort Ord "A" Aquifer Wells, MCPCA 35-Foot Aquifer Wells, and MPWSP MW-5S) Fall 2015; Figure 10 - Groundwater Elevations – "Dune Sand Aquifer" (Using MCPCA -2-Foot Aquifer Wells, and MPWSP Shallow Completions and showing Fort Ord "A" Aquifer Monitoring Wells) Fall 2015; Figure 11- Groundwater Elevations – "180-FTE/180-Foot Aquifer" (Using Fort Ord Upper 180-Foot Aquifer Wells and MPWSP Middle Completions) Fall 2015

In contrast to this finding, EKI used water level data collected from CalAm[7] and Fort Ord wells to map hydraulic gradients in the Dune Sand Aquifer and 180-Foot Aquifer in the northern portion of MCWD's Service Area. These maps are presented on Figures 5 and 6, respectively, and present water level data measured in:

(a) Cal Am monitoring wells on 3 May 2016, immediately prior to the restart of extraction from the slant well[8], and
(b) Fort Ord wells in early June 2016, as part of the self-monitoring program conducted by the Army.

As shown on Figure 5, groundwater in the Dune Sand Aquifer in the northern portion of MCWDs Service Area is significantly above sea level and flows west towards Monterey Bay. In contrast, as shown in Figure 6, groundwater in the 180-Foot Aquifer flows eastward towards a regional pumping center in the interior of the Salinas Valley. Based on the head differences between these aquifers it is apparent that the Dune Sand Aquifer is "perched" on the Salinas Valley Aquitard in inland areas but has some degree of connection with the 180-Foot Aquifer as one moves west towards the Bay (i.e., the head difference between the two aquifer systems lessens near the Project Site).

MCWD-EKI-3.1 cont.

These water level data in combination with water quality data obtained from Fort Ord indicate that fresh water from the Dune Sand Aquifer seeps down into the upper portion of the 180-Foot Aquifer upgradient of coast and the Project site and then "U-turns" and flows back into the basin. The exact location and volume of groundwater that seeps from the Dune Sand Aquifer into the upper 180-Foot Aquifer and makes this "U-Turn" has not been quantified. However, data from Fort Ord indicates that seepage from the Dune Sand Aquifer near Monterey Bay (where water levels are above sea level) into the underlying 180-Foot Aquifer (where water levels are below sea level) has effectively stopped salt water intrusion in the upper 180-Foot Aquifer in that area. This natural mounding has maintained freshwater in the upper portion of the 180-Foot Aquifer under much of Fort Ord (see Figures 3 and 4). This natural barrier appears to have been undermined north of Fort

[7] Cal Am installed 8 well clusters (MW-1 and MW-3 through MW-9) in the northern portion of MCWD's Service Area in 2015. These wells were installed pursuant to the requirements of Coastal Development Permit and a request by the Monterey County Water Resource Agency ("MCWRA").

[8] Water level data from MRWPCA-1 collected during the baseline period ending on 11 April 2015, indicates that the potentiometric head elevation was -5 ft MSL. Although the transducer in this well apparently failed after the baseline period, review of water level data from nearby Cal Am 180-Foot Aquifer monitoring wells (MW-7M, MW-5M) indicates that water levels measured in 2015 are generally consistent with those measured in 2016, outside of the direct influence of the slant well and that water levels declined approximately 2 to 4 feet between April and May in the 180-Foot Aquifer in 2015 and 2016. Therefore, an estimated water level of -7 ft MSL has been included on Figure 6 for MRWPCA-1, for general reference. Replacement of the transducer in this well is recommended along with hand measurements to verify hydraulic gradients in this area.

Ord through groundwater extraction and/or salt water discharges into the Dune Sand Aquifer at the CEMEX Plant, and would likely be further disturbed by the Project. MCWD-EKI-3.1 cont.

3.2 The DEIR/EIS Does Not Adequately Characterize Water Quality Conditions in the Dune Sand Aquifer and 180-Foot Aquifer

The water quality data included in the DEIR/EIS for the Dune Sand Aquifer and the 180-Foot Aquifer is limited to the immediate vicinity of the CEMEX facility where salt water intrusion has occurred and does not accurately characterize water quality as more broadly observed in these aquifer zones. For example, statements made in the DEIR/EIS indicate that groundwater within Dune Sand Aquifer and the 180-Foot Aquifer are directly and widely impacted by sea water[9,10]. However, the absence of inclusion of data from Fort Ord leads to an incomplete understanding of hydrogeologic conditions and the importance of the Dune Sand Aquifer in actually limiting saltwater intrusion and providing fresh water recharge to the 180-Foot Aquifer within the northern portion of MCWD's Service Area and inland of the Project site. Contrary to statements made in the DEIR/EIS, water level and water quality data obtained at Cal Am's recently installed monitoring well clusters MW-5, MW-6, MW-7 and Monterey Regional Water Pollution Control Agency ("MRWPCA") wells 1 and 2, indicate that chloride and TDS concentrations in the Dune Sand Aquifer and upper portion of the 180-Foot Aquifer meet SWRCB Resolution No. 88-63 criteria as a potential drinking water source and California Secondary Drinking Water Standards for these constituents[11]. Maps depicting TDS and chloride concentrations detected in groundwater samples most recently collected from Fort Ord and CalAm wells screened in these zones over the last 10 years (i.e., 2006 through 2016) are presented on Figures 3 and 4. These figures show that, outside of the immediate area of the CEMEX Site, groundwater in these aquifer zones is <u>not brackish</u> as characterized in the DEIR/EIS. MCWD-EKI-3.2

[9] On page 4.4-6 and 4.4-8 the DEIR/EIS states *Water quality of the Perched A Aquifer and Dune Sand Aquifer is directly influenced and controlled by seawater. Because of the aquifer's proximity to the ocean, most of the water in the Dune Sand Aquifer has been intruded by seawater and is considered saline to brackish (Kennedy/Jenks, 2004). This influence decreases inland where the infiltration of precipitation and applied agricultural water has more of an influence.*

[10] On page 4.4-11the DEIR/EIS states *Based on the recent groundwater testing data discussed in the Groundwater Quality subsection below, the quality of water in the 180-FTE Aquifer is directly influenced by seawater; this influence extends for miles inland, as discussed below in the Seawater Intrusion section. The lower portion of the proposed slant wells at the CEMEX site would have well screens installed across and would draw water from these deposits*

[11] The recommended and upper secondary maximum contaminant levels for chloride are 250 mg/L and 500 mg/L. The recommended and upper secondary maximum contaminant level for total dissolved solids (TDS) is 500 mg/L and 1000 mg/L, respectively. (California Code of Regulations, Title 22. Division 4 Environmental Health, Chapter 15. Domestic Water Quality and Monitoring Regulations, Article 16, dated 27 September 2006.

The information presented in Figures 3 and 4 is consistent with data collected at Fort Ord in the late 1990's which was presented in Harding ESE's, *Final Report Hydrogeologic Investigation of the Salinas Valley Basin in the Vicinity of Fort Ord and Marina Salinas Valley, California,* prepared for MCWRA dated 12 April 2001. (Harding, 2001). A copy of selected figures which depict water quality information from the upper 180-Foot Aquifer zone are included in Appendix A, hereto.

Geologic, water level, and water quality information from Fort Ord indicates that there are multiple clay zones within the 180-Foot Aquifer. As one moves deeper within this aquifer the salinity increases. A north-south transect that extends from Fort Ord into the area inland of the CEMEX facility was constructed (Figure 7). The transect identifies well screen depths and TDS and chloride measurements in wells screened in the 180-Foot Aquifer (Figure 8). These figures show that wells at Fort Ord that are screened in the upper 180-Foot Aquifer contain fresh water, but that salinity likely increases with depth. This is particularly apparent at well MCWD#05[12], which has a long screened interval that extends across the upper and lower portions of the aquifer[13]. Vertical profiling conducted in 1991 during groundwater extraction indicated:

MCWD-EKI-3.2 cont.

- TDS concentrations of <1,000 mg/L in the upper portion of the screen interval (i.e., elevations above -155 ft MSL); and
- TDS concentrations of approximately 5,000 mg/L at bottom of screen interval (i.e., elevations between -195 ft MSL to -235 ft MSL) (Stalle, Gardner & Dunne, Inc., 1991).

These data provide insight regarding TDS concentrations detected in wells with long screened intervals, such as those constructed by CalAm, which likely reflect a mix of lower salinity (fresh) water from the upper portions of the 180-Foot Aquifer and more saline water from the deeper portion of the aquifer. Therefore, data from these wells is difficult to interpret and inadequate for characterizing salinity within the upper portions of the 180-Foot Aquifer. It is likely that the well known saltwater intrusion maps prepared by MCRA and cited in the DEIR/EIS are based on wells screened in the lower portion of the 180-Foot Aquifer[14].

[12] Well MCWD#05 is screened in the 180 Foot Aquifer and was shut down in 1983 due to elevated TDS concentrations (i.e., up to 4,000 mg/L).
[13] The screen at well MCWD#05 extends from approximately 216 ft below ground surface ("bgs") to 370 ft bgs; corresponding to an elevation of -91 feet mean sea level ("ft MSL") to -245 ft MSL
[14] In locations where wells screen across both fresh water and saline water and vertical gradients exist between zones TDS concentrations measured in the well bore may only reflect the salinity of groundwater from the zone at higher hydraulic head, as groundwater flows down the well bore from the zone with higher head to lower head, and therefore samples collected are not reflective of water quality in both zones. Such conditions were observed at MCWD#05, where vertical profiles of EC measurements during pre-pumping static conditions were all 500 micro

Arguments have been made that extraction from the upper 180-Foot Aquifer would inevitably draw water from deeper zones. However, numerous groundwater extraction wells have been operating within the upper 180-Foot Aquifer at Fort Ord to facilitate remediation of volatile organic compounds. These wells have maintained low salinity levels, demonstrating the significant vertical stratification of salinity within higher permeability sediments within the 180-Foot Aquifer. These conditions confirm the aquifer's beneficial use designation within the Basin Plan and substantiate remedial action objectives established at Fort Ord, which are reviewed by the U.S. Environmental Protection Agency every five years, and continue to drive remedial efforts at Fort Ord to bring groundwater back to drinking water standards. As such, statements made in the DEIR/EIS that dismiss the beneficial use and conditions of the local groundwater system are inconsistent with the data and minimize the potential impact that the Project will have on degrading groundwater quality.

MCWD-EKI-3.2 cont.

4. THE PROJECT WILL IMPACT GROUNDWATER CONDITIONS AND MCWD'S ABILITY TO IMPLEMENT GROUNDWATER RECHARGE AUGMENTATION AT ARMSTRONG RANCH

4.1 Impacts of the Project on Groundwater Conditions

Construction and operation of the Project as proposed will (a) limit recharge of fresh water from the Dune Sand Aquifer into the upper 180-Foot Aquifer, (b) influence this natural hydraulic barrier and (c) decrease the existing freshwater zone within a portion of MCWD's service area. The estimated area of impact from the Project's proposed intake system on the Dune Sand and 180-Foot Aquifer is presented on Figures 9 and 10. This figure shows that the zone of influence extends anywhere from 1.5 miles to 4.5 miles inland based on modeled results[15]. As shown in these figures, withdrawal of groundwater from the proposed slant wells will draw fresh water from Dune Sand Aquifer, which in turn will decrease recharge of such water into to the 180-Foot Aquifer. The full extent of these impacts is unknown and must be evaluated prior to Project approval.

MCWD-EKI-4

Further, water within both the Dune Sand Aquifer and upper 180-Foot Aquifer will be fully saline within the zone of capture of the slant wells, as ocean water will be drawn into these areas by the slant wells. The predicted lateral extents of these capture zones based on groundwater modeling

siemens (i.e., 270 mg/L TDS). These conditions could explain, low salinity levels measured in samples collected in Some Cal Am wells and MRWPCA wells 1 and 2, which are screened at the base of this aquifer zone.

[15] Figure E3 of Appendix E2 of DEIR EIS

results are depicted on Figure 5.6 of Appendix E2 of the DEIR/EIS and have been included on Figures 11 and 12, herein. No current water quality data exists in the southern portion of these capture zones which may extend into areas where non-saline water currently exists. Further characterization of water quality in these areas is needed prior to Project approval to verify that degradation of the beneficial uses of groundwater will not occur at these locations. In addition, it is anticipated that the salinity of groundwater within the Dune Sand Aquifer and 180-Foot Aquifer will increase immediately inland of these capture zones as saline water is drawn into these areas to backfill groundwater that is withdrawn. The DEIR/EIS discounts such impacts as it erroneously characterizes all water within the area as salt water intruded and does not recognize its designated beneficial use. The modeling in the DEIR/EIS must estimate changes in salinity within MCWD's Service Area.

4.2 Impacts of MPWSP on MCWD's Ability to Implement Groundwater Recharge Augmentation at Armstrong Ranch

MCWD-EKI-4 cont.

The Project will also affect MCWD's ability to utilize the Dune Sand Aquifer for storage and/or groundwater recharge augmentation at Armstrong Ranch. Armstrong Ranch is a 230 acre property located with MCWD's sphere of influence and owned by MCWD (Figures 1 and 2). MCWD has conducted multiple studies to evaluate the potential for groundwater recharge augmentation at Armstrong Ranch. These studies include:

- Todd Engineers, 2008. *Phase I Investigation Armstrong Ranch Groundwater Storage Project.* Marina Coast Water District, Marina;
- RMC, 23 May 2008. *Preliminary Draft Technical Memorandum, Armstrong Ranch: Seasonal Subsurface Storage of Recycled Water, Modeling TM;*
- RMC, 2 October 2008. *Draft Technical Memorandum, Marina Coast Water District – Water Augmentation Project; and*
- EKI, 16 January 2017. *Technical Memorandum, Preliminary Feasibility Assessment – Potential to Conduct Augmented Groundwater Recharge at the Armstrong Ranch Property*

These studies evaluate the potential for infiltrating and or/storing surplus Salinas River storm flows and/or tertiary treated recycled water from MRWPCA in the Dune Sand Aquifer and potentially extract stored water from the Dune Sand or 180-Foot Aquifers. The studies include:

(a) Compilation/evaluation of historic water levels from (3) existing Dune Sand Aquifer monitoring wells located on Armstrong Ranch, completion of four (4) borings and four cone penetrometer testing ("CPT") sites to assess geologic conditions in the Dune Sand Aquifer at Armstrong Ranch, (Todd, 2008);
(b) Numerical groundwater monitoring to estimate the volume of water that could be stored in the Dune Sand Aquifer through infiltration, (RMC, 2008a);
(c) Conceptual plans and cost estimates for storage of Salinas River winter storm flows that exceed National Oceanic and Atmospheric Administration National Marine Fisheries ("NOAA") instream requirements within the Dune Sand Aquifer (RMC, 2008b);
(d) A feasibility study assessing the viability and potential costs for increasing MCWD's water supplies through augmented groundwater recharge at the Armstrong Ranch Property (EKI, 2017).

MCWD-EKI-4 cont.

The studies conclude that local hydrogeologic conditions would support enhanced groundwater recharge at Armstrong Ranch. One of the simplest and most cost effective options evaluated as part of the EKI's (2017) feasibility study focuses on direct infiltration of surplus Salinas River storm flows and/or tertiary treated recycled water from MRWPCA into the Dune Sand Aquifer for later extraction from the 180-Foot Aquifer at Armstrong Ranch[16]. Further description of this option is illustrated on Figure 13.

Implementation of such an option could be used to augment MCWD groundwater supplies by approximately 1,500 acre-feet per year ("AFY") to 3,000 AFY, and could aid in limiting salt water intrusion within the 180-Foot Aquifer. The Project as proposed, however, would preclude MCWD from utilizing the Dune Sand Aquifer for storage and/or groundwater recharge augmentation at Armstrong Ranch, because groundwater within the Dune Sand Aquifer downgradient of Armstrong Ranch would be drawn into the Project's slant wells and not return to the groundwater system within MCWD's service area.

5. THERE ARE SIGNIFICANT DEFICIENCIES IN THE GROUNDWATER MODELING APPROACH AND PRESENTATION

MCWD-EKI-5

The DEIR/EIS provides inadequate documentation of groundwater modeling inputs and outputs to facilitate transparency and public review of results. For example, the DEIR/EIS does not include

[16] Salinas River storm flows could be augmented by tertiary treated wastewater flows, if it were demonstrated that waste water flows had at least one (1) year of residence time within the aquifer.

figures identifying assumed and calibrated baseline water levels in each aquifer zone so hydraulic gradients can be verified. This issue is of particular concern south of the Salinas River for the 180-Foot Aquifer and the Dune Sand Aquifer where model calibration results for Fort Ord wells are extremely poor and water quality conditions are mischaracterized in statements made in the DEIR/EIS (see Section 3.1 herein). The DEIR/EIS also does not identify groundwater flow paths prior to and after Project implementation so changes to salt water migration patterns can be assessed and effects of boundary conditions can be evaluated. The use of a superposition model, also precludes verification of modeling results through future monitoring and obscures potential model deficiencies. Most importantly, the modeling does not assess potential water quality changes to the Dune Sand Aquifer and the upper 180-Foot Aquifer that will occur as a result of reduced recharge from the Dune Sand Aquifer and induced saltwater migration inland of the Projects slant wells. In order to evaluate potential impacts of the Project on salt water intrusion and water quality, a well calibrated density dependent fate and transport model must be used.
The absence of this information does not meet the requirements specified by the SWRCB in its 2013 letter, discussed in Section 1 herein, and does not address the extent of the project's potential degradation of groundwater which would be in direct violation of the Basin Plan.

MCWD-EKI-5 cont.

6. IN-LIEU RECHARGE DOES NOT ADDRESS PROJECT IMPACTS ON MCWD'S SERVICE AREA

The DEIR/EIS states that slant wells will draw water and create water level declines within in the Dune Sand Aquifer and 180-Foot Aquifer approximately 1.5 to 4.5 miles inland of the slant wells within MCWD's service area, but does not acknowledge that any negative impacts to water quality will occur as a result of such withdrawals as it dismisses potential beneficial use of groundwater within these aquifer zones. Cal Am proposes to replace groundwater withdrawn from these aquifer zones by in-lieu recharge of the 400-foot aquifer within other areas of the SVGB. This replacement water does not mitigate impacts or avoid harm to MCWD water rights, nor does it recognize that the Project will preclude MCWD from utilizing the Dune Sand Aquifer for storage and/or augmentation of groundwater supplies through surface water recharge at Armstrong Ranch.

MCWD-EKI-6

7. CONCLUSIONS

The DEIR/EIS does not demonstrate the proposed Project "*will not harm or cause injury to other basin users*" as required by the SWRCB for CalAm to appropriate groundwater from the SVGB, (SWRCB, 2013). These comments demonstrate that prior to Project approval Cal Am must at a minimum:

MCWD-EKI-7

(a) Further characterize baseline hydrogeologic and salinity conditions in the Dune Sand and 180 Foot Aquifers in MCWD's Service Area, including installation of additional groundwater monitoring wells to establish baseline water quality conditions and facilitate future monitoring of groundwater within the Dune Sand Aquifer and upper and lower portions of the 180-Foot Aquifer within the predicted capture zone of the slant wells

(b) Expand/modify groundwater modeling and use a well calibrated density dependent fate and transport model to assess changes in salinity within each aquifer, including the upper 180-Foot Aquifer zone, to demonstrate that the Project will not degrade groundwater quality in MCWD's Service Area and not preclude MCWD's options for groundwater augmentation at Armstrong Ranch.

(c) Commit to future long-term monitoring of water levels and water quality within MCWD's Service Area if the Project is implemented to demonstrate that the Project does not degrade groundwater conditions within MCWD's service area and provide a mitigation plan to address any degradation in water quality that is observed. Such monitoring and mitigation should be conducted under the oversight of the RWQCB, to verify that the Project does not violate the provisions of the Basin Plan.

Attn: Mr. Keith Van Der Maaten
General Manager

Dear Mr. Van Der Maaten:

Subject: Monterey Peninsula Water Supply Project
Draft Environmental Impact Report/Environmental Impact Statement

Intake Works LLC has reviewed the Draft Environmental Impact Report/Environmental Impact Statement for the Monterey Peninsula Water Supply Project prepared for California Public Utilities Commission and the Monterey Bay National Marine Sanctuary (dated January 2017) and provides these comments regarding potential alternatives to the proposed MPWSP slant well intake system and desalination plant, as requested. As we previously informed you, our review of the DEIR/EIS was initially hampered by delays in receiving references cited in the DEIR/EIS and ultimately the lack of any references for most of the DEIR/EIS's conclusions regarding alternative intake technologies. Based on information provided in the DEIR/EIS and the limited reference materials cited in the document and appendices, the DEIR/EIS's conclusion that slant wells are the only potentially feasible subsurface intake system for the MPWSP is unsupportable. While we generally agree with the DEIR/EIS's conclusions regarding the unacceptable impacts of open water intakes, there are several alternative subsurface intake technologies that are likely feasible (based on available information) and would avoid or reduce the MPWSP's significant impacts as discussed below. MCWD-IW-01

Comments on MPWSP DEIR/EIS

In preparing these comments, we have reviewed the relevant portions of (1) the DEIR/EIS (2) the DEIR/EIS appendices; (3) references cited in the DEIR/EIS and DEIR/EIS appendices (where available); and (4) publicly available information referenced in these comments. We have also conducted independent research regarding intake technologies based on work in this area and our experience in seawater desalination. MCWD-IW-02

I. Comments on Open-Water and Subsurface Intakes (Appendix I1)

As requested, our comments focus on whether there are potentially feasible intake technologies for the MPWSP that could reduce the project's environmental impacts. Therefore, our review was primarily focused on Appendix I1 (and the limited reference materials cited in the appendix). We provide the following comments on Appendix I1, which are identified under section headings for ease of reference:

A. ***Comments on Operations and Maintenance Considerations for Open-Water Intakes (I1-3)***

The Open-Water Intake section's statement that maintenance would occur every 3 to 5 years is not supported by any research and appears unrealistic (See p. I1-3). Based on reports from existing seawater intakes in the Monterey Bay National Marine Sanctuary and other intakes along the Monterey Bay, it is more likely that Intake Screens would need to be cleaned every 3 to 5 months.[1] The Intake pipelines would also need to be "pigged" at least annually.[2] MCWD-IW-03

B. ***Comments on Subsurface Intakes (I1-3 through I1-7):***

The General Comments section of Subsurface Intakes states: "*the magnitude of potential entrainment of marine species into the bottom sediments caused by continuous subsurface intake operations has not been systematically and scientifically studied to date*" citing WateReuse 2011 (See p. I1-3). While a full citation of the reference was not provided in the DEIR/EIS reference materials, we assume the citation referred to in Appendix I1 is the white paper entitled "Desalination Plant Intakes Impingement and Entrainment Impact and Solutions" from the WateReuse Foundation which states, "to date there are no studies that document the actual level of entrainment reduction that can be achieved by these types of intakes." (WateReuse 2011, p. 9).[3,4] This nonsensical statement appears to repeat comments from proponents of open-ocean intakes. If there was impingement of marine species on the surface of the seabed, especially marine fish larvae, there would be an accompanying biological response which would be noteworthy. To our knowledge, there is no field observation of increase biomass, increase primary production, increase in fish density (or diversity) or other marine invertebrates' population increase in zones of subsurface infiltration. Studying a non-significant biological event is extremely difficult (i.e. expensive) and, therefore, it is not surprising that no agencies have funded a study of entrainment for intakes that draw water through several feet of natural sediment or artificial media. MCWD-IW-04

The appendix, next addresses the advantages of subsurface intakes compared with open ocean intake (See p. I1-3). This discussion is based on work done for a regional desalination project in Santa Cruz involving the adjacent Soquel Creek Water District and the City of Santa MCWD-IW-05

[1] Eric Quanmen, Facilities Systems Manager, Monterey Bay Aquarium, e-mail February 15, 2017.

[2] As per Wikipedia, "Pigging in the context of pipelines refers to the practice of using devices known as "pigs" to perform various maintenance operations. A "pig" in the pipeline industry is a tool that is sent down a pipeline and propelled by the pressure of the product flow in the pipeline itself."

[3] WateReuse Association, 2011. Desalination Plant Intakes: Impingement and Entrainment Impacts and Solutions. *WateReuse Association White Paper*.

[4] Similar to comments by Daniel P. Cartamil, Marine Biologist from Scripps Institution of Oceanography in his opinion piece "Evidence to Support an 'Eco-Friendly' Desalination Technology Lacking when comparing subsurface infiltration galleries with open-ocean intakes systems" that appeared in The Scientist (http://www.the-scientist.com/?articles.view/articleNo/47085/title/Opinion--Evidence-to-Support-an--Eco-Friendly--Desalination-Technology-Lacking/).

Cruz Water Department that advocated for a direct intake system.[5] While reference is not on point, we agree there are significant advantages of using *appropriate* subsurface intakes for seawater desalination.

First, the elimination of impingement and entrainment of marine organisms through subsurface intakes is a serious issue and provides many benefits. Not only from a regulatory perspective (Desalination Amendment to the Ocean Plan encourages indirect or subsurface intake technologies), but also from an operational perspective, removal of organic material prior to reverse osmosis membrane is beneficial to the desalination plant operation. The RO membranes are designed to separate water from salt in an aqueous solution. The reverse osmosis membranes are not designed to deal with fluctuating biological (organic) loads, which require additional pretreatment systems. Employing subsurface intakes, there is a substantial reduction in pretreatment equipment, smaller footprint, lower chemical usage (including costs for training of personnel and storage of chemical supplies), and reduced energy consumption – which all add up to real cost savings over the lifecycle of the plant.[6]

MCWD-IW-05 cont.

The second advantage listed in the appendix is that "*natural water filtration and pretreatment provided by ocean floor sediments, which in some cases can reduce the need for some treatment chemical during the desalination process.*" Again, we concur with this statement.

For example, data from Neodren systems[7] show that Neodren filtrate, the source water delivered through the under-the-sea intake conveyance, has reduced range or variation in temperature[8] that allow for more stable operations. The data also show the filtrate has reduced turbidity compared with ambient natural seawater conditions.[9] This is an important attribute because RO membrane manufactures require low turbidity waters for processing. Manufacturers

[5] Kennedy/Jenks Consultants. 2011. scwd2 Seawater Desalination Intake Technical Feasibility Study (ITFS). September 21.

[6] To illustrate this point, a proposal for a nearby open ocean desalination plant with approximately 12 MGD production includes an engineer's estimate of the amount of waste derived from the pretreatment process. The estimate of dry sludge is 27.6 tons per day requiring 20 dump trucks per week to haul waste offsite. Draft Process Design Report for the People's Moss Landing Water Desal Plant prepared by Watek Engineering, February 27, 2015. see http://thepeopleswater.com/Draft_Process_Design_Report_and_Cost_Information.pdf

[7] Neodren systems (discussed in more detail in section on Horizontal Wells below) are seawater intake subsystems in which filter pipes are installed in boreholes executed from the back of the beach by drilling subsoil and boring into geological formation offshore (see Figure 1 below)

[8] Peters, Thomas and Pintó, Domènec. 2006. Sub-seabed drains provide intake plus pretreatment. Desalination & Water Reuse, Volume 16. 2006

[9] Typically, turbidity values for a Neodren system are much less than 2.0 NTU. Nephelometric Turbidity Unit (NTU) refer to EPA Method 180.1. Peters, Thomas and Pintó, Domènec. 2006. Sub-seabed drains provide intake plus pretreatment. Desalination & Water Reuse, Volume 16. 2006

of the seawater reverse osmosis membranes recommend a silt density index (SDI[10]) of 5 or lower for seawater reverse osmosis membrane systems.[11] In our experience, when using the Neodren systems, particle concentrations are lower than ambient natural seawater conditions;[12] total suspended solids – a measure of the dry weight of particles trapped by a filter – are lower;[13] and total organic carbon, a measure of the amount of Carbon bound in organic compounds is reduced.[14,15]

The third benefit listed in the appendix is that "*minimal growth of marine organisms that occurs inside the intake pipeline*." Again, we agree this is an important consideration as biological fouling prevention is important for overall operational efficiency. The more biological material that is prevented from entering the desalination subsystem, the better the system will perform over a longer period before diminished yield, failure, repair or other faults.

And finally, we generally agree with the statement that if intake technologies are not appropriately sited, subsurface intakes can adversely affect coastal aquifers and increase the risk of saltwater intrusion in freshwater aquifers (see p. I1-4). We note, however, that the vertical and slant wells are far and away the most likely to impact *adversely* affect coastal aquifers and *increase* the risk of saltwater intrusion in freshwater aquifers as explained more fully below.

MCWD-IW-05 cont.

1. Comments on Vertical Wells conclusions (I1-4 through I1-5):

While the DEIR/EIS's overall description of vertical wells as applied to the MPWSP appear to be generally accurate, its conclusion that they are not a potentially feasible alternative intake source for the MPWSP lacks any supporting factual information. Vertical wells have been in use for a long time, have a good track record, and are used in seawater desalination internationally. The celebrated case is in Malta where the Pembrooke desalination plant has a capacity of 9.5 MGD from a field of vertical wells in a sandstone formation is of similar size the proposed MPWSP. Notably, for smaller systems on the order of 5 MGD, there is documented life cycle costs saving approaching 17% when vertical wells at the beach are installed.[16] As the appendix notes, the primary limitation for vertical wells is logistics of dealing with multiple well heads spread out over some expanse. We also agree it is preferable to locate beach wells as close to the coastline as possible to minimize impacts on inland aquifers, because the influence over groundwater supplies inland of the sea are a concern as noted. That said, vertical wells can be

MCWD-IW-06

[10]Silt Density Index – a measure of fouling capacity of RO membranes systems – is greatly reduced to less than 5.0 (SDI_{15}) SDI_{15} is notation used for ASTM Standard D4189 Standard Test Method for Silt Density Index (SDI) of Water at 15-minute interval.

[11] Membrane Manufacturers will not guarantee their products if SDI is above 5.

located outside of or inland of environmentally sensitive habitat areas. They can also be sited in areas where studies show the greatest amount of seawater has intruded (or areas indicating a preferential seawater inflow) to reduce groundwater impacts. Neither the appendix nor the DEIR/EIS provides any information regarding these possibilities. MCWD-IW-06 cont.

We further note that expansion of the current Sand City desalination system or similar system may meet the water requirements of the MPWSP with a smaller overall ecological and environmental impact. Therefore, we would recommend DEIR/EIS address the capacity for expanding the existing Sand City Desalination facility. If this is not feasible, we would recommend the DEIR/EIS examine the use of pre-engineered, so called "packaged" desalination systems which could result in avoiding or substantially lessening the proposed project's significant impacts. Smaller desalinations systems (even if two are required) can be accomplished with significantly less environmental impacts and can be more economical because package solutions are available for desalination plants that are up to 5 MGD. To illustrate, IDE Technologies Ltd. has a modular RO which can be bought, leased or contracted for water purchase (see http://www.ide-tech.com/solutions/ide-progreen/). Modular systems also reduce site work, come pre-assembled, and reduce installation time. In the case of the IDE Technologies system, no chemicals are required as the systems uses the brine concentrate to purge the membranes. The system also has a relatively low electrical consumption (10 – 12 kWhr/1000 gal), and consequently lower OPEX. Several other firms that have similar offerings. (See Exhibit 1 - Summary of City of Santa Barbara Desalination Plant Reactivation Project choice of a modular approach in 2016). We also note that packaged or modular systems reduce consulting engineers custom design work, foster concurrent civil site work and fabrication of SWRO modules, allow consistency between multiple desalination sites, similar parts, similar training and can be controlled remotely and thus reduce operational costs. MCWD-IW-07

In summary, using a package system with vertical wells may provide sufficient supplies to meet CalAm's water demand in conjunction with the Pure Water Monterey Groundwater Replenishment (GWR) Project noted in the DEIR/EIS. Obviously with the implementation of the GWR Project, the number of vertical wells required for feed water supplies would be substantially lower than the 24 estimated in Apppendix I1. (see p. I1-4.) This reduction could address the unspecified economic, legal (permitting) and environmental factors noted in the Appendix. However, without any information regarding these factors, we cannot assess this conclusion is accurate. We only note that given the *potential* reductions in environmental impacts and costs, we were surprised the DEIR/EIS did not evaluate vertical wells in its alternatives analysis.

2. Comments on Infiltration Galleries conclusions (I1-5):

The DEIR/EIS's limited and conclusory discussion of infiltration galleries as applied to the MPWSP seems wholly inadequate. The DEIR/EIS dismisses this alternative intake option stating because of the extent of temporary and permanent disturbance that an infiltration gallery would have on the sand dunes and sensitive marine habitat, it is considered infeasible based upon environmental, social and legal factors. Again, no analysis or information is provided regarding the environmental, social and legal factors that would make this infiltration galleries infeasible. MCWD-IW-08

We note that beach infiltrations galleries were examined in the CCC's "Final Report: Technical Feasibility of Subsurface Intake Designs for the Proposed Poseidon Water Desalination Facility at Huntington Beach".[17] Their conclusion that infiltration galleries located closer to the beach were potentially a feasible options for subsurface intakes for the proposed Poseidon Water Desalination Facility, which proposes producing 50 Million Gallons per Day (MGD) of potable water, five times as much as the current project. The CCC's Report notes that:

> ***A key aspect of a beach gallery system is that it underlies the surf zone of the beach, fully or in part. This means that the active infiltration face of the filter is continuously cleaned by the mechanical energy of the breaking waves and is therefore self-cleaning*** (Maliva and Missimer, 2010). ***Also, the location within the intertidal zone allows the gallery to be continuously recharged with no impact on the inland shallow aquifer system. The vertical flow of water from the sea assures that the inorganic chemistry is not significantly altered over time***… The gallery system is unaffected by variations in the deeper groundwater, which could be fresh or brackish in nature at the shoreline. The uppermost natural sand layer is the primary treatment zone within the filter and will likely allow the removal of all algae and a high percentage of bacteria and naturally occurring organic compounds (e.g., natural organic matter). The long-term data collected at the seabed gallery in Japan shows that the SDI was reduced below two, which is at the approximate level produced by conventional SWRO pretreatment systems (Shimokawa, 2012).
>
> ***The beach gallery would reduce or eliminate the impingement and entrainment of marine fauna. Also, upon completion of construction, the gallery would be located below the surface and could not be observed by beach users.***

(Id. at p. 40.)

MCWD-IW-08 cont.

The DEIR/EIS does not address why the same would not hold true for the MPWSP. Notably, the DEIR/EIS's apparent conclusion that infiltration galleries result in permanent disturbance to habitat does not appear to be consistent with the CCC's report. (*Ibid.*; see also *id.*, Figure 3.6 on p. 41.) Moreover, the DEIR/EIS, does not address whether an infiltration gallery could be designed in such a way that would not require the massive excavation and artificial prescribed fill used in the existing infiltration case in Fukuora, Japan cited in the CCC Report. Unlike the Fukuora location (on the semi-protected coast of the Sea of Genkai),[18] it may be possible to lay out sections of filter pipe on the sandy seabed and allow natural forces to bury the system over time. The sandy bottom biological community in Monterey is adapted to moving sands and may not be significantly impacted. Regardless, without any discussion or information

[17] http://www.coastal.ca.gov/pdf/ISTAP_Final_Phase1_Report_10-9-14.pdf.
[18] The infiltration gallery in Fukuora, Japan has a capacity of 27.2 MGD operating since 2005 (Missimer et al 2013).

regarding the potential impacts at the CEMEX site (or elsewhere) it is impossible to comment further on this issue.

Importantly, beach infiltration gallery would not adversely impact the coastal aquifers as they do not pump groundwater. Therefore, because infiltration galleries are at least potentially feasible and could eliminate some of project's significant impacts, the DEIR/EIS's failure to address the potential options for infiltration galleries or its environmental impacts is not supported by the any available information.

MCWD-IW-08 cont.

3. Comments on Horizontal Wells conclusions (I1-5)

The DEIR/EIS's limited discussion of horizontal (or HDD) wells as applied to the MPWSP wholly inadequate. The Appendix states that it describes each subsurface intake type to include "*typical suitable locations, examples of existing technology, general construction methodology, operation and maintenance, and capabilities and limitations*" (page I1-4). Given our particular expertise as it relates to Horizontal Wells, we were shocked that DEIR/EIS—in less than 200 words---dismissed this technology in an Appendix without citation to a single reference material. (See Appendix I1 Open-Water and Subsurface Intakes, p. I1-5.) Importantly, the DEIR/EIS dismisses the feasibility of horizontal wells without adequately describing the technology, its advantages over the project's proposed slant wells intakes and its appropriateness for the Monterey Bay coastal environment as the Appendix suggests.[19] Therefore, we provide the following information for your background regarding Horizontal Wells using the Neodren subsurface intake systems.[20] While our comments address Horizontal Wells using Neodren subsurface intake systems, please note there are other Horizontal Well technologies that could also be employed and could be investigated by the CPUC or Sanctuary. Following this background, we explain why none of the reasons listed for rejecting Horizontal Wells are accurate.

MCWD-IW-09

a) Background on Horizontal Wells Not Included In the DEIR/EIS

Directional boring also known as Horizontal Directional Drilling (HDD) is "a steerable trenchless method of installing underground pipes, conduits and cables in a shallow arc along a prescribed bore path by using a surface-launched drilling rig, with minimal impact on the surrounding area."[21] A key aspect is the shallow arc as shown in Figure 2 below.

Horizontal Wells have been installed using directional boring techniques at multiple locations internationally. While there is currently no installation in California, this is not

[19] We note that in the past couple of years with the flurry of activities involving subsurface intakes and the interest in HDD, no one from the CPUC or MBNMS has contacted Catalana de Perforacions (developers of Neodren subsurface seawater intake systems) for information regarding its feasibility for the MPWSP. We find this remarkable because the technology has been discussed at various desalination conferences (including in California) on panels with Geoscience (the developers of the Slant Well technology for the MPWSP). A copy of Neodren Subsurface Intake Technology presentation at recent California Conference is attached as Exhibit 2.

[20] Attached as Exhibit 3 is a bibliography on Neodren.

[21] https://en.wikipedia.org/wiki/Directional_boring

surprising because most seawater desalination is performed outside the United States. In fact, there are only a handful operational seawater desalination plants in California, and even fewer operational seawater desalination plants in California that use subsurface intakes.

The technology of HDD, however, is well known in California having been conceived to cross rivers by Martin Cherrington in the early 1970s. When excavating or trenching is not practical, HDD is commonly used in a wide variety of environments including crossing under

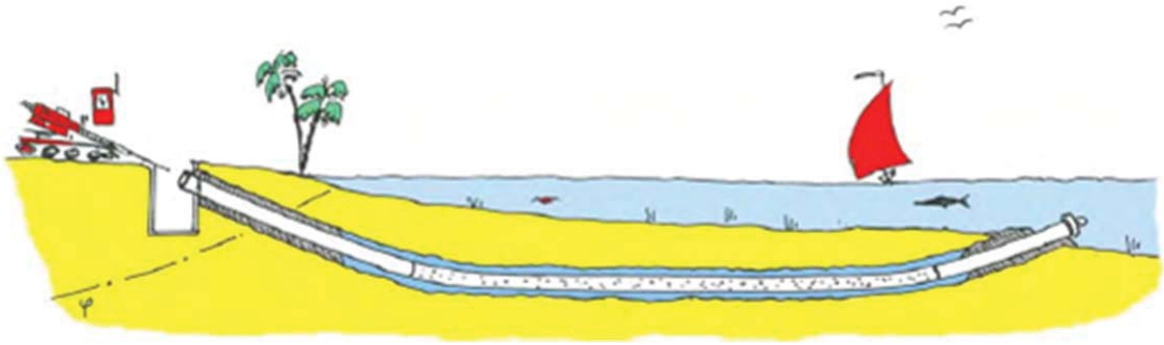

Figure 1. Cross section of stylized Neodren installation.

MCWD-IW-09 cont.

waterways, roadways, congested areas, sensitive environmental areas and areas where other methods are more destructive or expensive.

The technology of HDD, however, is well known in California having been conceived to cross rivers by Martin Cherrington in the early 1970s. When excavating or trenching is not practical, HDD is commonly used in a wide variety of environments including crossing under waterways, roadways, congested areas, sensitive environmental areas and areas where other methods are more destructive or expensive.

The constellation or spatial pattern of lateral wells is dependent on the site and its hydrogeological properties. Note that in the existing operating intakes joined to seawater desalination plants, none of them are in 3 or 4 well clusters as advertised in the DEIR/EIS (page I1-5).

Typical Suitable Locations

In the case of Neodren subsurface seawater intake systems, coastal sites with appropriate offshore geological formation for transmission of water through the upper 15 to 30 ft of the seafloor are ideal.

Examples of Existing Technology

Neodren systems have been installed at various sites in Spain (Table 1). The Neodren drains are engineered to ensure the correct scheduling per pipe specification, pipe path positioning and punch out location. Using basic installation techniques, HDD allows multiple

curves in plan and section, striving to avoid submerged structures and geological stratums with no productive yield. Drain filter pipes are installed in the excavated borehole, ensuring a long-term intake, and ensuring stability of the borehole. In total, 36 lateral drains comprising over 5 miles of pipe drawing in 63.4 MGD are operating at seawater desalination plants.

Table 1. Neodren Installations in Spain.

Year	Location and description	m^3/day	l/s/m	Status

MCWD-IW-09 cont.

General Construction Methodology

The general construction methodology can be divided into the construction of the borehole and the insertion of the filter pipe. To establish an appropriately sized borehole, first a pilot hole is drilled with a guidance system to steer the drilling head along the desired route. A reamer is added to the drill string to expand the annulus of the borehole. Once the reaming is complete, the hole is swapped to insure passage of the filter pipe. General guidance on HDD is available[22,23,24] as well as industry standards.[25]

Float-and-Sink Method. For the insertion of the filter pipe, the preferred method is the float-and-sink method outlined in Chapter 10 Marine Installations of the Plastic Pipe Institute'

[22] Willoughby, David (2005). Horizontal Directional Drilling, p. 1-263. McGraw-Hill, New York. ISBN 0- 07-145473-X.
[23] Short, Jim (1993). Introduction to Directional and Horizontal Drilling, p. 1-222. PennWell Books, Tulsa, Oklahoma. ISBN 0-87814-395-5.
[24] HDD Consortium. (2008). Horizontal Directional Drilling–Good Practices Guidelines.
[25] ASTM International F1962, Standard Guide for Use of Maxi-Horizontal Directional Drilling for Placement of Polyethylene Pipe or Conduit Under Obstacles, Including River Crossings

Handbook of Polyethylene Pipe[26]. Conventionally, filter pipes are pulled into the borehole with the float-and-sink method. Obviously, care and attention are required to the details of the design to insure a safe and successful operation.

The 'Push' Technique. Alternatively, a newer process developed by The HDD Company, is similar as drilling a water well. By directionally boring from shore into and through the offshore aquifer, a steel casing can be put into the borehole to greatly aid insertion of the well screen and avoid release of drilling fluids into the marine environment. Once the casing has been installed, the well screen is inserted, then the casing pipe can be removed and lateral well can be completed. Multiple wells can be placed into the aquifer.

A significant benefit of this "push" approach is the virtual elimination of marine support operations, thus considerably reducing installation costs and most disturbances to the seafloor. This benefit is an important development in subsurface intakes especially along environmentally sensitive coast lines in California. Operating well back from the beach, under the sea intakes can operate effectively with low environmental impact on the marine environment, nearshore coastal environment and foreshore habitat.

MCWD-IW-09 cont.

Permits should not be any more difficult than a permit for a typical water well. No fisheries would be impacted. The procedure is virtually the same as vertical water wells with the exception that HDD can drill further and place more well screen (horizontally) into the aquifers.

Operation and Maintenance

The operation and maintenance requirement are minimal with the Neodren system. According to Jordi Camps Querol, Technical Director of Catalana de Perforacions, who has been involved since the beginning of Neodren development, Neodren "only needs to be able to have some backwash, in case of fine sands." [27] Some installations prefer occasional backwash of the subsea intake system at approximately twice the inflow rate. Discussions with Neodren consultant Dr. Thomas Peter indicated that most plants do not backwash. Neodren systems have been deployed since 1996, and that experience shows Neodren is a long-lasting and less expensive solution over the long term.

b) The DEIR/EIS reasons for not analyzing Horizontal Wells are unsupported and inaccurate.

The DEIR/EIS (at p I1-5) states: "*Horizontal wells are not evaluated further for the following reasons: (1) the amount of pipeline that would be pushed under the sea floor (upwards of 2,500 feet) would be challenging in terms of construction time, physical limitations and the disposal of drilling sludge (and consequently much more expensive than other options); (2) installing artificial filter packs to stabilize unconsolidated formations like those found in the project area has yet to be demonstrated successfully and on a consistent basis, and; (3) HDD would not avoid or minimize any of the impacts associated with the proposed action.*" There is no evidence provided to support any of the conclusion. As explained below, all three conclusions are inaccurate.

MCWD-IW-10

[26] Available online at the Plastic Pipe Institutes web site. The Plastic Pipe Institute Handbook of Polyethylene Pipe, Chapter 10 Marine Installations

[27] Email from Jordi Camps Querol to A.T. Jones, February 20, 2017

First, the DEIR/EIS dismisses the capabilities of Horizontal wells, but does not adequately address the limitations of this technology. The DEIR states that *"wells are not evaluated further for the following reasons: (1) the amount of pipeline that would be pushed under the sea floor (upwards of 2,500 feet) would be challenging in terms of construction time, physical limitations and the disposal of drilling sludge (and consequently much more expensive than other options)"*

Construction Time. The construction time for developing horizontal directionally drilled drains or lateral wells would be considerable shorter than the proponent's preference for angle wells based on construction times along the Spanish Mediterranean Coast for Neodren system. The closest example is Alicante II where an additional eight (8) laterals were commissioned using one HDD drilling rig. The drilling schedule was not the critical path for completion of the project. Construction on this project took about four (4) months. The intake flow was 20.15 MGD.[28]

Multiple HDD maxi-rigs could be used to accelerate schedules, if that is a requirement. The HDD Company (Cameron Park, CA) through its affiliate, The Crossing Company, operate 27 HDD rigs in western North America. As it is likely, if not certain, that Horizontal Wells could be constructed in less time that proposed slant wells, we believe the decision to exclude this alternative from analysis in the DEIR/EIS is unsupportable.

MCWD-IW-10 cont.

Physical Limitations. The DEIR/EIS's conclusions regarding the physical limitations of HDD are based on either no information or outdated information. In fact, the physical limitations of HDD are much less than the slant well technology proposed for the MPWSP. For example, in terms of length, HDD can extend further than the 2,500-foot maximum mentioned in the description of Horizontal Wells (Appendix I1 p. I1-5). Table 2 below summarizes select recent activities that highlight lengths more than 2,500 feet specifically related to shore approaches or ocean outfalls.[29] As a result, HDD wells can be located significantly further inland than slant wells and avoid impacts to sensitive habitats and impacts associated with potential exposure from erosion.

Table 2. Selected HDD Projects with Shore Approaches or Ocean Outfalls.

Project Name	Location		Formation
FASTER Cable Project	Bandon, Oregon	Beach Approach: Pacific Ocean 5,000' of 5" Steel Pipe	Sandstone / Siltstone Rock
ZA1 - 230KV UG Line	San Francisco, California	(6)-Beach Approaches into S.F. Bay 12" & 3" HDPE Bundle	Rock and Bay Mud
Mayport Naval Base	Jacksonville, Florida	Beach Approach - 4000' of 5" steel	Sand/Silts

[28] See attached Appendix with site profiles and photographs during construction.
[29] 'Shore approaches' or 'ocean outfalls' are terms used in HDD to describe drilling out under the sea.

OOI RSN	Pacific City, Oregon	(2) Beach Approaches 5000' of 5" Steel Pipe (ea.)	Sands/Silts/Clays
Hueneme Outfall Replacement	Port Hueneme, California	2540' of 36" HDPE Ocean Outfall in the Pacific Ocean	Sand, Silts, Cobble and Boulders
Wastewater Treatment Plant Outfall		4600 feet of 18" Steel Outfall Columbia River. Installation of 80-foot diffuser, pig launching facility, 500 feet of Ductile	Silt, Sand and Gravel
Twin Rocks Sanitary District Ocean Outfall	Twin Rocks, Oregon	4400' Beach Approach. 8" coated steel pipe.	Sand, Silt and Gravel
Effluent Disposal System.	Port Orford, OR	2200' of 12" HDPE for an Ocean Outfall	Mudstone
NOSD HDD Outfall Replacement	Netarts, Oregon	4150' of 14" HDPE Ocean outfall	Mudstone and Basalt

Source: The HDD Company

Moreover, unlike slant wells, HDD wells can avoid unfavorable subsurface conditions. Notably, The HDD Company has installed pipelines and utilities for ocean outfalls, under rivers, ship channels, creeks, wetlands, buildings and highways. The company is noted for execution in difficult situations. Therefore, as there is no support for rejecting Horizontal Wells on this basis, we believe the decision to exclude this alternative from analysis in the DEIR/EIS is unsupportable.

MCWD-IW-10 cont.

Disposal of Drilling Sludge. Finally, the disposal of drilling sludge is not an issue for this site. There are options within Monterey County including Johnson Valley part of the Salinas Valley Solid Waste Authority. Importantly, the proposed Slant Wells would have the same issues relating to drilling sludge, if not further concerns related to chemical nature of their deeper geologic materials. Therefore, as there is no support for rejecting Horizontal Wells on this basis, we believe the decision to exclude this alternative from analysis in the DEIR/EIS is unsupportable.

Number of Wells and Expense. The DEIR/EIS Appendix states that approximately 10 to 12 horizontal wells would be needed to provide sufficient source water for the 9.6-mgd MPWSP Desalination Plant. We believe this estimate is potentially reasonable, but would need additional information that was not provided in the DEIR/EIS to confirm. While we believe the DEIR/EIS's suggestion that Horizontal Wells would be more expensive than other options is likely inaccurate, there is insufficient information provided to comment on this issue. Based on our knowledge of the costs of slant wells to date, we do not believe that drilling Horizontal Wells is likely to be more expensive. We also note that using Horizontal Wells would eliminate the need for return water and the proposed Castroville Pipeline, which ironically would be installed beneath the Salinas River and Tembladero Slough using HDD. (See DEIR/EIS, p. 4.6-142.) Therefore, we believe that Horizontal Wells could actually reduce the MPWSP's costs.

Finally, there are more operating Horizontal Wells conveying seawater to reverse osmosis plants in the world than Slant Wells drawing water from deep aquifers for desalination. In fact, we are unaware of any operating Slant Wells drawing water from deep aquifers for desalination. Given the observed reduction in efficiency over a short period at Dana Point Slant Well (discussed below), it is possible, if not likely, that less Horizontal Wells would be needed to supply the required feedwater than slant wells over the life of the project.

Second, the DEIR/EIS's statement that "*(2) installing artificial filter packs to stabilize unconsolidated formations like those found in the project area has yet to be demonstrated successfully and on a consistent basis*" (Appendix I, page I1-5) is inaccurate.

Artificial Filter Packs. Starting in 1985 in the United States, artificial gravel-pack filters around horizontal well screens have been designed, constructed and operating per plan. One drilling and construction company, Layne, has installed tens of thousands of lineal feet of gravel-packed lateral well screens. Sites have been coastal and inland. Subsurface deposits at potential sites in and around the Monterey Bay area would fall within the range of depositional environments in which screens have been successfully installed.

Moreover, to date, artificial filter packs have not been required when utilizing the Spanish technology Neodren. The function of the artificial filter pack is to prevent unwanted sands and fines from entering the plant. The Neodren system accomplishes this goal by utilizing well screens with high porosity (35% to 45%) that match soil formation characteristics. The nature of the sintered high molecular weight polyethylene well screen allows uniform pore size distribution. A scanning electron micrograph of the material shows polymer structure with closely controlled pores allowing water movement towards the inner conduit (Figure 2).

MCWD-IW-10 cont.

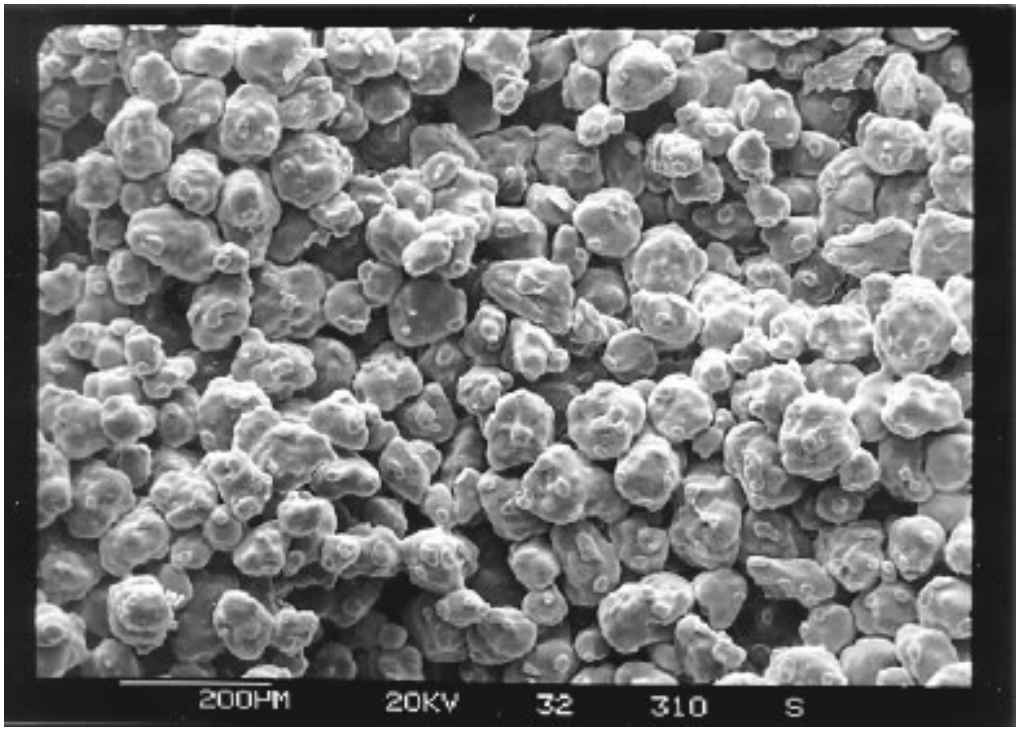

Figure 2. SEM Micrograph of sintered HDPE well screen

MCWD-IW-10 cont.

To illustrate this point, in the case of the current Intake Test Program comparing side by side screened open ocean intake with a subsurface intake, the San Diego County Water Authority selected a Neodren system which will have an average grain cut off size of 60 microns.

Finally, if filter packs are required, an offshore oil and gas product that uses an open-cell foam, which allows normal fluid production while controlling sand migration, could be used here.

Again, there is no support for rejecting Horizontal Wells on this basis. Therefore, the decision to exclude this alternative from analysis in the EIR/EIS is unsupportable.

Third, the DEIR/EIS's conclusion that "*HDD would not avoid or minimize any of the impacts associated with the proposed action"* is also based on unsupported conclusions and unsupportable for the reasons explained below.

MCWD-IW-11

Horizontal Wells Have the Potential to Avoid or Substantial Reduce the Projects Significant Environmental Impacts. At the CEMEX site, construction activities for the HDD intake could be located well further inland and outside any endangered species habitat avoiding impacts to endangered species along the coast. If HDD intake is designed to extract water from upper section of the marine sediment with direct conductance to the overlying seawater, then impacts to groundwater basin water levels would be circumvented and the groundwater quality would not be impacted. There would be no take from the Salinas Valley Groundwater Basin (SVGB), so there would be no need for the return water obligation. This method would reduce impacts associated with return water pipeline, reduce amount of water needed (thus less wells

and less disturbance). As noted above, the Castroville Return Water Pipeline, would be installed beneath the Salinas River and Tembladero Slough using the same HDD drilling technology as Horizontal Wells to avoid impacts.

At the Potrero site, drawdown impacts on groundwater basin could be avoided, if properly designed and installed HDD intakes to take advantage of the transmission of seawater in the upper 15 to 25 feet of sea bottom sediments, therefore, eliminate impacts to Elkhorn Slough. If seawater is drawn into a HDD intake in the upper most section of the seafloor, the groundwater from SVGB would not be impacted and thus there would be no obligation to convey desalinated product water to the interior, which would reduce all impacts associated with return water pipeline.

MCWD-IW-11 cont.

By drawing seawater from the uppermost strata and eliminating the need for returning water to the SVGB as proposed, HDD intakes would avoid the impacts associated with the return water pipeline and reduce the amount of supply water necessary for the MPWSP thereby also reducing energy needs and impacts on GHG.

We would also note that Horizontal Wells could potentially be located at numerous other locations along the Monterey Coast Shoreline, including locations closer to CalAm's service area.

4. Comments on Ranney Wells

The DEIR/EIS's decision that Ranney Wells would have similar impacts to the MPWSP's proposed slant wells and, therefore, need not be evaluated further is based on the limited discussion in Appendix I1 and conclusory allegations in the DEIR/EIS. (DEIR/EIS, p. 5.3-18.) The discussion of Ranney Wells in Appendix I1, like the DEIR/EIS's conclusions is not supported by any meaningful analysis and appears to be inaccurate.

To illustrate Ranney Collector Wells functioning in the marine environment, the DEIR/EIS (at p. I1-6) cites the California Academy of Sciences in San Francisco as an example. Unfortunately, the Ranney Well that served the Steinhart Aquarium in Cal Academy has been shut down since July 2010.[30] Ranney seawater collector wells in Mexico, however, have been operating since 2000. The site was revisited by the Project Manager about ten (10) years after commissioning and showed no signs of "discernible degradation of the well screens." [31]

MCWD-IW-12

The DEIR/EIS's description of the approach in this analysis related to requiring a shaft 90 to 260 feet deep seems ridiculous if they are attempting to tap into the shallow marine aquifer. As proposed it is an extension of a vertical shaft with lateral jacked radial arms serving to extract groundwater from the deeper aquifers. This error, could be the reason the DEIR/EIS concludes the Ranney Wells would have similar groundwater impacts. If the Ranney Wells were properly designed to tap the shallow marine aquifer, this alternative would likely significantly reduce groundwater impacts.

[30] Ed Miller, Senior Aquarist (retired), Steinhart Aquarium, personal correspondence with Arnell Bautista, Chief Engineer, Steinhart Aquarium, February 10, 2017.
[31] Henry Hunt, Senior Project Manager, Layne, personal correspondence, February 14, 2017.

The DEIR/EIS's statement about distance between Ranney Wells of 350 to 500 feet should be clarified to indicate that the objective of spacing Ranney Wells is to minimize hydraulic interference and is dependent on the well yields and aquifer characteristics.

The DEIR/EIS's statement that the construction area for a Ranney Well set up is larger than a Geoscience Slant Well construction site is suspect. If photographs during the construction phase of the Geoscience Dana Point Test Slant Well are indicative, then a Ranney Well could occupy the same footprint according to experts in Ranney Collector Wells operations.[32] As with other subsurface systems, the infrastructure including electrical panels can be below grade, if there is an aesthetic concern.

The construction process for Ranney Wells does not include dewatering as described in the Appendix I1. An upcoming Ranney Collector Well site is ½ acre, half the size used in this analysis. The duration of construction could be as short as 4 months and extend over a year depending on limitation to seasonal construction.

Contrary to the statements on page I1-7 related to submersible pumps, most collector wells employ vertical turbine pumps, although submersible pumps have also been used. Collector Wells could be connected by piping in such a way that the wells drain by gravity into a common wet well with pumping station located outside any sensitive habitat. For the MPWSP, vertical turbine pumps work satisfactory.

MCWD-IW-12 cont.

Regarding the DEIR/EIS's suggestion on the limitation on the lateral lengths, if they have any experts advising them, they should be aware that laterals are routinely installed to 150 to 300 feet using conventional Ranney technology, but that longer horizontal wells screens are available using modified methods. One project had lengths out to 800 ft. Thus, the statement that Ranney Collectors for water supply are limited to 150 feet is unsubstantiated and outdated. Typical projects are 150 to 200 feet or more in lateral extent.[33]

The DEIR/EIS's statement related to equivalency of Slant Wells occupying the same physical area is also unlikely. There would be, depending on the number of collector wells needed, likely fewer Ranney Wells than Slant Wells, which would reduce the Ranney Well footprint.

In summary, the DEIR/EIS will need evaluate the Ranney Wells as they are both feasible and would at least potentially reduce the project's significant impacts at the CEMEX site.

We also note, that one could envision Ranney Collectors at two or three sites along the Carmel Beach providing adequate feedwater for the smaller desalting option of 6.4 MGD. The relatively larger sand size at this site would be ideal for transmission of seawater from the shallower marine aquifer. This intake site could avoid issues of endangered species and is closer to where the water is to be delivered, thus is could drastically cut cost of conveyance of product water. Carmel Beach is a 2-km long continuous beach, part of the Carmel River littoral cell which delivers sand and sediment in a principally southward direction. According to the USGS,

MCWD-IW-13

[32] Henry Hunt, Senior Project Manager, Layne, personal correspondence, February 14, 2017.
[33] Henry Hunt, Senior Project Manager, Layne, personal correspondence, February 14, 2017.

the Carmel Beach has had a long-term accretionary trend from 1896 to 2002.[34] However, along the southern segment of the beach, the shorter-term influences (1952 to 2002) have been erosionary at a rate of 1.7 m/yr.[35] Finally, we note that with uncertainty in Pacific Ocean climate, having flexibility among several intake systems to draw feed water, is something the DEIR/EIS should consider.

MCWD-IW-13 cont.

5. Comments on Slant Wells

The DEIR/EIS's discussion of slant wells ignores the fact that slant wells are experimental unproven technology, with no track record in terms of long term operations. As noted above, we find this particular problematic given the DEIR's rejection of Horizontal Wells on this basis. Notably, an independent scientific technical advisory panel for an ocean desalination facility in Southern California convened as part of the California Coastal Commission proceedings addressed concerns about the engineering performance of a slant well in this manner[36]:

> Only one slant well has been successfully constructed to date, although a major installation to provide 20 MGD of feedwater capacity is under consideration in the Monterey Bay area *[this project*]. The successfully completed well is at Dana Point. When it was built and tested in 2006, it was test pumped at 2000 gpm and displayed a well efficiency of 95%. Recent longer term testing of the completed test well in 2012 documents the reduction in well efficiency from the original value of 95% in 2006 to 52% in 2012 (GeoScience 2012). Given this observed reduction in efficiency over a short period, the long-term performance of the technology has yet to be confirmed.
>
> … Slant wells completed in the Talbert aquifer would draw large volumes of water from the Orange County Groundwater Basin, which in itself is considered a fatal flaw. Recent public comments have suggested that pumping seawards of the Talbert Salinity

(P. Dartnell and S.A. Cochran, eds.), 2016, California State Waters Map Series—Monterey Canyon and Vicinity, California: U.S. Geological Survey Open-File Report 2016–1072, 48 p., 10 sheets, scale 1:24,000, http://dx.doi.org/10.3133/ofr20161072.

[35] Hapke, C.J., Reid, D., Richmond, B.B., Ruggiero, P., and List, J., 2006, National assessment of shoreline change part 3—Historical shoreline change and associated coastal land loss along sandy shorelines of the California coast: U.S. Geological Survey Open-File Report 2006–1219, 72 p., available at http://pubs.usgs.gov/of/2006/1219/.

[36] CCC's "Final Report: Technical Feasibility of Subsurface Intake Designs for the Proposed Poseidon Water Desalination Facility at Huntington Beach, dated October 9, 2014, pp. 37, 56, 64, available at http://www.coastal.ca.gov/pdf/ISTAP_Final_Phase1_Report_10-9-14.pdf

> Barrier could have beneficial impacts in managing seawater intrusion. In the Panel's opinion, however, this benefit is too uncertain to overcome the ISTAP conclusion about the fatal flaw of this technology as applied to the proposed Huntington Beach site. The advantage of having a subsea completion is largely lost in confined aquifers**.** The performance risk is considered medium, as the dual-rotary drilling method used to construct the wells is a long-established technology, but there is very little data on the long-term reliability of the wells. Maintainability is also a critical unknown issue.
> … Slant wells tapping the Talbert aquifer would interfere with the management of the salinity barrier and the management of the freshwater basin, and further, would likely have geochemical issues with the water produced from the aquifer (e.g., oxidation states of mixing waters).

MCWD-IW-14 cont.

This report was available over two years prior to the release of the DEIR/EIS. Remarkably, the DEIR/EIS fails acknowledged or address the conclusions in the report. The DEIR/EIS's failure to disclose and discuss the reduced efficiency of the Dana Point Slant Well testing is particularly noteworthy because one of the representative on the Hydrogeology Working Group authored the report on the Slant Well's decline.[37]

The DEIR/EIS's failure to disclose and address the findings in both reports must be acknowledged and addressed in the DEIR/EIS as it bears on the project's potential environmental impacts. Specifically, the DEIR/EIS must evaluate the how many slant wells will likely need to be replaced over the course of the foreseeable life of the project, and the impacts of replacing that number slant wells. Even under a best-case scenario, it is likely that all of the slant wells will need to be replaced at least once if not more. Notably, the selection of metallic components for the well screen and well, even if stainless steel, are not advisable in the highly corrosive seawater environment. The use of sacrificial zinc anode to deter galvanic corrosion is putting a band aid on a pulsating wound. Corrosion will continue; requiring replacement of the Slant Wells. The DEIR/EIS must be revised to address these impacts and address the impacts of replacement slant wells.

II. Comments on DEIR-EIS Project Description

Comments on *Pretreatment System* (3.2.2.1)

Without some understanding of the source water chemistry, it is difficult to comment on the pretreatment process outlined. Note that the decision on the pretreatment filtration (media versus pressure filtration) has not been decided, probably for the same reason that the water quality of source water is unknown.

The coagulation and flocculation processes outlined in the pretreatment subsystem may not be relevant to subsurface intake sourced feedwater. If subsurface intakes are properly installed, the dissolved organic matter generally seen in natural seawater is not a factor in RO operations. In discussions with the design-build consultants on the desalination facility, they did not have access to water quality of the feedwater, so a conservative approach of introducing the possibility of a coagulation and flocculation steps was acknowledged. MCWD-IW-15

Comments on *Reverse Osmosis System* (3.2.2.2)

The configuration of the SWRO process is conventional with a first stage, followed by a partial second stage to reduce boron concentration to level acceptable to the drinking water standards of California (1 mg/l B). Other developers in the Monterey County have proposed a similar RO design.[38] MCWD-IW-16

Comments on *Operation of the Seawater Intake System, MPWSP Desalination Plant, and Brine Discharges* (3.4.1)

The statement about periodic maintenance of slant wells, "*The slant wells would require maintenance every 5 years*." (3-57), seem highly optimistic given the state of development of the Slant Well technology. This information is unknown as there are no operating wells to derive maintenance records. When the casing is withdrawn, the slumping sand could enter the well screen. Additionally, after the first maintenance efforts, when the gravel/sand filter pack gets agitated, the introduction of sand into the well is likely. Attempts to mitigate this issue have been presented by GEOSCIENCE such as a half-moon cover of the well screen area to alleviate sand migration. MCWD-IW-17

Comments on *Power Demand* (3.4.5)

Most seawater desalination plants with capacity proposed in this project built in the last ten years incorporate energy recovery, whether isobaric or centrifugal, as means to lower energy consumption which can be a significant cost component of the operating budget. MCWD-IW-18

Qualifications of Intake Works LLC and Anthony T. Jones, Ph.D.

[38] Draft Process Design Report for the People's Moss Landing Water Desal Plant prepared by Watek Engineering, February 27, 2015. see http://thepeopleswater.com/Draft_Process_Design_Report_and_Cost_Information.pdf

Intake Works LLC is a group of oceanographers, marine geologists, marine ecologists, HDD drilling specialists and marine construction professionals engaged in developing under-the-sea intakes for delivering low-turbid ocean water for industrial processes such as desalination. The company has surveyed existing seawater desalination intakes internationally and visited intake facilities in Malta, Spain, Saudi Arabia, Mexico, US Virgin Islands, and the Bahamas, besides installations in Massachusetts, Florida and California. We have studied various types of seawater intake systems and been involved in developing a synthetic infiltration system for porting the correct filter media to a proposed site.[39] The company is currently comparing subsurface intake systems with a direct wedge-wire screen open intake system at Camp Pendleton for the San Diego County Water Authority. Additionally, we have projects in Baja California providing intake installation for an aquaculture development.

As it relates to HDD, we work closely with Catalana de Perforacions (Barcelona, Spain), the drilling company that developed the Neodren process of installing microporous filterpipe under the sea from shore with horizontal directional drilling. Intake Works is the licensed provider of this technology in California. A brochure from Catalana de Perforacions describing their project history with Neodren installations (Exhibit 3).

Anthony T. Jones, Ph.D is the primary author of these comments. Prior to joining Intake Works, Anthony T. Jones, Ph.D was the Chief Technology Officer for Campbell Applied Physics Inc. and its predecessor, Oases Global System, where he led a team that developed advanced seawater desalination systems incorporating technology transferred from the US Department of Energy national laboratories. The team he led demonstrated, at a $1/8^{th}$ scale, 30% lower energy consumption and up to 70% lower carbon footprint for seawater reverse osmosis potable water production. As it relates to this assignment, he served as a taxonomic expert and provided science support for U.S. Navy studies on marine biological fouling in San Diego Bay as part of a Congress-mandated study of an anti-fouling paint, tributyl tin. While participating in a study of sediment transport along shore and down submarine canyons for the US Army Corp of Engineers, he made more than 200 dives in the head of Scripps Canyon and La Jolla Canyon to observe firsthand the migration of sand down canyons. Additionally, his scientific diving training began at dive sites along the Monterey Peninsula. His first research cruise was off Monterey coring the deep-sea Monterey and Delgada fan on a US Geological Survey research vessel. Finally, he worked on a retrofit of Marina Coast Water District's seawater desalination in 2002.[40] A copy of his CV is attached as Exhibit 4.

[39] Jones, A. T. (2008). Can we reposition the preferred geological conditions necessary for an infiltration gallery? The development of a synthetic infiltration gallery. *Desalination*, *221*(1-3), 598-601.

[40] Campbell, R. L., Hanlon, J., Seamon, F., & Jones, A. T. (2003). Retrofit of a California coastal desalination plant: add technology, lower costs. In *OCEANS 2003. Proceedings* (Vol. 1, pp. 246-248). IEEE.

Conclusion

For the reasons outlined in the foregoing comments, we conclude the DEIR/EIS's conclusions regarding the Alternatives are unsupportable. To consider a reasonable range of alternatives, the DEIR/EIS must be revised to analyze, at minimum, the following potentially feasible alternatives, which would likely reduce the project's significant impacts:

(1) Horizontal Wells at CEMEX site

(2) Horizontal Wells at the Potrero site and/or other sites closer to CalAm's service area.

(3) Ranney wells at CEMEX and Potrero Road sites.

(4) Ranney wells at sites along Carmel Beach or other suitable locations closer to CalAm's service area.

MCWD-IW-19

As discussed above, each of these alternatives was dismissed based on misinformation about the design, installation, maintenance and cost savings in comparison to the unproven Slant Well technology proposed for the MPWSP. At minimum, the each of these alternatives is potentially feasible, would avoid or reduce the project's significant environmental impacts, and meet all (or most) the project objectives as well as the stated purpose and need statements declared in the EIR. Without a fuller analysis of these alternatives, the DEIR/EIS does not consider a reasonable range of alternatives, and lacks support for its conclusion regarding the environmentally superior alternative.

Sincerely,

Anthony T. Jones, Ph.D.
President

Re: Information to Consider in the Environmental Review of the Monterey Peninsula Water Supply Project (CPUC Proceeding A-12-04-019)

Dear Mr. Zigas, Ms. Borak, and Ms Grimmer:

On March 29, 2017, the Marina Coast Water District (MCWD) provided comments regarding Cal Am's Monterey Peninsula Water Supply Project Draft Environmental Impact Report/Environmental Impact Statement that was prepared for the California Public Utilities Commission and the Monterey Bay National Marine Sanctuary. Since that time, MCWD has performed additional studies of the Salinas Valley Groundwater Basin as part of the District's responsibilities as a Groundwater Sustainability Agency in both the DWR Bulletin 118 Monterey Subbasin and the 180/400 Subbasin. We are providing the reports from those studies for your consideration in the environmental review process for the proposed Monterey Peninsula Water Supply Project.

Enclosed is a June 16, 2017, preliminary report from Stanford University (Gottschalk and Knight), "Preliminary Interpretation of SkyTEM Data Acquired in the Marina Coast Water District"; a September 29, 2017, memo report by Hopkins Groundwater Consultants, "Monterey Peninsula Water Supply Project Return Water"; and a memo report by EKI Environmental and Water, "Groundwater Remedial Actions and Establishment of Remedial Goals at Fort Ord Marina Coast Water District, California". The final report from Stanford University on the Airborne Electromagnetic Survey (SkyTEM) is expected to be complete in early 2018 and we will provide that report as soon as it is available.

Very truly yours,

Keith Van Der Maaten, PE
General Manager

MEMORANDUM

To: Mr. Keith Van Der Maaten
General Manager, Marina Coast Water District

From: Curtis J. Hopkins
Principal Hydrogeologist, Hopkins Groundwater Consultants, Inc.

Date: September 29, 2017

Subject: Monterey Peninsula Water Supply Project Return Water

Introduction

Hopkins Groundwater Consultants, Inc. (HGC) provides this memorandum to update our January 22, 2016, report to Marina Coast Water District (MCWD) regarding the Monterey Peninsula Water Supply Project (MPWSP or the project) return water proposal that was submitted to the California Public Utilities Commission (CPUC) with Curtis Hopkins' direct testimony dated January 22, 2016, including estimates regarding "return water" volume. This memorandum supplements that analysis and provides our professional opinion on why providing return water to the Castroville area as proposed in the Return Water Settlement Agreement will not address or mitigate the adverse groundwater impacts caused by the project in the North Marina Area of the 180-400 Foot Aquifer Subbasin within the Salinas Valley Groundwater Basin (SVGB). As explained in our prior memorandum and expanded upon herein, providing return water north of the Salinas River may beneficially affect groundwater in those aquifers, but it will not mitigate the project's primary adverse impacts to the aquifers south of the Salinas River and its water users. This memorandum further addresses new evidence, including the recent airborne electromagnetic (AEM) data collection by a team from Stanford University led by Dr. Rosemary Knight and the preliminary report on the data, which supports our original analysis regarding the extensive groundwater resources in the shallow aquifers along the coastline around the CEMEX site that will be adversely impacted by the MPWSP. This new evidence also confirms the importance of preserving and protecting the groundwater resources in these coastal aquifers. As requested, HGC provides our professional opinion regarding California American Water Company's (Cal-Am's) revised estimates regarding the volume of "return water" that the proposed MPWSP will be obliged to return to the SVGB.

In preparing these comments, we have reviewed the relevant portions of: (1) the MPWSP Draft Environmental Impact Report/Environmental Impact Statement (DEIR/EIS) prepared for the CPUC, dated January 2017; (2) the DEIR/EIS appendices; (3) Direct Testimony of Ian Crooks, dated September 15, 2017; (4) Settlement Agreement on MPWSP Desalination Plant

P.O. Box 3596, Ventura, California 93006 Phone: (805) 653-5306 e-mail: chop4@earthlink.net

Return Water, filed on June 14, 2016 (Return Water Settlement); (5) the documents provided to HGC in response to MCWD's data and public records act requests that were made available before September 26, 2017; (6) publicly available information referenced at the end of our comments; and (7) Preliminary Interpretation of SkyTEM Data Acquired in the MCWD, Ian Gottschalk and Rosemary Knight, dated June 16, 2017 (SkyTem Data Report). We note that while the initial SkyTem data (or AEM data) supports our prior analysis, our discussion of the SkyTem Data Report will need to be updated once the report is finalized. As explained below, this regional survey and the AEM data of subsurface resistivity values greatly assists the understanding of the presence of freshwater and saltwater in the coastal aquifer system and the type and location of extraction facilities that might effectively target seawater production in a beneficial manner. The AEM data provide a valuable source of information and this type of survey should have been conducted as part of the Cal-Am MPWSP original siting study.

Preliminary Statement Regarding Updated Professional Opinion Regarding Proposed Return Water Settlement Agreement and Cal-Am's Estimates of the Amount of Return Water Needed to Meet Its Estimated Demand.

Cal-Am proposes to return to the SVGB the percentage of the raw water (or feedwater) pumped from the MPWSP intake wells that is determined to be groundwater as opposed to ocean water. Our January 22, 2016, report discussed several options that Cal-Am had proposed to meet its return water obligations because Cal-Am had not selected a return water method at that time. Our report explained why several options under consideration would not satisfy Cal-Am's return water obligations, but concluded that Cal-Am had not provided sufficient information to evaluate its proposed methods for returning groundwater. Subsequent to our report, Cal-Am entered into a proposed return water settlement agreement, which provides in relevant part:

> Pursuant to the terms of this Settlement Agreement, the Parties propose that Cal Am deliver Return Water to the Castroville Community Services District (CCSD) and to the CSIP ***to satisfy Return Water requirements that may arise out of the Agency Act, CEQA, or California groundwater law,*** in accordance with terms and conditions and general principles contained in this Settlement Agreement and separate Return Water Purchase Agreements between Cal Am as seller and CCSD and the Agency, respectively, as purchasers of Return Water.

(Settlement Agreement on MPWSP Desalination Plant Return Water, p. 4 [¶AA].) As explained below, available information indicates the proposed return water settlement agreement will not satisfy the MPWSP's return water requirements under the California Environmental

Quality Act (CEQA) or California groundwater law.[1] As we explained in our original report, it is critical that the return method selected ensure the protective groundwater levels in the Northern Marina Subarea [2] are maintained to prevent increased seawater intrusion and would erase the substantial conservation efforts that have restored this portion of the SVGB. This is corroborated by the recent SkyTem data and Report, which further demonstrates that the aquifers in the Northern Marina Subarea contain substantial groundwater capable of supporting beneficial uses and is not entirely seawater intruded as Cal-Am claims. As we explained in our original report, modeling that correlates actual data—rather than unproven assumptions—from the MPWSP test slant well project (TSW) and monitoring well data from the aquifers within the Northern Marina Subarea affected by the project must be performed to provide any reasonable scientific basis for estimating the MPWSP's return water obligation and the efficacy of the method selected. As explained below, updated modeling to date is inadequate to evaluate the MPWSP's direct and cumulative impacts on water levels in the Northern Marina Subarea aquifers and entirely fails to evaluate how the project or return water method will impact water quality in the Northern Marina Subarea aquifers affected by the project.

Finally, HGC provides its comments regarding Cal-Am's revised demand testimony that estimates the MPWSP source water return water obligation at 7%. (Ian Crooks Direct testimony, dated September 15, 2017, p. 14:25-26.) Our January 22, 2016, report addressed Cal-Am's estimated amount of return groundwater included in its overall demand estimates, which were based on Cal-Am's plant sizing technical memorandum, which assumed that 875 acre-feet per year (afy) of groundwater, representing approximately 3.2 percent of the project's feedwater, would need to be returned to the SVGB for a 9.0 million-gallon-per-day (mgd) desalination plant without the Pure Water Monterey Groundwater Replenishment (GWR) Project.[3] (RBF Consulting, Memorandum from Paul Findley to Richard Svindland, Recommended Capacity for

---

[1] / This memorandum does not address the adequacy of the DEIR/EIS or whether the Cal-Am's preferred MPWSP alternative that proposes slant wells as the CEMEX site in Marina, CA complies with California water rights law, the Monterey County Water Resources Agency Act's ("Agency Act"), the Sustainable Groundwater Management Act, pumping limits imposed by Marina Coast's 1996 Annexation Agreement pertaining to the CEMEX property, or other legal requirements. We have attached our comments on the DEIR/EIS for reference as they provide further information and explain why the Settlement Agreement on MPWSP Desalination Plant Return Water is inadequate.

[2] / For purposes of the memorandum, the Northern Marina Subarea is defined as that portion of the 180/400 Foot Aquifer Subbasin located south of the Salinas River and north of the northern boundary of the adjoining Seaside Area Subbasin. The CEMEX property is located in the southwest corner of the Northern Marina Subarea. Six of MCWD's water supply wells are located along the northern boundary of the Seaside Area Subbasin.

[3] / HGC understands that Cal-Am's current proposal includes a 9.6 mgd desalination plant without the GWR Project or a 6.4 mgd desalination plant with the GWR Project.

the MPWSP Desalination Plant, dated January 7, 2013.) The technical memorandum further estimated that 550 afy of groundwater would need to be returned to the SVGB for a 5.4 mgd desalination plant with the GWR Project. Our report concluded that the TSW project monitoring data available at that time demonstrates that Cal-Am's 2014/15 modeling and its estimates regarding the percentage of groundwater that would be pumped by the MPWSP were not accurate and needed to be updated. We further explained that updated modeling using information developed from the TSW field investigations and available from other studies in the Marina Subarea must be used to refine the MPWSP modeling to accurately simulate aquifer conditions and evaluate alternative methods of returning the groundwater pumped by the MPWSP and to provide a reasonable estimate of the amount of return water that will be required for the project to operate.

There is no supporting documentation or explanation as to how Cal-Am estimated the 7% source water return water obligation used to estimate demand in Mr. Crooks testimony. As explained below and our comments on the DEIR/EIS, the updated modeling to date does not estimate or provide any information useful to estimating the amount of groundwater that will need to be returned to the SVGB. The modeling in the 2017 DEIR/EIS bracketed the return water percentage between 0% to 12%, but failed to calculate the amount of return water that would be necessary to replace the groundwater drawn from the SVGB. The DEIR/EIS did not provide any discussion or information to support bracketing the return water percentage between 0% to 12%. As explained below, it is likely that MPWSP's return water obligation would be more than 12%, especially in the initial years of operation. As explained in our original report, until updated modeling correlated with actual data—rather than unproven assumptions—from the MPWSP TSW and monitoring well data from the aquifers within the Northern Marina Subarea affected by the project, there can be no reasonable estimate to inform Cal-Am's demand numbers and the efficacy of the MPWSP.

North Marina Area Geology Differs from the Geology North of the Salinas River.

As discussed in our prior report, the geology in the North Marina Area differs from the geology north of the Salinas River in the main portion of the 180-400 Foot Aquifer Subbasin and has been described in detail by studies conducted for the MPWSP. As shown and as described by previous study (Geoscience, 2014 and 2015, KJC, 2004), the terrace deposits that comprise the 180-Foot Equivalent Aquifer (180-FTE) in the North Marina Area grade into the alluvial deposits that comprise the 180-Foot Aquifer in the main portion of the basin around the present location of the Salinas River. This is illustrated in Figure 1 – Cross-Section A-A', which provides an interpretation of subsurface deposits within this specific coastal area using a portion of a subsurface profile constructed by Geoscience Support Services, Inc. from borehole data collected in the area (Geoscience, 2014). The approximate location of Cross-Section A-A' is shown in Figure 2 – Groundwater Basin Boundary Map.

Figure 1 – Cross-Section A-A'

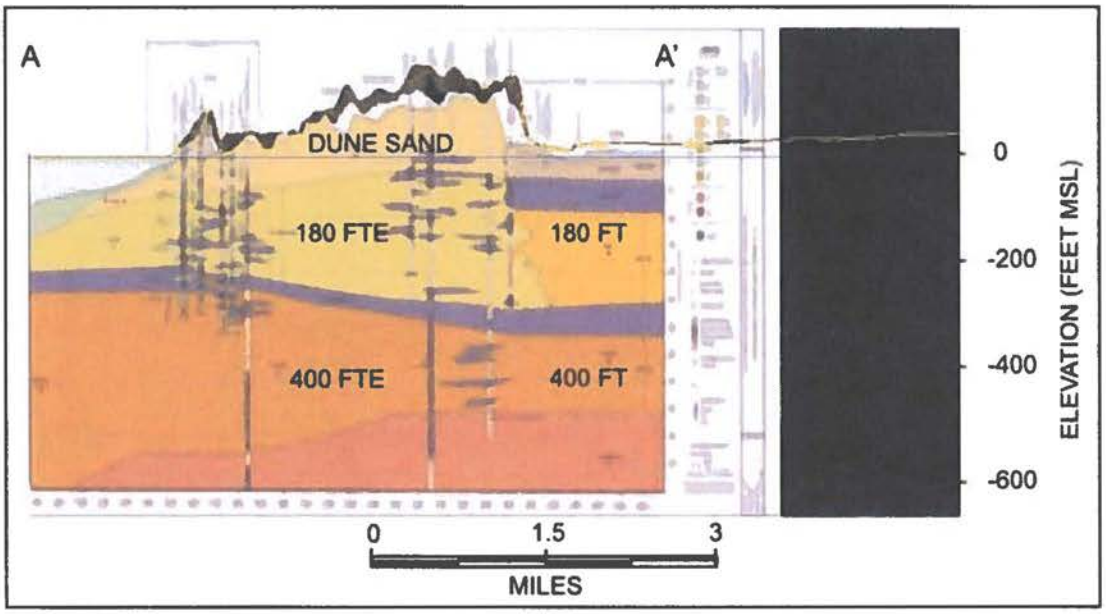

Figure 2 – Groundwater Basin Boundary Map

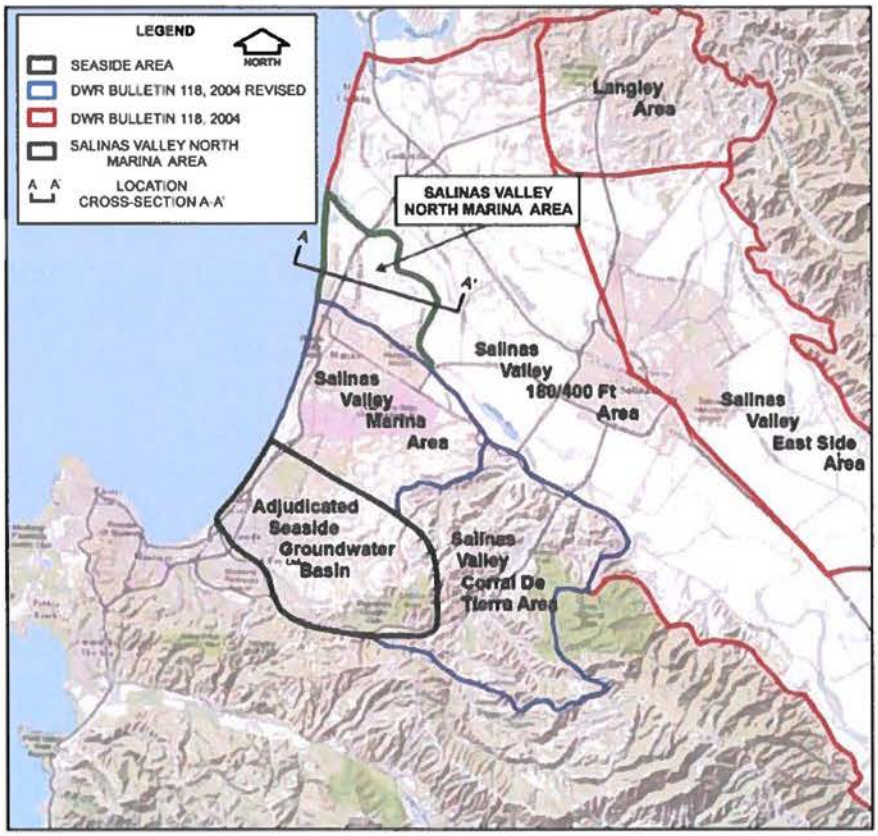
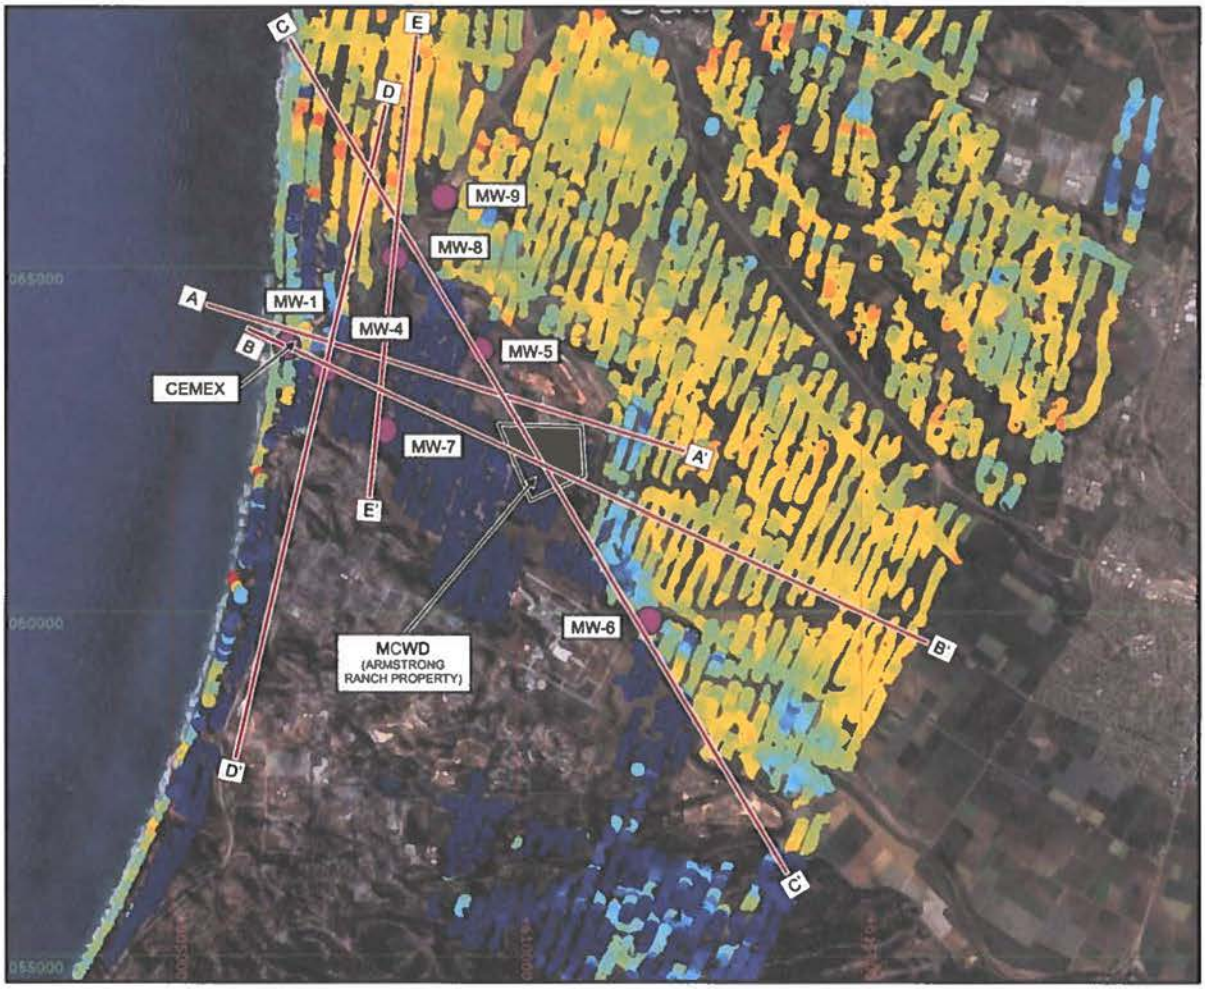


E:\HOPKINS RETURN WATER MEMO 9-29-17 FINAL.DOCX

Investigation for the MPWSP includes the installation of a test slant well and multiple monitoring wells in and around the CEMEX property where the MPWSP intake wells are proposed to be located. The monitoring well network is being used to generate background water level and water quality data within the North Marina Area of the 180-400 Foot Aquifer Subbasin. The location of the monitoring facilities is shown on Figure 3 – Well Location, Geophysical Data Lines, and Resistivity Profile Map.[4]

Figure 3 – Well Location, Geophysical Data Lines, and Resistivity Profile Map



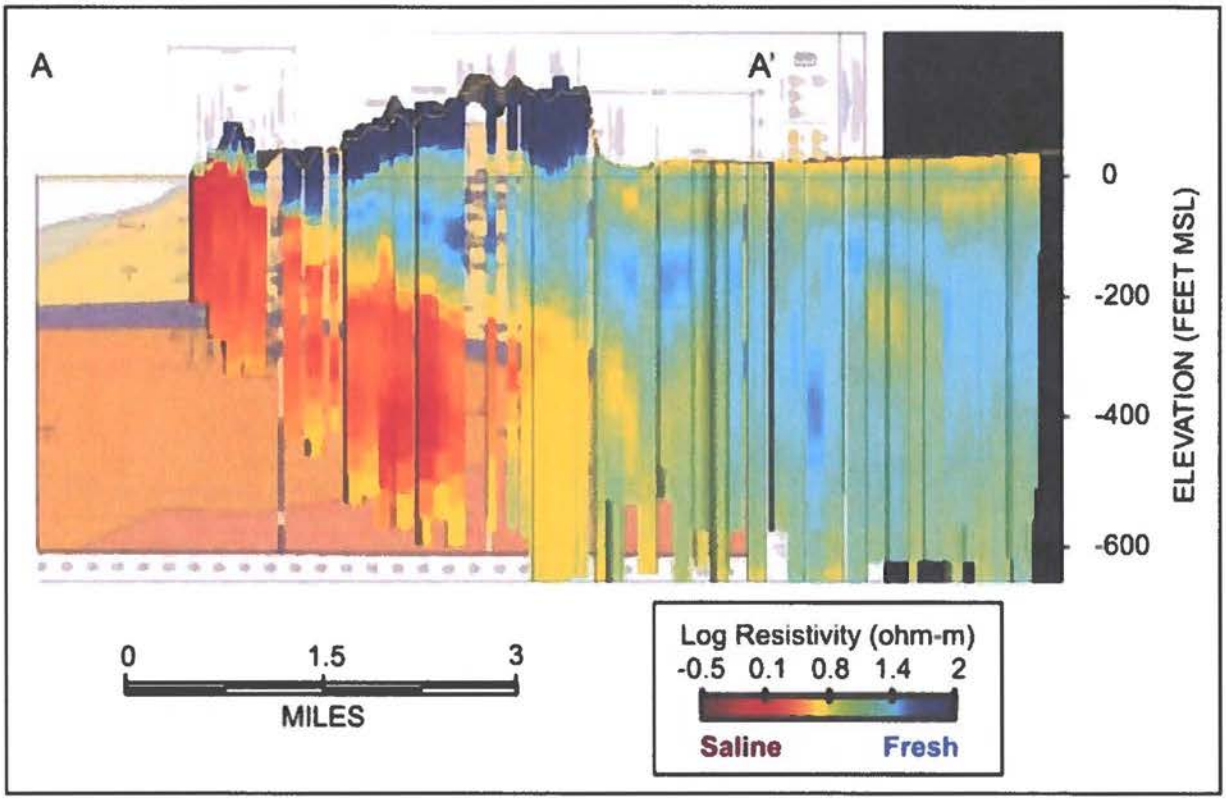
In addition to showing the approximate locations of the MPWSP monitoring wells, Figure 3 above, shows the substantial area of undeveloped land in and around the North Marina

[4] The pre-project studies indicate that MW-1S, MW-3S, MW-4S, and MW-7S likely are connected to the Dune Sand Aquifer zone recognized as the -2-Foot Aquifer that is identified beneath the County landfill site (Geoscience, 2016). The elevation and thickness of this zone indicates it likely has a hydraulic connectivity to the A-Aquifer zone in the main portion of the SVGB located north of the river.

Subarea that the AEM survey was able to target and obtain resistivity data. Each dot represents a location that resistivity data was collected. The color of the dots signifies the uppermost resistivity value at the measurement location where the electrical readings were collected. Figure 3 also shows the location of the hydrogeologic cross-sections/resistivity profiles provided in Figures 4, 6, 8, 17 and 18 below. Each cross-section/profile shows the resistivity by depth along the line shown in Figure 3. The resistivity profiles are presented in subsequent figures to illustrate the study findings at specific locations within the study area. Additional resistivity profiles are included in Attachment A – Regional Resistivity Profiles to further illustrate the changes in groundwater conditions across the entire study area. As explained in the SkyTem Data Report by Dr. Knight, those areas that are blue and green are more resistive where the groundwater is fresher and likely supports beneficial uses. Areas that are yellow, orange, or reddish are less resistive and likely contain more brackish groundwater. Nonetheless, these less resistive areas may still contain groundwater that supports beneficial uses. Additional information is needed to confirm the beneficial users that may be supported in these areas as explained by Dr. Knight in her preliminary report.

An overlay of these AEM survey data on the hydrogeologic cross-section from Figure 1 is provided in Figure 4 – Cross-Section A-A' with AEM Data, which starts along the coastline at the CEMEX site and runs directly inland several miles.

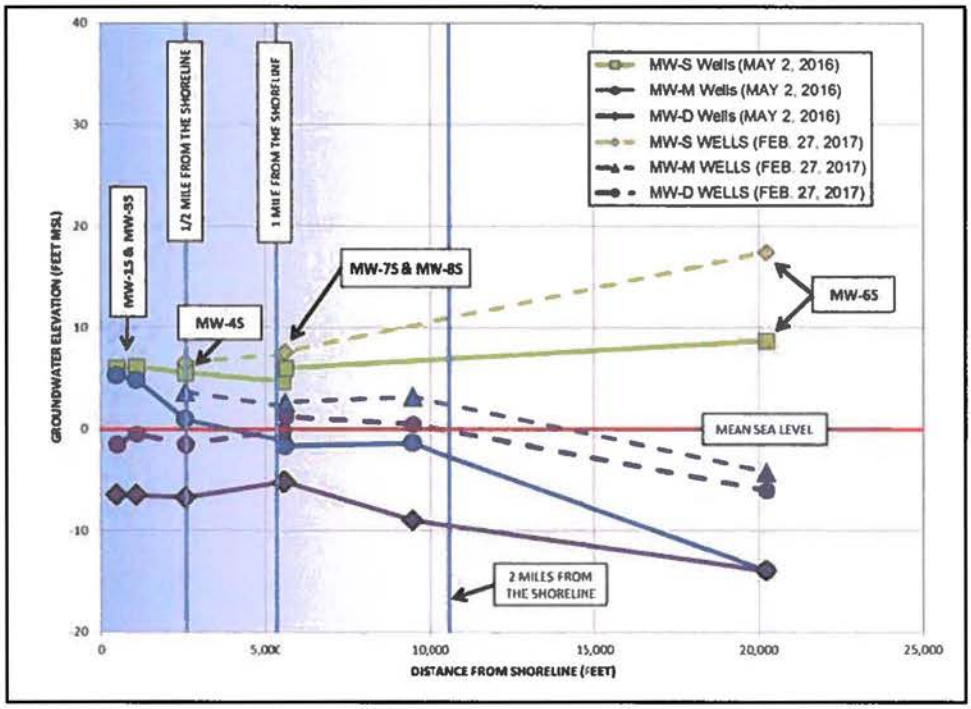
Figure 4 – Cross-Section A-A' with AEM Data



These data from this cross-section indicate a substantial amount of fresh water inland of the coastline and within the Dune Sand and 180-FTE Aquifer zones of the North Marina Subarea. These data further substantiate the opinions we provided in our original report that we noted were based on relatively sparse monitoring well water quality data that indicated this freshwater presence.

Also discussed below, recent data obtained regarding the gradient beneath the landfill (near MW-5) shows recharge from the river that creates a groundwater gradient toward the coastline. Importantly, this is consistent with the elevated heads in MW-6S where it also receives recharge from the river. Figure 5 – Water Level Elevation and Shoreline Proximity compares available data that were collected just prior to restarting the long term pumping test on May 2, 2016, and the high water level conditions observed on February 27, 2017. [5] This diagram shows the wells that are constructed in the Dune Sand Aquifer zone that is equivalent to the -2-Foot Aquifer zone along with MW-6S, which is in the A Aquifer zone (Geoscience, 2016). As shown by these data, there is a groundwater gradient that moves water from the river area of recharge toward the coastline in the Marina Subarea of the SVGB.

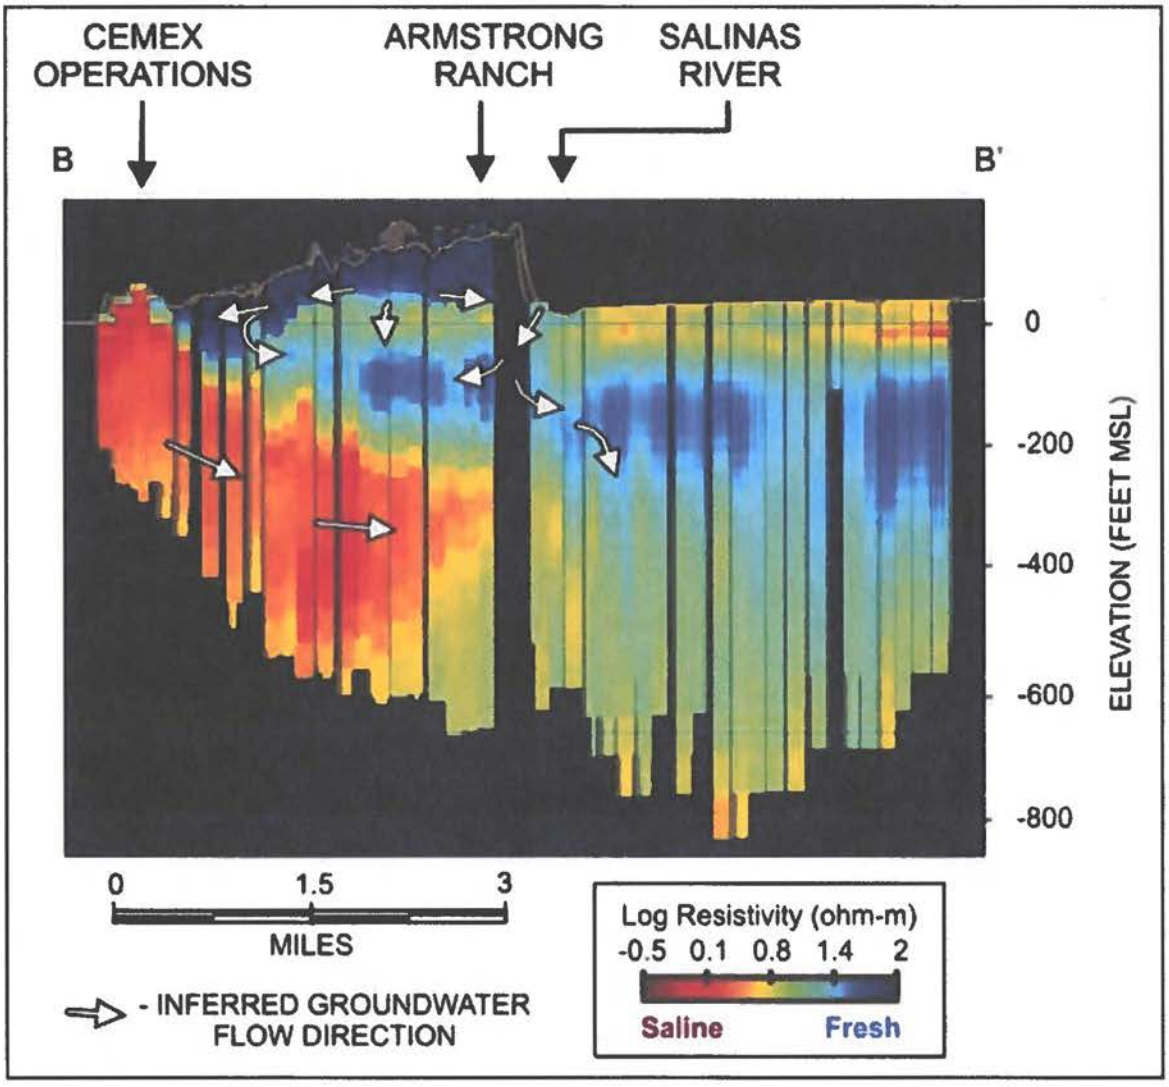
Figure 5 – Water Level Elevation and Shoreline Proximity



[5] Monitoring Well MW-5S data with water levels in excess of 35 feet amsl were not included in Figure 5 because it is now recognized to be screened in a semi-perched dune sand layer on top of the aquitard layer identified as the Fort Ord Salinas Valley Aquitard (FO-SVA). The FO-SVA layer overlies the -2-Foot Aquifer/Dune Sand Aquifer, which is reportedly 30 to 40 feet thick and rests on the Salinas Valley Aquitard near the river in the Marina Subarea northeast of the project site (Geoscience, 2016).

The significance of this condition south of the Salinas River is illustrated by Figure 6 – Resistivity Profile B-B' Groundwater Flow Direction which shows the inferred groundwater flow directions that could create this large area of freshwater. The survey reveals that along the shoreline, seawater is present in varying amounts in almost all aquifer zones but is neither ubiquitous nor present in all aquifer zones away from the coastline in the North Marina Area. These data demonstrate that there is a substantial freshwater resource in the Marina Subarea and that our inference in our original report that were based on the sparse water quality data made available from the project was not a selective manipulation of data or "cherry picking" as Cal-Am has claimed. These data indicate conditions within the aquifer within the North Marina Area are not well understood, but likely have significant effects on the actual occurrence and movement of groundwater.

Figure 6 – Resistivity Profile B-B' Groundwater Flow Direction



The dune sand area south of the river is readily recharged by rain water and storm water detention basins in the developed MCWD area south of the project which recharges the underlying 180-FTE aquifer. The Salinas River appears to provide a substantial source of fresh water recharge around the North Marina Subarea which decreases the effects of the pumping stress from the main portion of the 180/400 Foot Basin located north of the river.

While these freshwater recharge mechanisms in the North Marina Area have not be thoroughly investigated to date, the AEM data indicate they provide a key source of protection to the aquifers in the groundwater basin located inland of the Marina Subarea. The magnitude of pumping proposed by the project will disrupt the natural balance that has controlled seawater intrusion to its present location. It is clear that the modelling preformed for the MPWSP to date does not predict its presence, the protective head it provides, or the impedance to seawater intrusion it provides. In fact, the MPWSP modelling indicates a much faster rate of seawater intrusion than presently indicated by these data. Figure 7 – Particle Tracking 180-FTE Aquifer – shows the simulated movement of groundwater in the 180-FTE Aquifer under assumed historical conditions.

Figure 7 – Particle Tracking 180-FTE Aquifer

Because of the lack of data within the North Marina Subbasin coastal area included in the MPWSP modelling to date, the inferred model conditions simulate movement of seawater in the 180-FTE Aquifer zone(s) from the coastline to MW-5 within 14 to 15 years. Overdraft conditions in the 180-400 Foot Aquifer Subbasin have persisted for decades, if this assumption had been accurate. Both the AEM data and the test well monitoring results show this is not the case. Notably, the rate of movement simulated in the MPWSP modelling would have driven the saltwater front miles further than presently observed if the groundwater model parameters and assumptions were accurate.

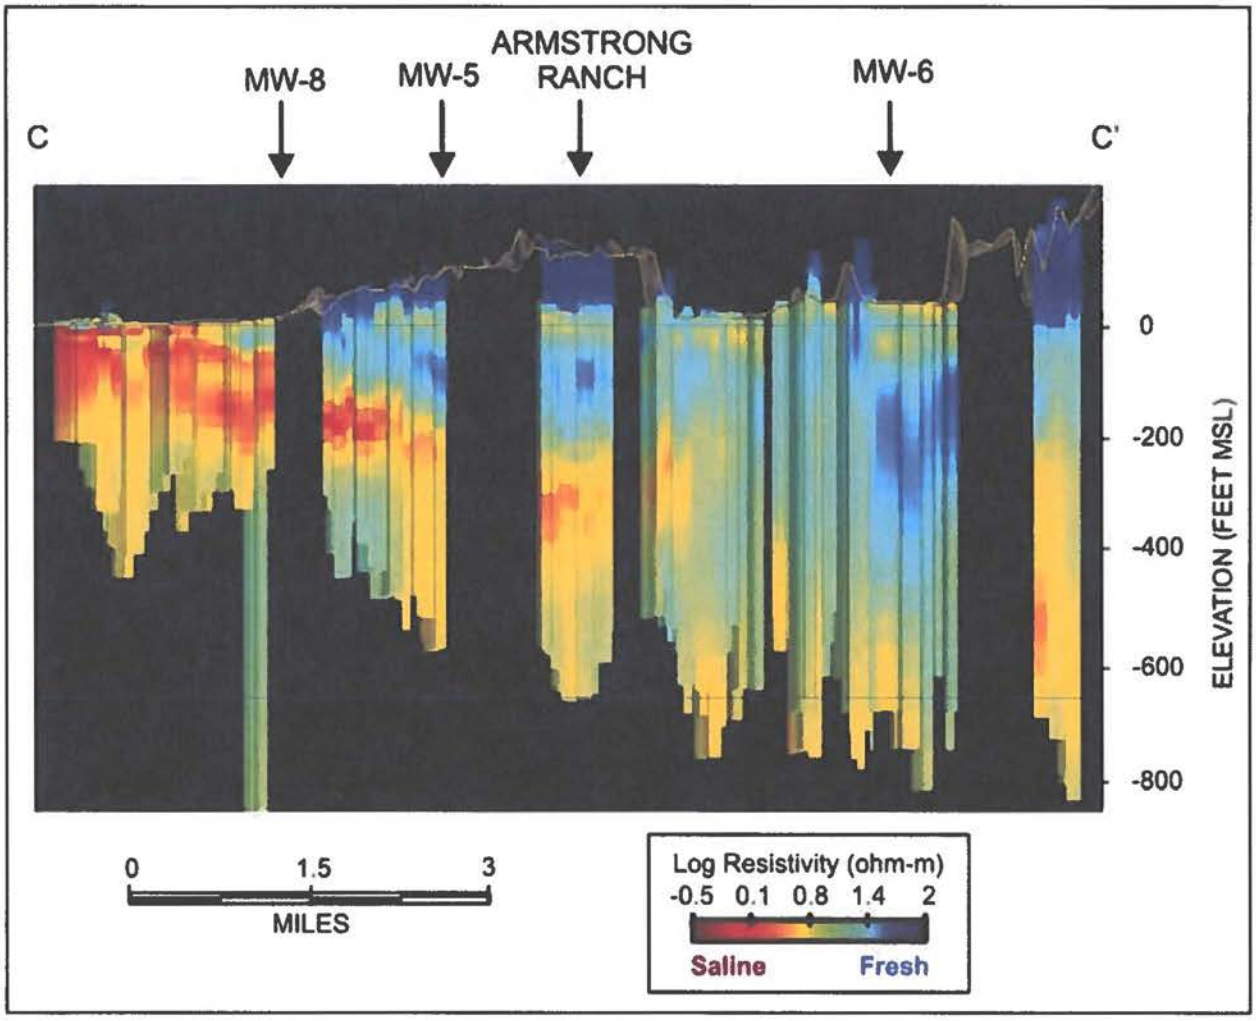
Given the potential magnitude of the increased groundwater production in the Dune Sand Aquifer and the 180-FTE Aquifer, the impacts to the SVGB, in particular the North Marina Subarea are grossly understated by the MPWSP modelling to date. Therefore, a well calibrated model is needed to quantify the project's potential impacts with a reasonable scientific basis to evaluate the mitigation that will be required and to calculate the amount of return water that will be required. Specifically, a model that utilizes all the recharge and discharge components included in the older Salinas Valley Integrated Groundwater Surface Water Model (SVIGSM), and constructed with a level of detail reflecting our present understanding and knowledge of the hydrogeological system in the Marina Subarea is needed. Moreover, because seawater is an issue, a variable density model should be used to allow calculation of the head differences between the ocean water offshore and onshore, and freshwater in the aquifer zones inland and to allow prediction of water quality changes and the concentrations of feedwater that would be produced by the proposed project.

Water Quality in North Marina Area Aquifers.

Water quality data developed as part of the test slant well project are summarized in the tables included in Attachment B – Laboratory Water Quality Test Results. The first table shown in Attachment B provides the only data published for wells other than the test slant well and MW-4 (Geoscience, 2015a). This table includes laboratory results for wells including MW-1, MW-3, MW-4, MW-5, and the test slant well. The second table in Attachment B is a compilation of laboratory data received by MCWD in October 2015 in response to a data request in the CPUC proceedings. This table includes data for monitoring wells MW-6, MW-7, MW-8, and MW-9 that to our knowledge, have not been published in any of the MPWSP documents.

Figure 3 indicates the location of additional subsurface resistivity profiles provided below to show the results of the AEM survey. Figure 8 – Resistivity Profile C-C' shows the subsurface resistivity values for a line drawn past MW-8, MW-5, and MW-6. The significance of these data is that they indicate beneficial conditions have developed (or have always existed) in the shallow aquifer zones in the North Marina Area of the 180-400 Foot Aquifer Subbasin and appear contrary to information published by the Monterey County Water Resources Agency (MCWRA).

Figure 8 – Resistivity Profile C-C'



The recent investigation that is being conducted in and around the North Marina Area as part of the MPWSP has uncovered an occurrence of freshwater within the shallow Dune Sand Aquifer and the underlying 180-FTE Aquifer within the area delineated as seawater intruded by the MCWRA. As previously shown, water level data from wells in the shallow Dune Sand Aquifer indicate that there are protective water levels sufficiently above sea level to prevent seawater intrusion in the shallower sediments. This condition, combined with the lack of pumping in the 180-Foot Aquifer in the North Marina Area, appears to have slowed seawater intrusion in the aquifers in this portion of the coastline.

This is further illustrated by the water quality test results for total dissolved solids and chloride concentrations in these two uppermost aquifer zones are shown on Figures 9 and 10 – Average Total Dissolved Solids Concentrations in Groundwater and Average Chloride Concentrations in Groundwater, respectively.

Figure 9 – Average Total Dissolved Solids Concentrations in Groundwater

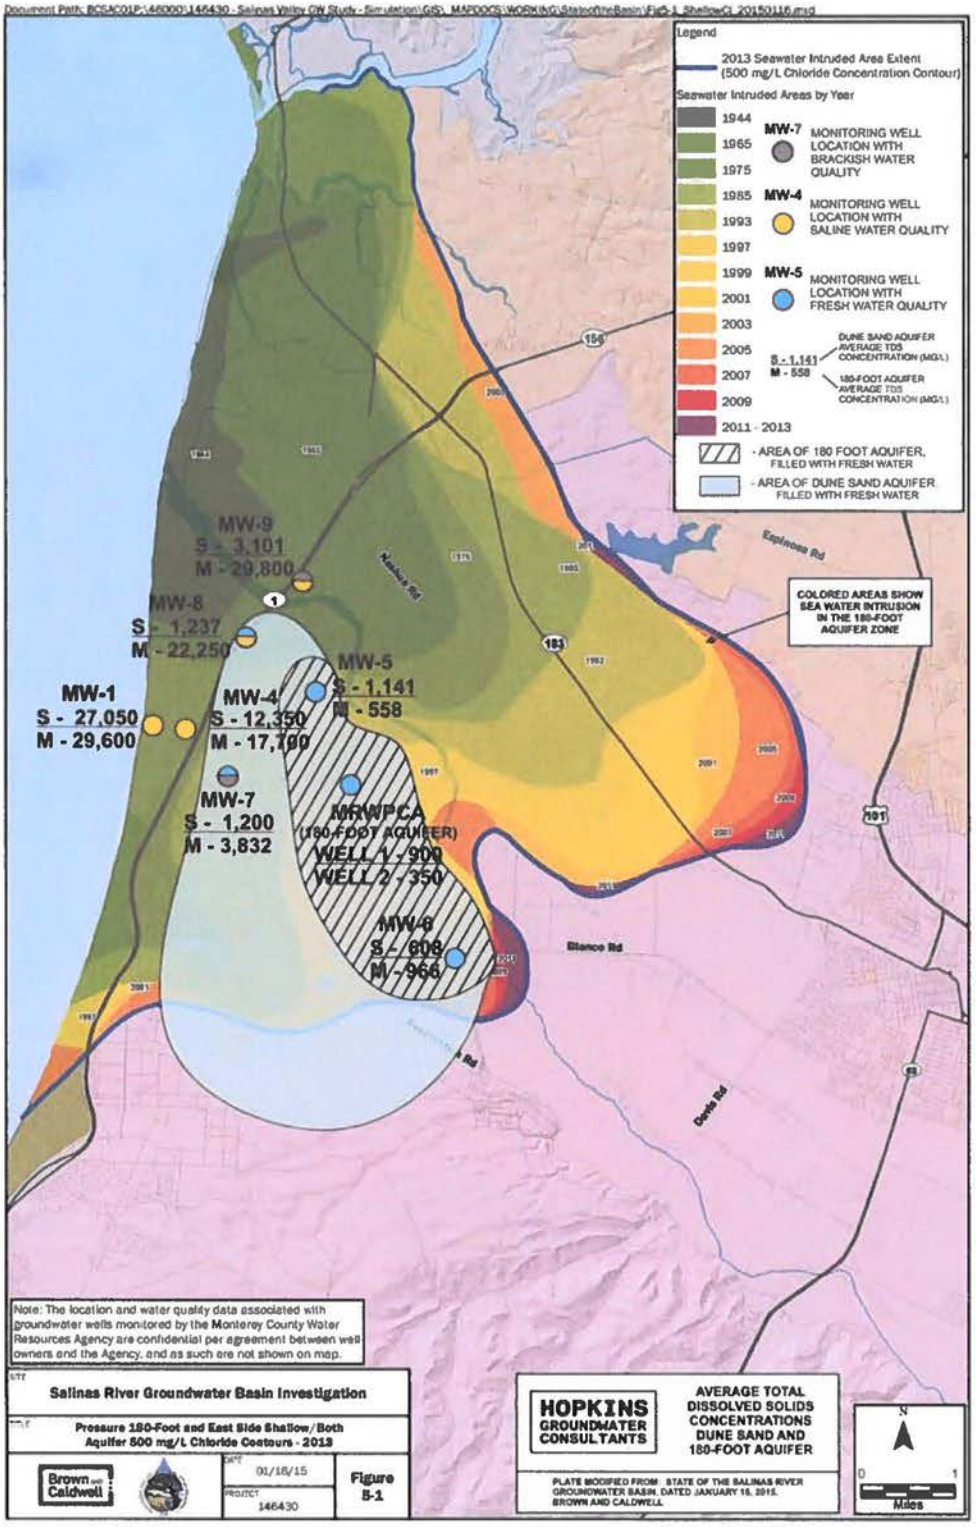


Figure 10 – Average Chloride Concentrations in Groundwater

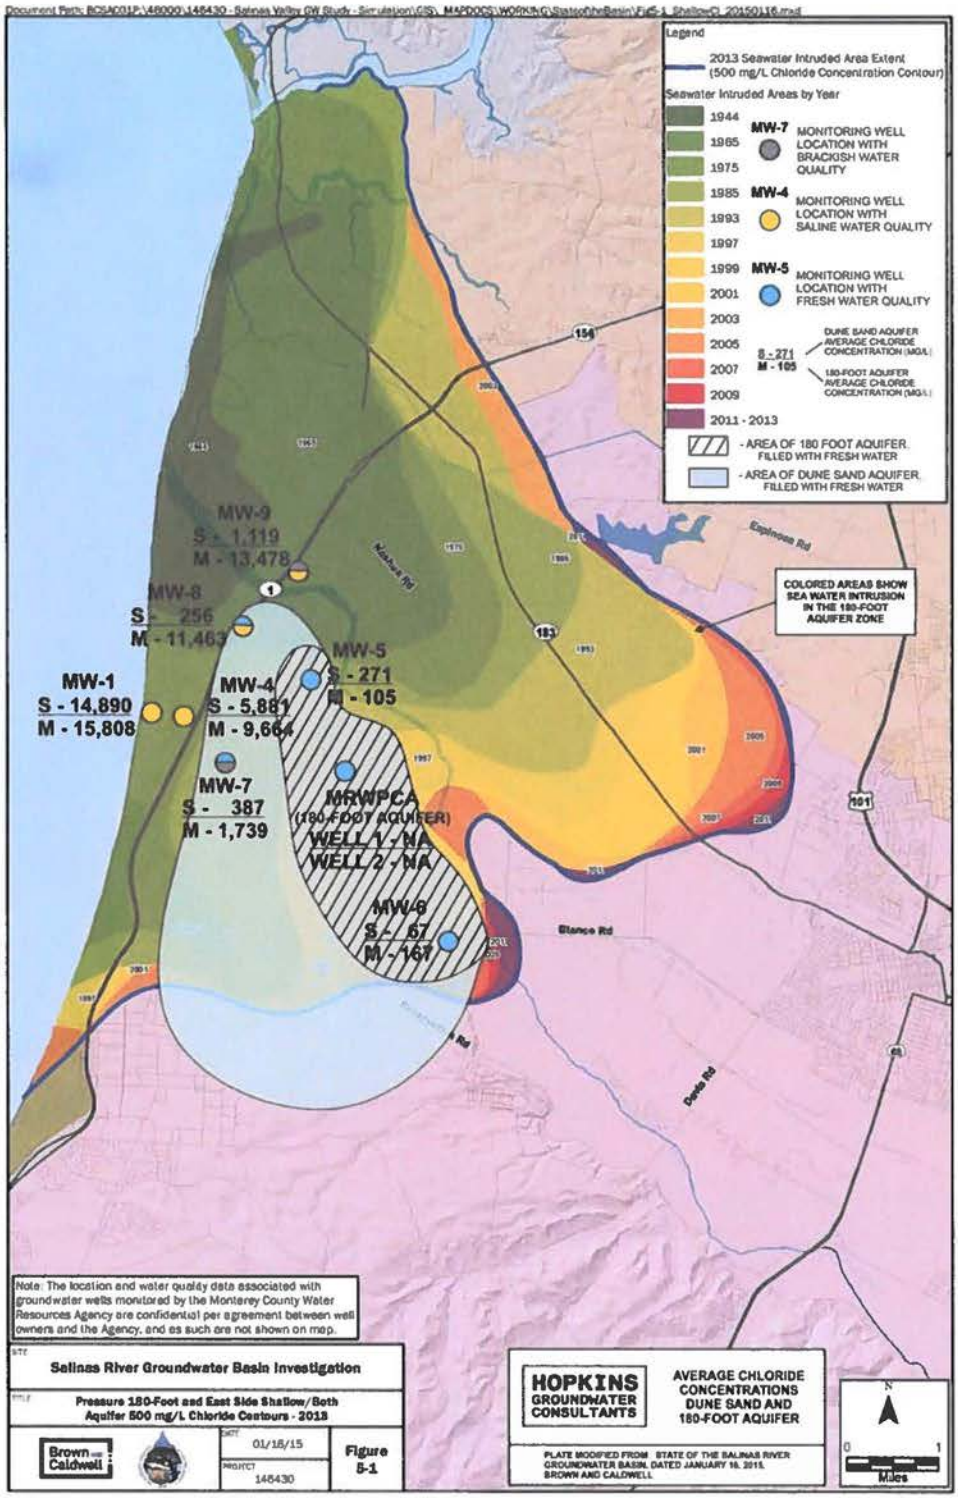
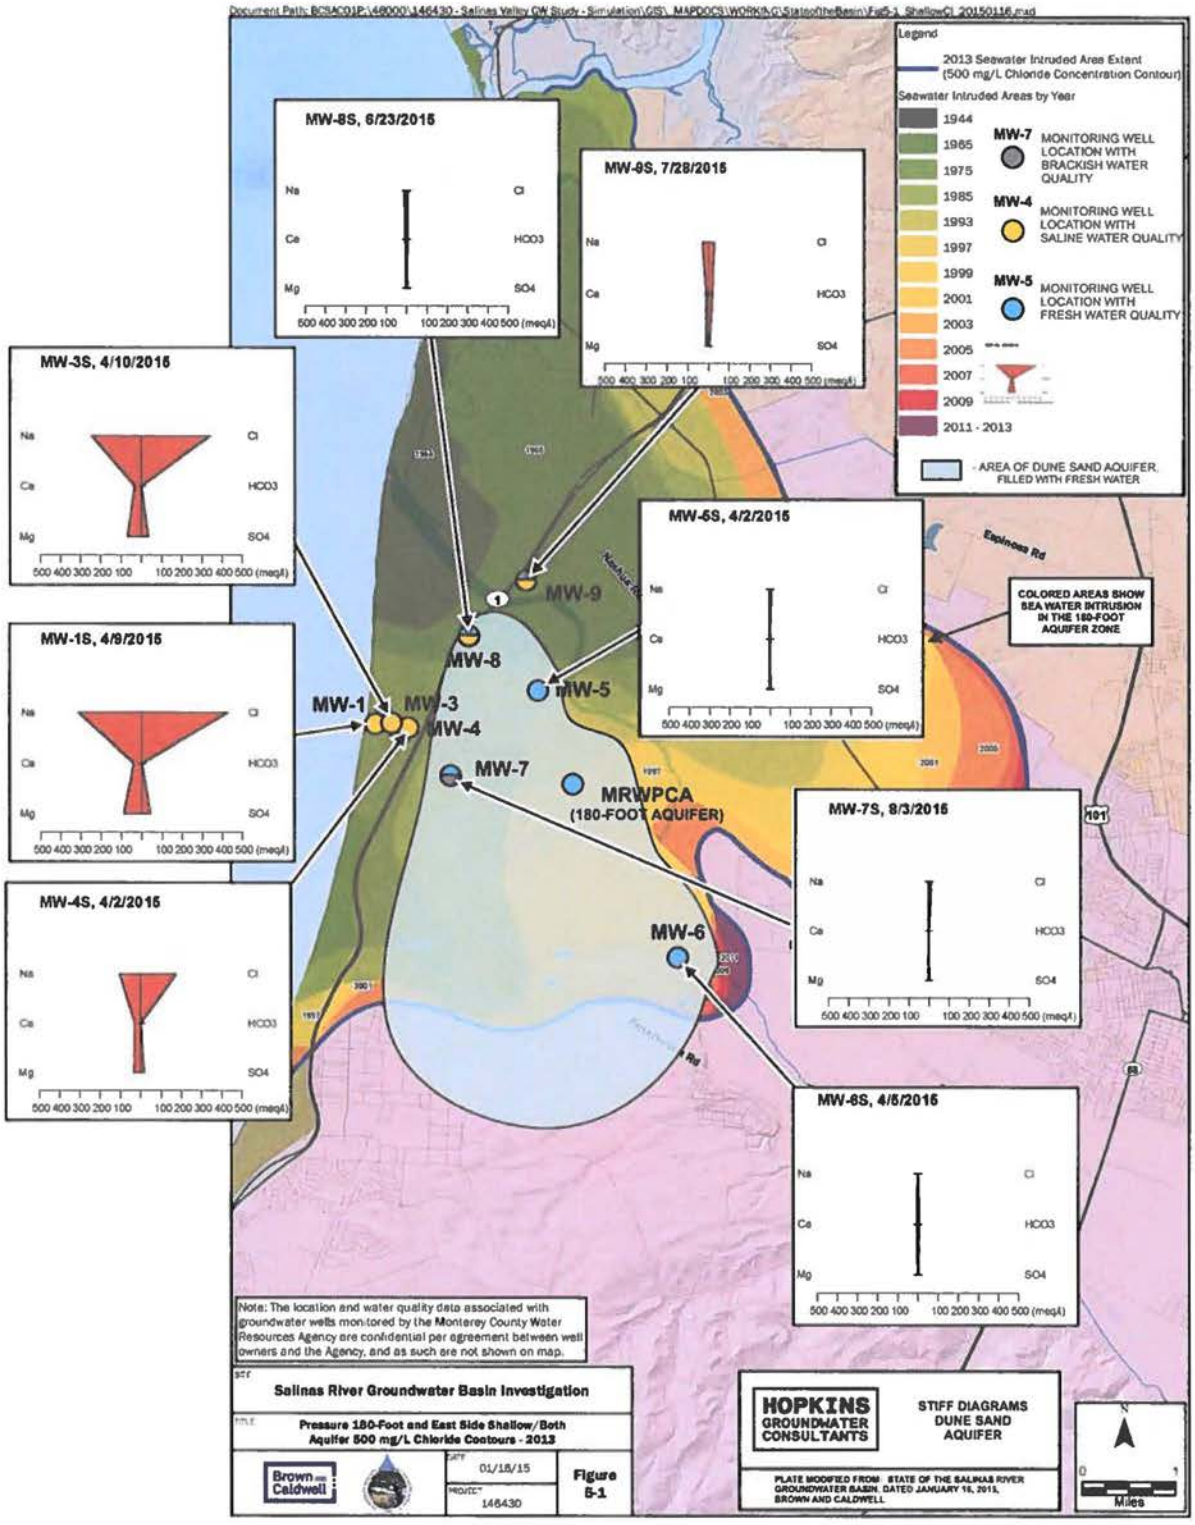


These data indicate a change of groundwater conditions in this coastal section of the aquifer or alternatively, they may reveal the groundwater conditions that existed in an area largely lacking historical data. While the freshwater in this area contains some salts and nutrients that are derived from overlying land uses that include agriculture, landfill, and wastewater treatment plant and composting facilities, the chemical character is not sodium chloride, which is indicative of seawater intrusion.

Figures 11 and 12 – Stiff Diagrams of Dune Sand Aquifer Groundwater and 180-Foot Aquifer Groundwater, respectively show that the chemical character of groundwater in the new wells away from the coast is predominantly calcium chloride and calcium bicarbonate. Additionally, elevated concentrations of nitrate are present in monitoring wells MW-5S, MW-7S and MW-8S and range from 115 milligrams per liter (mg/l) to 237 mg/l. The concentration of nitrate decreases with depth at all of these sites, and is the highest at MW-5, which is closest to the landfill and the wastewater treatment facilities. While additional investigation is needed to determine the extent to which this area can be used as a direct source of potable groundwater supply, existing conditions show effective abatement of seawater intrusion in these shallower aquifer zones in this coastal portion of the SVGB. As explained in the EKI report, this condition could support the future beneficial uses of the 180-Foot Aquifer zone, including aquifer storage and recovery of highly purified recycled water for indirect potable reuse (EKI, 2017).

These data further substantiate the conclusions in our original report that a unique condition exists in the North Marina Subarea south of the Salinas River that provides a significant degree of protection against seawater intrusion in the shallower aquifers under the present and recent past hydrologic conditions.

Figure 11 – Stiff Diagrams of Dune Sand Aquifer Groundwater



E:\HOPKINS RETURN WATER MEMO 9-29-17 FINAL.DOCX

Figure 12 – Stiff Diagrams of 180-Foot Aquifer Groundwater

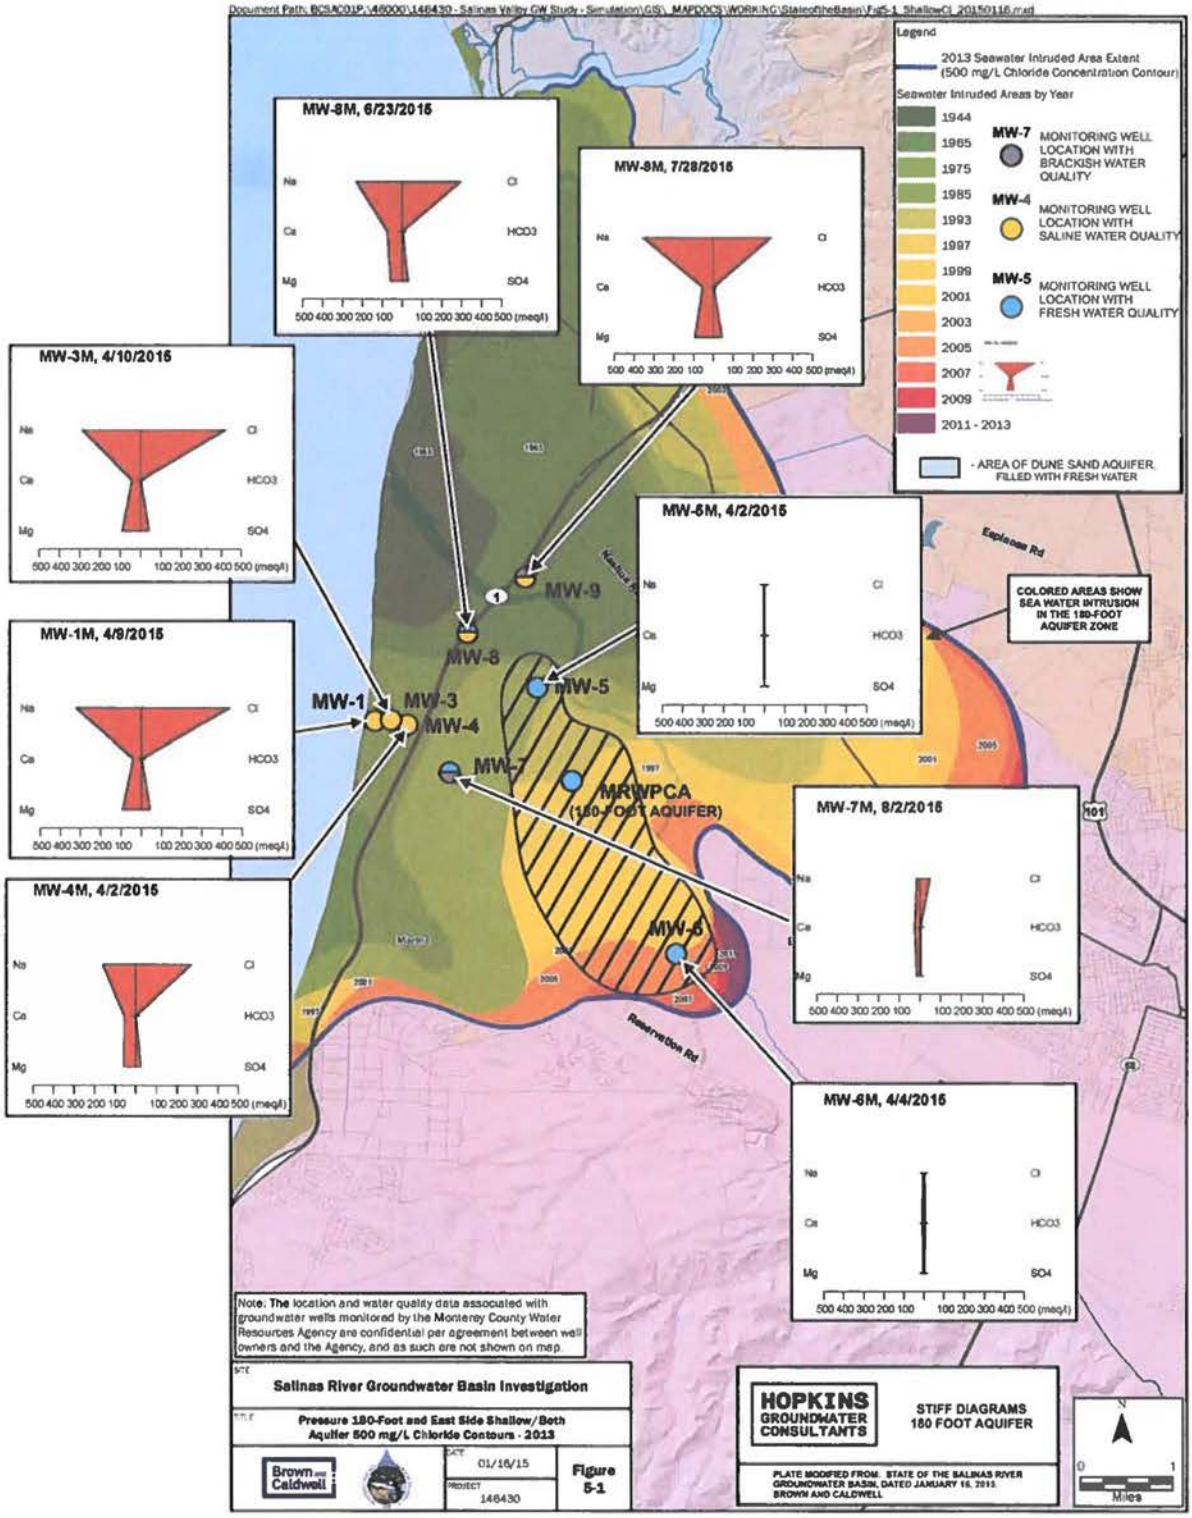


Figure 13 – Percent Groundwater with Distance From the Shoreline provides an updated rudimentary calculation of groundwater percentage versus ocean water percentage in the 180 FTE and 400-foot aquifers in the CEMEX area using the same equation applied to the test slant well discharge. The percentage of fresh groundwater in well water samples was calculated using the following equation:

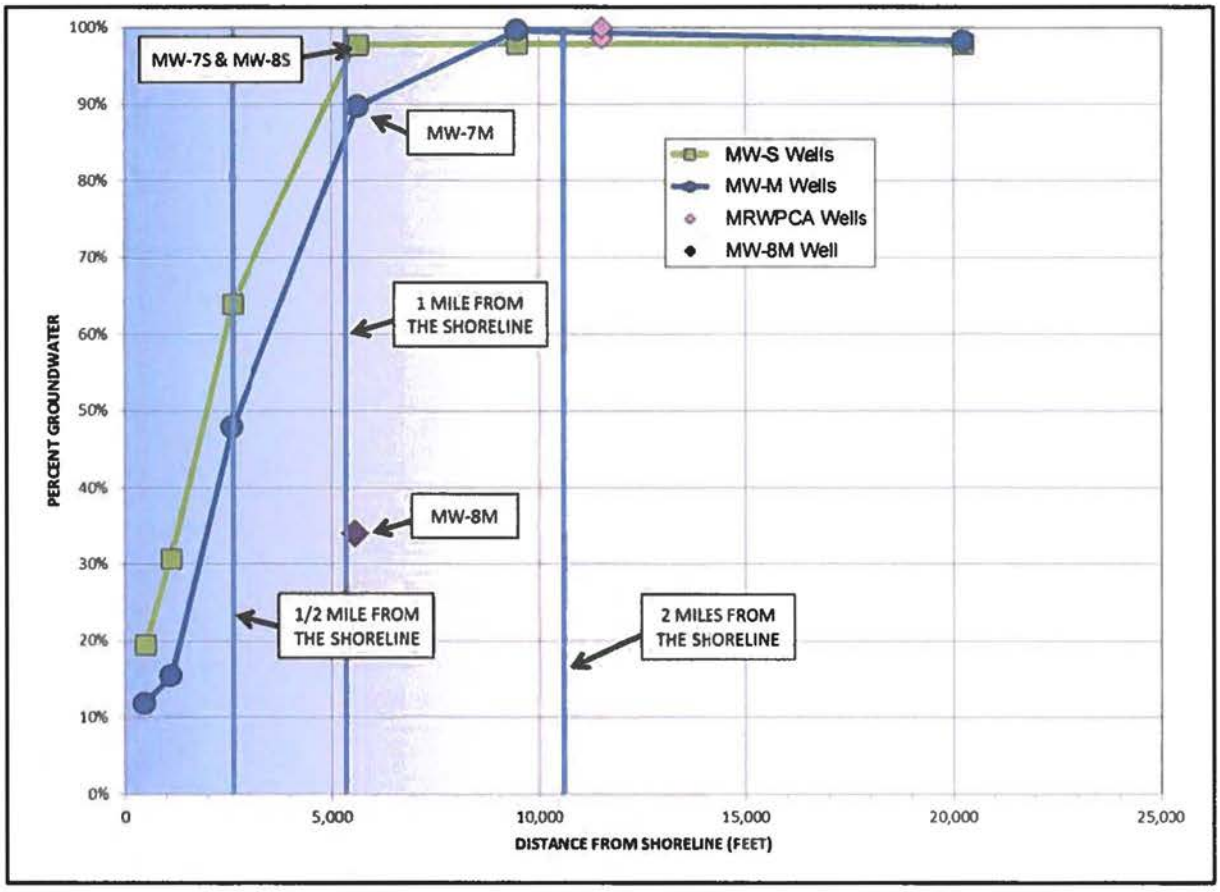
$$GWP = [1 - (WSS - GWS/OWS - GWS)] \times 100$$

Where:

GWP = Percent Groundwater
WSS = Well Sample Salinity (mg/l)
GWS = Groundwater Salinity (420 mg/l)
OWS = Ocean Water Salinity (33,500 mg/l)

Figure 13 – Percent Groundwater With Distance From the Shoreline



Water quality data used in this analysis were provided by the laboratory test results summarized in Attachment B. These available data show that the percentage of ocean water

decreases significantly within a short distance from the coastline in the North Marina Area and the salinity of groundwater that is comparable to seawater is not up to 8 miles inland in the 180-Foot Aquifer as assumed by previous study and modeled by the project proponent. Calculation of percent ocean water using this method cannot differentiate between salts from overlying land uses and salt from ocean water.

This calculation assumes that all salt in groundwater with a total dissolved solids (TDS) above a concentration of 420 mg/l is from ocean water. As shown in Figure 9, monitoring wells MW-5M and MW-6M along with the Monterey Regional Water Pollution Control Agency (MRWPCA) Wells are located in the 180-Foot Aquifer and the average TDS concentration for samples from these wells ranges from approximately 558 to 966 mg/l and is also considered fresh water (See Figure 9 and Attachment B). However, the TDS concentration for MW-7M (3,832 mg/l) and MW-8M (22,250 mg/l) show that closer to the coast and closer to the main portion of the SVGB north of the river, seawater has impacted the underlying 180-Foot Aquifer as shown in Figures 9 and 10.

Cal-Am's Estimates of Groundwater That Must Be Returned Are Substantially Understated.

As noted above, there is no supporting data or explanation for the 7% return water estimate included in Cal-Am's updated demand number. It does not appear to be based on the DEIR/EIS or any other information that has been made available. As we have previously addressed, the DEIR/EIS failed to disclose the amount of return water that would be necessary to replace the groundwater drawn from the SVGB as proposed in the Project Description. Also, the DEIR/EIS did not provide any discussion or information to support bracketing the return water percentage between 0% to 12%. In fact, it is likely that the return water obligation would be more than 12%, especially in the initial years of operation. Even the North Marina Groundwater Model ($NMGWM^{2016}$) calibrated model, which likely underestimates the slant wells production of groundwater, predicts up to 22% of groundwater will be produced from the Dune Sand Aquifer and another 3.5% of groundwater will be produced from the 180-FTE Aquifer during the initial time step.[6]

[6] / Modeling summarized in Appendix E1 of the April 30, 2015 MPWSP Draft EIR (Geoscience, 2014a, Figure 20) indicates that the initial groundwater production would be much greater during the initial production period (50 to 40 percent during the first year) and would decrease over a 4-year period to an estimated 4 percent after 4 years of production. Our review of the $NMGWM^{2016}$ calibrated model results indicates that initially over 25 percent of the production will come from groundwater and that after 5 years, the component predicted to come from the SVGB is approximately 10 percent. The $NMGWM^{2016}$ calibrated model, like the prior modeling, likely underestimates the slant wells production of groundwater (See Comment Nos. 3 and 9,

While it is not stated exactly how the range of 0 to 12 percent estimates were determined in the DEIR/EIS, an analysis of the salinity of the feedwater using ocean water with a TDS concentration of 33,500 mg/l and groundwater with an average TDS concentration of 440 mg/l can yield an estimate. Using these values and the laboratory test results obtained during the MPWSP's TSW production period and included in the water quality report to the Hydrogeologic Working Group (HWG) (Geoscience, 2015p, Table 2), the TSW produced water with an average TDS concentration of 25,033 mg/l and was comprised of 25.6 percent groundwater and 74.4 percent ocean water.

Over the initial period of the long-term pumping test, the TDS concentration had reached approximately 29,100 mg/l prior to cessation of the test in early June 2015. Subsequent laboratory test results indicate that on December 12, 2016, and January 19, 2017, the TDS concentration had reached approximately 30,200 mg/l and 31,700 mg/l, respectively. Using these values along with the average June and July 2017 value of 29,150 mg/l, we can estimate a range of return water quantities by considering the groundwater component produced if a groundwater TDS concentration of 1,000 mg/l (State Drinking Water secondary standard) or 3,000 mg/l (Regional Water Quality Control Board (RWQCB) Water Quality Control Plan (WQCP) for the Central Coast Basin, water quality defined for beneficial uses) were used compared to the reported 440 mg/l average groundwater TDS concentration. Table 1 – Feedwater Composition Based on TDS Concentrations shows a comparison of the results using these values.

As shown in Table 1, approximately 13.3 to 14.4 percent of the feedwater was groundwater when pumping was initiated. While higher salinity feedwater was produced by the TSW in December 2016 and January 2017, the concentration declined by June and July 2017, where approximately 13.2 to 14.3 percent of the groundwater produced would need to be returned. As explained below, the water quality bias of the TSW to be more saline than other comparable wells located away from the CEMEX operations is a result of the dredge pond location and the salt water discharges that occur inland of the TSW location. As discussed below, this bias is unlikely to exist at the proposed slant well locations further south of the current MPWSP test well or continue at the current test well location after CEMEX ceases operations.

Notably, if a greater percentage of groundwater is produced than presently estimated by the DEIR/EIS, which is highly likely, or if usable groundwater salinity increases, the annual amount of return water to the SVGB would increase accordingly. The higher return water volumes required during the initial production period when a greater component of groundwater is pumped is not addressed in the DEIR/EIS return water proposal. Please note that our comment here should not be interpreted to suggest the return of all groundwater to the SVGB as

---

Hopkins, 2017) and should not be considered to represent maximum amount of groundwater that may need to be returned to comply with the Agency Act.

proposed MPWSP's return water proposal would mitigate the project's impacts to the North Marina Subarea. The inadequacy of the DEIR/EIS's analysis of the MPWSP's return water proposal and DEIR/EIS's failure to mitigate the project's cumulative impacts on groundwater is still an issue.

Table 1 – Feedwater Composition Based on TDS Concentrations

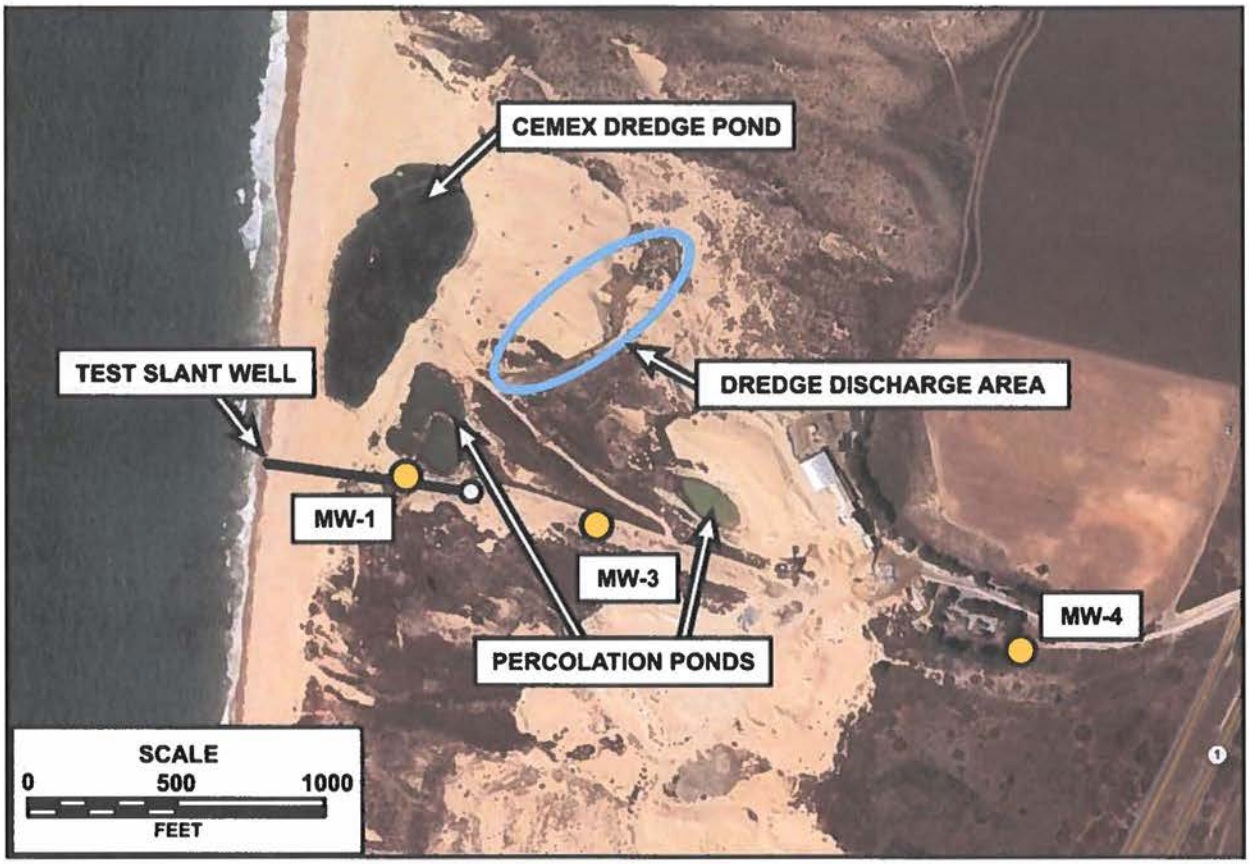
OCEAN WATER SALINITY (MG/L)	GROUNDWATER SALINITY (MG/L)	FEEDWATER SALINITY (MG/L)	GROUNDWATER PERCENTAGE	OCEAN WATER PERCENTAGE
33,500	440	29,085	13.3	86.7
33,500	1,000	29,085	13.5	86.5
33,500	3,000	29,085	14.4	85.6
33,500	440	30,200	10.0	90.0
33,500	1,000	30,200	10.2	89.8
33,500	3,000	30,200	10.8	89.2
33,500	440	31,700	5.4	94.6
33,500	1,000	31,700	5.5	94.5
33,500	3,000	31,700	5.9	94.1
33,500	440	29,150	13.2	86.8
33,500	1,000	29,150	13.4	86.6
33,500	3,000	29,150	14.3	85.7

Cal-Am's return water estimates again fail to address how CEMEX's operations affected the TSW discharge water quality and whether they would have similar effects on the 9 additional slant wells proposed further south and away from the dredge pond, the dredge pond discharges, and wash water containment ponds infiltration. Notably, due to CEMEX operation, the measured values relevant to salinity (specific conductivity, TDS, and practical salinity units (PSU)) provided by the TSW laboratory results and field measurements are not representative of what is expected from the larger MPWSP source wells array. At the time the higher salinity water quality samples were taken, the CEMEX dredge pond, which is in close proximity to the test well and inland of the shoreline, was breached for a significant period of time and directly filled by ocean water. It is likely the significant increase in salinity readings in the TSW during and following this period of time were the result was a large surge of ocean water into the dredge

pond area overlying the inland portion of the beach adjacent to the test well. This condition will not persist throughout the year and is not present at the other proposed MPWSP source well locations.

Additionally, the CEMEX plant operations have influenced shallow groundwater quality in this section of shoreline for decades. As shown on Figure 14 – CEMEX Surface Water Features August 2013, the test slant well is located adjacent to numerous sources of saline water that are not present at other locations along the coast in particular where the other source water wells are proposed.

Figure 14 – CEMEX Surface Water Features August 2013

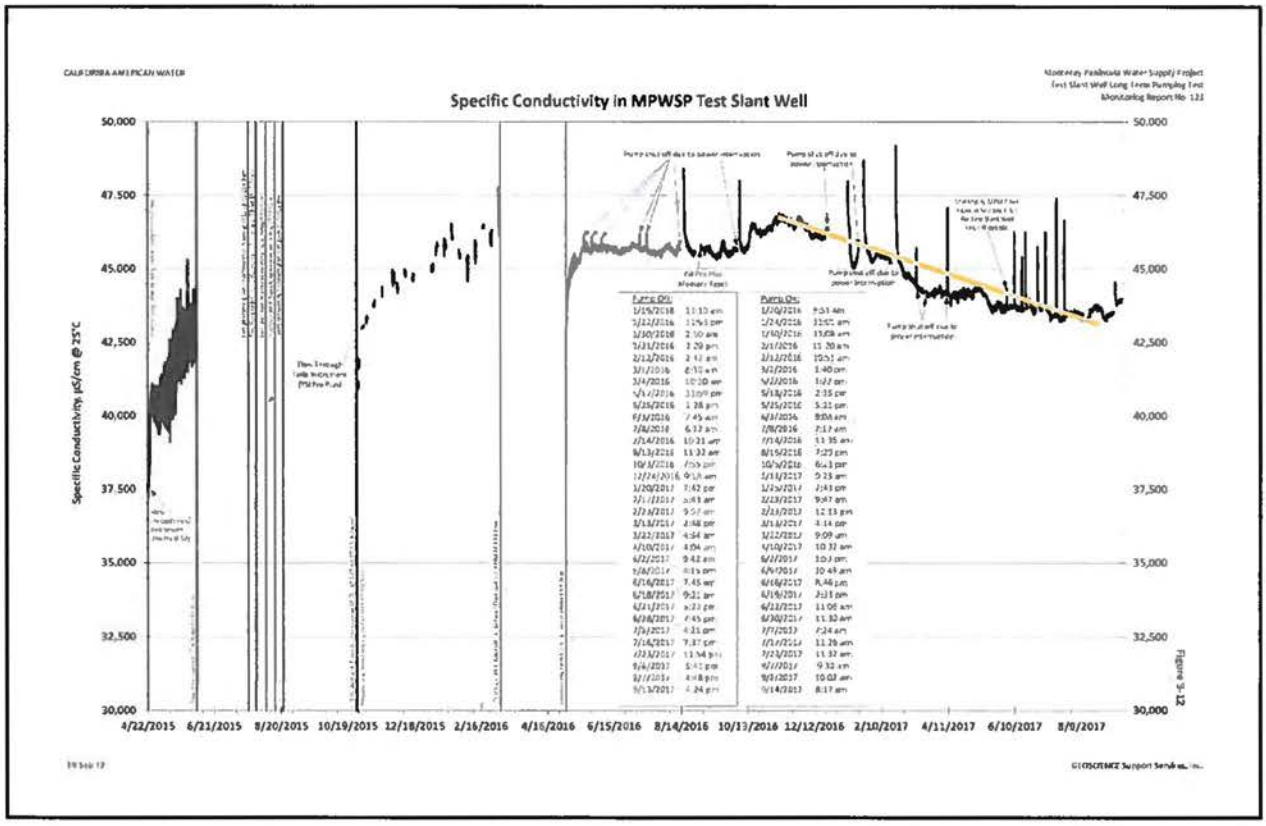


These localized sources of salt water shown in Figure 14 significantly influence the quality of the shallow groundwater that is observed in MW-1, MW-3, MW-4 and produced by the TSW. The result is a substantial overestimation of the seawater component flowing landward from the shoreline and an underestimation of the return water that will be required for mitigation.

The depletion of these landward sources of seawater is evident in Figure 15 – TSW Specific Conductance Values and shown by the declining specific conductance trend for the

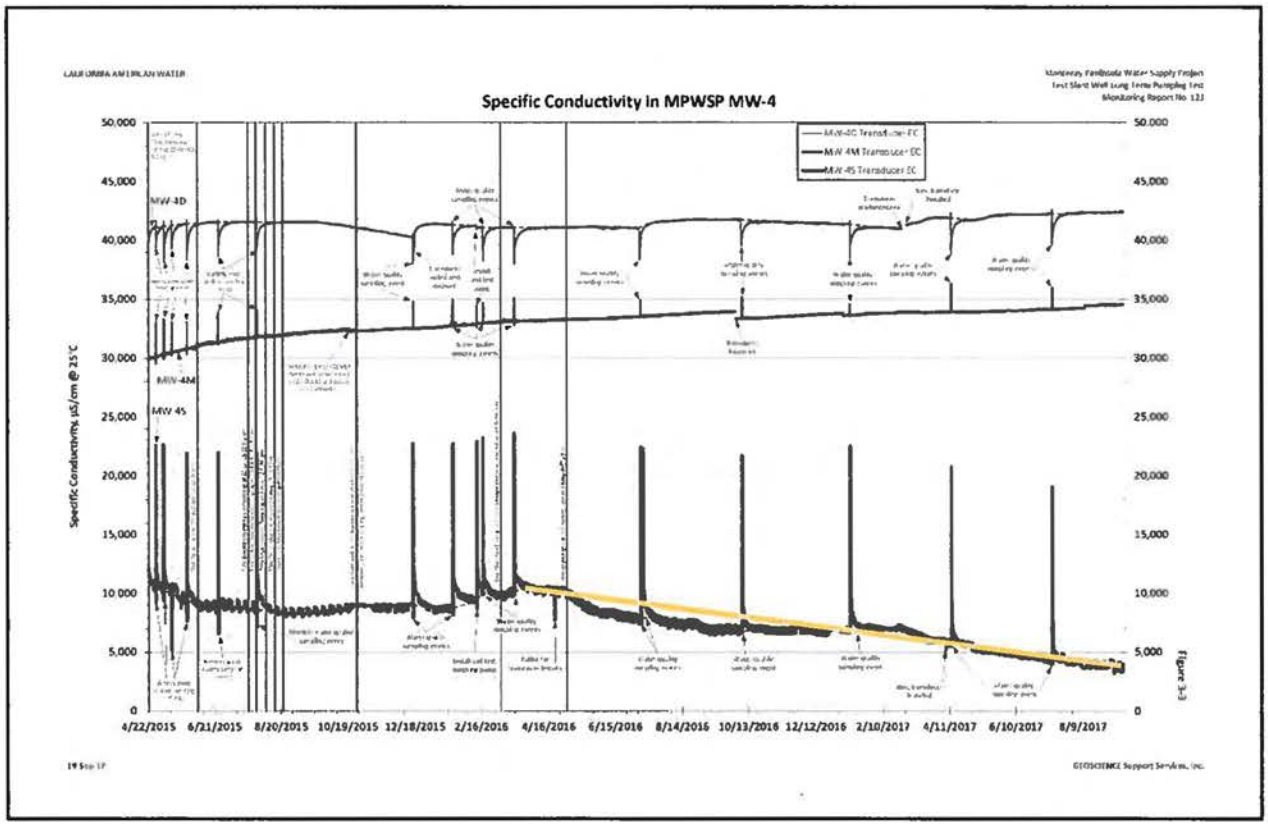
TSW since November 2016 over a period when dredge operations were not active (from Figure 3-12, Geoscience, 2017). Dredge pond operations were observed to be active in early August 2017. If there is a direct correlation between inland salt water discharges and the TSW produced water quality, the specific conductance values should begin to rise again.

Figure 15 – TSW Specific Conductance Values



The overall decline in specific conductance trend in MW-4S since operation of TSW is shown in Figure 16 – MW-4 Specific Conductance Values (from Figure 3-3, Geoscience, 2017) and is an indication of the seaward gradient caused by the mounded fresh water inland of the TSW location. These conditions are also evident in the AEM Survey data that show a mound of saline water at the coast on the CEMEX site (see Figure 6). This localized saline mound has been established by the decades of salt water discharge in the vicinity of the TSW (see Figure 14). Using the TSW data to estimate return water volumes is biased by this anomaly and the fact that the TSW operations were initiated at the end of a drought. Cessation of the CEMEX operations will result in removal of this site specific saltwater influence and in a decline in the TSW salinity. Because this influence is not located further south along the coast where the intake facilities are proposed, the proportion of fresh groundwater contribution to the feedwater supply is expected to be much higher.

Figure 16 – MW-4 Specific Conductance Values



The AEM Survey data confirm that the shallow coastal aquifers in the CEMEX area as far inland as MW-4 are impacted by the saline water discharge operations. Figure 17 – Resistivity Profile D-D' shows the subsurface resistivity values in the vicinity of MW-4 where a conductive mound of salt water is located (also see Figure 6). The increase in fresh/slightly brackish groundwater that is indicated by the available laboratory data, as we move a short distance away from the coastline (see Figure 13) is also shown in the AEM Survey data provided as Figure 18 – Resistivity Profile E-E' which crosses through MW-7 and MW-8. The location of Profiles D-D'and E-E' is shown on Figure 3.

Figure 19 – CEMEX Dredge Barge shows the dredge mining operations that consist of using a barge equipped with a suction pump that literally pulls sand off of the bottom of the pond and pumps it over the sand dunes in a slurry of seawater. Figure 20 – Dredge Slurry Discharge Line shows the pipeline that conveys the saltwater slurry over the sand dunes to the point of discharge as shown in Figure 14. While we do not know the rate of discharge, it must be relatively high (between 1,000 and 2,000 gallons per minute) in order to keep the sand from settling in the pipeline as it makes its way uphill.

Figure 17 – Resistivity Profile D-D'

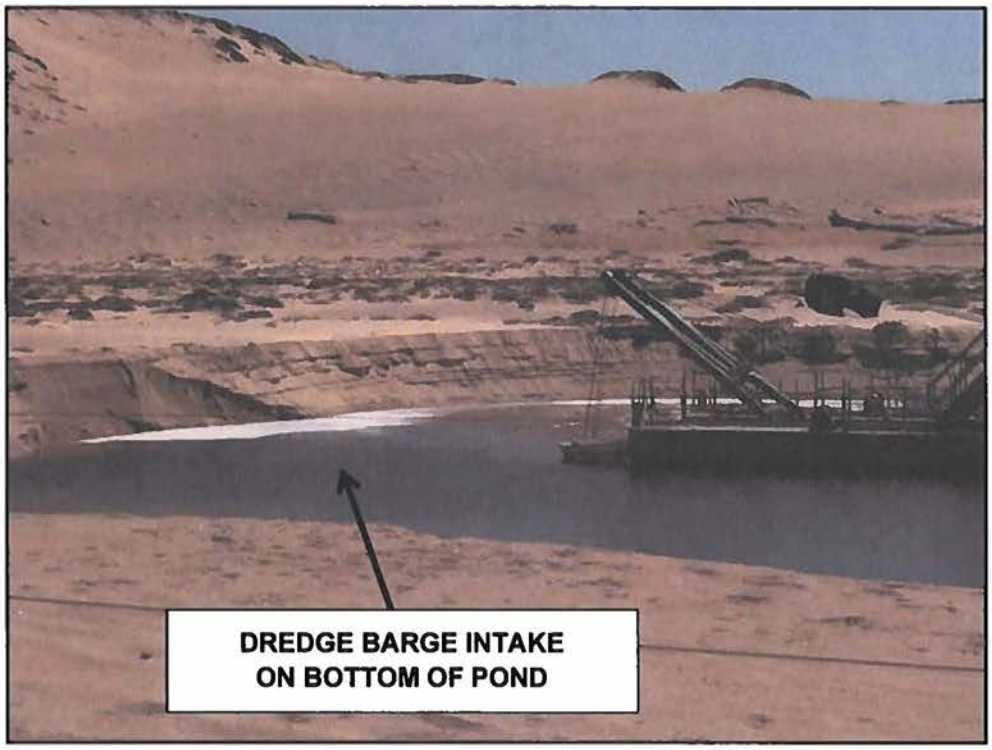

Figure 20 – Dredge Slurry Discharge Line

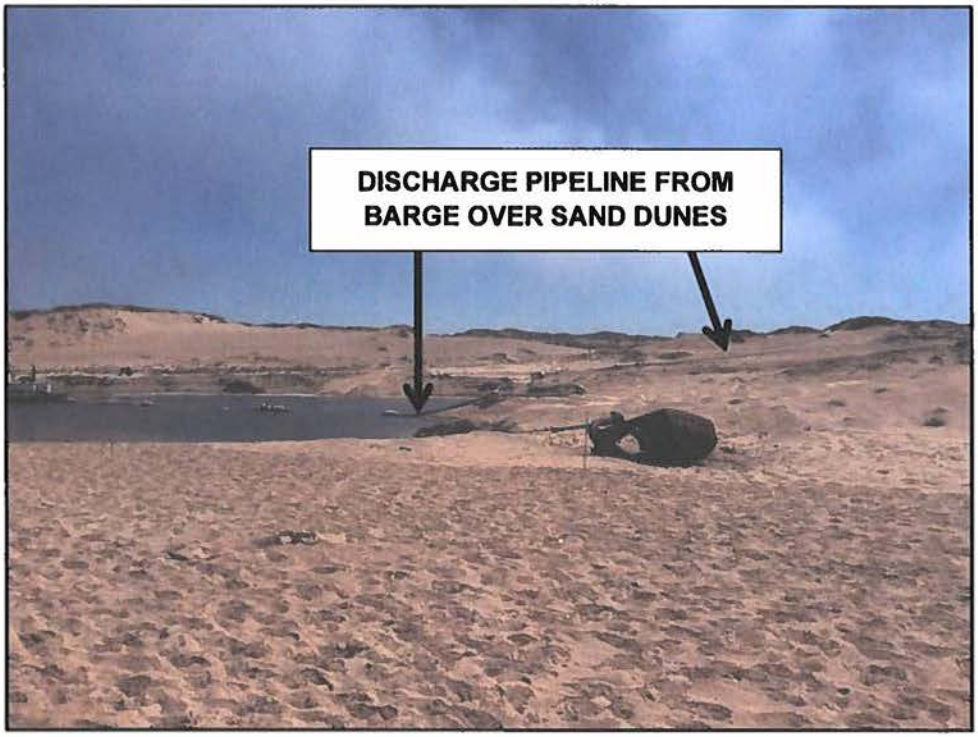


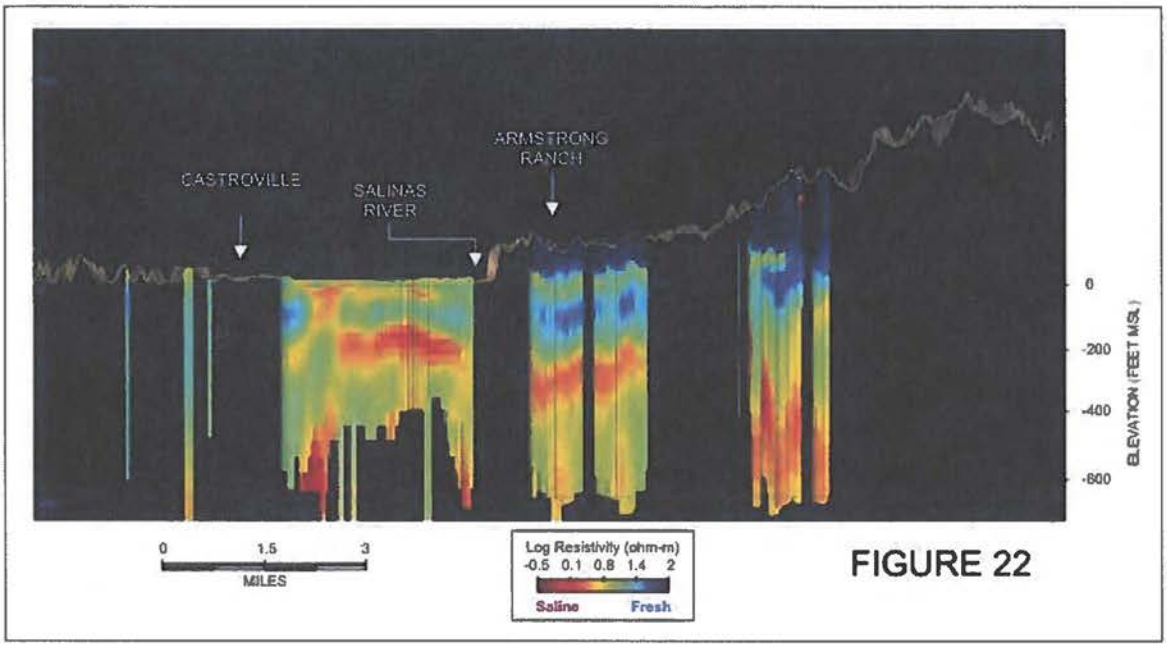
Proposed Return Water Settlement Agreement Does Not Mitigate MPWSP's Adverse Groundwater Impacts to North Marina Area Aquifers.

Under Cal-Am's proposed Return Water Settlement Agreement, all of the groundwater extracted by the MPWSP source wells from the North Marina Area aquifers would be returned to water users north of the Salinas River [i.e, CCSD and Castroville Seawater Intrusion Project (CSIP)]. Notably, the return water is provided ostensibly to reduce groundwater pumping from those users' groundwater wells. The wells that allegedly would not be pumped (or where pumping would be reduced) to mitigate the impacts of the MPWSP source wells, however, are located north of the Salinas River outside of the areas most impacted by the proposed MPSWP supply wells. Cal-Am's demand estimates assume that the "Settlement Agreement on MPWSP Desalination Plant Return Water" will mitigate the project's groundwater impacts to the SVGB and the North Marina Subarea. There is no support for this assumption as explained below. To illustrate this discussion we will use the AEM Survey geophysical data at the locations shown on Figure 21 – Castroville Resistivity Profiles Location Map. The map shows the location of a profile that extends from Castroville through the MCWD Armstrong Ranch property and a profile that extends further inland into the Fort Ord area where there is a greater coverage of geophysical data.

Figure 21 – Castroville Resistivity Profiles Location Map

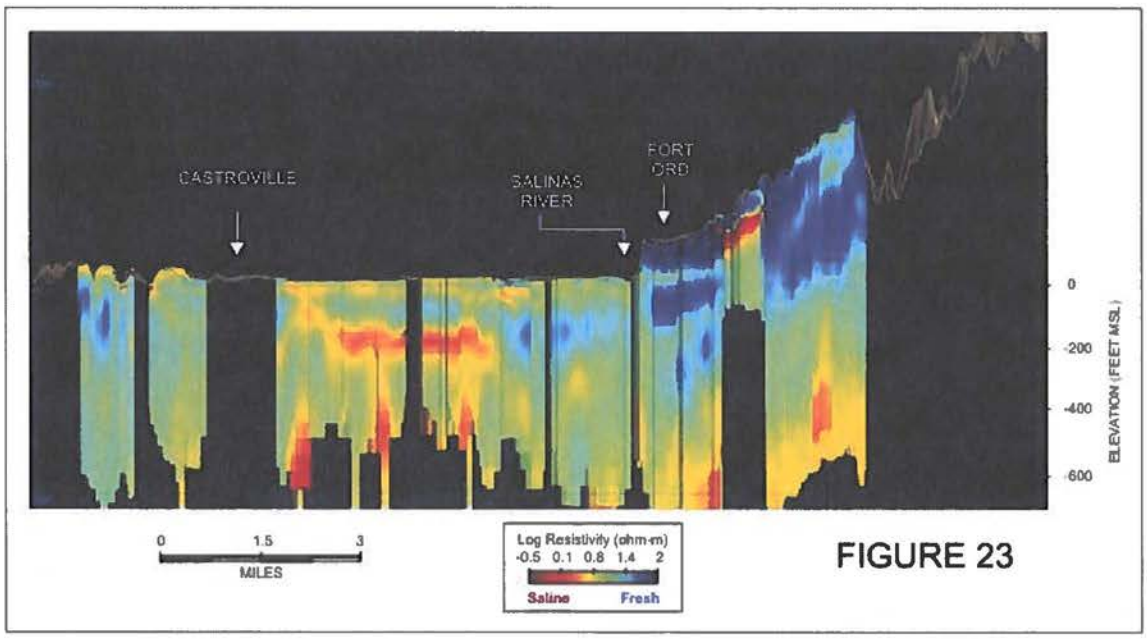
As shown in Figure 22 – Resistivity Profile of North Marina Subarea, the hydrogeological framework and the groundwater quality indicated by the AEM data are substantially different than the subsurface conditions in the vicinity of Castroville where the return water is proposed to be delivered. Impacts from the MPWSP proposed production in the aquifer zones in the upper 300 feet of the North Marina Subarea cannot be mitigated by delivery of return water to Castroville, which is located several miles to the north.

Figure 22 – Resistivity Profile of North Marina Subarea



Likewise, Figure 23 - Resistivity Profile Inland of North Marina Subarea, indicates the difference between the hydrogeology south of the Salinas River from the hydrogeology north of the Salinas River. Return water to CSIP may benefit the main portion of basin, but not mitigate the impacts to the portion of the basin impacted south of the river.

Figure 23 – Resistivity Profile Inland of North Marina Subarea



Initially, the 175-acre feet of return water would be provided to the CSIP at the start-up of the MPWSP grossly underestimates the amount of groundwater that modeling shows will be pumped during the initial start-up period as discussed above.

In addition, Cal-Am's claim that the proposed return water settlement would benefit each of the aquifers by either reducing the area of influence of the MPWSP or by increasing groundwater levels in other areas is misleading. While the proposed return water agreement would likely increase groundwater levels in other areas, it would not reduce the area of influence within the North Marina Subarea. Moreover, it fails to acknowledge that it does not address potential harms to present and future legal users in the North Marina Subarea. Perhaps more importantly, the CCSD and CSIP wells where pumping will be reduced (or cease) do not pump water from the Dune Sand or 180-FT Aquifers from which the MPWSP will extract its groundwater supply. This is important for two reasons.

First, as discussed above, groundwater conditions in the Dune Sand or 180-FTE Aquifers inland of the proposed MPWSP intake system create protective heads in the shallow dune sand that is evident by the water levels in monitoring wells MW-4S, MW-6S, MW-7S, and MW-8S and the available water quality data. Downward recharge into the underlying 180-FTE was observed to elevate the groundwater levels above sea level during 2015-2016 winter season, which occurred after a 4-year drought, and subsequently again in the 2016-17 winter season where above average rainfall occurred. The benefits from these unique groundwater recharge conditions creating shallow mounding in the North Marina Area will be removed by the project and delivery of return water north of the Salinas River to reduce pumping will not mitigate the potential impacts realized by the changed conditions.

Moreover, as indicated by water levels in MW-6M and MW-6D (or 6ML), there is direct vertical recharge between aquifers at certain locations with the North Marina Area where aquitard layers are discontinuous. Leakage through these layers can facilitate vertical flow of seawater that is induced into the North Marina Area by the project. Cal-Am's return water proposal does not address the increased seawater intrusion that the project will cause within the North Marina Area by lowering existing protective heads and removing freshwater in storage. Given the groundwater gradients in the North Marina Area, water injected north of the Salinas River simply will not flow towards the North Marina Area, but rather away from it. For this same reason, reduced pumping north of the Salinas River will not mitigate the reduced water levels and induced seawater intrusion in North Marina Area that will result from the MPWSP.

Second, providing water north of the Salinas River as proposed in Cal-Am's Return Water Settlement Agreement will not remedy the harms to the water users in North Marina Area from reduced water levels and water quality caused by the MPWSP source wells. Again, none of the water provided to the CCSD or CSIP will flow towards the North Marina area or lessen the Project's impacts in this area. Thus, the Cal-Am's proposed Return Water Settlement Agreement will not mitigate impacts to the North Marina area or its water users (i.e., MCWD).

Therefore, the water users receiving the offset supply to reduce pumping must be located in the Marina Subarea of the SVGB affected by the project (i.e., south of the Salinas River) in

order mitigate the MPWSP's groundwater impacts and satisfy Cal-Am's return water obligations.

As we noted in our January 22, 2016 memorandum, providing return water though injection wells or percolation basins within the Northern Marina Subarea may provide Cal-Am with a viable option to meet is mitigation requirements and return water obligations. Any such proposal would need be studied to ensure the proposed injection sites will not degrade water quality in the North Marina Subarea or adversely affect the beneficial conditions that exist in the these aquifers discussed above and in our prior comments. We note that placing the wells in the wrong location could actually push groundwater impacted by seawater into aquifer areas that are currently fresh to slightly brackish in quality, but usable (see AEM data in Figures 6 and 8). Additional information and analysis is needed to determine whether these possible options would offset the impacts of the project on the Northern Marina Subarea aquifers and the groundwater users within the subarea. To evaluate such an alternative, we would need know the location where the water is proposed to be injected or percolated, the zones and rates for an injection proposal, and what quality of water would be injected or percolated.

Conclusion.

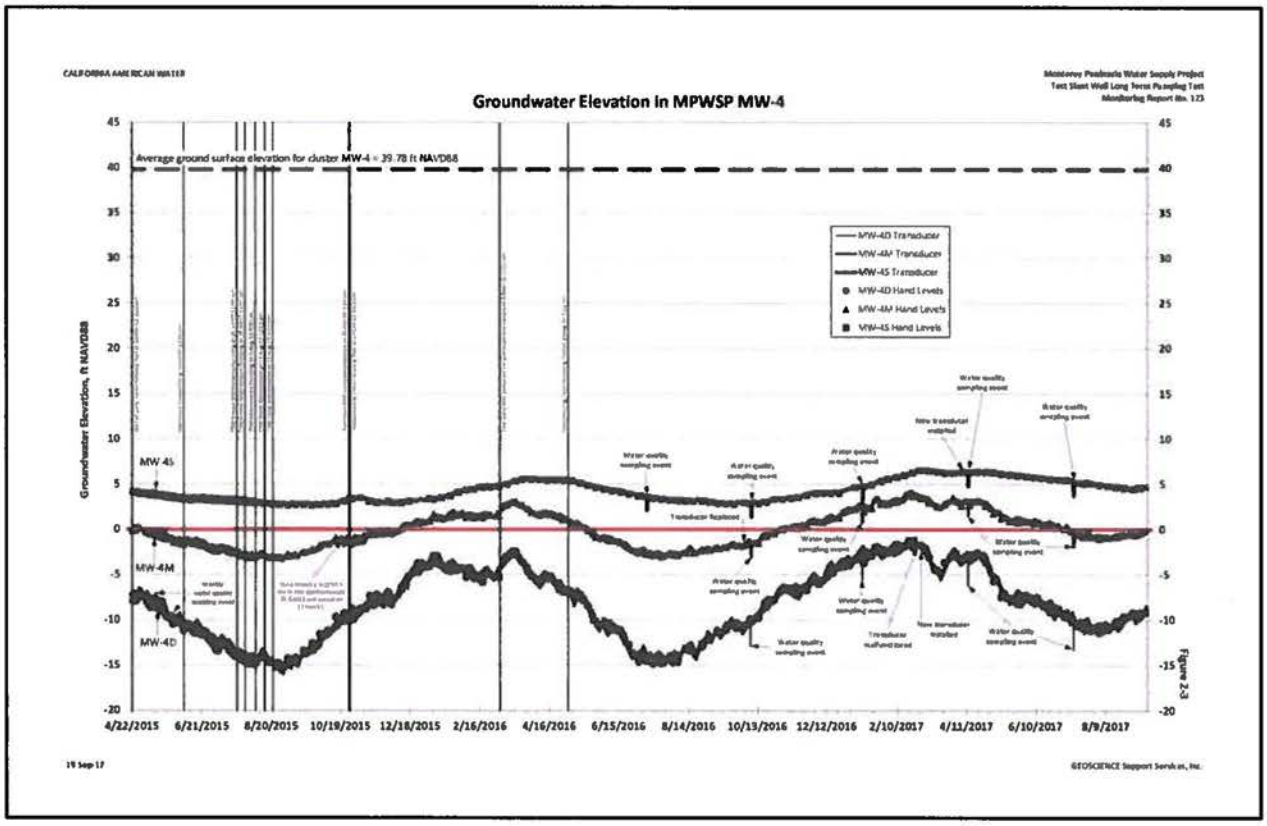
In sum, Cal-Am's Return Water Settlement Agreement does not consider or address the adverse impacts that would result from the MPWSP's source wells. The return water method selected must ensure that the protective water level elevations within the Northern Marina Subarea aquifers are maintained to prevent further seawater intrusion at an accelerated rate within this portion of the SVGB. Unless a return water method ensures that the protective conditions discussed above are not harmed, the MPWSP will induce seawater intrusion into the Dune Sand Aquifer (and will exacerbate seawater intrusion in the 180-Foot Aquifer and 400-Foot Aquifer through vertical leakage) in the Northern Marina Subarea and likely result in cumulative impacts to aquifers and wells much further inland. It will also delay (or eliminate benefit from) efforts to reverse the trend of seawater intrusion in the Northern Marina Subarea and throughout the SVGB. The MPWSP will also undercut extensive efforts by MCWD and others to eliminate the long-term overdraft condition and to respond to the serious existing drought conditions.

As indicated in our prior January 22, 2016 memorandum, updated modeling using information developed from the TSW field investigations and available from other studies in the North Marina Subarea must be used to refine the MPWSP modeling to accurately simulate aquifer conditions. Additional analysis regarding a method for returning groundwater pumped by the proposed MPWSP source wells that demonstrates the protective conditions that currently exist in the Northern Marina Subarea are not adversely impacted to the detriment of the groundwater users in and inland of the subarea is still necessary. Without this updated modeling and additional analysis, it is impossible for the public and public agencies to provide meaningful testimony regarding Cal-Am's return water proposal. Nonetheless, it is clear that Cal-Am's Return Water Settlement Agreement will not mitigate the MPWSP's groundwater impacts to the

groundwater aquifers within the North Marina Area where the fresh water conditions have been identified.

Finally, the TSW project was initiated toward the end of a drought cycle when water levels in the North Marina Subarea were depressed from lack of recharge and continued inland pumping stresses. Aquifer conditions that result from multiple years of normal or wet periods with average or above average rainfall have not been observed and are not available as background data to inform the public of pre TSW pumping conditions. Figure 24 – Monitoring Well MW-4 Hydrograph shows the seasonal water level fluctuations in all three aquifer zones relative to mean sea level. The high and low water level elevations in MW-4S were at least 2 feet higher during 2017 compared to the same seasonal time periods in 2015. The high and low elevations in MW-4M and MW-4D were at least 3 feet and 5 feet higher, respectively over this same time period. These water level recoveries from the initial drought conditions that were documented certainly help explain why there is freshwater in the shallower aquifer zones inland of the CEMEX site.

Figure 24 – Monitoring Well MW-4 Hydrograph



Figures 25, 26, and 27 – Monitoring Well MW-7, MW-5, and MW-6 Hydrographs, respectively, show how all the monitoring wells in or inland of the North Marina Subarea show water levels that recovered during the 2016 and 2017 annual water cycles. These data show that

the shallowest aquifer monitored (Dune Sand Aquifer) rose approximately 5 feet in MW-5S and MW-7S over this period, while MW-6S had a huge peak when the Salinas River had substantial flows during the 2017 rainy season. These data also show that between MW-5 and MW-7 the 180-FTE and 400-Foot Aquifers had very similar elevations near mean sea level. It is our professional opinion that it is this type of water level condition, relatively high with a flat gradient, that has impeded seawater intrusion in the shallower aquifer zones in the project area. As shown by the geophysical data (see Figure 4), salt water intruding into the North Marina Subarea is restricted near the coast in the upper 200 to 300 feet and has mostly intruded the 400-Foot Aquifer zone. While the deep 400-Foot Aquifer monitoring wells within the North Marina Subarea have relatively elevated water level, the water levels north of the Salinas River show a significant decline MW-6M and MW-6D (changed to ML).

Figure 25 – Monitoring Well MW-7 Hydrograph

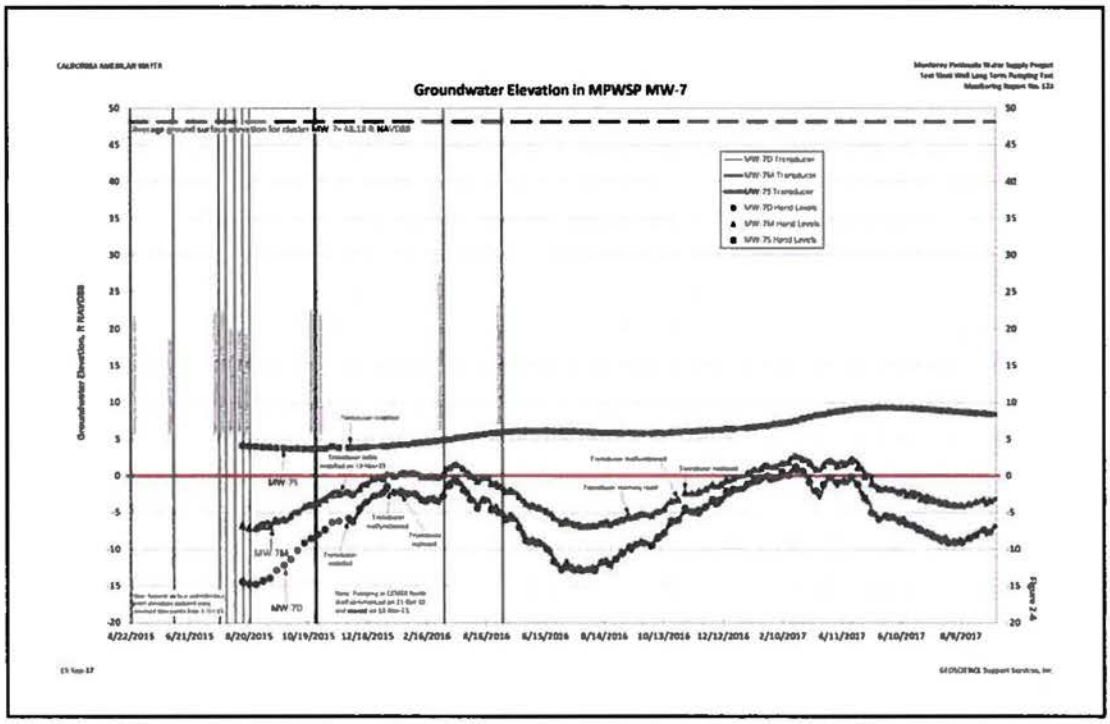


Figure 26 – Monitoring Well MW-5 Hydrograph

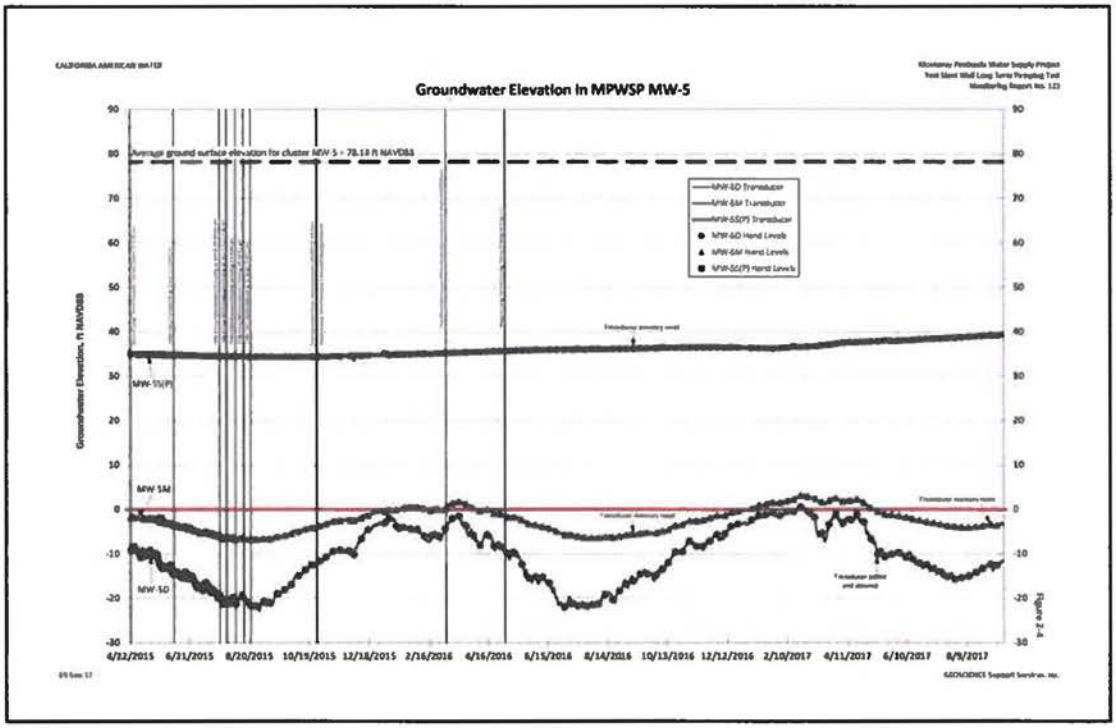

Figure 27 – Monitoring Well MW-6 Hydrograph

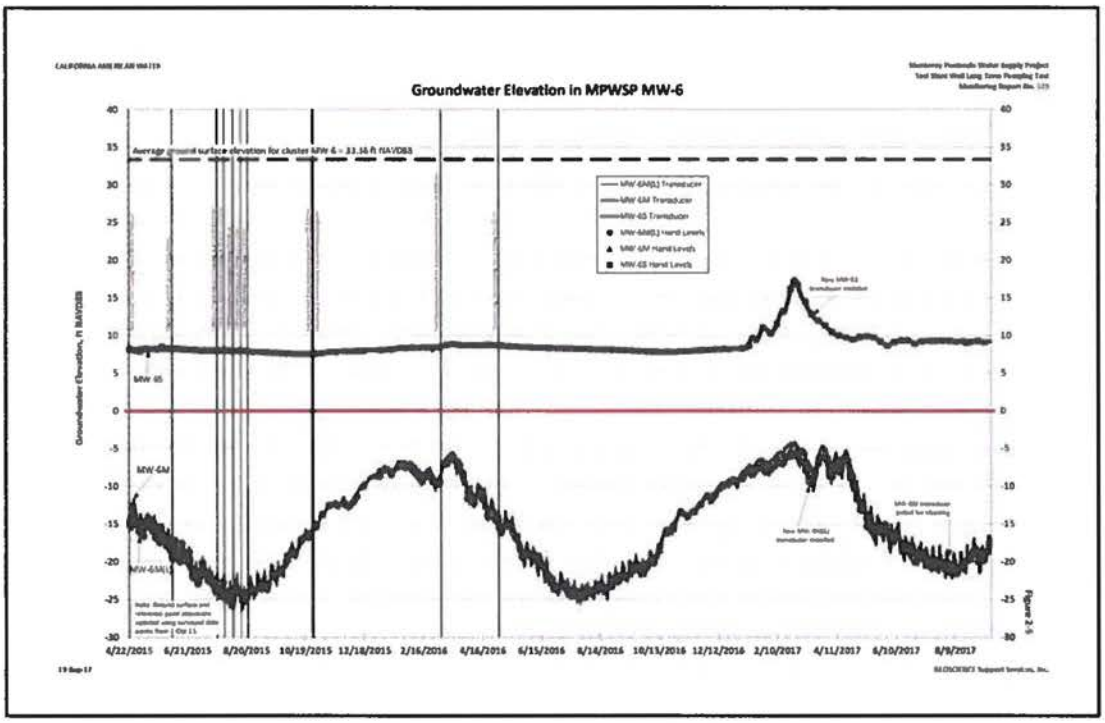

From these data we conclude that there is much about the hydrogeology and the mechanisms of groundwater recharge south of the Salinas River that are not well documented and that previous assumptions that this area was the same as the main portion of the 180-400-Foot Basin north of the river are not accurate. The present conditions observed by the AEM Survey and the MPWSP monitoring program indicate that the protective fresh water conditions present in the North Marina Subarea have contributed to the protection of the groundwater basin, which would be adversely impacted by the MPWSP as designed. Cal-Am's proposed Return Water Settlement Agreement would not reduce or lessen these significant impacts. And as explained above, even if it could, Cal-Am's estimate of the required volume of groundwater that would need to be returned is substantially understated.

Sincerely,

Notes:

°C	= Degrees Celsius
CU	= Color Units
mg/L	= Milligrams per Liter
NTU	= Nephelometric Turbidity Units
pg/L	= Picograms per Liter
TON	= Threshold Odor Number
µg/L	= Micorgrams per Liter
µmhos/cm	= Micromhos per Centimeter
H	= Analyzed outside of hold time
MPN/100mL	= The most probable number (MPN) of coliform or fecal coliform bacteria per 100 milliliter
ND	= NOT DETECTED at or above the Reporting Limit or Practical Quantitation Limit. If J-value reported, then NOT DETECTED at or above the Method Detection Limit (MDL)
N/A	= No Lab Results available
RP	= Results to be provided

[1] Laboratory water quality reports will be provided in the Test Slant Well and mornitoring well completion report.
* Laboratory water quality results pending.

ATTACHMENT

Preliminary Interpretation of SkyTEM Data Acquired in the Marina Coast Water District

Ian Gottschalk and Rosemary Knight
June 16, 2017

Objective:

Airborne electromagnetic (AEM) data were collected in the Northern Salinas Valley, CA, within and around the Marina Coast Water District (MCWD). The data were processed and inverted with lateral constraints by Aqua Geo Frameworks (AGF), and the resulting resistivity models given to Stanford. The work described in this report focuses on the region of a suspected isolated freshwater lens. Figure 1 shows the region of interest. "Isolated freshwater lens" is defined here as a water-bearing unit with anomalously low concentrations of total dissolved solids (TDS) in an area otherwise known to be saltwater intruded. Figure 2 shows a highly simplified schematic of the current understanding of the hydrostratigraphy and distribution of fresh and salt water in the region of interest. There is considerable interest in the interpreted isolated freshwater lens, which is suspected to lie in the Dune Sand and 180-Ft and 180-Ft Equivalent Aquifer. The objective of this report is to review the resistivity models obtained through inversion of the AEM data to determine whether we see evidence of the presence of freshwater in the area mapped as the freshwater lens.

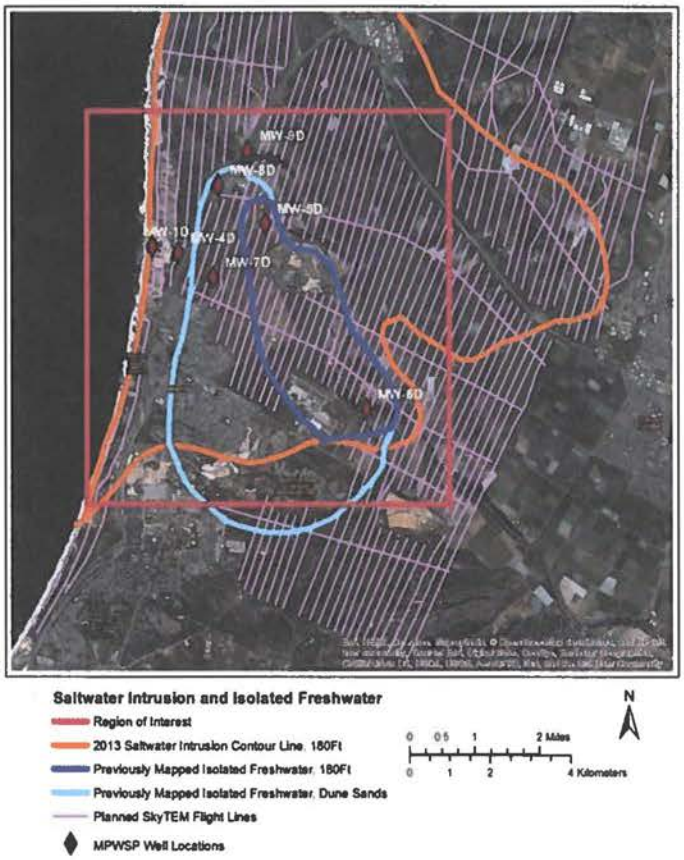

Figure 1: Region of interest (pink box) showing previously mapped saltwater intrusion (orange) extent in the 180-Ft Aquifer and the previously mapped extent of the isolated freshwater (light and dark blue) in the Dune Sand and 180-Ft Aquifers. Also shown are the 7 MPWSP well clusters with geophysical borehole logs as well as continuous data loggers in all screened intervals, and the planned SkyTEM flight lines for the AEM data acquisition

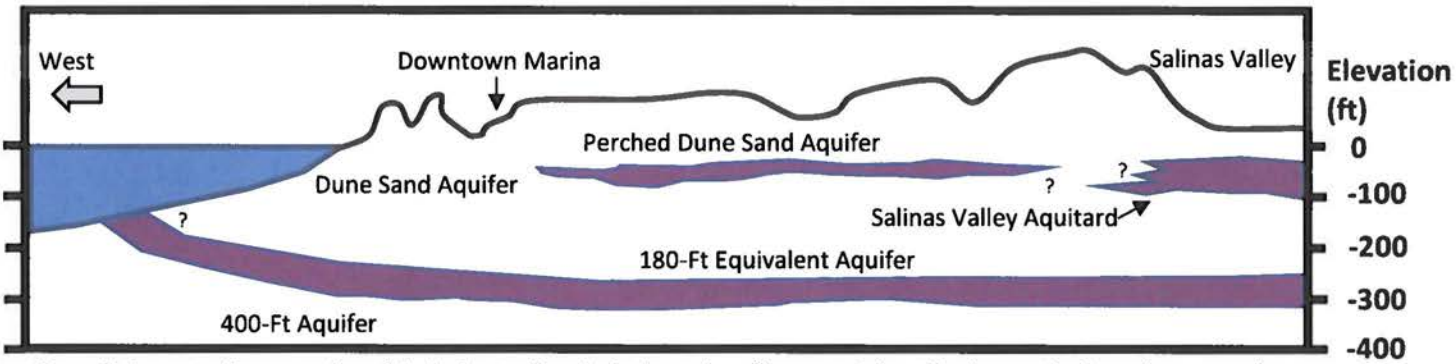

Figure 2: Conceptual cross-section of the hydrostratigraphy in the region of interest. Isolated freshwater has been documented to exist in the 180-Ft/180-Ft Equivalent Aquifers, and in the Dune Sand/Perched Dune Sand Aquifers.

Existing Hydrologic Data:

We have assembled from the study area a database of well location and lithology information. Much of the analysis in this report will use information provided from nine monitoring well clusters drilled by California American Water for its Monterey Peninsula Supply Project (MPWSP), due to the high quality data collected in the wells, and the continuous monitoring within them. These nine MPWSP monitoring well clusters were drilled using a sonic drilling method, with retrieved cores.

Geophysical borehole logs were collected in seven of the monitoring well clusters, shown in Figure 1. Each of the seven well clusters is comprised of three wells, each screened at a different elevation, corresponding roughly to the three aquifers nearest to the ground surface in the region: The Dune Sand Aquifer, the 180-Ft Equivalent Aquifer, and the 400-Ft Aquifer, ranging from highest to lowest elevation. The logs include induction-based resistivity (deep and medium length), spontaneous potential, and gamma radiation. The full geophysical borehole fence diagram for the seven MPWSP well clusters is shown in the Appendix Figure A3. Geophysical logging measurements were collected near the time of drilling which was spring 2015. A baseline geochemical analysis of water from each screened interval was reported approximately 1-2 months after borehole geophysical data collection; wells were bailed before taking a geochemical lab sample. This process has been repeated monthly since then, but the data are not publically available. A continuously logging pressure transducer and electrical conductivity meter was installed in every well in each cluster, and reports submerged pressure, water density, and electrical conductivity every 5 to 15 minutes. Well and transducer specifications are reported by Geoscience Support Services, Inc., shown in the Appendix Table A1. The trend in electrical resistivity on a monthly time scale is negligible, based on the data collected by the continuous data logger in each well; therefore, we consider the lab water quality assessment and the borehole geophysical data to be contemporaneous.

In addition to well lithology (developed from review of the core samples) and geophysical measurements from the MPWSP monitoring wells, previous hydrogeological studies in the area provide a background knowledge of the hydrostratigraphy of the area (Fugro, 1995; Harding, 2001; Kennedy/Jenks, 2004; Geoscience, 2014; Hopkins, 2016).

Overview of SkyTEM Data

635 km of AEM data were acquired in the Marina area May 16-18, 2017, using a SkyTEM 304M system. The locations of the as-flown flight lines are shown in Figure 3, taken from the AGF's QA/QC and Preliminary LCI Report. In this study, we focus on the line-km overlying the study area, shown by the bounding box in the Figure 1.

The inversion of the SkyTEM data by AGF has provided 2-D sections along the SkyTEM flight lines that display the variation in electrical resistivity of the subsurface. The cutaway section in Figure 4 displays data in the region of interest, along with a map of the same area from the 2016 Hopkins Consulting report (Hopkins Consulting, 2016). In all images, we show inverted data considered to be very well determined to determined, with a resistivity standard deviation of <1.5 (Behroozmand et al., 2013). The standard deviation cutoff of 1.5 corresponds to a depth of investigation of nearly 50 mbgs in especially saline regions of the coast, down to over 150mbgs in more resistive inland regions. Inverted resistivities span a wide range in MCWD region of interest, reaching well above 500 ohm-m above the water table in the Fort Ord area, and below 1 ohm-m in zones near the coast.

Figure 3: As-flown flight lines in the MCWD SkyTEM data acquisition. From the AGF "QA/QC and Preliminary Laterally Constrained Inversions Report from the Airborne Electromagnetic Survey of Selected Areas Within the Marina Coast Water District"

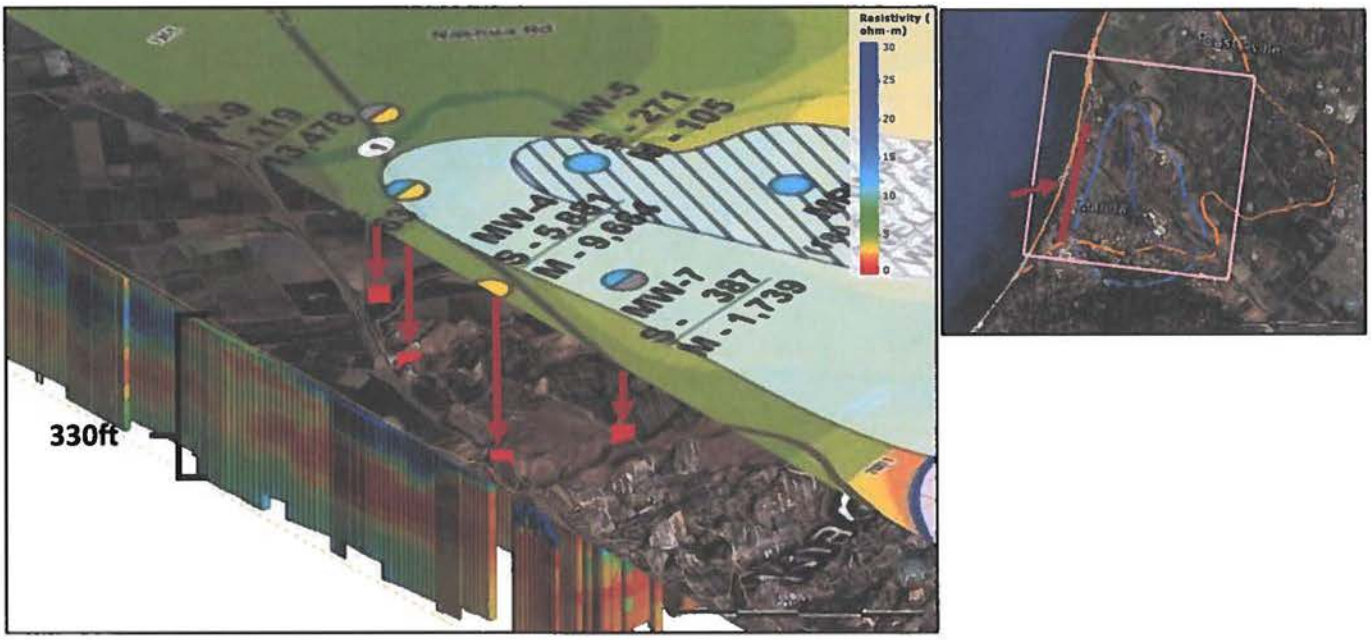

Figure 4: Oblique cutaway view of inverted AEM data in the region of interest, facing northwest from the Monterey Bay. Superimposed above the topography is an image of previously mapped freshwater in the region of interest (Hopkins, 2016). MPWSP wells are shown in red on the topography, and red arrows show the same wells from the superimposed image. The near-surface high-resistivity zone in the Marina area generally extends to the Salinas River.

Figure 5 shows a series of cutaways of the AEM data in the region of interest. Plotted alongside the AEM data are borehole resistivity measurements, for reference. In most locations, borehole resistivity measurements agree very well with the nearest AEM data. This correlation gives us confidence in the AEM data. Although the borehole resistivity measurements were made in 2015, the changes in the subsurface have not made the difference between the datasets very large. Some exceptions are in areas where the pore fluid has changed significantly in the past 2 years (e.g. MW-4 in Figure 5a), which is supported by the trends in EC recorded by the continuous data loggers in the MPWSP wells.

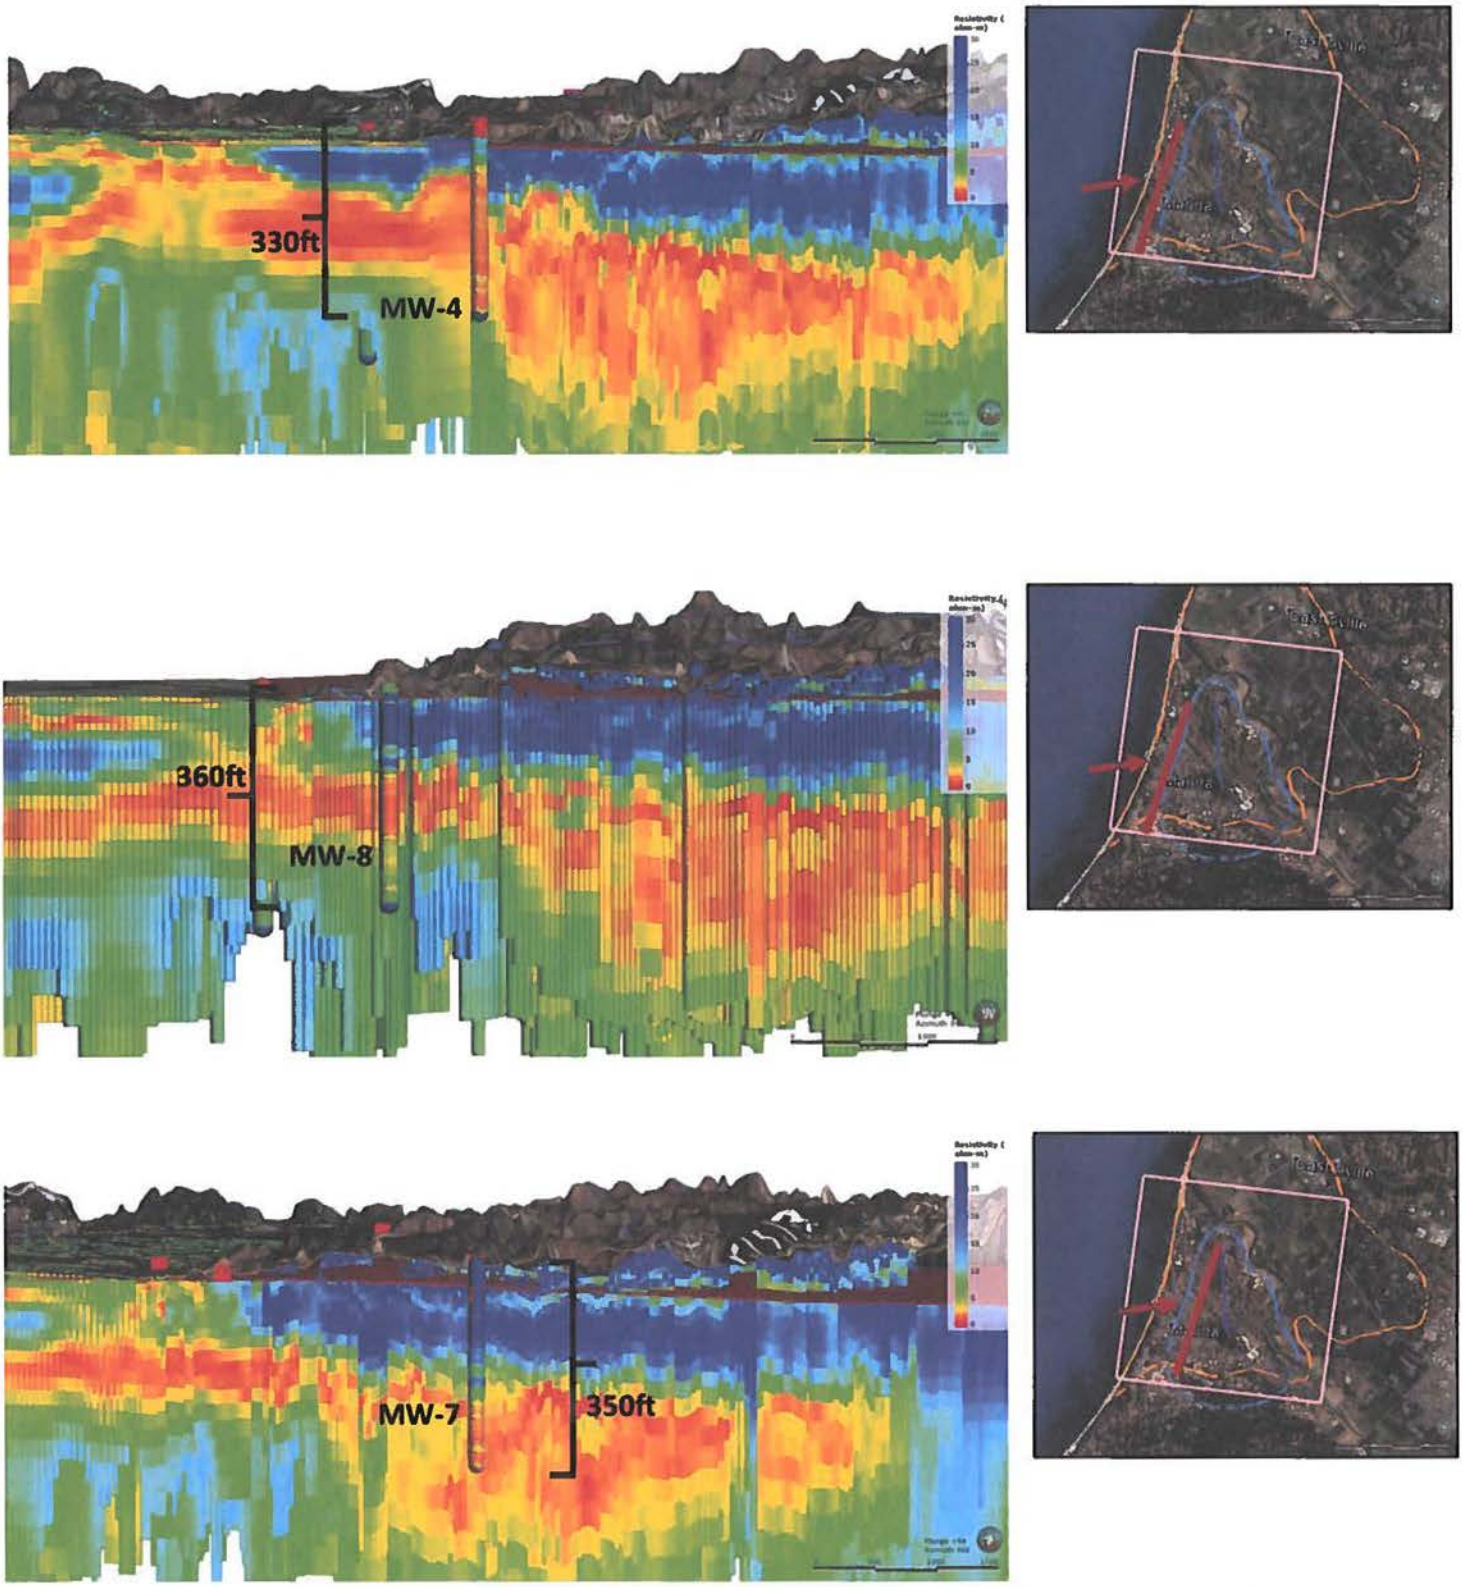

Figure 5: Cutaway slices of AEM data, along with nearby borehole geophysical data (long induction resistivity), and a plan view showing the slice and viewing direction. The top figure shows a notable discrepancy between the geophysical log at the top of MW-4 and the nearby AEM data. This difference emphasizes the changes in water quality since 2015, when MW-4 was logged. The changes observed (increasing in resistivity since 2015) are consistent with the trend of EC in MW-4 since 2015.

Interpretation of the SkyTEM Data

Our objective was review AEM data for the existence of possible freshwater within the region where isolated freshwater had been documented. Resistivity measured by the SkyTEM system is a function of not just water quality, but of sediment mineralogy as well. In order to reliably extract water quality information in the region of interest, our workflow included the following steps:

1) Map the water table in order to separate the unsaturated from saturated zone,
2) Define the resistivity of freshwater and saltwater-saturated zones in order to identify these zones in the AEM data, and
3) Apply the resistivity cut-off values defined above to the data.

1) Mapping the Water Table

1.1) Interpolating a Water Table Surface

In the region of interest, isolated freshwater is suspected to be present in the Dune Sand Aquifer and the 180-Ft/180-Ft Equivalent Aquifer. Since isolated freshwater may be in contact with the unsaturated zone, and both will appear relatively resistive in the AEM data, it is important to delineate between for an accurate assessment of the freshwater resources. Most wells in the region are not screened in the unconfined (Dune Sand) aquifer. However, water table level measurements contemporaneous with the collection of AEM data were available in nine MPWSP wells, recorded by the continuous pressure transducers. A schematic for the conversion used to calculate groundwater elevation from pressure transducer readings is shown in Figure A2 in the appendix, taken from a MPWSP long-term pumping report.

Water table elevations tend to be a muted expression of the surface topography: in high elevation areas, the water table often elevates, and sinks where the topography depresses. In order to model the water table surface to reflect the true water table, control points are needed especially in hilly regions, where the topography changes quickly. In the case of this study, few control points exist in the central and northeastern sections of Marina, where dune deposits create hilly topography (Figure 6b).

Using the available water table data from the MPWSP well measurements, an estimated map of the water table was created with a kriging interpolation. The variogram ranges were calculated automatically from the data, and the groundwater level at the ocean was set at 0m.

Near control points and in regions where topography does not change dramatically, the interpolated water table are expected to reflect the true water table elevation. However, in areas where topography varies quickly, the interpolated water table can be inaccurate. Since the majority of available control points are at lower elevations, the interpolation is biased toward lower elevations. Therefore, in hilly, high elevation regions, the interpolated water table surface is likely to underestimate the elevation of the true water table.

1.2) Applying a Resistivity Cutoff for the Unsaturated Zone

The AEM data itself also helps to define the water table elevation. The absence of water in the subsurface has a profound effect on the resistivity: above the measured water table at control

points, the inverted AEM resistivities are found in the range of 100-1000 ohm-m; however, below the water table at control points, nearly all data are below 50 ohm-m. This stark contrast normally exists at the interface between the unsaturated and saturated zone. By applying a resistivity cutoff to allow only <75 ohm-m data, we can compare the interpolated water table surface with the elevation at which the AEM resistivity spikes. Figures 6c and 6d display the topmost AEM data, between the ground surface and the interpolated water table surface. (In these two figures, the interpolated water table surface is draped with the satellite image of Marina, for spatial reference.) Figure 6c shows data above the interpolated water table, but with no resistivity cutoff. Figure 6d introduces the 75 ohm-m cutoff. With an accurate interpolated water table surface and the appropriate resistivity cutoff, the top of the AEM data in Figure 6d should closely match the interpolated surface. Notice that the areas with few control points and hilly terrain in Figure 6b (e.g. NE of Marina and the coastal dunes) correspond to regions where larger volumes AEM data does not match the interpolated surface.

Because of the dramatic resistivity change between saturated and unsaturated zone in this area, using a resistivity cutoff helps to map out the unsaturated zone in regions where water table data is not available. However, in order not to underestimate the amount of freshwater in the near surface, more water table measurements are critical in hilly, high elevation areas in the region of interest.

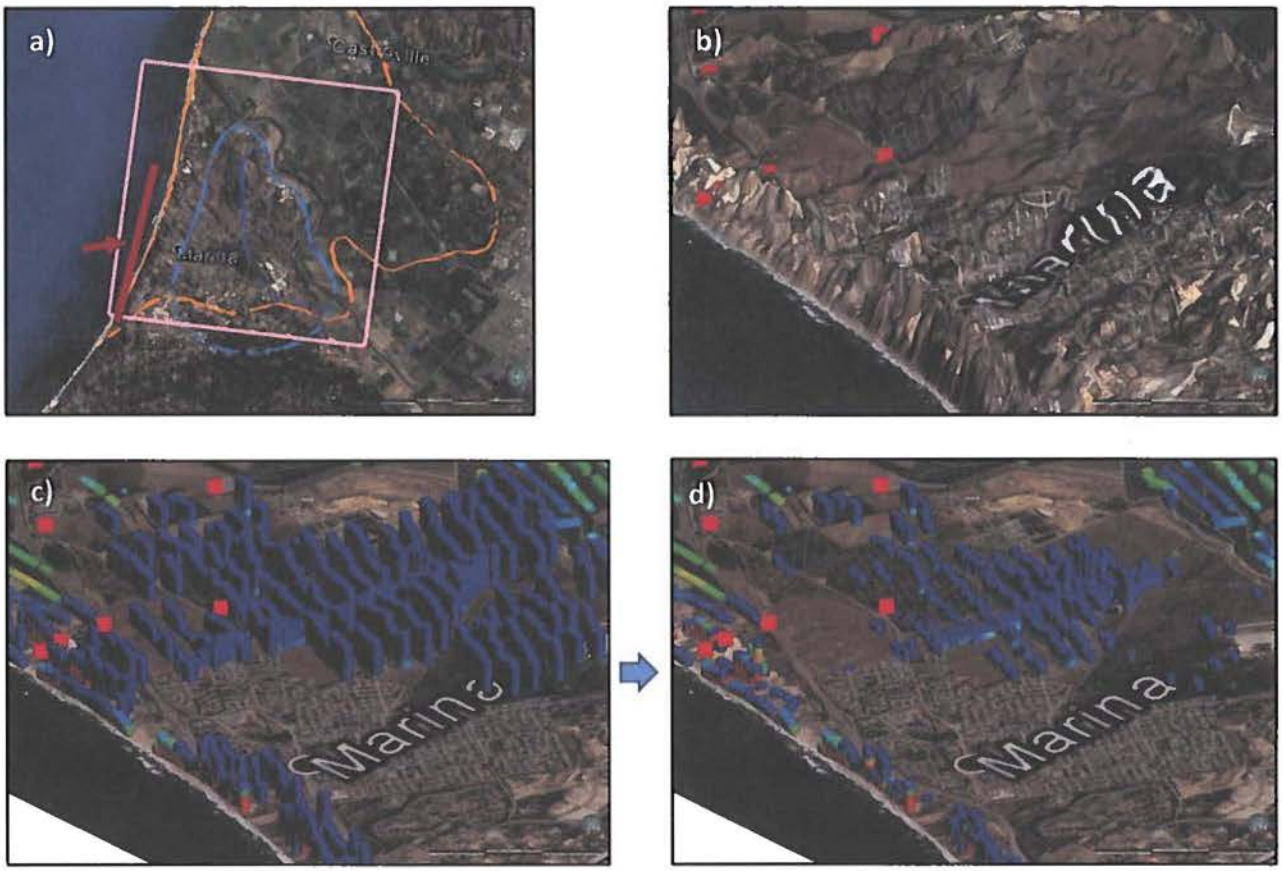

Figure 6: Oblique view of SkyTEM AEM data between the ground surface and the interpolated water table, displaying of few control points on the interpolated water table.
***a)** Plan view showing region of interest, viewed line (red line) and viewing direction (red arrow)*
***b)**Oblique view showing topography of Marina area and control points from which the interpolated water table surface was created (vertical exaggeration x15)*
***c)** All AEM data, bounded beneath by the satellite map of the area set to the elevation of the interpolated water table surface*
***d)** A conservative <75 ohm-m cutoff is applied to the data to remove data which have a high probability of being in the unsaturated zone. Between water table control points, the water table surface smoothly varies. In areas with few control points and hilly terrain (such as in the northern Marina area, the coastal dunes, or the Fort Ord area), the water table surface will deviate from reality.*

Defining the resistivity of freshwater and saltwater-saturated zones

Within the saturated zone, resistivity values vary significantly. In order to use the AEM data to interpolate between and extrapolate beyond water quality information from wells, we need to have information on the bulk resistivity of the various sediments containing water of variable quality; i.e., what is the resistivity of a freshwater-saturated sand unit? What is the resistivity of a saltwater-saturated sand unit? What is the resistivity of a freshwater-saturated clay unit? In a lithologically homogenous subsurface, changes in resistivity can be attributed simply to changes in the pore water resistivity, and therefore to changes in salinity. In the case of this study area, the lithology of the subsurface is documented as being very heterogeneous, where aquifer units contain silt and clay lenses from fluvial and alluvial deposits. The presence of finer-grained—especially clay-bearing —sediment affects the resistivity of the bulk material, and therefore affects the return signal in an AEM survey in the same way that pore water resistivity does.

The ranges of resistivity expected in different sediments and water quality from the coastal Seaside area are reported from a recent study in Table 1 (Goebel et al., 2017). While resistivities vary based on both lithology and salinity, we can conclude that the lowest resistivity values will always correspond to saltwater-saturated sediments and the highest resistivity values will always correspond to freshwater-saturated sediments.

Table 1: Expected resistivities of sediments in coastal Seaside area, CA (adapted from Goebel et al., 2017).

Resistivity (ohm-m)	Sand and Gravel	Silt	Clay
Freshwater Saturated	30–70	N/A	7–12
Saltwater Saturated	0.7–3	1.2–3	1.5–5

We developed the analogous table for the Marina area sediments using the geophysical borehole logs in the seven MPWSP wells and pore water TDS measurements made at the time of the logging, where fresh, brackish and saltwater are defined by total dissolved solids thresholds of <3,000, 3000-10,000, and > 10,000 mg/L, respectively. These thresholds are defined according to the EPA Guidance for the Determination of Underground Sources of Drinking Water. The results are shown in Table 2. Given the quality of the lithology cataloging, data were available for multiple lithology categories, beyond sand, silt, and clay. We see a trend similar to the one found in the Seaside area sediments: saltwater-saturated sediments, regardless of lithology, have the lowest resistivity values. Similarly, freshwater in coarser-grained sediments have a distinctively high resistivity, but freshwater in finer-grained sediments can be convoluted with sediments in brackish water. To make conservative estimate of zones that are freshwater-saturated, we apply a 30 ohm-m cutoff to the data defining all freshwater-saturated sediments. A similar estimate can be made for saltwater-saturated zones by applying a 3 ohm-m cutoff, defining all saltwater-saturated sediments.

Table 2a: Expected resistivities in the coastal Marina area, compiled from MPWSP geophysical well logs (long induction resistivity)

Resistivity (ohm-m)	Gravel/ Boulders	Sand and Gravel	Sand	Silty Sand	Clayey Sand	Silt/Loess	Silty Clay	Clay
Freshwater-saturated	N/A	65.00	31.40	15.37	N/A	N/A	11.58	16.98
Brackish-saturated	N/A	7.36	22.98	N/A	N/A	N/A	N/A	N/A
Saltwater-saturated	1.69	1.58	1.76	1.42	1.58	1.65	N/A	1.68

Table 3b: Summary of expected resistivities in the coastal Marina area

Resistivity (ohm-m)	Range	Average	SD
Freshwater-saturated	11-65	28.06	21.97
Brackish-saturated	7-23	15.17	10.38
Saltwater-saturated	1.4-1.7	1.62	0.11

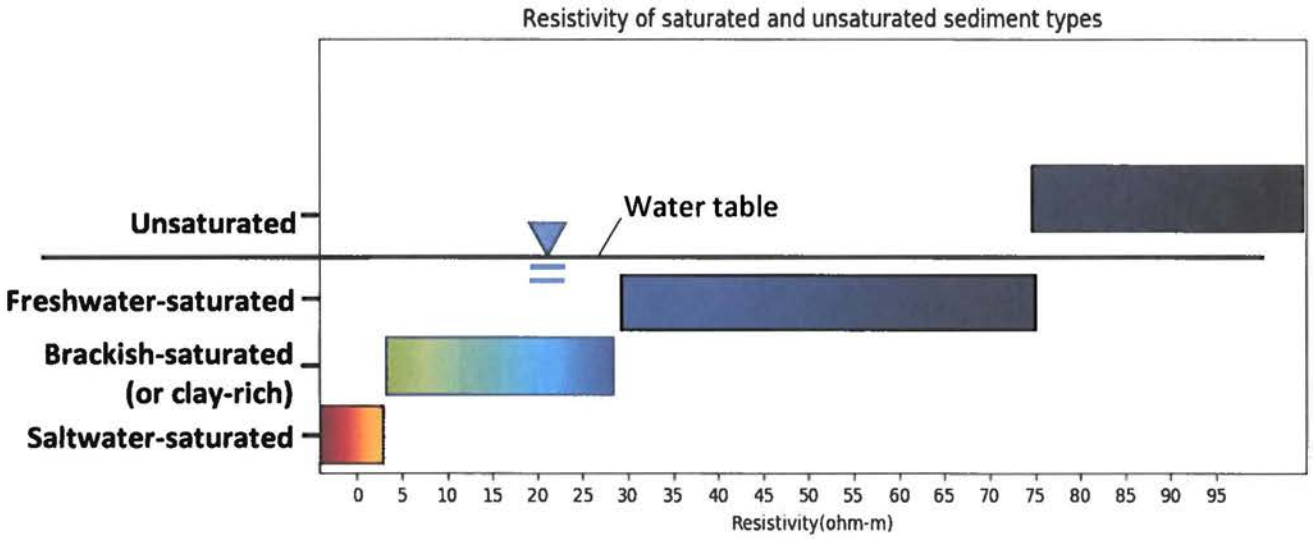

Figure 7: Range of resistivities expected in the region of interest based on Table 2, along with the cutoff values for each classification:
Saltwater-saturated: <3 ohm-m; Freshwater-saturated: 30-75 ohm-m; Unsaturated: > 75 ohm-m.
The range between saltwater-saturated and freshwater-saturated is less certain; sediments could be coarse in brackish water, or clay-rich.

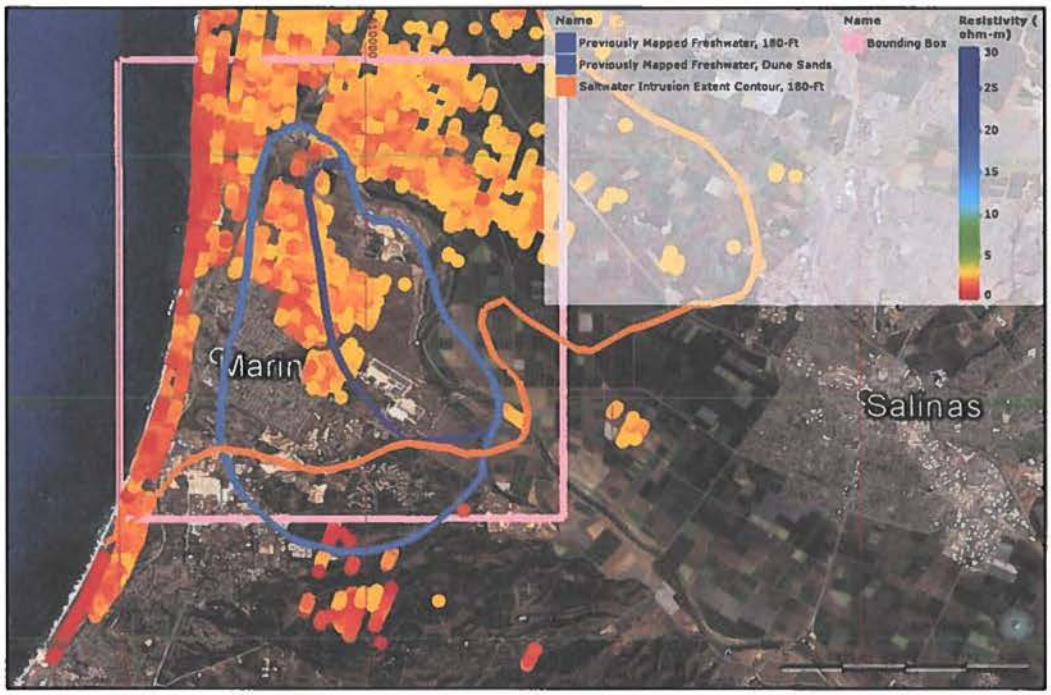

Figure 8a: Plan view showing resistivity below 3 ohm-m to a depth of -150m elevation. Map is shown at -150m elevation

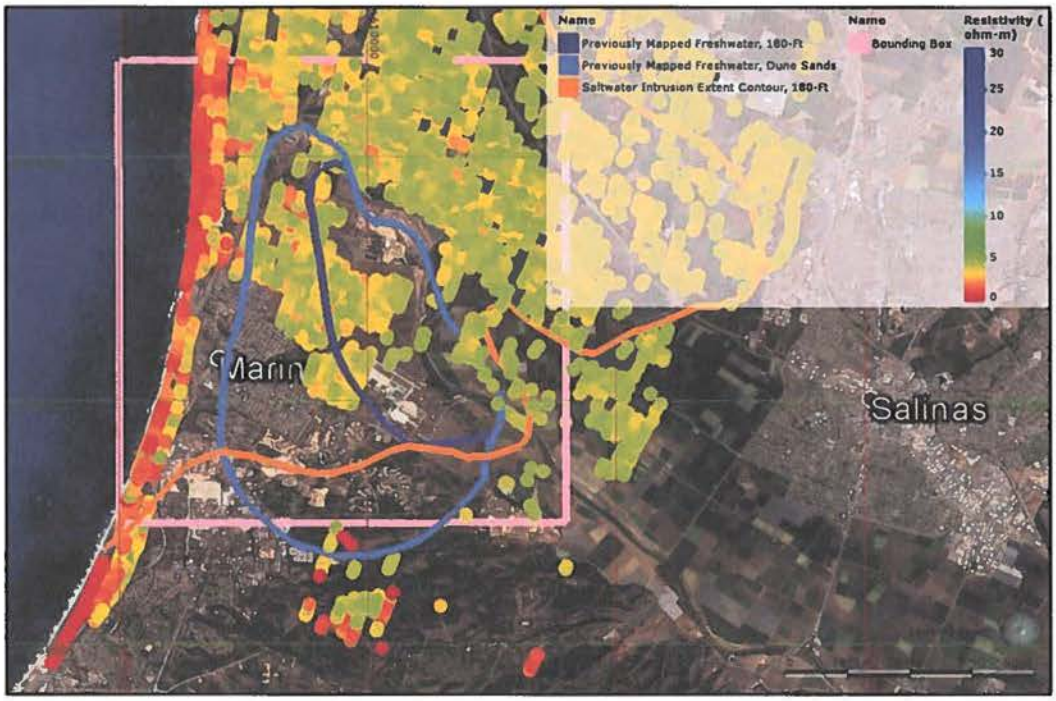

Figure 8b: Plan view showing resistivity below 5 ohm-m to a depth of -150m elevation. Map is shown at -150m elevation

3) Fresh and Saltwater in AEM data

Figure 8 shows the applied saltwater cutoff found from the geophysical well logs (3 ohm-m). Saltwater intrusion tends follow the contours from the previously mapped saltwater intrusion contour in the 180-Ft Aquifer. For comparison, a cutoff of 5 ohm-m is shown in Figure 8b. Figure 9 displays the region of interest with the applied freshwater cutoff found from geophysical well logs (>30ohm-m), and a >20ohm-m cutoff (Figure 9b), for comparison.

It is distinctly clear that areas in the region of interest have a significant volume of freshwater in the near subsurface. In the Marina area, the thickness of freshwater grows, which corresponds to previous water quality measurements in the MPWSP wells, as well as a 2016 report by Curtis Hopkins. The AEM data furthermore show the extension of the isolated freshwater beyond the area formerly thought to contain freshwater in the near surface (in the Dune Sand Aquifer), likely up until near the Salinas River.

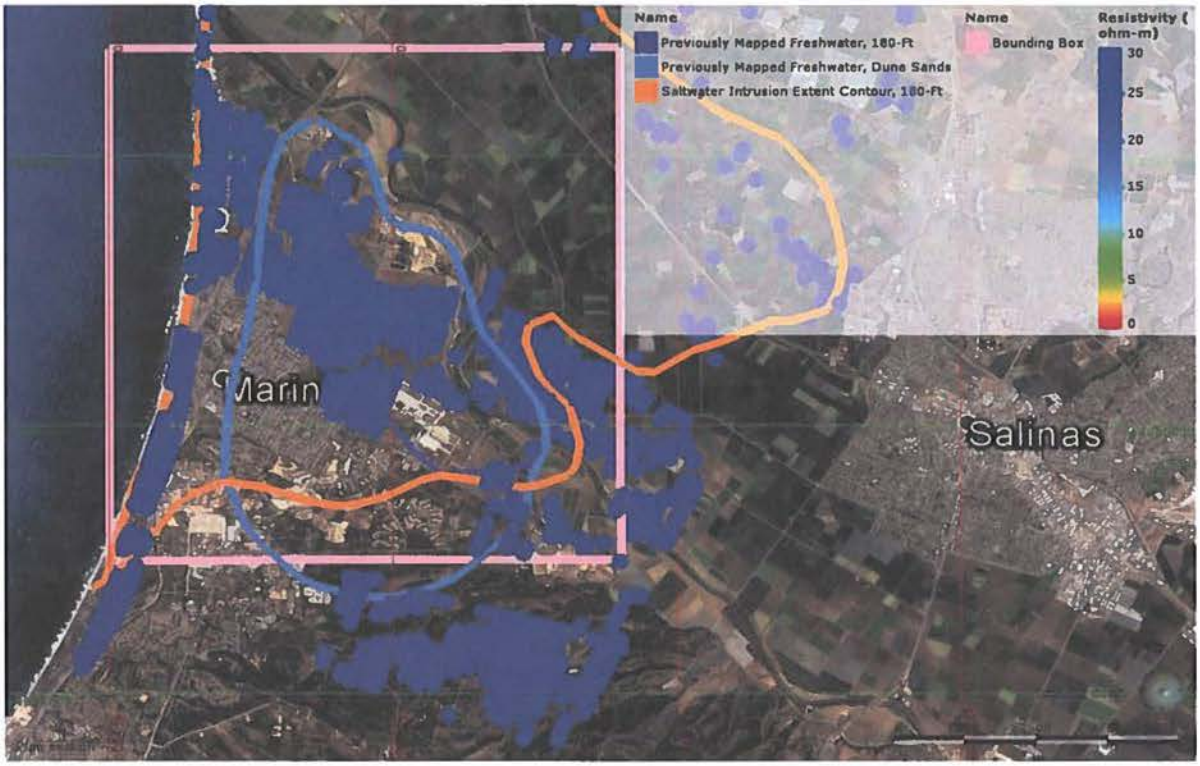

Figure 9a: Plan view showing >30ohm-m resistivities between elevations -100 to 29masl.

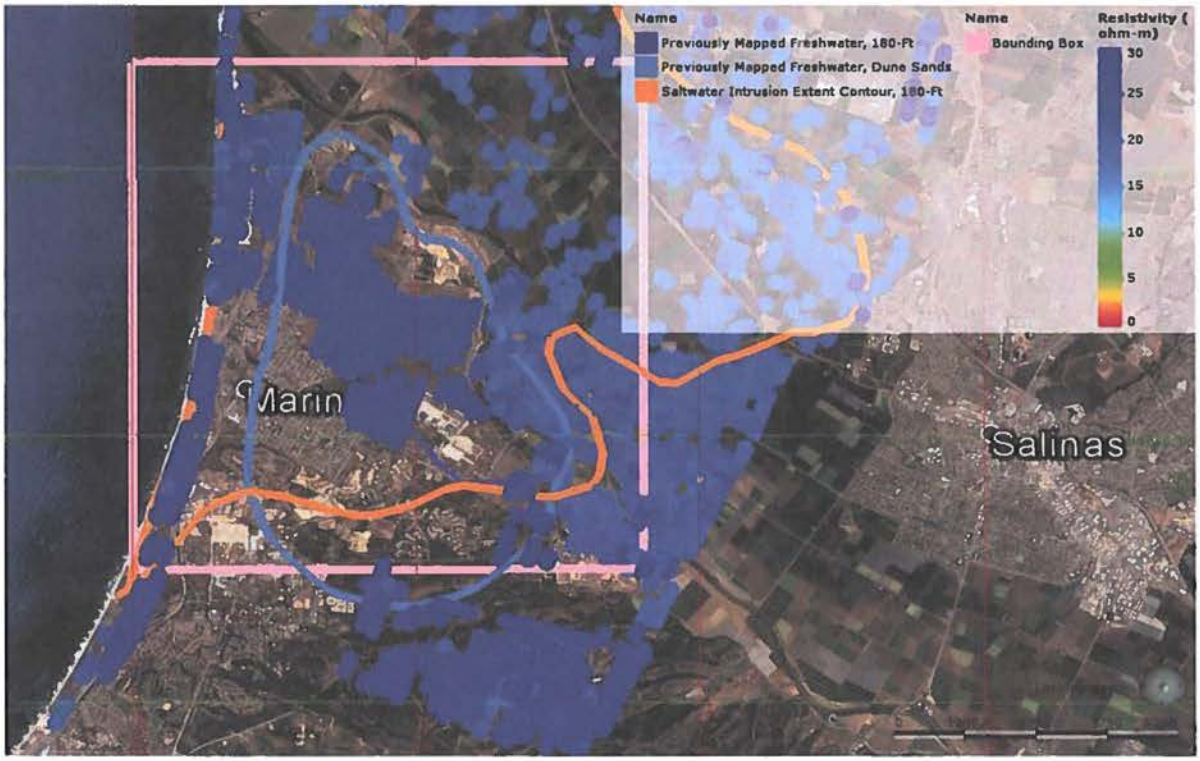

Figure 9b: Plan view showing >20ohm-m resistivities between elevations -100 to 29masl

Summary

We have made a preliminary interpretation of AEM data collected in the Marina region in May 2017. From geophysical logs and water quality measurements, we have conservatively defined an interpolated water table surface, which is likely to underestimate the volume of isolated freshwater in the region of interest. We have compared this interpolated water table, based on few control points, with a conservative resistivity cutoff of <75 ohm-m, to distinguish the saturated zone from the unsaturated zone. Based on borehole geophysical measurements, we defined a lower bound resistivity cutoff of 3 ohm-m to distinguish between freshwater-saturated sediment and saltwater-saturated sediment, considering that saltwater-saturated materials have a uniquely low resistivity range.

The AEM dataset provided by the SkyTEM system and processed by AGF offers an abundance of information into the hydrogeology of the region of interest, in and around the MCWD-operated Salinas Valley Marina Area. The 3-dimensional interactions between fresh and salt water shown by this data can deliver valuable information for groundwater management by MCWD, and offer insight into future action by the District.

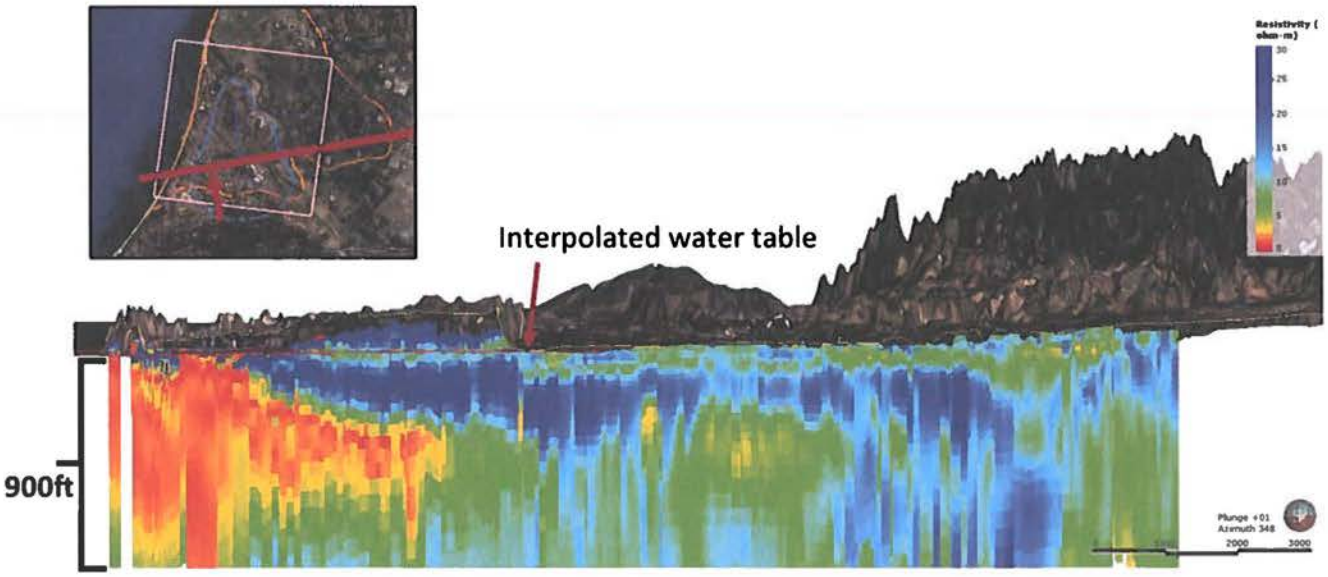

Figure 10: Cross-sectional cutaway view of AEM data, displaying larger-scale structures within the inverted AEM dataset. Interpolated water table surface is shown in red. The large conductive feature on the coast extends inland and downward, while the near-surface resistive body pinches out near the coast.

MEMORANDUM

To: Keith Van Der Maaten, P.E., Marina Coast Water District
Michael Wegley, P.E., Marina Coast Water District

From: Vera Nelson, P.E., EKI Environment & Water, Inc.

Subject: Groundwater Remedial Actions and Establishment of Remedial Goals at Fort Ord Marina Coast Water District, California (EKI B60094.02)

EKI Environment & Water, Inc. ("EKI"; formerly known as Erler & Kalinowski, Inc.) is pleased to provide Marina Coast Water District ("MCWD") with this memorandum outlining the groundwater remedial actions and establishment of remedial goals in the Dune Sand Aquifer (identified as the A- Aquifer at Fort Ord) and 180-Foot Aquifer at former Fort Ord. These remedial goals are based on drinking water standards and are consistent with the beneficial use designation of groundwater within these aquifer zones articulated in the Central Coast Water Quality Control Plan ("Basin Plan").

SUMMARY

EKI's understands that MCWD and its counsel intend to meet with the Central Coast Regional Water Quality Control Board ("Central Coast RWQCB") and the California State Water Resources Control Board ("State Board") to discuss the potential environmental impacts of the proposed California America Water Monterey Peninsula Water Supply Project ("Cal Am Project" or Project").

The Cal Am Project includes a seawater intake system consisting of 10 subsurface slant wells at the CEMEX sand mining site near the City of Marina. The Cal Am Project has the potential to degrade water quality within the Dune Sand Aquifer and 180-Foot Aquifer that underlie MCWD's service area. The Draft Environmental Impact Report/Environmental Impact Statement, released on 13 January 2017 ("DEIR/EIS") for the Cal Am Project characterizes the Dune Sand Aquifer and 180-Foot Aquifer as having poor water quality and being impacted by salt water intrusion. The DEIR/EIS does not acknowledge that further Project-related degradation of the groundwater quality in these aquifers violates the Water Quality Control Plan for the Central Coastal Basin

("Basin Plan;" RWQCB, 2016), which designates all groundwater within the Salinas Valley Groundwater Basin as a potential drinking water source.[1]

State and Federal agencies have required cleanup of groundwater within the Dune Sand Aquifer and 180-Foot Aquifer at former Fort Ord to drinking water standards, consistent with the Basin Plan's beneficial use designation. Millions of dollars have been, and continue to be, spent to remediate groundwater within these aquifers and to restore groundwater to drinking water standards. The DEIR/EIS findings directly contradict these restoration efforts and the remedial action requirements and remedial action objectives upon which they are based.

The DEIR/EIS implies that Project-related degradation of groundwater within the aquifers is acceptable because they are of "poor quality." The Cal Am Project should be held to the same standards as restoration efforts at Fort Ord, given the potential for the Project to impact the beneficial use of the Dune Sand Aquifer and 180-Foot Aquifer. We believe that the RWQCB should take an active role in reviewing the potential impacts to groundwater quality of the Project and oversee monitoring of baseline conditions within each aquifer. RWQCB oversight will aid in ensuring that the Project does not adversely impact the beneficial uses of the aquifers.

HISTORY AND REGULATORY OVERSIGHT OF ENVIRONMENTAL CONDITIONS AT FORMER FORT ORD

Former Fort Ord is adjacent to Monterey Bay in northwestern Monterey County, California, approximately 80 miles south of San Francisco. The former military base consists of approximately 28,000 acres adjacent to the cities of Seaside, Sand City, Monterey, and Del Rey Oaks to the south and Marina to the north. Former Fort Ord overlies the Monterey Subbasin, the Seaside Subbasin, and a small portion of the 180/400 Foot Subbasin (Figure 1). It is located immediately south of the Cal Am Project proposed seawater intake system at the CEMEX sand mining site near the City of Marina. The base was closed in 1994 and portions of the base have been transferred to various entities and are slated for redevelopment.

Environmental investigations began at former Fort Ord in 1984 at the direction of the Central Coast RWQCB (i.e., Cleanup and Abatement Orders 84-92, 86-86, and 86-315). Initial investigations indicated the presence of organic compounds in soil and groundwater at the Fire Drill Burn Pit (Operable Unit 1 or OU1). In 1986, further investigations were performed at former Fort Ord Landfills (Operable Unit 2 or OU2) and in 1990, former Fort Ord was placed on the EPA's National Priorities List ("NPL"), primarily because of volatile organic compounds ("VOCs") found in groundwater at OU2. A Federal Facility Agreement ("FFA") was signed in 1990 by the Army,

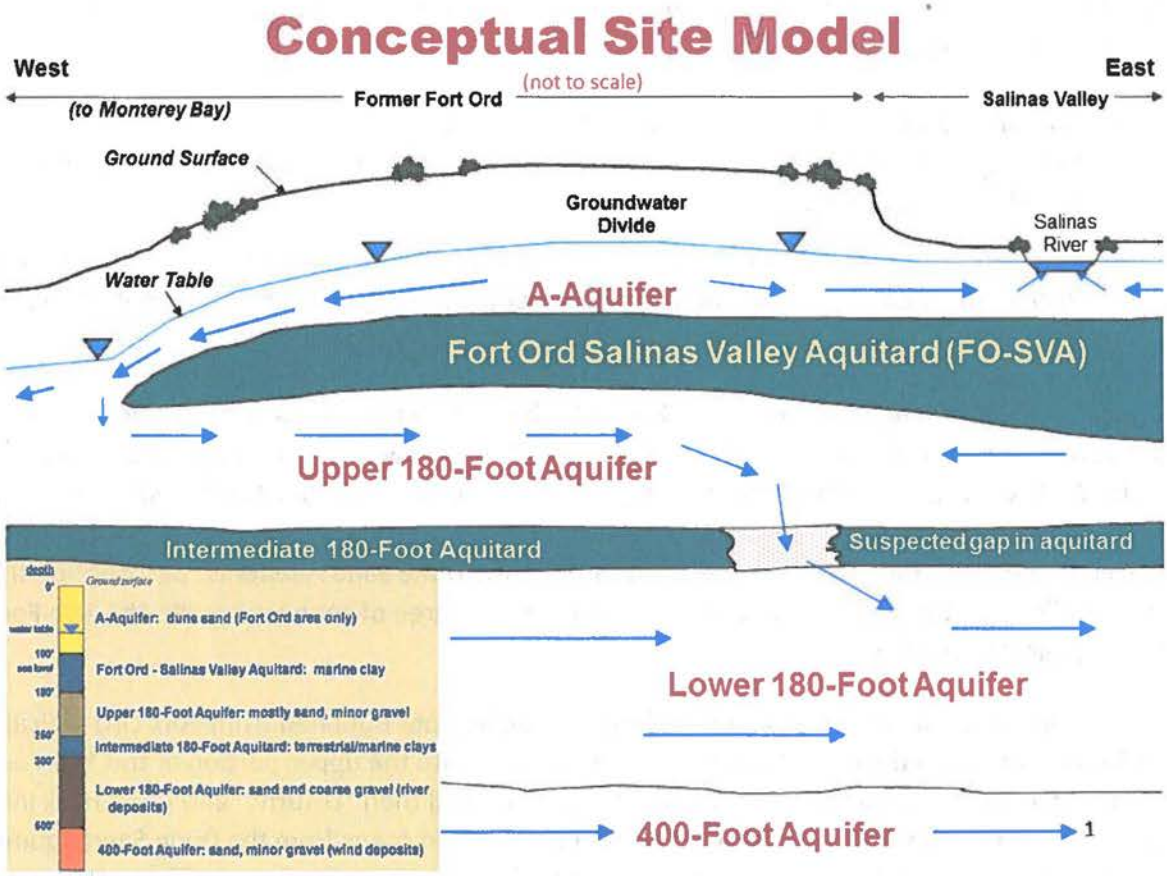
[1] Basin Plan *Chapter 2.I. Present and Potential Beneficial Uses*. States: "Ground water throughout the Central Coastal Basin, except for that found in the Soda Lake Sub-basin, is suitable for agricultural water supply, municipal and domestic water supply, and industrial use."

U.S. EPA, DTSC (formerly the Department of Health Services or DHS), and the Central Coast RWQCB.

The FFA established schedules for performing remedial investigations and feasibility studies, and required remedial actions be completed as expeditiously as possible. The base wide Remedial Investigation Feasibility Study ("RI/FS") commenced in 1991. The Army performs these activities pursuant to the Comprehensive Environmental Response, Compensation, and Liability Act ("CERCLA") also known as Superfund.

CHARACTERIZATION OF HYDROGEOLOGY AND GROUNDWATER USE AT FORT ORD

The below diagram depicts the conceptual site model ("CSM") of the hydrogeology for the northern portion of former Fort Ord, which overlies the Monterey Subbasin, as characterized by the Army and endorsed by U.S. EPA, DTSC, and Central Coast RWQCB. The CSM is based upon groundwater investigations conducted by the Army over the last 30 years, during which over 300 monitoring wells have been installed and water levels monitored to assess vertical and horizontal groundwater gradients.



Source: http://fortordcleanup.com/programs/groundwater/

Four aquifers, each separated by an aquitard, have been identified in the northern portion of former Fort Ord. The upper-most, or shallowest, aquifer is called the A-Aquifer. Deeper aquifers consist of the 180-Foot Aquifer, which is split into the Upper and Lower 180-Foot Aquifers, and the 400-Foot Aquifer. The names of these three deeper aquifers relate to their depth below ground surface in the Salinas Valley.

The **A-Aquifer** is encountered between 60 feet and 100 feet deep, and is not used as a public water supply. Sediment within the A-Aquifer is generally composed of ancient dune sand. The A-Aquifer also is referred to as the Dune Sand Aquifer.

The **Upper 180-Foot Aquifer** has been used as a public water supply, but is not currently used as a source of drinking water for either former Fort Ord or the City of Marina. Sediment within this aquifer is composed of mainly sand with some gravel.

The **Lower 180-Foot Aquifer** and the **400-Foot Aquifer** consist of gravel and sand with some clay. Both are major sources of drinking water for Fort Ord and farms in the Salinas Valley.

The CSM is consistent with the hydrogeologic characterization of the aquifer system presented by EKI in the following memoranda:

- Preliminary Feasibility Assessment – Potential to Conduct Augmented Groundwater Recharge at the Armstrong Ranch Property, Marina Coast Water District, California, dated 16 January 2017.
- Comments Regarding California America Water Monterey Peninsula Water Supply Project Draft Environmental Impact Report/Environmental Impact Statement, Released 13 January 2017 Marina Coast Water District, California, dated 28 March 2017.

As described in EKI's memoranda, groundwater in the A- or Dune Sand Aquifer in the Monterey Subbasin, (Figure 1) is significantly above sea level and flows west towards Monterey Bay (Figure 2). In contrast, as shown on Figure 3, groundwater in the 180-Foot Aquifer flows eastward towards a regional pumping center in the interior of the Salinas Valley. Based on the head differences between these aquifers it is apparent that the Dune Sand Aquifer is "perched" on the Salinas Valley Aquitard within inland areas but has some degree of connection with the 180-Foot Aquifer nearer to the Bay.

These water level data in combination with water quality data obtained from Fort Ord indicate that fresh water from the Dune Sand Aquifer seeps down into the upper portion of the 180-Foot Aquifer upgradient of Monterey Bay and the Project site and then "U-turns" and flows back into the basin. The exact location and volume of groundwater that seeps from the Dune Sand Aquifer into the Upper 180-Foot Aquifer and makes this "U-Turn" has not been quantified. However,

data from Fort Ord indicates that seepage from the Dune Sand Aquifer near Monterey Bay (where water levels are above sea level) into the underlying 180-Foot Aquifer (where water levels are below sea level) has effectively stopped salt water intrusion in the Upper 180-Foot Aquifer in that area. This natural mounding has maintained freshwater in the upper portion of the 180-Foot Aquifer under much of Fort Ord (see Figures 4 and 5).[2] This natural barrier appears to have been undermined north of Fort Ord through groundwater extraction and/or salt water discharges into the Dune Sand Aquifer at the CEMEX sand mining site, and would likely be further disturbed by the Cal Am Project.

Water level and water quality data obtained at Cal Am's recently installed monitoring well clusters MW-5, MW-6, MW-7 and Monterey Regional Water Pollution Control Agency ("MRWPCA") wells 1 and 2, indicate that chloride and TDS concentrations in the Dune Sand Aquifer and the Upper 180-Foot Aquifer meet SWRCB Resolution No. 88-63 criteria as a potential drinking water source and California Secondary Drinking Water Standards for these constituents.[3] Maps depicting TDS and chloride concentrations detected in groundwater samples collected from Fort Ord and Cal Am wells screened in these aquifers over the last 10 years (i.e., 2006 through 2016) are presented on Figures 4 and 5. These figures show that, outside of the immediate area of the CEMEX site, groundwater in these aquifers is not brackish as characterized in the DEIR/EIS.

CHEMICAL IMPACTS, REMEDIAL ACTIONS, AND COSTS TO ADDRESS GROUNDWATER CONTAMINATION AT FORT ORD

The majority of groundwater contamination at former Fort Ord is present in the A-Aquifer, also known as the Dune Sand Aquifer, and the Upper 180-Foot Aquifer. Small amounts of contamination below drinking water standards have been measured in the Lower 180-Foot Aquifer and no contamination has been detected in the 400-Foot Aquifer.

Four areas of groundwater contamination have been identified at former Fort Ord. The most frequently detected chemicals in these areas are trichloroethene ("TCE") and carbon tetrachloride ("CT"). Suspected sources, locations, primary contaminants, affected aquifers, and status of remedial actions are summarized in Table 1. The locations and estimated lateral extent of groundwater plumes in 2006 and 2010 are shown on Plates 3 and 4 in Attachment A.

---

[2] The information presented in Figures 4 and 5 is consistent with data collected at Fort Ord in the late 1990's which was presented in Harding ESE's, Final Report Hydrogeologic Investigation of the Salinas Valley Basin in the Vicinity of Fort Ord and Marina Salinas Valley, California, prepared for MCWRA dated 12 April 2001. (Harding, 2001).

[3] The recommended and upper secondary maximum contaminant levels for chloride are 250 mg/L and 500 mg/L. The recommended and upper secondary maximum contaminant level for total dissolved solids ("TDS") is 500 mg/L and 1000 mg/L, respectively. (California Code of Regulations, Title 22. Division 4 Environmental Health, Chapter 15. Domestic Water Quality and Monitoring Regulations, Article 16, dated 27 September 2006.

(U.S. Department of the Army, 2012). As indicated by these plates, the lateral extent of the plumes has significantly decreased as a result of remedial actions implemented at Fort Ord.

As indicated on Table 1, remedial actions implemented at Fort Ord to address contaminated groundwater include:

- Capping of the Fort Ord landfill and excavation of chemically impacted soil to limit further leaching of chemicals to groundwater.
- Installation and operation of groundwater extraction and treatment facilities to limit further chemical migration (see Plate 5a, 5b, 6 and 7 in Attachment A).
- Treatment of extracted groundwater using granular activated carbon ("GAC") to remove chemicals and allow groundwater reuse at former Fort Ord for irrigation or reinjection into the aquifer (see Plate 5a, 5b, 6 and 7 in Attachment A).
- Injection of lactate at the Operable Unit Carbon Tetrachloride Plume ("OUCTP") to stimulate in-situ biodegradation of VOCs in groundwater (see Plate 8 in Attachment A).
- Long-term monitoring of water levels and chemical concentrations utilizing wells screened in individual aquifers (i.e., A-Aquifer, Upper 180-Foot Aquifer, and Lower 180-Foot aquifer) to assess groundwater flow directions and the lateral and vertical extent of chemical impacts.

Total estimated cost spent through 2015 to remediate soil and groundwater contamination at former Fort Ord is reported to be **320 million dollars.**[4] The costs specifically related to groundwater contamination versus soil are not identified, but likely represent a significant portion of overall costs given groundwater remedial actions have been ongoing for over 25 years and requirements for soil remediation are often driven by concerns over chemicals leaching to groundwater.[5]

---

[4] In the Report to Congress Fiscal Year 2015, is included as Attachment B and was provided by William K. Collins Environmental Coordinator, Fort Ord BRAC Field Office by e-mail on 6/82017. Contaminated groundwater investigation and remediation costs are included in the "IRP" columns but also include the costs for soil and landfill investigations and remedial actions. The munitions investigations and remedial action costs are identified under "MMRP" and are independently tracked and not part of groundwater remedial action costs.

[5] Estimated costs identified as part of feasibility studies completed by the Army to implement selected remedial alternatives for identified groundwater plumes in OU1, OU2, Sites 2/12, and OUCTP are presented in Table 1. These values are based upon estimates presented in the ROD and ESDs for these areas, and in many cases have not been updated since the 1990s, and likely underestimate actual costs.

ESTABLISHMENT OF REMEDIAL ACTION OBJECTIVES AND CONTINUED COMMITMENT TO MEET THESE OBJECTIVES AT FORMER FORT ORD

Groundwater remedial action objectives and aquifer cleanup goals at Fort Ord are established within the *Records of Decision* ("ROD") and subsequent *Explanations of Significant Difference* ("ESD") prepared for each operable unit where groundwater impacts have been detected (U.S. Department of the Army, 1994; 1995a; 1995b; 1996; 1997a; 1997b; 2003; 2006; 2007a; 2007b; 2010; 2012; 2015). These documents are part of the administrative record and have been endorsed by state and federal agencies, including the Central Coast RWQCB. The RODs document all facts, analyses of facts, and site-specific policy determinations considered in the course of selecting a remedial action, and how nine remedy selection criteria were used to decide the remedy (NCP §300.430(f)(5)(i)). The RODs also describes statutory requirements as they relate to the scope and objectives of the remedial action (NCP §300.430(f)(5)(ii)) including:

- How the selected remedy is protective of human health and the environment, explaining how the remedy eliminates, reduces, or controls exposures to human and environmental receptors.
- The federal and state requirements that are applicable or relevant and appropriate ("ARARs") to the site that the remedy will attain.
- The ARARS of other federal and state laws that the remedy will not meet, the waiver invoked, and the justification for invoking the waiver.
- How the remedy is cost-effective, (i.e., explaining how the remedy provides overall effectiveness proportional to its costs).
- Goals (i.e., cleanup levels) that the remedy is expected to achieve. Remediation goals shall establish acceptable exposure levels that are protective of human health and the environment.

RODs completed for the four areas where chemical releases have impacted groundwater at former Fort Ord are included as Attachment B.

ARARS AND AQUIFER CLEANUP LEVELS AT FORMER FORT ORD

For a remedial alternative to pass into the detailed analysis stage of the RI/FS and thus become eligible for selection under CERCLA, it must comply with ARARs or waivers need to be identified and justifications provided for invoking them. An alternative that cannot comply with ARARs, or for which a waiver cannot be justified, is eliminated from consideration for further discussion as a potential alternative in the Proposed Plan or ROD. ARARs include any federal or state standards,

requirements, criteria, or limitations that are determined to be legally applicable or relevant and appropriate to a CERCLA site or action.

One of the primary ARARs identified in the Fort Ord RODs that address groundwater contamination is the Basin Plan, which designates all groundwater within the Salinas Valley Groundwater Basin as a potential drinking water source.[6] As such all aquifer cleanup levels at Fort Ord are based on federal or state Maximum Contaminant Levels (MCLs).[7] These cleanup levels have driven the selection of groundwater remedial actions at Fort Ord. ARARS and aquifer cleanup levels identified in RODs completed for the four areas where releases of VOCs have impacted groundwater at Fort Ord are highlighted in Attachment C.

The continued requirement and commitment to achieving these remedial action objectives is reiterated in the 1st, 2nd and 3rd 5-Year Review Reports, prepared by the Army in 2002, 2007, and 2012, respectively (U.S. Department of the Army, 2002; 2007a; 2012). These 5-Year Review Reports provide a statutory review every five years after initiation of remedial action to ensure that the remedy is, or will be, protective of human health and the environment, until such time as hazardous substances, pollutants, or contaminants remaining on-site are not above levels that allow for unlimited use and unrestricted exposure. The next 5-Year Report for Fort Ord is scheduled for completion in the fall of 2017. The continued commitment/requirement to meet drinking water standards at Fort Ord was recently reiterated in the ESD for Sites 2/12, dated 28 April 2015, where groundwater contamination still exists. This document states:

> The Army's overall cleanup strategy for Sites 2/12 is to return groundwater to a condition that will allow beneficial uses to occur, including potential future use as a drinking water source without unacceptable risks to users... to reduce concentrations of VOCs to levels that will not result in concentrations of VOCs in groundwater that continue to exceed ACLs [Aquifer Cleanup Levels] and thereby prolong the period of unacceptable human health risk due to contamination in groundwater. (U.S. Department of the Army, 2015).

CAL AM PROJECT APPROVAL AND CENTRAL COAST RWQCB OVERSIGHT

The Cal Am project should be held to the same standards as remedial actions at Fort Ord, given the potential for the Project to impact the beneficial use of groundwater within the Monterey Subbasin. Modeling done to date does not adequately assess potential salinity impacts to

---

[6] Basin Plan Chapter 2.I. Present and Potential Beneficial Uses. States: "Ground water throughout the Central Coastal Basin, except for that found in the Soda Lake Sub-basin, is suitable for agricultural water supply, municipal and domestic water supply, and industrial use."

[7] In some cases ACLs but may be lower than the MCLs based on risk calculations, or may be based on Preliminary Remediation Goals where a MCL is not established.

groundwater in the vicinity of the Project.[8] Eight monitoring well clusters screened in the A- or Dune Sand Aquifer, 180-Foot Aquifer, and 400-Foot Aquifer have been installed inland of the CEMEX site to assess pre-pumping conditions and impacts during initial pilot testing of an individual slant well. However, many of those wells are screened over the entire 180-Foot Aquifer (i.e., have 100 to 200 feet well screens) and do not characterize the different salinity characteristics within the Upper 180-Foot Aquifer and Lower 180-Foot Aquifer that are observed at former Fort Ord. No monitoring wells have been installed north and south of the slant wells, where inland groundwater gradients outside of the capture zone of the slant wells are likely occur. It is also unclear what, if any, additional monitoring wells will be installed if the Project goes forward.

Given the potential for the Project to disrupt the complex hydrogeologic conditions and increase salt water intrusion, more extensive monitoring of current and potential future water quality conditions is required. We believe that the Central Coast RWQCB should take an active role in reviewing the potential impacts to groundwater quality of the Project and oversee monitoring of baseline conditions within each aquifer. RWQCB oversight will aid in ensuring that the Project does not adversely impact beneficial uses of the aquifers that have been the focus of extensive groundwater restoration efforts at former Fort Ord.

Email: MPWSP-EIR@esassoc.com

SUBJECT: DEIR/EIS for Cal-Am Monterey Peninsula Water Supply Project

Dear CPUC/MBNMS:

Thank you for providing the Monterey Bay Air Resources District (Air District) the opportunity to comment on the above-referenced document.

The Air District has reviewed the document and has the following comments:

1. Table ES – 2 Air Quality, Mitigation Measures, Page ES-40 – The table indicates significant and unavoidable impacts due to excessive emissions during construction. A suite of mitigation measures are presented which include using high tiered engines, idling restrictions, a fugitive dust control plan and paving the reservoir access road. While the District supports these measures we would further encourage the use of clean construction equipment powered by electricity or natural gas whenever feasible. This would have the added benefit of reducing diesel exhaust emissions which would be particularly beneficial when working near sensitive receptors, such as day care centers, schools and residential neighborhoods. MBARD-1

2. 3.3.4 Pipeline Installation, Page 3-49 – This section indicates that approximately 21 miles of pipelines will be installed near the Monterey Peninsula Recreational Trail, mostly using conventional open-trench methods. Please note, if older asbestos containing pipes or materials are encountered during the trenching operation, the requirements of Air District Rule 424 National Emissions Standards for Hazardous Air Pollutants could be triggered. Rule 424 contains the investigation and reporting requirements for asbestos. If you have questions about District Rule 424, please contact Mike Sheehan, Air District Compliance Inspector III, at (831)647-9411 x 217. MBARD-2

3. Table 4.10-5 Estimated Maximum Daily Construction Emissions, Page 4.10 - 22 – The table shows maximum unmitigated daily NO_x emissions estimated at 384 lb/day. Mitigation Measure 4.10-1a **Equipment with High Tiered Engine Standards** is proposed which reduces estimated emissions by about 60 lbs/day to 324 lbs/day, still nearly 2½ times the Air District's 137 lb/day significance threshold for NO_x. MBARD-3

In order to limit the extent of this Significant and Unavoidable impact, the Air District suggests that the following measures be considered:

- Upgrade to Tier 4 engines which can produce significant emission reductions over Tier 3 engines.
- Use non-diesel or non-gasoline powered equipment wherever feasible. This could include electric powered equipment as well as equipment powered by natural gas or propane.
- Avoid scheduling the highest emitting activities simultaneously, particularly during the May-October ozone season.

MBARD-3 cont.

MBARD-4

MBARD-5

Alternatively, in order to mitigate excess NO_x emissions, the applicant may consider:

- Working with the Air District to fund an off-site mitigation program to reduce NO_x emissions from other NO_x sources in the area not associated with the project.
- Developing an on-site mitigation program to reduce NO_x from sources within the operation. For example, the motor vehicle fleet associated with the operation could be replaced with electric vehicles. Partial funding for such a fleet conversion may be available through the Air District. Please contact David Frisbey, Planning and Air Monitoring Division Manager if you would like to consider that option. His number is 831-718-8016.

MBARD-6

MBARD-7

4. Mitigation Measure 4.10-1c: Construction Fugitive Dust Control Plan, Page 4.10-25 – The Air District appreciates inclusion of Mitigation Measure 4.10-1c as a starting point for the Fugitive Dust Control Plan as well as Measure 4.10-1d which will pave the Terminal Reservoir access road. However, given the high level of unmitigated PM_{10} emissions (279 lbs/ton per Table 4.10-5) and the finding that mitigated emissions (75 lbs/day) are only slightly below the threshold, additional actions may be needed to maintain compliance with the California air quality standard for PM_{10} as well as Air District Rule 402, Nuisances. These could include more frequent watering and modulating activity when dust producing operations are being conducted, particularly when working along populated corridors.

MBARD-8

Feel free to contact me if you have any questions. I can be reached at (831) 718-8027 or bnunes@mbard.org.

Best Regards,

Robert Nunes

Subject: Comments on Draft EIR for MPWSP (SCH#2006101004)

Dear CPUC/MBNMS,

The Monterey County land use departments have reviewed the subject Draft EIR and have the following comments:

RMA-Planning

1. The Draft EIR does not address visual impacts, in particular with regard to the proposed desalinization plant located in the unincorporated area north of Marina off Charles Benson Road. The Draft EIR should include a visual analysis of the facility and discuss consistency with applicable Monterey County General Plan policies. — MCRMA-1

2. Page 4.8-19 (Monterey County Local Coastal Program). The discussion incorrectly states that "The five land use plans stand alongside the 2010 Monterey County General Plan ...." It should say the "1982 General Plan." — MCRMA-2

3. Page 4.8-25. The discussion of Policy LU-1.11 incorrectly states that the desalinization plant site may need to be redesignated to accommodate the plant. The applicant has applied for a Use Permit which, if approved, would not require that the land use designation or zoning of the site be changed. — MCRMA-3

4. Page 4.8-26. The discussion of North County LUP Policy 4.3.4 does not indicate whether or not the project is consistent with this policy. — MCRMA-4

Agricultural Commissioner's Office

The elements of the project description with the potential for impacts to farmland are numerous and not clear in the analysis. For example, in the "Consistency with Regulatory Requirements" section of the document, it states that the proposed project would not be subject to FPPA requirements because the *project would not irreversibly convert farmland to nonagricultural use (emphasis added)*. However, this statement contradicts other portions of the analysis in the Agricultural Resources section. — MCRMA-5

No mitigation for the conversion of the 25-acre MPWSP Desalination Plant site, designated as Permanent Grazing, has been proposed. The DEIR states:

> ....the land has been vacant since 1913 (RBF Consulting, 2012). Therefore, construction of the MPWSP Desalination Plan would not temporarily disrupt agricultural activities, as none currently are conducted on the site, and would have a less-than-significant impact with respect to conversion of land zoned for agricultural use to non-agricultural uses because no agricultural uses currently are present in this location.

MCRMA-5 cont.

Regardless of the land's current or historic fallowness, the loss of agricultural land to development must be addressed in the analysis and mitigation. Specifically, the Ag Land Trust should be consulted to determine what the estimated value of the loss of this type of agricultural land would cost, and appropriate mitigation funds should be required to acquire like lands elsewhere in the region to compensate for the permanent loss of agricultural land. Other projects have been partially mitigated by moving topsoil to avoid the loss of that resource in addition to contributing to a mitigation bank, which the Ag Land Trust has also assisted with.

Additionally, this project must be reviewed by the County Agricultural Commissioner's Ag Advisory Committee for input on the best way to mitigate the impacts of construction, maintenance, and operation of the site. For example, although construction will take place in existing farm roads for some portions of the project, the remaining land will be potentially impacted during construction and plantings and access to planted crops may be impacted. Individual landowners must be consulted to determine what the best schedule for construction is and to determine how to minimize temporary and/or permanent impacts to agricultural land.

MCRMA-6

Sincerely,

Bob Schubert, AICP

Subject: **Comments on the Draft EIR/EIS for the Monterey Peninsula Water Supply Project dated January 2017 (SCH# 2006101004)**

Dear CPUC/MBNMS:

The Monterey County Water Resources Agency (MCWRA) has received the DEIR/EIS for the Monterey Peninsula Water Supply Project (MPWSP). This letter conveys correspondence and recommendations concerning issues that are relevant to the MCWRA's areas of responsibility.

The MCWRA has reviewed the DEIR/EIS, particularly with respect to any potential impacts the proposed project may have on the Salinas Valley Groundwater Basin (SVGB). The DEIR/EIS Chapter 2, Water Demand, Supplies, and Water Rights, adequately describes the concept and need to provide return water to the SVGB. The DEIR/EIS adequately considers the effect of the return water in section 4.4, Groundwater Resources. Furthermore, the 2015 Draft EIR included a groundwater analysis which has since been updated by a new groundwater modeling consultant. MCWRA has reviewed the updated groundwater analysis made available in Appendix E. The updated groundwater analysis in the DEIR/EIS demonstrates that the proposed project will not harm or cause injury to other basin users. It is the opinion of the MCWRA that the concerns regarding groundwater modeling, SVGB impacts, and water rights have been adequately addressed throughout the DEIR/EIS. Additionally, MCWRA is developing an independent groundwater monitoring program, per the Settlement Agreement and Mutual Release (executed Dec 4, 2012). MCWRA-1

The MCWRA has reviewed Chapter 4, sections 4.3 Surface Water Hydrology and Water Quality and 4.4 Groundwater Resources and the associated mitigation measures. With respect to these sections, the DEIR/EIS adequately evaluates and describes any potential environmental impacts associated with the construction, operation and maintenance of the project, and identifies those impacts that could be significant. MCWRA has only a few general comments in regards to these sections which should be addressed for the Final EIR/EIS: MCWRA-2

From Section 4.2 Geology, Soils, and Seismicity,

- Pages 4.2-23 states that Nacimiento Dam was completed in 1961, but it was actually

completed in 1957. Also, on this same page, the text indicates that San Antonio dam was completed in 1965; it was actually completed in 1967. MCWRA-2 cont.

From Section 4.4 Groundwater Resources:

- With regard to groundwater basin nomenclature, I would suggest that Figure 4.4-1 be updated to reflect the basin boundary spatial definitions and names as published by DWR in October 2016. MCWRA-3
- Discussion of the Seaside Groundwater Basin should be carefully reviewed and, when appropriate, clarification added as to whether the text is referring to the "Seaside Groundwater Basin" as defined by the Seaside Watermaster and MPWMD or the "Seaside Area Subbasin," which is defined by DWR and is a subbasin of the Salinas Valley Groundwater Basin. Page 4-4.12 contains an example of where this is relevant. Since DWR published new groundwater basin/subbasin boundaries in October 2016, the geographic boundaries of both are the same, however, DWR does not further subdivide the Seaside Area Subbasin as is described on page 4-4.12. MCWRA-4
- On page 4.4-5 there is a reference to the Pressure Area being bounded on the south by the Seaside basin. This should refer to the Monterey Subbasin, as this portion of the groundwater basin is now known. MCWRA-5
- Page 4.4-19 references the 2015 Brown and Caldwell report as being "conducted for the MCWRA". The State of the Salinas River Groundwater Basin report, as it is titled, was actually conducted for the County of Monterey Resource Management Agency, not MCWRA. MCWRA-6
- The Salinas Valley Reclamation Project (SVRP) operates in tandem with CSIP to deliver recycled water, but SVRP is not mentioned in the discussion of CSIP on page 4.4-20. MCWRA-7
- Page 4.4-28 they are confusing TDS and chloride. Chloride concentrations from that of seawater (19,000 mg/L) down to 500 mg/L near the leading edge... The MCWRA define the leading edge of inland seawater intrusion a groundwater containing CHLORIDE at 500 mg/L. The following paragraph also has two places were TDS is used but it should be chloride. MCWRA-8

MCWRA finds the DEIR/EIS demonstrates that any water resources related impacts associated with the project can be sufficiently mitigated. MCWRA looks forward to reviewing the Final EIR/EIS. If you have any questions regarding this response, please contact me at 831-755-4860 or by email at chardavoyneDE@co.monterey.ca.us. Please send the Final EIR/EIS to the address above.

Sincerely,

David F. Chardavoyne

Re: Monterey Peninsula Regional Water Authority Comments on the Monterey Peninsula Water Supply Project Draft EIR/EIS

Dear Ms. Borak and Ms. Grimmer:

The Monterey Peninsula Regional Water Authority (Water Authority) is a joint powers authority comprised of the six cities of the Monterey Peninsula with a board of directors consisting of the six respective city mayors. The Water Authority generally supports the Monterey Peninsula Water Supply Project (Project) proposed by California American Water Company (Cal-Am) in Application 04-09-019.

The Water Authority contracted with Separation Processes, Inc. and its sub-consultant Geosyntec Consultants to conduct a technical review of the Draft EIR/EIS with respect to the intake structures (including modeling) and brine discharge. With the input of Geosyntec Consultants and the Water Authority's Technical Advisory Committee, we find the Draft EIR/EIS to be well done and commend the lead agencies and **Environmental Science Associates** for their excellent work.

MPRWA-1

The Water Authority offers the following comments and recommendations in the interest of further strengthening a few sections of the analysis for the Project's Final EIR/EIS.

I. Brine Discharge Analysis

Dr. Preston of Geosyntec Consultants reviewed the brine discharge analysis and has informed the Water Authority that the analysis is well done, thorough, and appears to be conservative in its estimation of the amount of brine dilution that is likely to occur. Dr. Preston did, however, offer two recommendations to further improve the analysis, which we request that you incorporate into the Final EIR/EIS. They are as follows:

1. We recommend that you update the temperature of the brine discharge to reflect its source from groundwater (not the ocean) and to also include the increase in temperature of the brine due to waste heat in the desalination process. The original near-field analysis by Flow Science (2014) that was presented in the April 2015 Draft EIR assumed that the temperature of the brine discharge was equal to the temperature of the ocean. The Revised Draft EIR/EIS (January 2017) updated the temperature profiles of the ocean water using site-specific data collected from February 2014 to December 2015, which were up to approximately 3°C warmer than the temperature profiles used previously. However, the Draft EIR/EIS does not include an update of the assumed temperature of the brine discharge in its dilution calculations. The assumption of using the same temperature for the brine discharge as the ocean water is potentially inaccurate on two accounts: (1) the source water is from the groundwater and not from the ocean water, and (2) the desalination process produces waste heat that will likely increase the temperature of the brine discharge. We recommend that you include these effects by using temperatures of water taken from the test slant well (e.g., *Monterey Peninsula Water Supply Project Test Slant Well Long Term Pumping Test Monitoring Report No. 48*, April 5, 2016) and add some increase in temperature attributable to the desalination process (e.g., it has been noted that the temperature of the brine may increase approximately 1.5 to 2°C [IDE, personal communication, February 2017]). Geosyntec Consultants anticipates that these corrections will have minimal effect on the near-field dilution calculations because the density of the brine (which is important to the mixing/dilution processes) is dominated by the salinity differences, rather than the temperature differences. However, for the sake of utmost accuracy, we recommend that the brine temperature assumptions be updated as discussed. It is likely only necessary to assess the effects of corrected brine temperature on a few select calculations and demonstrate negligible impact, rather than revising all of the calculations in the Draft EIR/EIS. MPRWA-2

2. We recommend that you revise the analysis of the potential for hypoxia. The Draft EIR/EIS cites a mass-balance analysis provided by Geosyntec (2015) to indicate that hypoxia is unlikely. However, that analysis used far-field modeling results that were provided in the April 2015 Draft EIR, but are not in the January 2017 Draft EIR/EIS. While the hypoxia mass-balance analysis is likely still valid, it should be revised so that it does not rely on the far-field analysis that is no longer provided. Additional analysis could range from calculations assessing potential for vertical mixing (i.e., Richardson number considerations) coupled with discussions of the favorable surrounding topology (i.e., flat slope with no depressions) that will limit potential brine pooling to more sophisticated far-field modeling. MPRWA-3

II. Greenhouse Gas Emissions

The analysis of operational greenhouse gas emissions at section 4.11.4.2 and in Appendix G2 calculates CO2 emissions from brine degassing. However, it does not take into account the reduction in CO2 emissions that will result from a reduction in groundwater production by both the Castroville Community Services District (CCSD) as a result of the receipt of Project water as "return water" to offset its groundwater production, and from Cal-Am's reduced extractions from the Seaside Groundwater Basin and from the Carmel River Valley. The reductions in CO2 emissions stem from both avoided energy that would otherwise be used to power CCSD's wells and other production and conveyance facilities and the avoided degassing from the groundwater that would otherwise be produced.[1] In other words, the analysis of operational greenhouse gas emissions should incorporate the aspects of reduced emissions as a result of the Project alongside the aspects of increased emissions and thereby provide a net emissions analysis. MPRWA-4

The analysis of operational greenhouse gas emissions should also incorporate a discussion of the local Community Choice Energy program known as Monterey Bay Community Power. A joint powers agreement to create a joint powers authority has been approved, or will soon be submitted for approval, by 19 local member agencies partnering in the program. One goal of the program is to source more of the Monterey Bay area's power supply from renewable energy. This will reduce the CO2 emissions resulting from the Project's operations. MPRWA-5

III. Other Comments

In Table 3-1, "60 inch diameter pipe" is repeated twice. One of the pipes should be "48 inch". MPRWA-6

In Appendix D-1, caption to figure 10 indicates "buoyant". It should read "negatively buoyant". MPRWA-7

In the last bullet on page 4.3-73 it states, "Estimate regions within the BMZ where salinity would exceed 2 ppt." It should be modified, since the 2 ppt limit applies to the *difference* from background salinity, not the absolute salinity. MPRWA-8

The Water Authority hopes these comments will be helpful in preparing a thorough Final EIR/EIS for the Project. Thank you for your consideration.

Sincerely,

Bill Kampe

Bill Kampe, President
Monterey Peninsula Regional Water Authority

[1] It appears that the analysis already does a net power consumption analysis for Cal-Am's groundwater production, but it does not appear to back-out the CCSD's avoided energy consumption nor the avoided CO2 degassing associated with CCSD's and Cal-Am's existing groundwater production.

8.5.7 Monterey Peninsula Water Management District (MPWMD)

March 20, 2017

SUBJECT: Draft Environmental Impact Report/Environmental Impact Monterey Peninsula Water Supply Project State Clearinghouse No. 2006101004

Dear Sir or Madam:

This letter from the Monterey Peninsula Water Management District (MPWMD or District) is written in response to the joint Draft Environmental Impact Report/Environmental Impact Statement (Draft EIR/E1S) issued in January 2017 for the California American Water Company (Cal Am) application to develop a replacement water supply for CalAm's Monterey District service area. The District serves as a Responsible Agency under the California Environmental Quality Act for this project because a MPWMD Water Distribution System (WDS) Permit Amendment is needed to amend the current water system to serve water within the District boundary (MPWMD Rule 20-A). MPWMD-1

ES.5 The Proposed Project: All references to a Terminal Reservoir should be removed. This is no longer a part of the Project.

p. 1-9, Section 1.4.2, item 3: CalAm has elected to forego the "Terminal Reservoir" but increase the storage at the desalination facility. It would be useful to conform the MPWSP description to the actual elements in this chapter and in the project description in Chapter 3, especially Section 3.23.5 and related Figures 3-2 and 3-9b. If any changes are required to the description of "Treated Water Storage Tanks" in Chapter 3 and Figure 3-5b, they should be made. All impacts, mitigations, or other discussion related to the Terminal Reservoir could be removed throughout. MPWMD-2

p. 2-2, Section 1 Introduction, 1st full paragraph: In the first sentence, the Monterey Airport District should be included in the description. The Monterey Peninsula Airport District was created in 1941 and is not incorporated into the city or the county. MPWMD-3

5 Harris Court, Building G, Monterey, CA 93940 • P.O. Box 85, Monterey, CA 93942-0085
831-658-5600 • Fax 831-644-9560 • http://www.mpwmd.dst.ca.us

"CalAm is proposing this project to replace part of its existing water supplies, which have been constrained by legal decisions affecting CalAm's diversions from the Carmel River and pumping from the Seaside Groundwater Basin. State Water Resources Control Board (State Water Board) Order 95-10, State Water Board Order 2009-0060 (also referred to as the Cease and Desist Order, or CDO), **State Water Board Order 2016-0016,** and the Monterey County Superior Court's adjudication …" MPWMD-4

p. 2-3, Section 2.2.1.1: In the paragraph following the bullet points under "Facility Overview" the statement is made that "CalAm's Carmel River supplies are supplemented, especially during the summer high-demand season, by groundwater production wells in the Seaside Groundwater Basin." This statement is not true. Due to the "hydraulic trough" near the Naval Support Activity (Naval Postgraduate School), as described at the top of page 2-4, there always exists a portion of customer demand in the north part of the service area that cannot be served by the Carmel River, must be served from the Seaside Basin, therefore the supply is not "supplemented." MPWMD-5

p. 2-4 to 2-5, Section 2.2.2.2: There is no emergency intertie between Hidden Hills and the CalAm main system. There is a connection between Toro and Hidden Hills. Theoretically, this intertie could result in water from the MPWSP being used in the Toro system unless it is removed, but it means Carmel River water cannot be provided to Hidden Hills during "fires and emergencies" from the Crest Tank.

In this section, it would be useful to state, just before the last sentence of the first paragraph on page 2-5, that the MPWSP facilities include permanent interconnections to the CalAm Main System as described in Section 3.2.3.9 and shown in Figures 3-2, 3-10a, and 3-10b. MPWMD-6

p. 2-4, footnote 6: Add "In January 2017, the MPWMD approved a contract for preparation of an alternatives study for Los Padres Dam and sediment management in the reservoir." MPWMD-7

p. 2-5, Section 2.2.2.3: There is an inaccurate explanation of the MPWRS. MPWRS is not only CalAm sources of supply, but includes supplies for non-CalAm pumpers in the Seaside Basin and in the Carmel Valley Alluvial Aquifer. MPWMD-8

p. 2-5, Section 2.2.2.4 Carmel River Flow Agreements: The text should also include State Water Board Order 20016-0016. MPWMD-9

p. 2-7, Section 2.2.3: In the third paragraph it states "If CalAm fails to meet a milestone, the Revised CDO specifies that the annual diversion limit will be reduced by 1,000 afy." However, the Revised CDO states, "If the State Water Board determines that the cause is beyond Applicants' control, it may suspend any corresponding reductions" in the effective diversion limit due to a missed milestone. MPWMD-10

p. 2-12, Table 2.3: For reasons cited in our comments on pages 6-13, 6-14, and 6-18 below, we do not believe the Pebble Beach entitlements or legal lots of record should be considered as "future demands." MPWMD-11

p. 2-14, Section 2.3.3.3: Estimates are outdated and unsupported. There has been development based on the Paralta and pre-Paralta allocations since the early 2000's. There was new connection (i.e. vacant lot) development pre-CDO. There is development from the Sand City, Malpaso, and Pebble Beach entitlements. The vacant lot study included vacant buildable lots on existing parcels, including developed parcels (such as in Pebble Beach and Carmel Valley) that may never be split apart from the main property and developed. Hence, new analysis may be warranted. MPWMD-12

p. 2-16, Section 2.3.4.2: Non-revenue water is discussed in the second paragraph. It should be noted that the direct testimony of CalAm's Eric Sabolsice filed July 1, 2016 stated the total water loss for the Monterey Main System was 250 AF for Calendar year 2015. By Cal-Am's calculation the NRW percentage is 2.7%. MPWMD-13

p. 2-18 Aquifer Storage and Recovery: MPWMD has recently revised its estimate of the average annual yield from the ASR Project to 1,600 acre-feet per year. Please see **Attachment 1 – Effects of Monterey Pipeline on ASR Yields by Water Year Type**. With additional improvements to the Cal Am system, MPWMD estimates that the yield from ASR will be 920 afy from Phase 1 and 1,080 afy from Phase 2 for a combined total long-term average of 2,000 afy. MPWMD-14

p. 2-20 and 2-21: Water rights Permits 20808A and 20808C are incorrectly numbered. This is also repeated in Section 4.4 and should be corrected. In addition, MPWMD owns the ASR Phase 1 site and Cal Am owns the ASR Phase 2 site. MWPMD and Cal-Am jointly hold water rights Permits 20808A and 20808C to divert Carmel River water to the ASR Project. MPWMD-15

p. 2-21, Section 2.4.6.2: The term "Water Use Permit subscriber" is used in several places. A Water Use Permit has a specific meaning at MPWMD and is used incorrectly here. For clarity, we suggest you simply use the word "subscriber." In the third paragraph, change "water use permit" to "Water Permit". MPWMD-16

p. 2-23, Section 2.5.2.1 Los Padres Reservoir: A recent resurvey of Los Padres Reservoir showed that the reservoir can hold 1,810 AF at the spillway level (see **Attachment 2 – Final Los Padres Reservoir Survey Study Report**). The actual safe usable storage at this facility is less than 1,400 af due to concerns about releasing anoxic water or water with hydrogen sulfide from the lowest portion of the reservoir. MPWMD now estimates the long-term sedimentation rate to be between about 11 afy to 19 afy, depending on how the effects of the Marble-Cone fire on sedimentation are treated. In addition, releases from Los Padres Dam were originally intended to flow approximately five miles through the Carmel River to San Clemente Dam and Reservoir, where water was re-diverted into the Cal-Am delivery system. When Los Padres Reservoir was operated this way, a relatively small amount of the releases were lost due to evapotranspiration and channel losses along the interdam reach, which is a narrow channel flanked in most places by steep, rocky slopes. MPWMD-17

Cal-Am has changed its operations in Carmel Valley to divert Carmel River flows through its downstream wellfield. Thus, flow releases from Los Padres Dam must travel at least 11 miles and up to about 22 miles through the river channel before being diverted. In practice, it is unlikely that a significant portion of the releases from Los Padres Reservoir are actually diverted into the Cal Am system. Even if the releases are beneficial to the downstream riparian corridor, it is a very inefficient method of delivery to the Cal Am system. This may call into question whether Cal-Am can continue to divert as much as it releases from storage in the future. A replacement supply of 510 af for these considerations appears to be low; however, because of the potential long-term nature of a change in supply available from Los Padres Reservoir, it is conceivable that the water supply freed up in the Seaside Groundwater Basin after 25 years of in-lieu replacement could help offset any losses in supply from Los Padres Dam and Reservoir. MPWMD-17 cont.

p. 2-25, Section 2.5.3.1: The completion date in the 7th line of the first paragraph should be 2017. MPWMD-18

p. 2-26, Section 2.5.3.3: See comment above for p. 2-16. MPWMD-19

p.2-27, Section 2.5.3.4: The County General Plan planning area titled "Greater Monterey Peninsula" contains the City of Marina and vast swaths of land south and east of Carmel Valley, none of which are connected to the CalAm system and should not be reflected in future demand. Further, even the 2030 estimates overstate future population and per capita water demand. Hence, these numbers are overstated. MPWMD-20

p. 2-29 and 2-30, Section 2.5.4 Assumptions about the Allocation of MPWSP Water: When it becomes clear that Cal Am will complete construction of replacement supplies, MPWMD will update the original 1990 Allocation Program EIR and evaluate the impacts to the environment from allocation of water from the Monterey Peninsula Water Resources System, including new supply projects built since 1990. The considerations that formed the basis of the 1990 allocation may or may not be the same in a future analysis. Environmental analysis will be based on the conditions present or foreseeable at the time MPWMD makes a determination about allocating new supplies.

Need the acronym "AFY after the numbers 16,294 and 16,994 on page 29. On page 30 it states, "any water left over would be allocated in general proportion to projected growth in the CalAm service area jurisdictions." That is unlikely true, MPWMD may not allocate all water, may choose to retain water to be allocated later as general plans change over time, retain a reserve for public benefit projects, maintain a reserve to offset Pebble Beach entitlements, maintain a buffer for fluctuating demand due to economic or climate issues, or retain allocable water to allow a lower plant capacity factor for operations. The future allocation process has not been defined. MPWMD-21

p. 2-35, Section 2.6.1: In footnote 34 "Salinas Valley Growers Association" should be changed to "Salinas Valley Water Coalition." MPWMD-22

p. 3-3, Figure 3-1: The segment labelled "Ambler*" includes a bigger portion that should be labelled "Toro*" MPWMD-23

p. 3-34, Figure 3-9b: Indicates "water produced during development of ASR-5 and ASR-6 Wells would be conveyed to this natural depression and infiltrated into the ground." This is further described in Sections 3.3.2.2 and 4.3.5.1. No other disposal methods are analyzed. This is the District's preferred method such that the water recharges the Seaside Basin and is not discharged outside of the Monterey Peninsula Water Resource System. MPWMD-24

p. 4.1-16, Table 4.1-2: Project No. 6 City of Sand City Coastal Desalination Plant is presently being reconfigured. The description should be changed in the Table after consulting with CalAm. MPWMD-25

p. 4.1-18, Table 4.1-2: Project No. 17 Monterey Downs. This project is no longer being considered. MPWMD-26

p. 4.3-63: The San Pablo Depression was not used for the spreading of development water from ASR Well 3. MPWMD-27

p. 4.4-3 Figure 4.4.1: This figure does not reflect the Bulletin 118 boundary adjustments approved by the California Department of Water Resources for the Seaside Area and the Corral De Tierra Area in 2016, and is therefore incorrect. The DEIR should reflect the 2016 Bulletin 118 Interim Update and should be updated with the newly modified shapefile from the DWR SGMA website. MPWMD-28

p. 4.3-11: At the top of the page, the capacity of Los Padres Reservoir has been reduced to about 60% of original capacity – not 2% as stated in the text. MPWMD-29

p. 4.4-12: Seaside Groundwater Basin is separated into sub regions not sub basins. The Seaside Groundwater Basin is a sub-basin of the Salinas Groundwater Basin. MPWMD-30

p. 4.4-25: Please cite the reference for the 22-30% estimate of injected potable water at Well PCA E. MPWMD-31

p. 4.4-28 top of the page: ASR extracted water will not be treated at the Ord Grove Ozone Plant, but rather will be treated at the Santa Margarita Chemical Building. MPWMD-32

p. 4.8-32, Section 4.8.2.4: Please delete the two references to the term "a Water System Expansion Permit" and replace with "an amendment to its Water Distribution System Permit". MPWMD-33

p. 4.4-34: RWQCB regulates ASR operations throughout California under SWRCB Order 2012-0010 General Waste Discharge Requirements for Aquifer Storage and Recovery Projects That Inject Water Into Groundwater. MPWMD operates the Seaside Basin ASR wells under an agreement with RWQCB that pre-dates issuance of Order 2012-0010. MPWMD-34

p. 4.4-36 Division of Water Rights Permit 20808C Amended Permit for Diversion and Use of Water: The description of Permit 20808 should be updated. This permit was split into three parts – 20808A, 20808B and 20808C. Please see **Attachment 3 – Genealogy of Water Rights Permit 20808**. MPWMD and Cal Am jointly own Permits 20808A and 20808C, which total 5,326 afy that are subject to instream flow requirements based on NMFS 2002 recommendations. The ASR Project to divert excess Carmel River water operates under these permits.

The requirement to limit recovered water to 1,500 af in a given year is associated with a side agreement between MPWMD, Cal Am, and CDFW concerning recovery of water injected into the Seaside Basin under Permit 20808A. The Quarterly Water Budget Group set up to determine how the Cal Am system should be operated can decide to extract less. This agreement does not include water recovered under Permit 20808C; however, Condition 7 in CDO 2016-0016 requires that all water injected under either Permit 20808A or Permit 20808C be recovered in the same year, unless CDFW and NMFS agree to an alternate recovery plan. Under the CDO, the first 600 afy of water diverted to ASR in any water year must go toward offsetting Carmel River diversions in the water year it is diverted in. MPWMD-35

These requirements and others placed by the SWRCB on ASR recovery will be lifted once the CDO is met, thus these limits will not be an operational or budgetary limit after replacement supplies are operational and Cal Am has reduced its Carmel River diversions to authorized amounts.

MPWMD owns Permit 20808B for 18,674 afy, which is referred to as the "remainder" permit and is associated with a project to build a new main stem reservoir on the Carmel River downstream of the existing Los Padres Dam. That permit has a different set of instream flow requirements that was fixed to the permit by the SWRCB in 1995 prior to NMFS listing steelhead as a threatened species. No water has been diverted under this permit.

p. 4.4-48 Return Water Considerations: This section states

> "…it is estimated that somewhere between 0 and 12 percent of the source water withdrawn for the project would comprise water originating from the inland aquifers, and thus would be returned to the basin."

The "Settlement Agreement on MPWSP Desalination Plant Return Water" dated June 14, 2016 states: MPWMD-36

> "J. For Project planning and engineering purposes, Cal Am submits that the Project source water wells have been designed so that approximately 4% of the source water produced by the Project will originate as brackish groundwater from the SRGB."

Data from "Test Slant Well Long Term Pumping Monitoring Report No. 93 (8-Feb. to - 15Feb.),"

and available on the MPWSP web site indicate that the amount of fresh water (as indicated by total dissolved solids) in samples taken during the period 21 January 2016 to 26 January 2017 averaged about 8% with a maximum of 11% and a minimum of 4%.[1]

It is MPWMD's understanding from Cal Am that the Hydrologic Working Group (HWG) has some confidence that design changes and long-term drawdown associated with production wells will result in the salinity of intercepted water exceeding 96% (i.e., 4% "fresh water" intercepted). MPWMD recommends that the analysis or opinion of the HWG be presented and/or referenced in the FEIR. The amount of fresh water intercepted by the slant wells is an issue of great importance to the success of the project and should be fully explained.

Instead of presenting a theoretical range concerning the composition of brackish source water, the Final EIR and EIS should describe a likely freshwater content with an upper and lower bound and should explain the rationale for determining this. The amount of fresh water intercepted at the beginning of the project and the long-term expected composition of the source water should also be described.

MPWMD-36 cont.

p. 4.4-49, Section 4.4.4.2: There is insufficient discussion to show the feasibility of delivery and use by CSIP of water in excess of the needs of CCSD.

MPWMD-37

p. 4.4-51: SEAWAT is not a component of the Seaside Basin Modflow Model. The Pacific Ocean boundary is simulated through freshwater equivalent head constant head boundary. The SEAWAT modeling effort was a separate effort completed with several 2D cross-sectional models extending offshore in order to determine the protective water levels at the coastal monitor wells.

MPWMD-38

p. 4.4-53: Who will prepare the groundwater contour maps and what time of year will the data be collected? Who is responsible for collecting the water levels? Is this a Quarterly Water Budget Process as these rules will affect how the group decides which sources to use for supply?

MPWMD-39

4.3-63: The San Pablo Depression was not used for the spreading of development water from ASR3.

MPWMD-40

p. 4.4-68, Section 4.4.5.2: In the last paragraph on the page, the sentence which starts with, "Although the program has not achieved 2,426 afy, …" should be revised to say, "Although, due to weather and constraints in the existing CalAm transmission system, the program has not achieved 2,426 afy, …"

MPWMD-41

Also, there is contradictory information concerning which aquifer desalinated water would be injected into. Initially, the text states that water would be injected into the Santa Margarita

MPWMD-42

[1] Testing began in April 2015 when the fresh water content at the well was about 23%. The total dissolved solids in the tests appear to stabilize in a range of approximately 30,000 to 32,000 ppt starting as early as February 2016 and continuing through January 2017. Ocean salinity at the site is presumed to be about 33,500 ppt.

Sandstone, which is the deeper of the potable aquifers. The text then goes on to state that water would be injected into the "Shallow Zone Aquifer."

It is MPWMD's understanding that ASR 5 and ASR 6 wells are to be screened in the Santa Margarita Sandstone. P.4.4-83 also states that desalinated water will be injected into the Santa Margarita Sandstone. If the intent is to describe injection of desalinated water into the vadose zone, please state this.

It should be noted that other water supply wells in the vicinity of the ASR wells are screened in both the Paso Robles and Santa Margarita formations.

Please clarify this section concerning where in the aquifer system injection and extraction will occur.

MPWMD-42 cont.

p. 4.4-69: The additional ASR wells 5 and 6 are not listed as places of use on any existing Carmel River water rights permits and therefore these wells will not help to improve the Carmel River ASR program unless these points of injection are added on to the water rights permits. A Petition for Change would have to be submitted to the SWRCB for approval to use these points of injection.

MPWMD-43

p. 4.4-69, Section 4.4.5.2: In paragraph 3 and 4 the CalAm recharge of the basin is described. However, CalAm is not actually returning 700 afy, rather it is not extracting 700 afy. While not extracting water to which it is legally entitled to is similar, it is not the same as delivering actual water. Unless natural inflow from precipitation delivers a like amount, in lieu recharge delivers paper water instead of wet water. This section could more adequately describe this as an in lieu recharge program.

MPWMD-44

p. 4.4-82, Section 4.4.5.2: The second paragraph refers to Figure 4.7-2 regarding location of contaminated sites. However, Figure 4.7-2 does not show any of the referenced sites. It may have intended to refer to Figure 4.7-1, but that figure does not show the ASR location.

MPWMD-45

p. 4.11-13 to 14, Section 4.11.4.2: Wouldn't CO2 be released from the 57% seawater component at the brine equalization basin which is open to the atmosphere, rather than once diffused back into the ocean?

MPWMD-46

p. 4.19-2, Table 4.19-1: California Department of Finance estimates included approximately 1,000 new housing units in the CAW system between 2010 and 2015. That is impossible given that there is a moratorium on setting new water meters. This should be corrected to reflect a more reasonable number.

MPWMD-47

p. 5.2-6, Section 5.2.5: Paragraph 2 on this page states that the Monterey County Agency Act has a "prohibition on out-of-basin transfers." Section 21 of the Act only refers to export of groundwater from the Salinas River Basin, not surface water.

MPWMD-48

p. 5.4-6, Section 5.4.2.3: The "Supply Shortages" first paragraph states that the No Project Alternative "assumes that potential demands associated with Pebble Beach water entitlements, hospitality industry rebound, and legal lots of record could not be served, and thus are not counted among demands under the No Project Alternative." This is an incorrect assumption in two regards: (i) the Pebble Beach build-out has been approved under a separate EIR and the entitlements, by agreement, are to be honored from existing supplies whether a project is built, or not; and (ii) economic rebound occurs in existing properties at existing service connections, hence could occur whether a project is built, or not. Those demands cannot be assumed away. MPWMD-49

p. 5.4-7, Section 5.4.2.3: In the discussion of 1,000 afy reductions for missed milestones, you fail to mention the Revised CDO states, "If the State Water Board determines that the cause is beyond Applicants' control, it may suspend any corresponding reductions" in the effective diversion limit due to a missed milestone (see comment for page 2-7, above.) Hence, the No Project Alternative with the reductions in effective diversion limits must presume that CalAm is at fault and "chooses" not to execute a project. The description should clarify its assumptions. MPWMD-50

p. 5.5-366, Section 5.5.21.2: The middle paragraph on the page states , "1,755 afy would support new development." This is a specious argument for two reasons: (i) the Pebble Beach build-out has been approved under a separate EIR and the entitlements, by agreement, are to be honored from existing supplies whether a project is built, or not; and (ii) a legal lot of record has already undergone environmental review by a local land use authority and its growth inducing impacts already analyzed. In both of these cases, the provision of water should not be considered "growth inducing." This impact should be revised to LS, Less Than Significant Impact. MPWMD-51

p. 5.5-368, Section 5.5.21.3: The conclusion that there are no indirect growth inducing effects from the No Project Alternative should be revised to reflect the likelihood of a contraction due to penalty rates and rationing, i.e. negative growth, which would be significant and unavoidable. MPWMD-52

p. 5.6-19, Table 5.6-1: Impacts 6.3-1 and 6.3-C should be changed to LS for the Proposed Action and SU↑ for the No Action alternatives, based on previous comments, above. MPWMD-53

p.6-3, Section 6.1: Revise the last bullet pursuant to comment on p.5.5-366, above. MPWMD-54

p. 6-5, Section 6.3.1: See comment for page 2-2 above MPWMD-55

p. 6-10, Section 6.3.2.3: The third sentence should read: "The MPWMD manages surface and groundwater resources within its jurisdictional boundary"

Revise the second set of bullets under "The MPWMD's responsibilities also include:" MPWMD-56

- computer modeling of water resources systems;
- hydrologic monitoring;

- issuing water ~~connection~~ permits ***for new connections and remodels***;
- allocating water to jurisdictions ***and tracking its use***;
- ~~adopting water conservation ordinances and performing inspections~~ ***developing, implementing, and enforcing water efficiency programs and ordinances***~~;~~
- determining when ~~drought~~ ***water supply*** emergencies exist and then imposing ***and enforcing*** rationing programs;

MPWMD-56 cont.

p. 6-13, Section 6.3.5.1: The District believes that the DEIR has errs in its evaluation of growth inducement. Previously, our comments have stated the following:

(i) The Pebble Beach build-out has been approved under a separate EIR, hence its impacts have already been analyzed and are, in effect already "in the system". The entitlements are to be honored from existing supplies whether a project is built, or not, and that has been recognized by the State Water Board and in written agreement between CalAm, the Pebble Beach Company, and MPWMD. The proposed action does nothing to change the effect of the Pebble Beach Entitlements.

(ii) Economic rebound occurs in existing properties at existing service connections, hence could occur whether a project is built, or not. Furthermore, this effect is broader than just restaurants and lodging, rather include all commercial, industrial, and institutional (CII) revival under an improved economy, much of which is ancillary to tourism. The proposed action does nothing to change the effect of an improved economy.

(iii) A legal lot of record has already undergone environmental review by a local land use authority and its growth inducing impacts already analyzed. It is a slippery slope to infer already approved projects are "induced" by the proposed action. While we recognize that the meter moratorium can only be lifted when the project or something similar occurs, an alternative approach might be a class-action lawsuit by such property owners, who should already have been served years ago.

In each of these cases, the provision of water should not be considered "growth inducing."

MPWMD-57

p. 6-14, Section 6.3.5.1: The section on Pebble Beach Entitlements and Hospitality Industry Rebound should be revised pursuant to the comments made above.

MPWMD-58

p. 6-16, Section 6.3.5.1: the last paragraph says, "For simplicity's sake, this analysis assumes that about 250 afy of supply designated for rebound of the hospitality industry would likely be used for this purpose and 250 afy would be available for new development." However, your own discussion in Section 2.3.3.2 showed that CII demand was 440 afy greater in the period prior to the recession. That discussion also indicated that MPWMD's direct testimony to the CPUC in February 2013 concluded the estimate of demand related to economic rebound (500 afy) was

MPWMD-59

reasonable. We find your assumption made for simplicity's sake is, in and of itself, growth-inducing. MPWMD-59 cont.

p. 6-18, Section 6.3.5.1: Top of 6.18 states, "That is, for purposes of this EIR/EIS, it is assumed that supply provided by the proposed project would be allocated to meet existing demand within the CalAm service area, and that water service capacity beyond that would be allocated to the jurisdictions in general proportion to an estimate – which the MPWMD has not yet developed – of their future water supply needs."

Existing demand would not result in an "allocation." As stated in our comment on page 2-29, MPWMD may not allocate all water, may choose to retain water to be allocated later as general plans change over time, retain a reserve for public benefit projects, maintain a reserve to offset Pebble Beach entitlements, maintain a buffer for fluctuating demand due to economic or climate issues, or retain allocable water to allow a lower plant capacity factor for operations. The future allocation process has not been defined.

This Section also states, "This analysis also recognizes that the MPWMD could choose not to allocate to the County the approximately 325 afy proposed to serve Pebble Beach water entitlement-holders, to ensure that adequate water supply would be available when development associated with those entitlements was proposed. If, on the other hand, the MPWMD did allocate this water to the County, the County could then elect to allocate at least a portion of the 325 afy to other development – if, for example, other development was proposed first or the County determined that the entitlement holders were unlikely to use the full amount. In either case, this portion of the proposed MPWSP supply would be used to serve new development." We believe that the DEIR incorrectly evaluates the Pebble Beach entitlements, which should be treated as existing demand or demand to be served irrespective of the source of supply, not "new development." Therefore, this is not plant capacity to serve new development, rather is plant capacity to further reduce diversions from the Carmel River, Pure Water Monterey, the Seaside Basin, or the Sand City desalination plant to serve the entitlements. MPWMD-60

An "Entitlement" is different from an "Allocation". Therefore, the above scenario would not happen. The Pebble Beach Entitlement is not recognized in the County's Allocation. It is a separate commitment of water to specific sites. Please see other comments earlier regarding the Pebble Beach Entitlement.

The third paragraph on the pages says, "Similarly, because there is no guarantee that the 500 afy proposed to meet demand associated with hospitality industry rebound will actually go to that use, this analysis assumes that either the MPWMD or the local jurisdictions could elect not to set aside 500 afy exclusively for use by existing businesses. Therefore, some portion of this 500 afy could actually serve new development within the service area." The top of the page uses MPWMD analysis to support this.

If 500 AF is not needed to "cover" CII water use as a result of recovery from the recession, the water would be subject to the MPWMD Allocation program. It would not be automatically available to the jurisdictions, nor could a local jurisdiction elect how to use it. As indicated in earlier comments, your decision to assume the 500 afy is in excess is an unprovable assumption. To fully allocate water designed to provide a buffer against a revived economy would be unlikely. MPWMD-60 cont.

p. 6-25, Table 6.3-7: AMBAG made projections on housing units and population. As the number of housing units in CalAm shown increases by approximately 3,000 between 2010 and 2020, one can assume that AMBAG did not anticipate the CDO and moratorium on new connections, and the data is of marginal value. MPWMD-61

p.6-36, Section 6.3.5.3 and Table 6.3-8: Reference is made to the 20x2020 water conservation requirement and the author notes that the 2006 MPWMD estimate may need to be reduced by 20%. And Table 6.3.8 reduced needs to 2,820 using this suggestion. However, the factors used by MPWMD in 2006 assumed water efficient plumbing fixtures that would meet or exceed the requirements of 20x2020. Water needs should stay at the revised 3,526 afy and the 2,820 afy value should be stricken. MPWMD-62

Other: In Appendix K Water Conservation and Demand Management, please note the following: MPWMD-63

1. Need to add that MPWMD requires retrofit upon change of ownership ***and remodel or change of use.*** (Pg K-3, last paragraph)

2. Table K-1 is missing MPWMD's CII mandatory retrofit requirement.

My staff and I are available to meet if further coordination is needed. I can be reached at dstoldt@mpwmd.net or 831/658-5650 if you have questions.

Sincerely,

David J. Stoldt
General Manager

RE: Comments to Monterey Peninsula Water Supply Project
January 13, 2017 Draft Environmental Impact Report/Statement (DEIR)/(DEIS)

Dear Madam/Sir:

Please find below the comments to the Monterey Peninsula Water Supply Project's January 13, 2017 Draft Environmental Impact Report/Statement (DEIR)/(DEIS) as prepared by the Monterey Regional Waste Management District (MRWMD). These comments are submitted for your review and consideration during the project approval process. Thank you for the opportunity to submit these comments.

1. Figure 3-5a on Page 3-20 illustrates three (3) of the proposed new pipelines to be located in relatively undeveloped land to the north of the Monterey Regional Waste Management District's (MRWMD) property for the Charles Benson Road. The "Optional Alignment" for the three pipelines is located on MRWMD property under and/or along approximately one mile of Charles Benson Road. MRWMD supports the alignment of these three proposed new pipelines to be located in the relatively undeveloped land to the north of the MRWMD property containing Charles Benson. MRWMD-1

2. Figure 3-5a on Page 3-20 illustrates three (3) of the proposed new pipelines to be located in relatively undeveloped land to the north of the Monterey Regional Waste Management District's (MRWMD) property for the Charles Benson Road. The "Optional Alignment" for the three pipelines is located on MRWMD property under and/or along approximately one mile of Charles Benson Road. Charles Benson Road is used by MRWMD employees (>100), MRWMD customers carry non-hazardous waste materials (permitted for 2,000 waste carrying vehicles per day), several third-party lease operations employees at MRWMD, the Monterey Regional Pollution Control Agency (MRWPCA), deliveries to MRWMD and MRWPCA facilities, and several of the agricultural entities operating in the vicinity. Along the proposed "Optional Alignment" of the three pipelines, Charles Benson Road is two lanes wide. Given that Charles Benson Road is the main access to both the MRWMD and MRWPCA facilities and due to the volume of traffic associated with the two facilities, conventional 'cut and cover construction installation methods with one-way traffic control' does not appear to be an acceptable option to MRWMD. MRWMD anticipates that it would be necessary to construct a third traffic lane in order to provide two-way traffic to the MRWMD and MRWPCA facilities at all times during the construction installation of the proposed pipelines along Charles Benson Road. The construction of a third lane along one side of Charles Benson Road would require the removal of more than 150 trees (primarily Monterey cypress Hesperocyparis macrocarpa and secondarily, Eucalyptus globulus 'Compacta'). MRWMD anticipates that appropriate mitigation would be required should tree removal occur. MRWMD-2

SUBJECT: Comments on the joint Draft Environmental Impact Report/Environmental Impact Statement (Draft EIR/EIS) for the Monterey Peninsula Water Supply Project (MPWSP)

To whom it may concern,

Monterey Regional Water Pollution Control Agency (MRWPCA) owns and operates the outfall facilities that would be used by the Monterey Peninsula Water Supply Project for desalination brine disposal. As the owner and operator of the facility, MRWPCA is a responsible agency for the proposed project, and any use of the outfall must meet standards specified by MRWPCA. MRWPCA hereby submits the following comments on the Draft EIR/EIS for the MPWSP to identify analysis and mitigation that MRWPCA will need for its decision whether to approve use of its outfall facilities. Attached to this letter are more detailed comments on specific sections of the EIR/EIS (**Enclosure 1**).

1) The Draft EIR/EIS analysis of the impacts of the proposed project (a 9.6-million gallon per day desalination plant and associated source water intake and distribution) and most alternatives does not assume operation of MRWPCA and Monterey Peninsula Water Management District's (MPWMD's) Pure Water Monterey Project (PWM). PWM is an approved project that is moving forward through design and implementation, with groundbreaking scheduled for May 5, 2017. **Enclosure 2** provides a summary of the status of project implementation and a list of entitlements, permits, and authorizations received to date. The project is expected to be operational in late 2018, and therefore, will be operating for over a year before the desalination

MRWPCA-1

plant becomes operational. In particular, the effects analyses of brine discharge from the desalination plant through the MRWPCA's outfall facilities should reflect that PWM reverse osmosis concentrate will be a consistent component of flows in the outfall. In addition, secondary-treated effluent flows from the MRWPCA Regional Wastewater Treatment Plant through the outfall will be lower with PWM than has been assumed in the project analysis. For MRWPCA to be able to rely on the EIR/EIS to support its approval of use of the outfall facilities, the EIR/EIS must analyze project impacts under conditions that include PWM.

MRWPCA-1 cont.

2) MRWPCA has identified several improvements that must be completed prior to MRWPCA allowing use of the outfall for disposal of desalination brine to the ocean. Recent reports have been prepared assessing the integrity and materials of the outfall including the land portion from the beach junction structure inland (Land Outfall) and the ocean portion that extends from the beach structure out into the ocean (Ocean Outfall). The environmental impacts of constructing and operating each improvement must be described and evaluated in the EIR/EIS so that MRWPCA can rely upon the EIR/EIS as a responsible agency when it considers whether to allow use of the outfall. The improvements include the following:

   a. *Land Outfall Protection.* The Land Outfall must be lined to protect it from corrosion by the brine which can substantially shorten the useful life of the outfall. MRWPCA contracted with Brown and Caldwell at the expense of, and with input from, California American Water Company (CalAm) to prepare a detailed analysis of the current outfall condition and recommendations for corrosion protection. **Enclosure 3** (Brown and Caldwell, *Technical Memorandum: Land Outfall Pipeline Evaluation and Protection Measures,* January 9, 2017) describes the two most promising and feasible options for ensuring that the land outfall is protected from corrosion for the life of the project. The EIR/EIS includes a description and impact analysis of a third option that is no longer being considered for engineering reasons. The EIR/EIS should include a description and impact analysis of the two most promising and feasible options to enable MRWPCA to rely upon the EIR/EIS for the required CEQA compliance to approve accepting MPWSP desalination brine into the existing ocean outfall.

MRWPCA-2

   b. *Brine Mixing Structure*. This structure is required to properly mix and monitor the water quality of brine and treated wastewater flows to be discharged via the MRWPCA outfall in compliance with MRWPCA's NPDES permit requirements. A brine mixing structure is not required for discharge of PWM reverse osmosis concentrate alone or in combination with municipal wastewater or trucked brine. It is being designed by E2 Consulting Engineers at the expense of and with input from Cal Am because it is necessitated by the proposed Water Supply Project when the proposed project is operating in combination with MRWPCA's operations including PWM. A value engineering study that describes this facility is contained in **Enclosure 4**. Although the EIR/EIS describes the need for the brine mixing structure, the EIR/EIS should include a description of the brine mixing structure and its environmental impacts to enable MRWPCA and the RWQCB to rely upon the EIR/EIS for associated approvals.

MRWPCA-3

   c. *Beach Structure Erosion Protection*. The EIR/EIS identifies the need to protect the first 100 feet of the Ocean Outfall pipe; however, the EIR/EIS should also recognize that MRWPCA will be undertaking a Beach Junction Structure and Outfall Protection Project that will affect the same pipe segment. MRWPCA's beach junction structure that

MRWPCA-4

connects the Land Outfall to the Ocean Outfall was recently exposed due to coastal erosion during high wave storm events in December 2015 through March 2016. The Draft EIR/EIS should be updated to reflect the need to replace, remove, and/or modify the Ocean/Land Outfall junction structure and adjacent 650 to 1,000 feet of Land Outfall pipe due to the potential for coastal erosion to damage these structures within the life of the desalination plant. **Enclosure 5** (Technical Memorandum: Beach Structure Evaluation and Protection Measures) contains a technical memorandum by Brown and Caldwell that evaluates alternative design concepts and feasibility of these improvements and recommends a preferred project construction method. The project could also be designed to include pipe material that would not corrode. It would be preferable for the improvements to the junction structure and westernmost portion of the Land Outfall be completed prior to accepting brine discharges into the outfall to ensure that the ability to discharge brine and other treated wastewater effluent is not interrupted for project construction.

MRWPCA-4 cont.

d. *WEKO Seal Band Replacement*. After the Loma Prieta earthquake, MRWPCA identified cracks in the Ocean Outfall pipe and they were repaired from the inside. The metal bands hold neoprene seals in place to stop leaking. The bands are expected to be Type 316/316L stainless steel, an alloy known to be susceptible to chloride corrosion. The seals and metal bands, or at a minimum, just the metal bands, must be replaced prior to operation of the desalination plant to ensure the integrity of the joint connections are maintained for the life of the project, and such that the outfall can be continuously used for discharging brine, PWM reverse osmosis concentrate, and secondary-treated effluent. A discussion of this issue is provided in **Enclosure 3** at page 2 and **Enclosure 5** at page 2. MRWPCA requests that the EIR/EIS describe these improvements and analyze their environmental effects given that MRWPCA will require completion of these improvements prior to operation of the desalination project to ensure that the joints do not fail during the life of the project.

MRWPCA-5

e. *Ocean Outfall End Gate Modification*. The end of the Ocean Outfall has an approximately 2-inch opening below the End Gate that allows sediments and water to flow out into the ocean. With secondary effluent discharges, this end gate configuration provides additional mixing with ocean water because secondary effluent is buoyant. When desalination brine will be the main or only discharge, brine containing little to no dilution by other waters in the outfall pipeline would flow through this opening onto the seabed without the velocity and associated dilution afforded by the duckbill diffusers. **Enclosure 3,** page 2, provides a discussion of this improvement. The end gate may need to be modified to comply with California Ocean Plan and permitting requirements of the Regional Water Quality Control Board. The EIR/EIS should describe the improvements to the end gate, and identify any associated environmental impacts of constructing and operating the improvements.

MRWPCA-6

3) The EIR/EIS approach states that the discharge to the ocean (brine, concentrate, trucked brine, and secondary effluent) may not meet Ocean Plan requirements. If Ocean Plan compliance cannot be achieved with the present design of the project, then Cal Am would build additional facilities (such as modifying the outfall or adding treatment processes at the desalination plant and/or the Regional Treatment Plant) or would make operational changes (such as pulsing flows

MRWPCA-7

of brine to increase velocity, and thus dilution, of discharge at the diffusers on the outfall). MRWPCA requests that the additional facilities or operational protocols needed for Ocean Plan compliance be thoroughly described in the EIR/EIS and their impacts evaluated in the EIR/EIS. It is unclear if the information in the EIR/EIS will be adequate to enable MRWPCA and the RWQCB to rely upon the EIR/EIS for their approvals as responsible agencies. The EIR/EIS must present and evaluate the indirect effects of the implementation of feasible mitigation measures. MRWPCA urges the CPUC to improve the analysis of this issue in the EIR/EIS to ensure that the project can feasibly comply with the Ocean Plan and be permitted, and to enable use of the EIR/EIS by MRWPCA and the RWQCB as responsible agencies for their subsequent project approvals. Several specific concerns about the mitigation measures presented as methods to meet Ocean Plan compliance requirements include:

MRWPCA-7 cont.

a. Adding up to 5 mgd of wastewater into the outfall to dilute the brine is not feasible. MRWPCA does not have rights to bypass secondary treated wastewater to the outfall to meet CalAm's needs for Ocean Plan compliance and does not expect those entities holding the rights to authorize that use.

b. Installation of a 20-inch pipe within MRWPCA's land and ocean outfall, with an extension of the 20-inch pipeline through the side of the Ocean Outfall to a dedicated brine outfall near one of the Angle Points, would result in an ocean discharge into the "Zone of Prohibition" and would require MRWPCA to pump secondary effluent to the existing ocean diffusers during high flow events rather than let it flow by gravity as it currently does. This solution appears to be infeasible and MRWPCA would not support pursuing this physical change to the outfall.

Thank you providing us the opportunity to comment on this environmental review document. We look forward to reading your response. Please contact Bob Holden if you have any questions at bobh@mrwpca.com or (831)645-4634. We would like to meet with you at your earliest convenience to assist you with responding to these comments to ensure that MRWPCA's future actions can rely upon the final document for its decision whether to approve use of its ocean facilities.

Sincerely,

Paul A. Sciuto, P.E.
General Manager

Enclosures:

1. Detailed Comments to Specific Section of the EIR/EIS
2. PWM Project Implementation Status with list of Entitlements, Permits, and Authorizations Received to Date
3. Land Outfall Pipeline Evaluation and Protection Measures
4. Brine Mixing Structure Value Engineering Report and Process Flow Diagram
5. Beach Structure Evaluation and Protection Measures

CC: Bridget Hoover, Karen Grimmer, Eric Zigas, Paul Sciuto, Dave Stoldt, Bob Holden

NOTE: MRWPCA comments are shown in *bold/italics and proposed text inserts are shown in bold/italics/underlined.*

1. Section 3.3.9 Construction Schedule (Page 3-55). Construction July 2018 through June 2020. Construction of the slant wells would be over 15 months. Section 3.3.2.1 Subsurface Slant Wells (Page 3-47) states that slant wells construction (15 months) can be anytime during the 24-month overall construction project. The section goes on to say (Page 3-48) that after each well is drilled that it would be pumped for 2 to 6 weeks for well completion and initial well testing and discharge into the MRWPCA ocean outfall.

   Comment: CalAm would need to obtain MRWPCA's agreement to accept seawater into its outfall. Use of the outfall may be precluded during construction of the Ocean Outfall Erosion Protection Project, WEKO Seal Protection, and End Gate Protection improvements (described in the letter).

MRWPCA-8

2. Section 3.4.1 Operation of the Seawater Intake System, MPWSP Desalination Plant, and Brine Discharges (Pages 3-56 through 3-58). The section states that after a shutdown, CalAm might operate the plant with all RO modules in service (11.2 mgd versus Proposed Project capacity of 9.6 mgd).

   Comment: A higher brine flow may increase outfall diffuser dilution when brine was the only water going to the ocean. However, when other waters must be discharged together with the brine (including 24 hours per day, 7 days per week when the AWPF is operating), the outfall dilution will be reduced. MRWPCA requests that the EIR/EIS include brine modeling to show how dilution would be affected by these high flow events.

MRWPCA-9

- ***Ocean Outfall End Gate Correction (Project No. 59e?). See Section 2.2.2, Page 2, of Brown and Caldwell January 9, 2017 report, Enclosure 3.***

MRWPCA-11

b. Regional Urban Water Augmentation Project (RUWAP) Desalination Element (Project No. 31).

Comment: Remove "/Salinas Valley Reclamation Plant" from "Planning Jurisdiction/Location".

MRWPCA-12

c. Regional Urban Water Augmentation Project (RUWAP) Recycled Water Project (Project No. 35).

Comment: Change to one pump station and a 2 million gallon storage tank. Project will be built in two parts. Remove "/Salinas Valley Reclamation Plant" from "Planning Jurisdiction/Location". Expect construction from August 2017 through September 2018.

d. Monterey Pipeline and Pump station (Project No. 60).

Comment: Include location: Cities of Seaside, Monterey, and Pacific Grove. Include other environmental reviews undertaken, namely approval of the Water Distribution System Permit and Pipeline Alignment modifications by MPWMD that included approval of two Addenda to the PWM EIR.

MRWPCA-12 cont.

5. Table 4.3-9 Monthly Average Flows of Secondary Treated Wastewater from the MRWPCA Regional Wastewater Treatment Plant (MGD) (1998-2012).

Comment: MRWPCA provided these data to ESA and the CPUC in 2013. We believe it would be more appropriate to use average flows from 2011 through 2016 or even more recent averages. In 1998, 1999, and the start of 2000, growers were still connecting to the CSIP system resulting in higher values for flow to the ocean than after those years. The crops grown in CSIP have been evolving since the beginning. The increased farming of strawberries increases the amount of water used during the winter and thus reduces ocean discharge. Cost of potable water and increased conservation has been reducing overall sewage flow to the Regional Treatment Plant with a downward trend since 2002 resulting in less ocean discharge. The net result is that the more recent flows to the ocean are probably the most relevant for ocean discharge estimates. PWM, currently out to bid, will further reduce ocean discharge, especially during the winter. The reduced ocean flows may affect Table 4.3-10 Proposed Project Discharge Scenarios Modeled.

MRWPCA-13

6. Table 4.3-10 Proposed Project Discharge Scenarios Modeled.

Comment: MRWPCA believes, as stated for Table 4.3-9, above, that more recent ocean flows should be used. As stated in Table 4.1-1, above, we believe PWM should be assumed to be operational under all proposed project and alternatives scenarios. As such, it would be appropriate to conduct modeling based on PWM concentrate and correspondingly reduced effluent flow to the ocean. In addition, previous studies included trucked brine as one of the constituents of ocean discharge in all situations. It is not present in the analysis and should be. The modeling in the EIR/EIS Appendix D1includes the Ocean Outfall having an opening underneath the End Gate at the termination of the outfall. As the Ocean Outfall exists now, it will allow 5% of all the brine discharge water (per Appendix D1 Page 52) onto the seafloor with minimal dilution during negative buoyant conditions. The End Gate must be closed for MRWPCA to accept brine. All dilution calculations should be revised accordingly.

MRWPCA-14

MRWPCA-15

7. Section 4.3.5.3 Results and Impact Discussion.

Comment: MRWPCA objects to this section and the appropriate appendices (D1, D2, and D3)

MRWPCA-16

that support this section. MRWPCA believes that due to its signed Water Purchase Agreement that the PWM project must be assumed to be operating under all proposed project and alternative scenarios. Data in this section was not calculated with that assumption. Thus Tables 4.3-15 and 4.3-16 do not reflect any contribution from the Advanced Water Purification Facility and thus do not evaluate the actual environmental impact. And as stated above, they do not reflect closing the opening under the End Gate. MRWPCA cannot rely on the EIR/EIS for approval of use of its outfall facilities unless the analsis includes operation of PWM and reflects closing the opening under the End Gate.

MRWPCA-16 cont.

Table 4.3-16 MPWSP Operational Discharge Scenarios: Estimated Concentrations at the edge of the ZID expressed as percentage of Ocean Plan Objective for Ocean Plan Constituents (Page 4.3-99 through 4.3-101).

Comment: MRWPCA believes that the discharge scenarios modeled (Table 4.3-10, Page 4.3-70) should be increased to also include the potential higher flows described after an outage (Section 3.4.1, Pages 3-56 through 3-58). Also, there is a large range between scenario 4 (2 mgd secondary effluent and 13.98 mgd brine) and scenario 6 (19.78 mgd secondary effluent and 13.98 mgd brine). In Table 4.3-16, scenario 5 (9 mgd secondary effluent and 13.98 mgd brine) has a very high (68%) value for ammonia. No data is shown to determine if a higher percentage might be found between scenarios 5 and 4 (2 to 9 mgd) or between scenarios 5 and 6 (9 to 19.78 mgd). Especially when PWM is considered as part of this calculation, it is likely that percentages will be over 80% and may even reach 100%. MRWPCA will need assurance that the project will meet Ocean Plan (and NPDES permit) requirements from the beginning and in all conditions in which PWM is operating.

MRWPCA-17

Mitigation Measure 4.3-5 Implement Protocols to Avoid Exceeding Water Quality Objectives (Pages 4.3-103 through 4.3-106). Impact 4.3-5: Violate water quality standards or waste discharge requirements or otherwise degrade the water quality of receiving water in Monterey Bay as a result of brine discharge from the operation of the MPWSP Desalination Plant. Section 5.5.3.8 Direct and Indirect Effects of Alternative 5 – Reduced Desal Project 5a (CEMEX) and 5b (Potrero Road)-(Pages 5.5-59 through 5.5-78). In particular, Table 5.5-11 (Page 5.5-76) shows expected violation of Ocean Plan.

Comment: MRWPCA requests that the EIR/EIS provide more description and impact analysis of feasible mitigation measures to allow MRWPCA to accept desalination brine from CalAm. The EIR/EIS should determine and present analysis to indicate whether effluent will meet the Ocean Plan requirements. If it will not, then additional mitigation measures should be included in the EIR/EIS to enable an analysis of indirect impacts of the mitigation and consideration of feasibility by CalAm and the decision-makers.

MRWPCA-18

The Mitigation Measure 4.3-5 measures to ensure Ocean Plan compliance include four separate approaches (pages 4.3-104 and 4.3-105) and Section 4.3.5.4 Secondary Impacts of Mitigation Measure 4.3-5, (Pages 4.3-106 through 4.3-110).

1) Additional pretreatment of source water to the Desalination Plant.
    a. Additional filtration at desalination facility
    b. Granular activated carbon (GAC) at desalination facility

Comment: Both options are acceptable to MRWPCA but do not improve Ocean Plan

MRWPCA-19

compliance for all constituents.

2) Treatment of discharge.
The three options provided include:
   a. GAC at desalination facility
   b. Advanced oxidation with ultraviolet light with concurrent addition of Hydrogen peroxide at desalination facility
   c. Biologically Active Filtration (BAF) at Regional Treatment Plant.

Comment: The two desalination facility options (GAC and Advanced Oxidation) are acceptable to MRWPCA but do not improve Ocean Plan compliance for all constituents of concern. The third option, BAF, could be acceptable to MRWPCA if it were for reverse osmosis concentrate but can no longer be located where it was shown within the PWM FEIR. MRWPCA's plans for the Advanced Water Purification Facility do not accommodate space or utility/operational demands of a BAF process. Also regarding the third option, the heading says Biologically Active Filtration System to Treat the Brine. Is it to treat the brine? MRWPCA is not aware of a BAF system for brine. MRWPCA's BAF system within its PWM FEIR was for AWPF concentrate and not for brine. This option is not acceptable as stated.

MRWPCA-19 cont.

3) Retrofitting the existing outfall to increase dilution. This would be accomplished through retrofitting the outfall diffusers to be inclined upward to increase dilution.

Comment: This option is not acceptable to MRWPCA as currently defined. This option might prevent MRWPCA from meeting its NPDES discharge requirements whenever the desalination facility was offline. MRWPCA could be agreeable to other mitigation measures to increase dilution such as reducing the number of open diffuser ports and/or reducing the size of the diffusers, and/or changing the Tideflex duckbill diffuser nozzles to a different type or removing them altogether.

MRWPCA-20

4) Flow augmentation. This would be accomplished through addition of up to 5 mgd of flows near the density of fresh water.

Comment: This option is not considered to be feasible, unless an additional/new secondary effluent or water having better quality that would not require treatment were identified and proposed. Secondary effluent is mentioned as possible water in Appendix D1 but neither CalAm nor MRWPCA has rights to use that water for diluting brine.

MRWPCA-21

8. Section 4.4.5.2 Operational Impacts and Mitigation Measures (Pages 4.4-57 through 4.4-87). Figure 4.4-15 (Page 4.4-62).

Comment: MRWPCA's two wells in the 180-foot aquifer should be shown.

Figure 4.4-16 (Page 4.4-63).

Comment: Two MRWPCA wells in the 180-foot aquifer are shown but are incorrectly shown as being located in the 400-foot aquifer. One additional well is in the 400-foot aquifer.

MRWPCA-22

Table 4.4-10.

Comment: The MRWPCA portion of the table incorrectly shows wells 14S/02E-20B01 and 14S/02E-20B02 as being in the 400-foot aquifer when they are in 180-Foot aquifer. Well14S/02E-20B03 is shown in the 900-foot aquifer when it is in the 400-Foot aquifer.

MRWPCA-22 cont.

9. Section 4.5.5.2 Operational and Facility Siting Impacts (Pages 4.5-51 through 4.5-66).

Comment: Please see MRWPCA comments on this issue as discussed under Section 4.3.5.3, above.

MRWPCA-23

10. Impact 4.13-5: Increased corrosion of the MRWPCA outfall and diffuser as a result of brine discharge associated with project operation (Page 4.13-25 through 4.13-31). There are two mitigation measures 4.13-5a for the Ocean Outfall (lining 100 feet of the pipeline) and mitigation measure 4.13-5b for the Land Outfall (line the entire length).

Comment: Protection of the Ocean Outfall will be ensured by the improvements identified in the MRWPCA comment letter of March 2017 not by the Ocean Outfall Lining described:

- ***a. Ocean Outfall Protection (See report "Beach Structure Evaluation and Protection Measures", dated January 30, 2017, by Brown and Caldwell, Enclosure 5).***
- ***b. WECO Seal Replacement (See Section 2.4.2.2, Page 5, of Brown and Caldwell January 30, 2017 report in Enclosure 5 and Section 2.2.3, Page 2, of Brown and Caldwell January 9, 2017 report in Enclosure 3).***
- ***c. End Gate Protection (See Section 2.2.2, Page 2, of Brown and Caldwell January 9, 2017 report in Enclosure 3). This is not a corrosion issue but is included here as it is an essential improvement for use of brine and essential to allow dilution of the brine before it reaches the ZID or BMZ. It is shown here as it is part of an ongoing corrosion study.***

Protection of the Land Outfall.

Comment: The Land Outfall lining project has been defined more fully.

- ***a. Land Outfall Protection (See report "Land Outfall Pipeline Evaluation and Protection Measures", dated January 9, 2017, by Brown and Caldwell, in Enclosure 3). MRWPCA would like last sentence of Section 4.13.5.2 to read, "<u>However, CalAm shall enter into an agreement whereby MRWPCA would obtain all necessary RWQCB approvals and permits to temporarily run the pipe along or below the ground surface</u>."***

Comment: MRWPCA requests that the EIR/EIS include a description and analysis of the construction and operation of a Brine Mixing Structure in accordance with the information in Enclosure 4.

MRWPCA-24

11. Table 5.3.2 Outfall Options Screening Results (Page 5.3-19 and 5.3-20) and Section 5.3.4.1 Outfall Option 1 – Modified MRWPCA Outfall and New Diffuser. Table 5.3-5 Outfall Options Evaluation – Preliminary Environmental Impacts Comparison (Pages 5.3-38 through 5.3-43)

Comment: The Outfall-1 Alternative proposes to suspend a 20-inch pipe within the existing outfall with a new diffuser section for use during wet-weather flows only. This option was "retained for Further Analysis". This is similar to a previous proposal, which is not considered

MRWPCA-25

to be feasible by MRWPCA due to restricting the outfall pipe's usefulness and removing the ability to repair the pipeline from the inside. In addition, this alternative would result in extreme disruption to the ocean outfall for the pipe insertion and the new diffuser construction. Ocean flow disruption might be limited to 0.5 acres if sheet piling is used. We think a well planned construction contract might only discharge undiluted effluent into the Zone of Prohibition for two or three days, and might be feasible. However we believe it would be very difficult, if not impossible, to achieve regulatory approval to discharge diluted brine into the Zone of Prohibition on a continuous basis.

MRWPCA-25 cont.

Typos (various locations):

- Change all use of the phrase "Ground Water Replenishment Project" to "Groundwater Replenishment Project"
- Change all use of the phrase "CSIP Pond" to the "Salinas Valley Reclamation Project (or SVRP) Storage Pond"
- Change all spellings of "Trussel" to Trussell

MRWPCA-26

Enclosure 2 - Pure Water Monterey Implementation Status as of March 17, 2017

Designs for the Pure Water Monterey first phase project components are complete and bids are being solicited for construction of those facilities. The first phases of construction are scheduled to being in May 2017 and conclude in the fall of 2018 with commissioning and start-up testing. Thus, the Pure Water Monterey project is on schedule to provide 3,500 acre-feet per year of water and approximately 4,000 to 5,000 acre-feet per year of agricultural irrigation water starting at the end of 2018. These new water supplies will allow CalAm to reduce Carmel River diversions and improve the conditions of local groundwater basins.

The Pure Water Monterey project has also received most entitlements needed to be constructed. By the end of April, all entitlements are anticipated to be in place to enable construction of the primary phases of facilities (Source Waters – Surface Diversions, Advanced Water Purification Facility, Product Water Conveyance, and Injection Facilities).

- MRWPCA approval of the project and certification of the EIR (October 8, 2015)
- California Public Utilities Commission approval of a Water Purchase Agreement with California American Water Company (September 22, 2016)
- State Water Resources Control Board (SWRCB) Division of Drinking Water approved the project's Title-22 Engineering Report with conditions (November 7, 2016)
- National Marine Fisheries Service Endangered Species Act Section 7 Consultation completed with a Letter of Concurrence (December 5, 2016)
- U.S. Fish and Wildlife Service Endangered Species Act Section 7 Consultation completed with Biological Opinion (December 20, 2016)
- Monterey County approved the Minor Use Permit Amendment for construction of the Advanced Water Purification Facility (February 22, 2017)
- Central Coast Regional Water Quality Control Board issued a Waste Discharge Requirement for the Advanced Water Purification Facility and the injection of purified recycled water into the Seaside Basin (March 9, 2017)
- SWRCB Division of Water Rights issued the water rights to use surface waters in Blanco Drain and Reclamation Ditch for recycling and reuse (March 17, 2017)

Other key approvals are anticipated in March or April, including the following:

- SWRCB Division of Water Rights issuance of a Water Quality Certification for components in riparian areas and waterbodies (expected March 31, 2017)
- SWRCB grant and loan initial funding agreements under Proposition 1 and the Clean Water State Revolving Fund (expected mid-April 2017)
- U.S. Army Corps Reissuance of Nationwide Permit for construction in waters of the United States (expected April 14, 2017)
- California Department of Fish and Wildlife Lake and Streambed Alteration Agreement for components in riparian areas and waterbodies (estimated April or May 2017)
- State Lands Commission - Land Lease approval (on the commission agenda for consideration on April 22, 2017)
- Various land owner lease and right of way agreements (ongoing)

8.5.1 Responses to Comments from City of Marina

8.5.1.1 Responses to Comments from City of Marina – Main Letter

Marina-A This comment provides an introduction to the fact that the City of Marina is a Responsible Agency for the proposed project under CEQA due to its authority to issue a Coastal Development Permit (see EIR/EIS Section 1.5.4.3), and that the City is providing comments on the CEQA adequacy of the Draft EIR/EIS on behalf of the citizens of Marina, and on the adequacy of the Draft EIR/EIS under NEPA. The comment explains who prepared the comments on behalf of the City and provides an overview of the organization of the expressed concerns, which include water demand, water rights, conflicts with the Sustainable Groundwater Management Act (SGMA), legal prohibitions, adequacy of the project description, the baseline, impacts on groundwater, adequacy of the groundwater modeling, impacts from brine discharge, impacts on coastal ecosystems, greenhouse gas emissions, impacts on historic resources, adequacy of the analysis of environmental justice and of alternatives. The concerns expressed in this comment are subsumed within the following, more detailed comments and responses.

Marina-1 CEQA Guidelines Chapter 3, Article 9 ("Contents of EIRs" §§ 15120-15132) does not require that a Draft EIR include a Mitigation Monitoring and Reporting Program (MMRP). Specifically, CEQA Guidelines Section 15126.4 ("Consideration and Discussion of Mitigation Measures Proposed to Minimize Significant Effects") requires that a Draft EIR describe proposed mitigation measures, but does not include mention of an MMRP. Further, CEQA Guidelines Section 15132 ("Contents of Final Environmental Impact Report") does not require the inclusion of an MMRP in a Final EIR. Rather, an MMRP is required to be prepared and adopted at the time a lead agency makes findings in preparation for approving a project (CEQA §21081.6; CEQA Guidelines §§15091(d) and 15097). The absence of an MMRP in the Draft EIR/EIS does not trigger a need to recirculate the Draft EIR/EIS (CEQA Guidelines §15088.5), nor does CEQA mandate that responsible agencies and other interested parties be given an opportunity to comment on the MMRP. Rather, CEQA Guidelines Section 15097(d) states that (at the time the MMRP is being prepared and considered for adoption), "Lead and responsible agencies should coordinate their mitigation monitoring or reporting programs where possible," but clarifies that "Generally, lead and responsible agencies for a given project will adopt separate and different monitoring or reporting programs." The Guidelines list several reasons that may occur, including that "each agency has the discretion to choose its own approach to monitoring or reporting."

The contents of an MMRP depend on what project or alternative is approved by the lead agency and which mitigation measures are being adopted by the agency to mitigate or avoid significant environmental effects. Those decisions have not yet been made and it would, therefore, be speculative to prepare an MMRP for public review at this stage. All mitigation measures that are currently proposed and that

would, at the time of preparing findings, be incorporated into an MMRP if relevant to the project or alternative being selected were included in full in the Draft EIR/EIS and are included, as revised, in the Final EIR/EIS as required by CEQA and NEPA. Nothing in this comment letter or the associated responses triggers a need for recirculation per CEQA Guidelines Section 15088.5. Furthermore, the Draft EIR/EIS was itself a revised, updated and enhanced version of the Draft EIR that was published by the California Public Utilities Commission for the MPWSP in April 2015. The environmental review for the MPWSP has entailed a lengthy process with multiple opportunities for public review and comment.

The comment states generally that many of the EIR/EIS mitigation measures lack sufficient detail to establish feasibility and methods of implementation. This comment lacks specificity needed to enable a substantive response; however, the Lead Agencies have carefully crafted the mitigation measures to be clear, comprehensive, feasible and to include performance standards for implementation.

Marina-2 The project objectives listed in EIR/EIS Section 1.3.1 were developed by the Lead Agencies; further discussion of the water needs associated with vacant legal lots of record, water supplies to pay back the Seaside Basin, and conveyance capacity is provided in EIR/EIS Section 2.3.3.3, Section 2.4.2, and Section 6.3.5.2. See also Master Response 13, Demand (Project Need) and Growth, specifically, Section 8.2.13.2. Objective and need statements provided by CalAm are included in Appendix H of its March 14, 2016 Amended Application, which is referenced in Chapter 2 as CalAm, 2016a.

Marina-3 See Master Response 13, Demand (Project Need) and Growth, regarding the estimate of existing annual demand and other service area demands proposed to be served by project water and CalAm's other supply sources. Two of the factors that have resulted in the decline in water use in recent years have been the "Great Recession" and the recent five-year drought, as discussed further in Master Response 13 and in EIR/EIS Section 2.3.

The meaning of the phrase "even after anticipated litigations and restrictions" is not clear. A purpose of the project is to replace Carmel River and Seaside Groundwater Basin water that CalAm had historically used because its use of those sources was reduced – not eliminated – by State Water Board and Superior Court decisions. This background is discussed in EIR/EIS Section 2.2. CalAm's other supply sources are discussed in Section 2.4 and in Master Response 13, Section 8.2.13.3.

As stated in the first paragraph of Chapter 2, the chapter describes the water demand, supply information and assumptions included in CalAm's application, and provides supplemental information about factors affecting water supply and demand and in the CalAm service area. The information on supplies and demands (Sections 2.1 through 2.5) is essentially descriptive and augments the Project Description. Section 6.3, Growth Inducing Impacts, analyzes the demand CalAm

anticipates and proposes to meet, to ensure that the growth inducing impact of the project is adequately disclosed and analyzed. The analyses presented in Chapters 4 through 6 evaluate the impacts of the project proposed to meet the demand, and the amount of water proposed to be pumped, treated, and delivered to the CalAm service area (immediately or via the ASR system). If it turns out that less water is needed, it is anticipated that CalAm would operate the desalination plant at a lower level, and impacts related to pumping and treatment would be somewhat less than presented in the EIR/EIS analysis. See also the discussion under "Water Available for Growth" in Master Response 13.

Marina-4 The EIR/EIS discussion of demand for and supply of water did not form the basis for the CEQA project objectives or the NEPA project purpose and need statement. The project objectives are set forth in full in EIR/EIS Section 1.3.1. As indicated there, the primary purpose of the proposed project is "to replace existing water supplies that have been constrained by legal decisions affecting the Carmel River and Seaside Groundwater Basin water resources." The list of project objectives includes nine primary objectives and two secondary objectives. Of those, only three contain set levels of water that the project seeks to satisfy, but these are not based on supply and demand. They are based upon the need for CalAm to meet clear legal requirements:

1. Replace existing Carmel River diversions in excess of CalAm's legal entitlement of 3,376 afy, in accordance with SWRCB Orders 95-10 and 2009-0060;
2. Reduce pumping from the Seaside Groundwater Basin from approximately 4,000 to 1,474 afy, consistent with the adjudication of the groundwater basin, with natural yield, and with the improvement of groundwater quality, and;
3. Pay back the Seaside Groundwater Basin by approximately 700 afy over 25 years as required of CalAm by the Seaside Groundwater Basin Watermaster.

None of these numeric goals is based upon demand assumptions. Master Response 13, Demand (Project Need) and Growth, discusses a variety of ways to view current and future supply and demand, and project alternatives that could be pursued under differing scenarios. See also EIR/EIS Section 2.6, Water Rights, and Master Response 3, Water Rights, concerning water rights issues, and EIR/EIS Section 4.4, Groundwater Resources, with respect to water supply and water quality impacts.

Marina-5 The commenter is correct that a water supply project needs to identify that it can obtain water from an identified source. However, so long as it is clear where the source water will come from (as is the case here), the subject of the rights to the source water is one of project feasibility because, without rights to the source water, the project would not be viable. See EIR/EIS Section 2.6, Water Rights, and Master Response 3, Water Rights, for details on this topic.

The cases cited by the commenter arose in different contexts and did not involve water supply projects. The issue in both *Santa Clarita Org. for Planning the Env't v. City of Los Angeles*, 106 Cal, App, 4th 715 (2003) and *Save Our Peninsula Comm. V. Monterey Cty. Bd. Of Supervisors*, 87 Cal. App. 4th 99 (2001) was whether there would be enough water to serve a housing development project, with the concern that if such water were not physically available, the homes would be built and occupied and there would be insufficient water for those homes and for the remainder of the community. The case of *Cadiz Land Co. v. Rail Cycle, L.P.*, 83 Cal. App. 4th 74 (2000) involved an EIR for a landfill project, with the concern being accurate baseline characterization of the aquifer over which the landfill would lie in order to fairly ascertain the risk posed by a landfill to a groundwater source. EIR/EIS Section 4.4, Groundwater Resources, describes the potentially affected aquifers in detail and examines possible impacts to them, including risks of exacerbating contamination. None of the cases cited in the comment involve water rights issues.

See Master Response 6, The Sustainable Groundwater Management Act, for discussion of the applicability and effect of this law on the project. See Master Response 8, Project Source Water and Seawater Intrusion, concerning project effects within the groundwater basin. With respect to Marina being a minority community, see EIR/EIS Section 4.20, Socioeconomics and Environmental Justice, where this is acknowledged and environmental effects are addressed accordingly.

Marina-6 See Master Response 3, Water Rights. Note that the cited SWRCB Report (EIR/EIS Appendix B2) does not discuss cumulative effects, but EIR/EIS Section 4.4.6 contains an analysis of cumulative effects on groundwater resources. See also Master Response 4, The Agency Act and Return Water; Master Response 7, The Deeper Aquifers of the Salinas Valley Groundwater Basin; Master Response 11, CalAm Test Slant Well, and; Master Response 12, The North Marina Groundwater Model (v. 2016).

Marina-7 The project's consistency with SGMA (concluding that the project would not result in the undesirable results addressed by SGMA) is addressed in Master Response 6, The Sustainable Groundwater Management Act, and in Section 4.4, Groundwater Resources. Water rights are addressed in Master Response 3, Water Rights. The commenter notes that Water Code section 10720.5 "bars the use of groundwater extraction after January 1, 2015 in high-priority basins (like the SVGB) to establish prescriptive water rights." While this is correct, the proposed project would not rely upon prescriptive water rights, but rather would expect to use appropriative water rights pursuant to California common law. Water Code section 10720.5(b) provides "Nothing in [SGMA], or in any groundwater management plan adopted pursuant to [SGMA], determines or alters surface water rights or groundwater rights under common law. . . ." It thus does not appear that SGMA would impair the ability of CalAm to possess water rights for the project under common law appropriative rights. Marina-8 See Master Response 3, Water Rights, and Master Response 4,

The Agency Act and Return Water. The EIR/EIS analyzes inconsistencies with applicable plans and policies within each topical section in Chapter 4. The Agency Act's statements of its general purposes do not constitute legal requirements, but set forth the underlying policies behind the requirements, which are themselves analyzed in the EIR/EIS. Furthermore, the topic of project effects on seawater intrusion is explored in EIR/EIS Section 4.4, Groundwater Resources, and in Master Response 8, Project Source Water and Seawater Intrusion, concluding that the project would not adversely impact, and may retard, the inland migration of seawater.

As to Ordinance 3709, whereby the County precludes the establishment of new wells within the 180-Foot Aquifer, the EIR/EIS has been updated in Sections 2.6.3 and 4.4, Groundwater Resources, to reflect the fact that the CEMEX property where project slant wells would be located does not lie within the area subject to the Ordinance. Thus, feasibility and operations of the proposed project would not be affected by Ordinance 3709.

Marina-9 See Master Response 3, Water Rights, Section 8.2.3.8, Effect of Annexation Agreement. Also see Master Response 4, The Agency Act and Return Water, and Master Response 8, Project Source Water and Seawater Intrusion. Changes have been made to Section 2.6, Water Rights, in response to this comment.

Marina-10 The project description in EIR/EIS Chapter 3 provides factual information about the proposed project location in text and figures. The wells are described in EIR/EIS Section 3.2.1.1 as being located in the City of Marina. EIR/EIS Table 3-1 explains that each slant well would extend beneath the coastal dunes, sandy beach, and the surf zone, terminating seaward of the Mean High Water (MHW) line within MBNMS, except #10 which would not extend past the MHW line.[1] The EIR/EIS also explains that each well would be screened for approximately 400-800 linear feet at depths corresponding to both the Dune Sands Aquifer and the underlying 180-Foot-Equivalent Aquifer of the Salinas Valley Groundwater Basin. However, in response to comments about the characterization of the source water in the Draft EIR/EIS, the EIR/EIS has been revised to include in Section 3.1.1.1, definitions of the components of source water that are used throughout the EIR/EIS and the EIR/EIS text has been revised accordingly for clarification. For example, Table 3-1 now explains the wells would draw ~~sea~~water from groundwater aquifers that extend beneath the ocean floor…for use as source water.

Furthermore, EIR/EIS Figure 3-3a presents an accurate, to-scale, geo-referenced plan view of the location of the proposed wells within the City of Marina relative to the MHW line, and Figure 3-3b (there is no Table 3-3b) is labeled "illustrative." While the EIR/EIS acknowledges the wells would be located in the groundwater aquifers and explains that the source water would be primarily seawater drawn through those aquifers, it does not represent that the groundwater aquifers

[1] Numbering in Figure 3-3a has been revised; this is now labeled Slant Well #10.

underlying the City of Marina contain ocean water. See also Master Response 2, Source Water Component and Definitions, for further explanation, and Master Response 8, Project Source Water and Seawater Intrusion. The legal references in the comment for definitions of groundwater are consistent with the geographic, locational definition of groundwater that is provided in Master Response 2. However, such groundwater may comprise seawater, brackish water, or fresh water, as those terms are defined by their chemical constituency in Master Response 2. These more specific definitions focus on the usability/functionality of the water and are more pertinent to the key analyses within the EIR/EIS of whether the project would adversely alter groundwater quality or adversely impact groundwater users (see Section 4.4, Groundwater Resources) and whether the project would cause harm to legal water users within the SVGB (see Section 2.6, Water Rights, and Master Response 3, Water Rights). For instance, it is only by considering the chemical constituency of water drawn into the project capture zone and water otherwise within the SVGB that the EIR/EIS could conclude that the project may help retard the rate of seawater intrusion within the area.

Marina-11 Text in EIR/EIS Section 3.2.1.1 has been revised as follows to reflect the evolving technology of slant wells:

> When compared to vertical wells, slant wells <u>are a new and evolving technology that</u> allow<u>s</u> for a substantially increased screen length in the target water source, resulting in higher production rates <u>than vertical wells</u>.

The Huntington Beach Independent Scientific Technical Advisory Panel (HB ISTAP) *Phase 1 Final Report* noted -- not concluded -- that based on the experience at Dana Point, "the long term performance of the [slant well] technology has yet to be confirmed." See Master Response 11, CalAm Test Slant Well, Section 8.2.11.8, where this document is cited as HB ISTAP, 2014.

The March 2016 Santa Barbara Subsurface Desalination Intake Feasibility Study Technical Memorandum No. 1 cited by the comment (Carollo, 2016) does not have a page 3-19, nor does it contain the presented quotes. However, the 2017 Final Feasibility Study (Carollo, 2017) does contain the presented quotes, the full context of which follows: "At present, no full-scale desalination plants exist that employ slant wells for source seawater collection. As discussed previously, the slant wells have been tested for over six years at the Dana Point test site and are currently being evaluated at a test site near Monterey, CA. The overall experience with Dana Point was positive, but results indicated the system did not collect only seawater but instead a mix of seawater and fresh water from the alluvial aquifer in the vicinity of the intake location." (Carollo, 2017, p. 3-19)

See Master Response 11, Section 8.2.11.8 for further discussion of this study and the Dana Point Test Slant Well. Furthermore, the construction of the Dana Point slant well did not take an unusually long time; the drilling of the slant well

borehole was initiated on February 4, 2006 and the well casing reached final depth on February 25, 2006 (USBR, 2009). Additionally, as discussed in Master Response 4, The Agency Act and Return Water, and Master Response 8, Project Source Water and Seawater Intrusion, the indication that the Dana Point test system collected both seawater and aquifer water is consistent with expectations for and analyses of the proposed intake system for the MPWSP. See also Master Response 2, Source Water Components and Definitions.

The alternatives analysis in EIR/EIS Section 5.3 evaluated 13 separate intake options, including alternative subsurface well locations, alternative subsurface well technology, and open water intake facilities and locations. The comparative evaluation is presented in Table 5.3-4 and conclusions of that evaluation are included in Section 5.3.6.

Nothing presented in this response meets the CEQA threshold for recirculation as defined in CEQA Guidelines Section 15088.5.

Marina-12 The test slant well is an existing project that underwent separate CEQA and NEPA review, described in Master Response 11, CalAm Test Slant Well, Sections 8.2.11.2 and 8.2.11.3. As such, its installation and ongoing operation were evaluated in this EIR/EIS as a cumulative project and is identified as project No. 47 in EIR/EIS Table 4.1-2. It is not part of the proposed MPWSP and thus extensive details of its construction and implementation are not appropriate for inclusion in Chapter 3, Description of the Proposed Project. For clarification, the estimated construction schedule shown for the test slant well in that table has been revised as follows:

> "April 2015 Construction completed, pilot program currently underway."

The test slant well data was employed to assess the 2016 version of the North Marina Groundwater Model ($NMGWM^{2016}$) performance, and results presented in EIR/EIS Appendix E2, Section 4.2 indicate that, "There is generally good agreement between the model-calculated and measured timing of drawdown and recovery" of the test slant well data. The results of the test well pumping are presented in a technical memo prepared by the HWG; see Final EIR/EIS Appendix E3.

Marina-13 The "acceptable level" was described in Draft EIR/EIS Section 3.2.2.5 on page 3-27: "The brine storage and disposal system would consist of … a brine aeration system to maintain dissolved oxygen concentrations in the brine at 5 mg/L." As described in EIR/EIS Section 4.3.1.3, Surface Water Quality, ambient dissolved oxygen levels in Monterey Bay at a depth of approximately 100 feet have ranged from 4.25 mg/L to 8.00 mg/L, and explains that dissolved oxygen in the range of 5 to 8 mg/L is considered protective of fish and marine biota depending on the species and life-stage.

Marina-14 See Draft EIR/EIS page at 4.17-3: "Active sand mining operations no longer occur in the southern portion of the CEMEX property, and this area is retired and under reclamation." See also Master Response 14, CEMEX Settlement Agreement, for an updated discussion of the status of the CEMEX site.

Marina-15 The text in Table 3-1 and Section 3.2.1.1 has been revised as follows:

> The wellheads (surface components) for the ten slant wells would be located at six sites ~~along the back~~ inland ~~side~~ of the dune~~s~~ face.

This change does not affect any analyses or conclusions of the EIR/EIS.

Marina-16 See Final EIR/EIS Section 1.5.3; Terminal Reservoir is no longer part of the proposed project, and has been removed from the project description and impact analyses.

Marina-17 The graded road at CEMEX shown on EIR/EIS Figure 3-3a would provide access to the slant well sites for maintenance activities and it would be accessed from the source water pipeline easement. CEMEX uses a graded access from the existing access road to the retired mining area that CalAm would use to access the wells. See Master Response 14, CEMEX Settlement Agreement, Section 8.2.14.2. EIR/EIS Section 3.4.1 explains that maintenance activities would disturb roughly 6-acres every 5 years. Since mining no longer occurs in this area (see response to Marina-14), there would be no conflict with mining operations. Potential long-term impacts on the 6 acres of dune complex from operations and maintenance activities at the slant wells were described in the Draft EIR/EIS starting on page 4.6-234, at page 4.6-244, and again at page 4.6-247 and some of these temporary acres of disturbance are conservatively considered to be permanent acres, because of the frequency of disturbance. Therefore, the potential impact from having to grade the road more frequently has been addressed and mitigation identified.

Marina-18 The text in EIR/EIS Section 3.2.1.2 has been revised to reference "well sites" instead of "well clusters."

The Source Water Pipeline Optional Alignment has been evaluated throughout the EIR/EIS in each Chapter 4 resource section. This analysis was included within the Draft EIR/EIS, so no changes are needed. The Project Area Boundary on Figures 3-4 and 3-5a has been revised to include this component.

Marina-19 Public tours of the desalination plant are not part of the proposed project. The 20-foot by 20-foot Overlook Tour Stop shown on EIR/EIS Figure 3-5b would include benches and landscaping and would accommodate desalination plant employee use, as well as occasional private tours for individuals or small groups of regulators, researchers, etc.

Marina-20 The temporary storage described in Section 3.2.2.5 is not intended to address longer-term brine storage in the event that outfall repairs may be needed. As described in Section 4.13, Public Services and Utilities (see Draft EIR/EIS page 4.13-24), "…the brine stream, when combined with instantaneous peak flows of wastewater effluent from the MRWPCA Regional Wastewater Treatment Plant, could exceed the capacity of the outfall and diffuser during large storm events. Based on previous studies prepared by Trussell Technologies…six hours of storage capacity would provide more than adequate storage during periods of peak effluent flow (Trussell Technologies, 2012). The 3-million-gallon brine storage basin described in Section 3.2.2.5 has sufficient capacity to detain flows from approximately 6 hours of desalination plant operations." Therefore, Section 3.2.2.5 has been revised to reflect 6, not 5, hours of storage time.

Section 3.4.1 describes operation of the desalination plant in the event of a shutdown, and such operational conditions are analyzed as appropriate throughout the EIR/EIS.

Marina-21 The last paragraph of Section 3.2.2.5 explains that the "ports are approximately 6 inches above the ballast rock and nominally 54 inches above the seafloor, although this varies." See Draft EIR/EIS Section 4.3, Surface Water Hydrology and Water Quality, at page 4.3-68; also Appendix D1, Section 3, Outfall Hydraulics, and Figure 6, where the outfall and dilution assumptions are further described.

The brine discharge modeling and analysis included several conservative assumptions, such as the height of the ports above the seafloor. The modeling results indicate that at 48 inches above the seafloor, the densest brine plume evaluated would contact the seafloor well within regulatory limits. If the ports were in fact at 54 inches above the seafloor, the additional height would allow for increased dilution before the plume makes contact. The impact summary and conclusion in Draft EIR/EIS Section 4.3.5.2 starting on page 4.3-85 includes a discussion of the conservative approach taken to the analysis. No new information is being provided in response to this comment; there is no cause for recirculation of the Draft EIR/EIS. See also response to comments from MRWPCA in Section 8.5.9.

Marina-22 Figure 3-6 is correct and matches the text in EIR/EIS Section 3.2.3.3. The New Desalinated Pipeline is described in Section 3.2.3.3 as running parallel to Lapis Road until it meets Del Monte Boulevard, at which point it would be built under the Monterey Peninsula Recreational Trail and Transportation Agency for Monterey County (TAMC) right-of-way.

The new Desalinated Water Pipeline was evaluated in the Draft EIR/EIS consistent with the description in Section 3.2.3.3. To be consistent with the text, the Project Area Boundary on Figures 3-4 and 3-5a has been revised to include this component. No further change to the EIR/EIS is required.

Marina-23 The EIR/EIS identifies seven paved parking lots and one sandy area that are proposed as construction staging areas in Table 3-4 and describes them in Section 3.3.1.2. All resource sections evaluate the staging areas as appropriate. Figures 3-6 through 3-8 have been revised to reflect a more accurate footprint for the trenchless pipeline ingress/egress locations; however, the EIR/EIS analysis for the use of these sites accurately addresses their size and location. There are no trenchless construction ingress/egress pits proposed within the area covered by Figure 3-9, and this figure has not been revised in response to this comment.

Marina-24 The engineering constraints mentioned in the discussion of the Pipeline to CSIP Pond in Section 3.2.3.8 are associated with the proposed Castroville Pipeline connection to CSIP, not the Castroville Pipeline. The issue is related to where in the CSIP system the return water is introduced: in the middle of the system as proposed with the Castroville Pipeline or at the head of the system via the Pipeline to CSIP Pond. The EIR/EIS provides coverage for both pipeline options in each topical section of Chapter 4. For example, see the tables in each section that present the regional and local land use plans, policies, and regulations pertaining to each applicable resource that were adopted for the purpose of avoiding or mitigating an environmental effect.

Marina-25 EIR/EIS Table 3-1 and the text in Section 3.2.1.1 explain that the five new well sites (i.e., those accommodating the nine new slant wells) would each include a 5,250- to 6,025-square-foot concrete pad for the aboveground facilities. Details of these pads are shown as an inset on Figure 3-3a. However, as a result of CalAm's comments on the Draft EIR/EIS (see Section 8.6.3), only the 18-foot by 11-foot (approximately 200 square feet) electrical enclosure would be on a concrete pad, eliminating approximately 25,000 square feet of impervious surfaces from the proposed project. Therefore, the table, the text and the figure in Section 3.2.1.1 have been revised accordingly in the Final EIR/EIS. Section 3.3.2.1 explains that construction activities at CEMEX would temporarily disturb approximately 9 acres of land within the project area boundary shown in Figure 3-3a, and Section 3.4.1 explains that slant well maintenance would disturb roughly 6 acres every 5 years. Potential impacts on the 9 acres of dune complex from the slant well construction were accurately described in the Draft EIR/EIS starting on page 4.6-124, at page 4.6-186, and again at page 4.6-209.

Aboveground facilities, including the wellheads, are described in EIR/EIS Section 3.2.1.1, and again in Section 3.3.2.1. Potential impacts on the 6 acres of dune complex resulting from operations and maintenance activities at the slant well sites are described starting on Draft EIR/EIS page 4.6-234, at page 4.6-244, and again at page 4.6-247.

Marina-26 The slant wells would be drilled into the Dune Sands, the Older Dunes Sands and the Terrace Deposits, all of which are composed of sand and some gravels, and described in the Draft EIR/EIS on page 4.2-8. The sand and gravel from the drilling

would be spread within the 9-acre construction area. See also response to comment Marina-73 and -89.

Marina-27 See Final EIR/EIS Section 1.5.3. The Terminal Reservoir is no longer a component of the proposed project.

Marina-28 The text in EIR/EIS Section 3.3.9 has been revised; the word "active" has been replaced with "retired."

Marina-29 Water Rights Permit 20808C limits the injection period of Carmel River supplies to December through May. Desalinated water does not have the same limitation. See EIR/EIS Section 3.4.2.

Marina-30 See response to comment MCWD-79 in Section 8.5.2.

Marina-31 The text in EIR/EIS Section 3.4.1 has been revised as follows:

> "All disturbance would occur on the ~~back~~ inland side of the dune~~s~~ face . . ."

Marina-32 EIR/EIS Section 3.4.2 describes the operation of the ASR system. Because the Terminal Reservoir is no longer a component of the MPWSP, the text in Section 3.4.2 has been revised accordingly. See EIR/EIS Section 4.4 for a description of the northern subbasin.

As described in EIR/EIS Section 3.2.4.1, the two proposed new wells, ASR-5 and ASR-6, would operate in conjunction with the existing Phase 1 and Phase II ASR wells (ASR-1 and ASR-2, and ASR-3 and ASR-4), which are described in EIR/EIS Section 2.4.3. With implementation of the MPWSP, any of the six ASR injection/extraction wells could be used to inject desalinated product water and Carmel River supplies.

Marina-33 The large use of energy is analyzed in EIR/EIS Section 4.18. The analysis assumed all electrical power needed for the project would be provided by the local PG&E power grid. As described on Draft EIR/EIS page 4.18-17, PG&E has indicated that it has adequate capacity and infrastructure to support the proposed project (PG&E, 2016c). An option for CalAm to use methane gas as an alternative energy source is described in Section 4.18.4.3 for information purposes and is discussed in Section 4.11.5 as a renewable energy option. Section 4.11.5 also presents the secondary impacts of the proposed mitigation measure.

Marina-34 See Master Response 10, Environmental Baseline under CEQA and NEPA. Regarding reference to requirements to analyze the No Project alternative, the No Project/No Action alternative was analyzed in compliance with both CEQA and NEPA (see EIR/EIS Section 5.5).

Marina-35 The cited statement in EIR/EIS Section 4.1.5 provides an incomplete summary of the requirements in 40 CFR §1502.16(c) and 40 CFR §1508.27(b)(10), which the Draft EIR/EIS cites as the basis for the NEPA evaluation of potential inconsistencies. The statement has been revised to read:

> Also, per NEPA, the analysis includes a discussion of the possible conflicts between the proposed project and ~~the objectives of~~ federal, regional, state, and local land use laws, requirements, policies, and/or plans for the area concerned that are imposed for the protection of the environment (40 CFR §1502.16(c) and 40 CFR §1508.27(b)(10)).

This revision accurately represents 40 CFR §1508.27(b)(10), and is consistent with the language in 40 CFR §1506.2(d), cited in the comment. Responses to City of Marina comments about specific instances of alleged inconsistency with federal, regional, state, and local laws, requirements, plans, and policies are provided below, where enough specificity is provided by the comment to allow a substantive response.

Marina-36 The EIR/EIS did not fail to analyze the MPWSP's potential to accelerate or exacerbate coastal erosion and dune retreat. Section 4.2.1.3, Geologic Hazards, discusses erosion in general, and then provides a specific discussion of sea level rise and coastal erosion, including the four existing mechanisms that combine to affect coastal retreat in Monterey Bay: long-term erosion, sea level rise, storm events, and rip embayments. Section 4.2.4.5, Coastal Retreat Study, discusses the results of the site-specific studies conducted to quantify the anticipated level of sea level rise and the resulting coastal erosion that would occur from 2012 through 2073.

Because of the anticipated rate of coastal retreat, the originally-proposed locations of the slant wells were relocated further inland specifically to avoid being exposed and thus accelerating or exacerbating erosion. In addition to the usual CEQA Guidelines Appendix G significance criteria, EIR/EIS Section 4.2.5, Direct and Indirect Effects of the Proposed Project, added the following additional significance criterion to specifically address the issue of coastal retreat: Impact 4.2-10: Accelerate and/or exacerbate natural rates of coastal erosion, scour, or dune retreat, resulting in damage to adjoining properties or a substantial change in the natural coastal environment. The Draft EIR/EIS concluded on page 4.2-70 that, "If exposed, the subsurface slant well could contribute to accelerated and/or exacerbated natural rates of coastal erosion, scour, and dune retreat that could alter the natural coastal environment." The potential for erosion to occur as a result of any other proposed project component is discussed in Section 4.2.5 and was determined to be less than significant.

To ensure that the slant wells would not accelerate or exacerbate coastal erosion and dune retreat, Mitigation Measure 4.2-10, Slant Well Abandonment Plan, requires CalAm to monitor the rate of coastal retreat, and to remove the slant wells

at risk of exposure in accordance with state well destruction standards, prior to their exposure. The implementation of this mitigation measure would ensure that the risk of exposure is eliminated, and the slant wells therefore would not accelerate or exacerbate coastal erosion and dune retreat. No revisions were made in response to this comment, but Mitigation Measure 4.2-10 was revised as a result of response to comment Surfrider-5.

Marina-37 As discussed in EIR/EIS Section 3.4.1, the source water supply system is designed to have 8 of the 10 slant wells operational at any given time, with 2 slant wells out of service for routine maintenance or on stand-by. Therefore, the project could operate with one well out of service. If CalAm needs to replace a slant well after abandonment, it will need to apply for a Coastal Development Permit to do so, with associated environmental review under NEPA and CEQA, as warranted.

The slant well abandonment procedures are discussed in Mitigation Measure 4.2-10, Slant Well Abandonment Plan. The slant wells would be removed in accordance with state well destruction standards, and prior to their exposure. The slant well casing would be pressure grouted such that the screened section is sealed. The sections of well casing and pipelines at risk of exposure would be cut and removed to a depth of five feet below the 2060, 100-year lower profile envelope as determined by the 2014 Coastal Erosion Study cited in Impact 4.2-10 or as directed by any permit condition. The installation of replacement wells is not part of this MPWSP, and since the closure of sand mining operations at CEMEX (see Master Response 14, CEMEX Settlement Agreement), the rate of erosion at the slant wells will be less than projected in the EIR/EIS. It is therefore unlikely that the slant wells will need to be replaced because of coastal erosion, but if and when they do need to be replaced, that would be a separate project subject to NEPA/CEQA review and new discretionary approvals.

Marina-38 EIR/EIS Section 4.3.2.2 provides a description of the California Coastal Act, including reference to the relevant Public Resources Code Section, and summary of the specific policies and requirements of the Act relevant to and sufficient for the assessment of impacts from the proposed project related to surface water hydrology and water quality. Additional discussion of the Act is provided in other resource chapter regulatory setting sections as relevant to those topics. See for example EIR/EIS Section 4.5.2.2, where a detailed description of the California Coastal Act, policies, and requirements is provided in the context of marine biological resources.

To provide more specificity to the description of the California Coastal Act, the description of the Act provided in EIR/EIS Section 4.3.2 has been revised as follows:

> The California Coastal Act (Public Resources Code Section 30000 et seq.) provides for the long-term management of lands within California's coastal

> zone boundary. The Coastal Act includes specific policies for management of natural resources and public access within the coastal zone. Of primary relevance to surface water hydrology and water quality are Coastal Act policies concerning protection of the biological productivity and quality of coastal waters. For example, Article 4 of the Act details policies related to the marine environment, such as biological productivity and water quality. Specifically, and relevant to surface water hydrology and water quality, the Act requires the quality of coastal waters, streams, wetlands, estuaries appropriate to maintain optimum populations of marine organisms and for the protection of human health be maintained and, where feasible, restored through, among other means, minimizing adverse effects of waste water discharges, controlling runoff, and substantial interference with surface water flow, encouraging waste water reclamation, maintaining natural vegetation buffer areas that protect riparian habitats, and minimizing alteration of natural streams (Cal. Pub. Res. Code §§ 30231).

A preliminary assessment of project consistency with these priorities is provided in the EIR/EIS. Final determinations regarding project consistency are necessarily reserved for the Coastal Commission. Operational discharges of the MPWSP under certain scenarios may exceed Ocean Plan water quality objective thresholds. Exceedances of these thresholds would be potentially inconsistent with Coastal Act policies. This issue is discussed further in Impact 4.3-5.

The evaluation criteria described in EIR/EIS Section 4.3.3 are appropriate and adequate for assessing the potential impacts related to surface water hydrology and water quality from implementation of the MPWSP. These evaluation criteria comprehensively apply and consider the applicable regulations discussed in the regulatory setting section (EIR/EIS Section 4.3.2). As detailed in EIR/EIS Section 4.3.4, Approach to Analysis, the evaluation and disclosure of environmental impacts determines if, and to what degree, the MPWSP would change the existing hydrology and water quality conditions (described in Section 4.3.1) based on the evaluation criteria (presented in Section 4.3.3) and whether it would comply with the relevant regulatory requirements, which are comprehensively described in Section 4.3.2.

Marina-39 The EIR/EIS assesses and discloses the potential environmental impacts of the MPWSP as described in Chapter 3. As described in EIR/EIS Section 3.2.2.5, the project proposes to discharge brine from the reverse osmosis process via the existing MRWPCA ocean outfall, comingling the brine with secondary treated wastewater when available. The potential for the proposed project to impact water quality or to violate water quality standards or waste discharge requirements is comprehensively evaluated in EIR/EIS Section 4.3.5.

As discussed under Impacts 4.3-4 and 4.3-5, the proposed project would not exceed or violate the Ocean Plan numeric water quality standards or degrade water quality

in terms of salinity and other constituents for which data is available. Because water quality data is unavailable for a limited number of constituents for which the Ocean Plan defines a numeric water quality objective, the EIR/EIS conservatively concludes that the MPWSP could result in exceedances of Ocean Plan objectives, resulting in a significant impact related to water quality standards, waste discharge requirements and water quality of receiving waters in Monterey Bay. Such impacts would be reduced to a less-than-significant level by implementing Mitigation Measure 4.3-5 (Implement Protocols to Avoid Exceeding Water Quality Objectives), which ensures that discharges would not occur if they would not conform to the Ocean Plan water quality objectives.

Mitigation Measure 4.3-5 specifies implementation of additional design features, engineering solutions (including but not limited to inclined diffusers), and/or operational measures to be implemented to reduce the concentration of water quality constituents in the operational discharges and/or to increase dilution at the outfall diffuser such that they conform with Ocean Plan water quality objectives.

EIR/EIS Appendix D1 provides detailed descriptions of the various model analyses conducted to assess potential water quality impacts for operational discharges that utilize the MRWPCA outfall diffuser. The model analyses described in Appendix D1, and discussed in detail as part of the impact analyses presented in Chapters 4 and 5 of the EIR/EIS relevant to surface water hydrology, water quality, and marine biological resources, assess operational discharges associated with the proposed project as well as Alternative 1, Alternative 2, and Alternatives 5a and 5b, which all propose use of the existing MRWPCA outfall diffuser. Modeling analyses at a comparable level of detail, described in EIR/EIS Section 5.5.3.6, was conducted for Alternative 3 (Monterey Bay Regional Water Project or Deep Water Desal), which proposes a new brine discharge structure that would discharge a higher volume of brine than the proposed MPWSP. As described in EIR/EIS Section 5.5.3.7, Alternative 4 (People's Moss Landing Desalination Project or People's Project) proposes to discharge brine through a rehabilitated existing outfall. As discussed in Section 5.5.3.7, the design of the Alternative 4 outfall diffuser is not yet advanced enough to conduct detailed model analyses comparable to the other alternatives. However, an impact analysis for Alternative 4 consistent with the requirements of CEQA and NEPA was conducted using the information available at the time of preparing the Draft EIR/EIS. Further, a detailed comparison of proposed alternatives was provided to facilitate public understanding of the impacts related to operational discharges (as well as other impacts) for all alternatives (see EIR/EIS Table 5.3-5).

Marina-40 The Draft EIR/EIS is not required to include a MMRP (see response to comment Marina-1) and Mitigation Measure 4.3-4 does not defer mitigation nor does it lack performance standards. Response to comment Marina-41 addresses issues of deferral related to updating water quality and marine biological resource data required by Mitigation Measure 4.3-4. The performance standards of Mitigation

Measure 4.3-4 are described as those outlined in Appendix III of the *Water Quality Control Plan – Ocean Waters of California*, also known as the Ocean Plan, prepared by the State Water Resources Control Board (SWRCB, 2016). The primary performance standard within this mitigation measure is clearly described as "compliance of operational discharges with the Ocean Plan receiving water salinity limitation, which specifies discharges shall not exceed a daily maximum of 2 parts per thousand (ppt) above natural background salinity, as measured no further than 100 meters (328 ft) horizontally from the discharge point" (see Draft EIR/EIS page 4.3-90). Response to comment Marina-42 further addresses performance standards. Response to comment Marina-1 addresses the requirements for preparing and circulating an MMRP.

Marina-41 Surveys conducted as part of Mitigation Measure 4.3-4 do not constitute deferral under CEQA of either a characterization of baseline conditions or the analysis of potential impacts from implementation of the proposed project or alternatives. A comprehensive and detailed characterization of baseline conditions relevant to the project area and adequate for assessing the potential environmental impacts of the proposed project and alternatives consistent with the requirements of CEQA and NEPA is presented in EIR/EIS Chapters 4 and 5. Specifically, baseline conditions in the marine environment of Monterey Bay relevant to the discharge of brine at the MRWPCA outfall diffuser are presented in Sections 4.3.1 and 4.5.1 for water quality and marine biological resources, respectively. As described in Sections 4.3.1 and 4.3.5, detailed and project-specific water quality and biological surveys were conducted and the results of these surveys are presented along with relevant information from a comprehensive literature review. A detailed analysis of the potential impacts of implementing the proposed project and alternatives on water resources and marine biological resources is presented in Sections 4.3.5, 4.5.5, and Chapter 5.

As described in EIR/EIS Sections 4.3.1 and 4.5.1, conditions relevant to water quality and marine biological resources, especially benthic community diversity and abundance, are dynamic over time and may be influenced by factors unrelated to the proposed project, such as other regional projects or long-term water quality trends. For this reason, existing baseline conditions related to water quality and marine biological resources have been characterized within the context of typical observed ranges and regional trends (such as species presence and abundance, seasonal ocean conditions, habitat conditions, and long-term water quality trends). Within that context, a detailed and comprehensive assessment of impacts to receiving ocean water quality from operational discharges and associated impacts to marine biological organisms is presented in EIR/EIS Sections 4.3 and 4.5 of the Draft EIR/EIS. Section 4.3.1 and Appendix D presents detailed baseline water quality information specific to Monterey Bay, including site specific water quality data for the area immediately surrounding the MRWPCA outfall diffuser, sufficient for assessing the potential impacts from implementation of the MPWSP. Under Impact 4.3-5, baseline water quality data is utilized to conservatively assess

impacts from a wide range of water quality constituents present in operational discharges (see Table 4.3-15 for a comprehensive list of constituents assessed). As described in Section 4.3.5, because implementation of the project may not occur for several years, Mitigation Measure 4.3-4 would, in part, ensure that adequate water quality and marine biological resources data are gathered at least one year prior to construction of the project to confirm conditions at the time of construction. Due to the dynamic nature of water quality and marine biological resource conditions, it is appropriate and scientifically defensible to confirm and/or re-establish ambient conditions, especially benthic community diversity and abundance, in the vicinity of the outfall diffuser in order to assess potentially adverse deviations from long-term trends in community diversity and abundance that may occur from implementation of operational discharges.

Marina-42 The conditions under which the RWQCB and MBNMS may, following detailed assessment, authorize CalAm to terminate the long-term monitoring of salinity compliance at the outfall diffuser required under Mitigation Measure 4.3-4 are defined and described in EIR/EIS Section 4.3.5. Specifically, Mitigation Measure 4.3-4 states, in part, that "[I]f at the end of five complete years of monitoring operational discharges, the 24-hour average salinity measured at the edge of the BMZ is less than 75 percent of the salinity performance standard for 45 days without interruption under all discharge scenarios representative of typical operations (i.e., irrigation season and non-irrigation season operations), and with approval by the RWQCB and MBNMS, the discharger(s) may terminate the monitoring and reporting specified as part of this mitigation measure (but not terminate monitoring and reporting required as part of compliance with NPDES permit conditions or Ocean Plan monitoring and reporting requirements for discharges into California ocean waters)."

Therefore, CalAm could not be authorized to terminate such monitoring unless at some point after five years of monitoring and assessment have occurred (i.e., a minimum of five years of monitoring must be completed), the salinity standard required under Mitigation Measure 4.3-4 is met for a continuous 45-day period for all discharge scenarios that occur under standard operations. If the terms described above are not met, the monitoring required as part of Mitigation Measure 4.3-4 will not cease. However, additional mitigation would not be required as the clearly defined standard for salinity under Mitigation 4.3-4 has conservatively been set at 75 percent of the salinity performance standard required in the California Ocean Plan. Failure to meet the conservative 75 percent threshold defined in Mitigation Measure 4.3-4 would not represent an exceedance of the Ocean Plan salinity requirement and would not, as discussed in Sections 4.3.5 and 4.5.5, result in additional impacts not previously disclosed in the EIR/EIS for discharges associated with desalination facilities.

Marina-43 As described in EIR/EIS Section 5.5.3.7, as for operational discharges associated with the proposed project and other alternatives, operational discharges from

Alternative 4 could locally increase salinity levels and could potentially exceed Ocean Plan water quality objectives, resulting in violation of water quality standards, waste discharge requirements and/or the degradation of water quality in Monterey Bay. Implementation of Mitigation Measures 4.3-4 and 4.3-5 would reduce water quality impacts to receiving ocean waters from desalination facility operational discharges to less than significant for Alternatives 1, 2, 3, 5a and 5b. It is acknowledged and disclosed in Section 5.5.3.7 that application of measures substantially consistent with Mitigation Measures 4.3-4 and 4.3-5 would reduce impacts to a less-than-significant level for Alternative 4. However, while the applicant for Alternative 4 may agree to comply with such measures or provide model analyses to demonstrate compliance with Ocean Plan objectives, the proposed "two new 16-inch-diameter diffuser ports" are not multi-port as preferred by the Ocean Plan. The effectiveness of the Alternative 4 diffuser design is currently unknown and, therefore, feasible mitigation and the effectiveness of that mitigation cannot be fully assessed at this time, without additional information related to facility design, operational protocols, and diffuser dynamics. Until such information is developed by the applicant (such as for analysis under CEQA and NEPA when Alternative 4 facility and operations are more fully developed) and shared with the Lead Agencies, it is logical to assume that Alternative 4 would result in an increased impact related to operational discharges and water quality for other Ocean Plan constituents compared to the proposed project and that such impacts would be significant and unavoidable.

Marina-44 Resolution No. 88-63 adopted by the SWRCB on May 19, 1988, and amended on February 1, 2006, provides that surface waters and groundwater that are considered to be suitable or potentially suitable for municipal or domestic water supply (MUN) should be so designated by regional boards in their water quality plans.

The Resolution presumes that surface water and groundwater are suitable for MUN designation except where:

a. The total dissolved solids (TDS) exceed 3,000 mg/L (5,000 uS/cm, electrical conductivity) and it is not reasonably expected by Regional Boards to supply a public water system, or

b. There is contamination, either by natural processes or by human activity (unrelated to the specific pollution incident), that cannot reasonably be treated for domestic use using either Best Management Practices or best economically achievable treatment practices, or

c. The water source does not provide sufficient water to supply a single well capable of producing an average, sustained yield of 200 gallons per day.

Resolution No. 88-63 at page 2. This standard was incorporated into the Water Quality Control Plan for the Central Coast Basin (latest edition, March 2016, see page 2-1 of the Basin Plan) for all groundwater resources. The Salinas River Groundwater Basin (a sub-basin of the Central Coast Basin, see Basin Plan

Figure 2-2), a groundwater resource within the Central Coastal Basin, is designated as suitable for MUN, agricultural water supply, and industrial use. See Basin Plan at page 2-1.

The Basin Plan and the beneficial use of groundwater resources, including the MUN designation, were discussed in the Draft EIR/EIS on page 4.4-35, such that it was not necessary to cite to the Resolution that informed the Basin Plan. The EIR/EIS provides in pertinent part:

> The Basin Plan for the Central Coast, originally adopted in 1971 and last amended in 2011, identifies the beneficial uses of water bodies and provides water quality objectives and standards for waters of the Central Coast of California. The listed beneficial uses for groundwater resources are:
>
> - Agricultural water supply (AGR)
> - Municipal and domestic water supply (MUN)
> - Industrial use (IND)
>
> . . . The RWQCB has established water quality objectives for selected groundwater resources; these objectives serve as a basis for evaluating water quality management in the basin. Specific water quality objectives have been defined for the 180-Foot Aquifer and 400-Foot Aquifer for the SVGB.

The Basin Plan's Total Dissolved Solids (TDS) water quality objective for the 180-Foot Aquifer is 1,500 mg/L TDS, and the water quality objective for the 400-Foot Aquifer is 400 mg/L TDS. The Basin Plan acknowledges that groundwater in the Salinas River Sub-basin has average TDS concentrations that range from 300 mg/L to over 3,000 mg/L. Basin Plan at page 3-12. The analysis conducted for the EIR/EIS also demonstrates that the groundwater within the capture zone for the project (where the water is projected to be derived) exceeds the 3,000 mg/L TDS requirement for MUN designation; see EIR/EIS Section 4.4, Groundwater Resources, and Master Response 8, Project Source Water and Seawater Intrusion. Therefore, groundwater that could be withdrawn from the 180-Foot Aquifer by project supply wells does not currently meet the Basin Plan objective of 1,500 mg/L TDS, nor would it be considered suitable for MUN designation under Resolution No. 88-63.

That alone, however, does not de-designate the MUN designation of the Salinas River Groundwater Basin, but it is instructive given that such groundwater is not considered suitable for municipal or domestic water supply. The Basin Plan states that if groundwater is beyond the levels or limits established as water quality objectives, controllable conditions shall not cause further degradation of water quality. (Basin Plan at page 3-1.) As demonstrated in EIR/EIS Section 4.4, Groundwater Resources, and Master Response 8, Project Source Water and Seawater Intrusion, the project would not cause further degradation of the water quality in the sub-basin. Therefore, the project does not conflict with and is consistent with the Basin Plan.

Marina-45 See Master Response 2, Source Water Components and Definitions, for definitions of brackish water, seawater, source water, and fresh water. EIR/EIS Section 4.4, Groundwater Resources, has been updated to be consistent with these terms. Brackish water is defined in EIR/EIS Sections 3.1.1.1 and 4.4.1.4 as water that is a combination of seawater and fresh water, and thus contains TDS levels between 500 mg/L and 33,500 mg/L.

The text in EIR/EIS Section 4.4.5.2 states that groundwater in the inland area of influence of the proposed MWSP slant wells is brackish with elevated TDS attributable to seawater intrusion; the groundwater in the Dune Sand, 180-FTE and 400-Foot Aquifer is, therefore, unsuitable for potable supply. That is a true statement based on the understanding that groundwater within the capture zone of the slant wells far exceeds 3,000 mg/L TDS and there are currently no groundwater extraction wells in that area. See Master Response 8, Project Source Water and Seawater Intrusion, Sections 8.2.8.1 and 8.2.8.2, for a description of water quality conditions in the slant well capture zone. See Master Response 3, Water Rights and response to comment Marina-44 for further clarification on the use of the term brackish water. The commenter indicates that it is a discrepancy to state that the groundwater in the project capture zone is unsuitable for potable supply when such water would be part of the project source water. However, the point of such text in the EIR/EIS is that the water in its existing form is not suitable for potable supply and could only become suitable through desalination, as proposed by the project.

EIR/EIS Figures 4.4-10 and 4.4-11 are the 2015 seawater intrusion maps that are produced annually by Monterey County Water Resources Agency; they are used in the EIR/EIS to illustrate the extent of seawater intrusion in the Salinas Valley Groundwater Basin, inland from the coast. This is considered the best available information showing the inland advance of the seawater intrusion front. Hydrostratigraphic and water chemistry data obtained from the CalAm test slant well and groundwater monitoring wells provide adequate information to characterize the hydrogeologic conditions in the region that would be affected by the slant wells. See Master Response 9, Electrical Resistivity Tomography (ERT) and Airborne Electromagnetics (AEM), Section 8.2.9.3, for information on the applicability and use of ERT/AEM in the EIR/EIS. The MPWSP would extract highly brackish to saline water for use as desalination feedwater from a coastal adjacent capture zone in the Dune Sand and 180-FTE Aquifers without negatively impacting the water supplies in the Salinas Valley Groundwater Basin. Refer Master Response 3, Water Rights, Section 8.2.3.5 regarding CalAm's right to extract water from this source.

Marina-46 Refer to Master Response 8, Project Source Water and Seawater Intrusion, Section 8.2.8.1 through and 8.2.8.4 for additional clarity on the slant well feedwater source. See Master Response 4, Agency Act and Return Water, Sections 8.2.4.1 and 8.2.4.2, for detailed information on the proposed project's compliance with the Agency Act and return water requirements, and Section 8.2.4.3, which presents the

results of the Hydrogeologic Working Group (HWG) evaluation of return water estimates. The HWG concluded that the anticipated actual annual volume of return water could be 10 percent in the first few months of project pumping (approximately 2,700 afy), but would be no more than 5 percent (approximately 1,350 afy) within 5 years of project pumping. See EIR/EIS Appendix E3. The 0 to 12 percent range used in the EIR/EIS and the NMGWM^{2016} is consistent with these conclusions, and no edits to the analysis relevant to return water presented in the Draft EIR/EIS are necessary. See also response to Marina-44; groundwater that could be withdrawn from the 180-Foot Aquifer by project supply wells does not currently meet the Basin Plan objective, nor would it be considered suitable for MUN designation under Resolution No. 88-63 adopted by the SWRCB on May 19, 1988, and amended on February 1, 2006.

Marina-47 EIR/EIS Sections 2.6.3 and 4.4.2.3 describe the MCWRA Agency Act and Ordinance 3709; Section 2.6.4 presents the effect of the Annexation Agreement on the proposed project. Master Response 2, Section 8.2.4.1 also addresses compliance with the Agency Act and Ordinance 3709. Master Response 8, Project Source Water and Seawater Intrusion, Sections 8.2.8.1 through and 8.2.8.4 provide additional context to understand the relationship between the projected slant well capture zone at the coast, which is a highly brackish to saline environment, and the projected area of influence of the slant pumping, which has more variable ranges of seawater intrusion.

Marina-48 Refer to Master Response 3, Water Rights, Section 8.2.3.5, for additional clarity of water rights and use of the seawater intruded groundwater. The EIR/EIS does not state that the water in the Dunes Sand, 180-Foot Aquifer and 400-Foot Aquifer *cannot* be extracted for domestic, agricultural, or industrial uses. Further, the EIR/EIS bases its conclusion of the existing extent of seawater intrusion in these aquifers on data publicly available from the MCWRA. The EIR/EIS correctly states in Section 4.4.5.2 that current groundwater production in those aquifers is limited to minor irrigation and dust control and that there are no water supply wells pumping potable water. Most of the wells in this area are no longer active because of seawater intrusion.

Marina-49 See Master Response 9, Electrical Resistivity Tomography (ERT) and Airborne Electromagnetics (AEM).

Marina-50 See Master Response 6, Sustainable Groundwater Management Act, Section 8.2.6.3, for a discussion of consistency of the proposed project with SGMA. A summary of the analyses to address each undesirable result identified in SGMA has been added to Final EIR/EIS Section 4.4 in Impacts 4.4-3 (groundwater supplies and recharge) and 4.4-4 (groundwater quality). The scientific information presented in EIR/EIS Appendix E2 indicates that the proposed project would not contribute to additional seawater intrusion or significantly lower groundwater levels. Figures 5.3 and 5.4 show drawdown contours due to slant well pumping at

the CEMEX site. The contour maps show the area where project pumping is expected to lower groundwater levels by 1 foot or more relative to groundwater levels in the absence of the project. Slant well pumping effects on the continued inland movement of saltwater due to background pumping were also assessed using the NMGWM^{2016} and MODPATH. Results show that slant well pumping would slow future saltwater intrusion in the southern portion of the 180-Foot/FTE Aquifer; slant well pumping would have little to no effect on the continuation of saltwater intrusion in the 400-Foot Aquifer.

Marina-51 See response to comment Marina-50.

Marina-52 See response to comment Marina-50.

Marina-53 The EIR/EIS states that the proposed project would extract groundwater that is highly brackish to saline from a capture zone along the coast at CEMEX where no other groundwater users are currently pumping groundwater from the Dunes Sand Aquifer or the 180-Foot Aquifer. The source of the slant well feedwater and the capture zone from where the feedwater originates is described in detail in Master Response 8, Project Source Water and Seawater Intrusion, Section 8.2.8.1 through and 8.2.8.4. The amount of return water is based on the ocean water percentage (OWP), which is the amount of seawater that contributes to the source water supply. In other words, the return water amount would be all source water that is not classified as ocean water but rather is characterized as groundwater, as explained in Master Response 2, Source Water Components and Definitions. The OWP is projected to increase with time as seawater replaces the highly brackish ambient groundwater in the coastal Terrace Deposits. See Master Response 4, Agency Act and Return Water, Section 8.2.4.3 for clarity regarding the OWP and calculation of return water. See also EIR/EIS Appendix E3.

Marina-54 See Master Response 12, The North Marina Groundwater Model (v. 2016). The NMGWM^{2016} is a MODFLOW model, which is a widely utilized groundwater modeling program accepted by the hydrologic community. It has been extensively tested and verified, making it state-of-the-art. The NMGWM^{2016} is a complex three dimensional flow model comprising 8 layers, and each layer has one or more zones that represent the distribution of aquifers and aquitards (see Table 2.1 in Appendix E2). The NMGWM^{2016} was employed in superposition mode to isolate the calculated water level decline (drawdown) in response to proposed project pumping. See Master Response 12, The North Marina Groundwater Model (v. 2016), for more information. Specifically, the model was primarily employed to estimate the cone-of-depression, which was defined as the area where the difference between model-calculated pumping and non-pumping water levels is greater than or equal to one foot. The NMGWM^{2016} was not employed to calculate changes in water quality and water density due to the mixing of ocean water and groundwater. The specified pumping stress and modeled aquifer properties have a much larger effect on the model-calculated drawdown than variations in water

quality and density. The specified pumping rates, return water volumes, projected sea level, aquifer parameter values, and the relative contributions of multiple aquifers to total slant well production have a greater influence on the extent of model-calculated drawdown than a contrast in groundwater density, and the effects of these factors on the uncertainty in the model-calculated cone of depression was rigorously tested and conservatively quantified for the NMGWM[2016].

Marina-55 EIR/EIS section 4.4.3 lists the thresholds of significance (referred to in this document as Evaluation Criteria) that are consistent with the questions set forth in Appendix G of the CEQA Guidelines. The two criteria listed pertain to groundwater supply and water quality and are published in Appendix G under the impact questions for Hydrology and Water Quality. As lead agencies frequently do, the EIR/EIS adapted these questions as significance criteria for the analysis of impacts in the Groundwater Resources section. Due to the complexity of the project, the criteria were expanded into several descriptions that were intended to elaborate on the CEQA Appendix G questions and clarify the significance thresholds for the reader. The phrase "net deficit in aquifer volume," precise language taken directly from Appendix G of the CEQA Guidelines, describes the potential for the project to interfere with recharge and draw down the aquifer (thus experiencing a net deficit in aquifer volume) to a point that it could cause harm to the well yields and wells of other users. This is an appropriate application of the CEQA Guidelines in developing a significance threshold.

The project impacts on the aquifer volume were adequately analyzed under Impact 4.4-3 in EIR/EIS, Section 4.4.5.2. The impact analysis evaluated whether the project would deplete supplies in the aquifer and appropriately concluded that the project would continue to extract only brackish, degraded groundwater from the coast and to a lesser extent from the inland portion of the aquifer, but would not deplete the supply in the aquifer to the extent that other groundwater users would be impacted. The analysis also evaluated the project's impact on water levels in local wells and determined that some wells would experience drawdown of 1 to 5 feet, but that such degree of drawdown would not reduce well yield or cause physical damage to the wells.

Master Response 8, Project Source Water and Seawater Intrusion, provides additional clarity regarding the hydrogeologic and water quality effects of the proposed project pumping. The information in Master Response 2, Source Water Components and Definitions, provides supplemental technical information but does not change the conclusion in the EIR/EIS. The return water component was also evaluated and it was determined that, under certain circumstances, water levels in the 400-Foot aquifer would increase due to in-lieu recharge; see EIR/EIS Section 4.4.5.2.

Marina-56 Given the location of the slant wells and characteristics of the groundwater capture zone, which is further discussed in Master Response 8, Project Source Water and

Seawater Intrusion, and the results of the NMGWM^{2016} groundwater modeling, the EIR/EIS, Section 4.4.5.2, Impact 4.4 concluded that: 1) localized change in groundwater quality that could occur as a result of slant well pumping is not expected to violate water quality standards or interrupt or eliminate the potable or irrigation groundwater supply available to other basin users, and 2) MPWSP pumping would be expected to retard future inland migration of the seawater intrusion front and provide a benefit for the basin. The EIR/EIS did not, as the comments states, "condense this water quality degradation inquiry into a narrow analysis of whether the extractions will move the 'seawater/freshwater interface' in the 180/400 Foot Aquifers." Rather, the water quality analysis presented in EIR/EIS Section 4.4.5.2, Impact 4.4-4: 1) considered potential water quality impacts to groundwater users in the slant well pumping area of influence; 2) evaluated the project's effects on SVGB seawater intrusion; 3) assessed water quality impacts associated with groundwater remediation systems; and 4) analyzed water quality impacts of the ASR wells. The EIR/EIS adequately addressed the potential groundwater quality impact associated with the MPWSP on current legal users; to opine on impacts to future legal users would be speculative and is not the focus of or required by CEQA and NEPA.

Marina-57 See Master Response 6, The Sustainable Groundwater Management Act, Section 8.2.6.3 and response to comment Marina-55. EIR/EIS Section 4.4.5 evaluates the short- and long-term impacts of the proposed project on current legal users; to opine on impacts to future legal users would be speculative and is not the focus of or required by CEQA and NEPA.

Marina-58 For SGMA related issues, see Master Response 6, The Sustainable Groundwater Management Act, Section 8.2.6.3. Information on the 900-Foot Aquifer is provided in Master Response 7, Deep Aquifers of the Salinas Valley Groundwater Basin. See response to comment Marina-56 for additional information on the water quality analysis. Contrary to the claims in the comment, EIR/EIS Section 4.4.5.2, Impact 4.4 provides a complete analysis of the potential water quality effects that could impact or harm other groundwater users, otherwise degrade groundwater resources, and exacerbate seawater intrusion. Supplemental discussion of the hydrogeological characteristics, graphic representation of the slant well capture zone, and supplemental discussion of water quality impacts are provided in Master Response 8, Project Source Water and Seawater Intrusion.

The coastal location of the slant wells, the inland gradient, and the capture zone created during slant well pumping would confine water quality changes to the capture zone. The water quality impacts at the slant wells would be localized at the capture zone and thus limited in areal extent. There are no groundwater users with active wells within the capture zone. Groundwater storage would not be substantially reduced because most of the water removed by the pumping slant wells would be recharged with seawater. Under steady state conditions, the slant wells would begin to capture seawater that would have otherwise flowed inland and contributed to seawater intrusion, resulting in a beneficial but localized water

quality effect. For this reason, the EIR/EIS concluded that the slant wells would not harm other groundwater users. The analysis employed particle tracking to assess changes to the MCWRA-defined seawater intrusion front. Results of the groundwater modeling indicate that slant well pumping would retard the migration of saltwater into the southern portion of 180-Foot Aquifer that would have otherwise contributed to the advancement of the seawater intrusion front; slant well pumping would have little to no effect on future saltwater intrusion in the 400-Foot Aquifer.

Marina-59 The "900-Foot Aquifer" is discussed in Master Response 7, The Deeper Aquifers of the Salinas Valley Groundwater Basin. The EIR/EIS has been revised to incorporate additional environmental setting information (see Section 4.4.1.2) and pertinent impact analysis regarding the deep aquifers (see Section 4.4.5.2). See also response to comment Marina-JJ&A-2. The additional information does not change the impact conclusions in the Draft EIR/EIS.

Marina-60 See Master Response 9, Electrical Resistivity Tomography (ERT) and Airborne Electromagnetics (AEM), for a complete discussion of the relevance of ERT and AEM to the EIR/EIS analysis. The preliminary results of the 2017 ERT/AEM survey presented a distribution of groundwater chemistry that is generally consistent with the findings of the hydrogeologic investigation conducted for the EIR/EIS and is generally consistent with the salinity mapping for the 180-Foot and 400-Foot Aquifers published by the MCWRA. The Stanford study also provides data to help interpolate between control points provided by the MPWSP monitoring network and confirms the work completed for the hydrogeologic investigation regarding the distribution of water quality in the MPWSP study area. While the ERT/AEM data is useful, it does not offer new information that would cause a change in the EIR/EIS conclusions regarding the proposed project's impacts on groundwater resources. See also response to comment Marina-61 and Marina-JJ&A-1 through -4.

Consistent with evidence in the EIR/EIS, the 400-Foot Aquifer in the project area is confined, and the 180/400-Foot Aquitard, although shown as inferred within dashed lines on EIR/EIS Figure 4.4.3, is most certainly present and restricts vertical flow from the 180-FTE aquifer above it. The EIR/EIS groundwater modeling (EIR/EIS Appendix E2) did in fact consider, model and evaluate potential effects to the 900-Foot Aquifer (Model Layer 8) from pumping of the proposed slant wells. See EIR/EIS Appendix E2, Figures 5.3a, 5.3b, 5.4a, and 5.4b and Master Response 7, The Deeper Aquifers of the Salinas Valley Groundwater Basin, Section 8.2.7.2. The modeling indicates that pumping of the MPWSP would not affect the 900-Foot Aquifer.

Marina-61 The NMGWM^{2016} does analyze the effects of slant well pumping on the Deep Aquifer (Model Layer 8), and results indicate the drawdown would be less than 1 foot everywhere within the model domain. See Master Response 7, The Deeper Aquifers of the Salinas Valley Groundwater Basin.

The NMGWM^{2016} was employed to calculate the water level decline and cone of depression, which is defined as the area where the differences between pumping and non-pumping water levels (the drawdown) would be greater than or equal to 1 foot. The model was also utilized to provide insight into the change in groundwater-flow directions in response to pumping. Particle-tracking methods were employed to show areas from which seawater recharge is extracted by the wells (the capture zone), and the retardation of existing saltwater intrusion.

The geophysical study prepared by Professor Knight provides a 2-D cross sectional resistivity map that also relied on modeling and inversion codes to visually plot the field collected data. Electro Resistivity Tomography (ERT) captures a static image – a point in time – and relies on actual conditions provided by monitoring well data for calibration. As outlined in Lucius et al., 2007, geophysical resistivity techniques are limited in that supplemental geologic information (such as borehole data or well logs) is needed to interpret the differences in resistivity observed within lithologic units. Additional limitations include the spacing of arrays required and avoiding potential sources of noise, such as pipelines or buried utility cables. Indeed, Professor Knight's work reports on the substantial vertical noise introduced into the ERT salinity cross-section by a pipe (Watsonville Wastewater ocean outfall pipe), which without knowledge of the interference could be inferred as indicating vertical saltwater flow (Goebel et al., 2017). Therefore, the ERT data will not necessarily produce greater certainty for a 3-D model because of the uncertainty in the ERT methodology; it is spatially limited because results presented to date represent a 2-D plane within the 3-D groundwater-flow system; it represents a single point in time rather than the time-series simulated by the model, and; it requires ground-truthing using much of the same data that is used by the groundwater model (well data) (Goebel et al., 2017). See Master Response 9, Electrical Resistivity Tomography (ERT) and Airborne Electromagnetics (AEM), Section 8.2.9.2.

The model is not "too simplified" to fully evaluate potential effects. Substantial care was exercised to incorporate the available lithologic and hydraulic conductivity data. Also, a range of parameter values was used to determine the uncertainty in model output and thus a range of values for drawdown. For example, (see EIR/EIS Appendix E2, Table 2-1), Model Layer 2 represents the shallow water-bearing sediments referred to as Dune Sand Aquifer, A-Aquifer, Perched Aquifer, Perched 'A' Aquifer, 35-Foot Aquifer, and -2 Foot Aquifer. Similarly, Model Layer 4 represents the 180-Foot Aquifer, 180-Foot Equivalent (FTE) Aquifer, Upper and Lower 180-Foot Aquifer, and Pressure 180-Foot Aquifer. The geographic and hydrogeologic characteristics of these water bearing units are not equivalent, and they are represented in the NMGWM^{2016} by different zones, and each zone is assigned a unique value for its water transmitting and storage property values. The NMGWM^{2016} is a MODFLOW model developed by the USGS, and is a widely utilized groundwater modeling program that is accepted by the hydrologic community. It has been extensively tested and verified, making it state-of-the-art. See Master Response 12, The North Marina Groundwater Model (v. 2016), for more

information as well as response to comment Marina-JJ&A-4. Consistent with evidence in the EIR/EIS, the 400-Foot Aquifer in the project area is confined and the 180/400-Foot Aquitard restricts vertical flow from the 180-FTE aquifer above it.

Marina-62 The inland movement of groundwater is driven by regional inland recharge and pumping patterns. Locally-focused efforts implemented near the coast by MCWRA and others to reduce groundwater pumping cannot reverse the effect of these regional gradients. To place this concept in perspective, locally-focused efforts would have to provide sufficient recharge to mitigate the inland pumping responsible for historical overdraft and seawater intrusion.

The slant wells would access subsurface water at and west of the shoreline, and rising sea levels are expected to increase the movement of seawater toward the wells. Seawater intrusion was first mentioned for the Salinas Valley in the early 1930s (see EIR/EIS Section 4.4.1.3), and even prior to that and before intense inland pumping for agriculture (for example, the 1920s), there was almost certainly a salt water wedge that dipped landward such as is described in Todd.[2] It is therefore unlikely that "most and possibly all of the water pumped by the slant wells would be groundwater from the Basin rather than seawater" because even if the seawater intrusion in the SVGB is reversed, the slant wells would draw in seawater because the brackish groundwater at CEMEX would be recharged from the ocean. See Master Response 8, Project Source Water and Seawater Intrusion.

Additionally, the water transmitting properties of aquifer materials near the coast are insufficient to supply the majority of the water extracted by slant wells. For example, the modeled horizontal conductivities of the inland A-Aquifer (2-4 feet/day) are one- to two-orders of magnitude smaller than the modeled Dune Sand Aquifer tapped by the slant wells (150-625 feet/day). Clearly, the water supplied to the slant wells that would originate as inland recharge to Model Layer 2 would necessarily be less than the water derived from the Dune Sand Aquifer at the coast and beneath the ocean. The combination of this hydraulic conductivity contrast and ample recharge available from the ocean make it implausible for the inland gradients to reverse and "strand" the project.

Marina-63 The National Marine Sanctuaries Act (NMSA; 16 USC §§1431-1445c) does not specifically list discharge of brine effluent as a prohibited activity in marine sanctuaries (16 USC §1436). Each sanctuary has unique regulatory prohibitions codified within a separate subpart of Title 15, Code of Federal Regulations, Part 922. The regulations implementing the NMSA in MBNMS (15 CFR 922, Subpart M) prohibit discharging or depositing from within or into the Sanctuary any material or other matter, except as otherwise specified in the section, and prohibit discharging or depositing from beyond the boundary of the Sanctuary any material or other matter that subsequently enters the Sanctuary and injures a

2 Todd, David Keith, 1976, Groundwater Hydrology, John Wiley and Sons

Sanctuary resource or quality, except as otherwise specified in the section. 15 CFR 922.132(a)(2)(i and iii). However, under NMSA regulations at 15 CFR 922.49, a person may conduct an otherwise prohibited activity in a Sanctuary if specifically authorized by a valid permit that is subsequently authorized by the Sanctuary. Regarding authorizations in MBNMS, 15 CFR 922.132(e) provides, "The prohibitions in paragraphs (a)(2) through (a)(8) of this section … do not apply to any activity authorized by any lease, permit, license, approval, or other authorization issued after the effective date of Sanctuary designation (January 1, 1993) and issued by any Federal, State, or local authority of competent jurisdiction, provided that the applicant complies with 15 CFR 922.49 … ."The term "authorization" in this context, and the specific authorizations MBNMS is considering relevant to the proposed project, are described in EIR/EIS Section 1.3.2.1. Additionally, the Guidelines for Desalination Plants in Monterey Bay National Marine Sanctuary (cited as MBNMS, 2010 in EIR/EIS Section 6.4) provide that all desalination plants should be designed to minimize impacts from brine discharge, and that the project proponent should evaluate the short and long-term impacts of discharge on marine organisms. EIR/EIS Section 6.4 contains a detailed discussion of the consistency of the MPWSP with the Guidelines. Finally, EIR/EIS Section 4.5.2.1 describes the NMSA provisions and MBNMS regulations that are relevant to the construction and operation of desalination plants, including restrictions on discharging material or other matter into the sanctuary and restrictions on activities that alter the submerged lands (aka seabed) as a result of the installation of desalination facility structures on or beneath the ocean floor (e.g. an intake or outfall pipeline).

With respect to their applicability to marine biological resources, other laws, regulations, policies, and guidance mentioned in the comment are discussed in the EIR/EIS as follows: the Magnuson-Stevens Fishery Conservation and Management Act, MBNMS Desalination Guidelines, Marine Mammal Protection Act, and Federal Endangered Species Act are discussed in Section 4.5.2.1. The California Endangered Species Act, Marine Life Protection Act, Marine Life Management Act, and California Ocean Plan are discussed in Section 4.5.2.2. Consistency with these and other components of the marine biological resources regulatory framework is discussed throughout Section 4.5.

Marina-64 The project study area for Marine Biological Resources is described in the first paragraph of EIR/EIS Section 4.5: "The marine biological resources study area encompasses the nearshore waters (within 5 miles from shore) of Monterey Bay and extends from the Salinas River southward to the northern limits of Sand City." It was established by delineating a region of the coastal marine environment that was several orders of magnitude greater than an area of potential impact resulting from the proposed project, consistent with CEQA Guidelines Section 21060.5. This paragraph in EIR/EIS Section 4.5 goes on to explain, "This area encompasses the ocean waters adjacent to the proposed subsurface slant wells site at the CEMEX sand mining facility and surrounding the Monterey Regional Water Pollution

Control Agency's (MRWPCA) existing ocean outfall…" There is no need or justification for the study area to extend further north, or south since the project has no potential to generate impacts at such distance. While the study area extends outward from the shoreline for five miles, the EIR/EIS demonstrates that project effects would be confined to a much smaller range.

Marina-65 Baseline conditions relevant to marine biological resources, especially benthic community diversity and abundance, are dynamic over time and may be influenced by factors unrelated to the proposed project, such as other regional projects or long-term water quality trends. For this reason, existing baseline conditions have been characterized within the context of typical observed ranges and regional trends (such as species presence and abundance, seasonal ocean conditions, habitat conditions, and long-term water quality trends). See response to comment Marina-41.

There are abundant scientific articles, reports and studies of the marine biological communities and habitats present in MBNMS to characterize the project study area. In fact, more than 130 scientific studies and reports are cited in Section 4.5, Marine Biological Resources, to support the impact assessments. Additionally, the assessment of project activities assumed that a specific marine taxa or species is present unless clearly known and documented not to be present in the project study area.

The EIR/EIS dismisses the presence of cold water seeps in the second page of EIR/EIS Section 4.5, since water depths in the project study area are less than 500 feet, and cold water seeps are located at depths greater than 3,000 feet.

As described in EIR/EIS Section 4.3.5, Mitigation Measure 4.3-4 would ensure that adequate marine biological resource data are gathered at least one year prior to construction of the project to confirm conditions at that time, and that the discharge would continue to meet Ocean Plan water quality objectives that are protective of marine biological resources.

The purpose of the plankton sampling was not to establish an environmental baseline. Because potential effects of shear stress associated with the brine discharge are related to organism size, with smaller organisms being most affected, the sampling was conducted to determine, at a single point in time, the relative proportions of organisms of different sizes. The plankton data were incorporated into the description of baseline conditions because they contribute to the available data gathered for this purpose. Nevertheless, in order to avoid further confusion, the text on page 4.5-6 has been revised, as follows:

> Small zooplankton was sampled near the MRWPCA outfall in the spring of 2016, to ~~characterize~~ provide an example of the assemblages that could be affected by the proposed discharge of desalination brine (AMS, 2016).

Moreover, the determination that impacts due to shear stress are less than significant was based on the small volume of pelagic habitat that would be affected by shear stress from the brine discharge and the very small percentage of organisms in the size range that would potentially be affected. Even if the plankton sampling included much larger organisms, as suggested by the commenter, this would cause the percentage of organisms affected to decrease even further.

EIR/EIS Section 4.5.1 establishes that the existing MRWPCA outfall is associated with rocky habitat in the form of ballast rock that supports a rich hard-substrate assemblage and that the majority of the seafloor habitat surrounding the outfall is soft substrate with associated infaunal and megafaunal species. EIR/EIS Figure 4.5-2 clearly indicates, to scale and with an arrow, the hard substrate habitat at the "MRWPCA Outfall (Existing)" and the text, as indicated above, indicates that the outfall consists of artificial hard substrate habitat and references the figure to illustrate the extensive areas within Monterey Bay that contain hard substrate habitat. Additionally, experienced marine biologists who routinely conduct diver and submersible assessments of hard and soft substrate habitats and assemblages reviewed the video footage (referenced in the EIR/EIS as Ballard, 2014) of the MRWPCA outfall inspection as part of the EIR/EIS preparation and provided the information on species composition of sessile and motile marine species inhabiting the ballast rock along the outfall, thereby negating the need to conduct additional field investigation to gather already available information. Furthermore, the potential impact analysis of project activities considered the species that make up both soft and hard substrate communities inhabiting the Monterey Bay near shore region.

Marina-66 EIR/EIS Table 4.5-2 lists all of the State and Federal special status species known and documented to have any potential to be present within MBNMS. The basis for determining their potential occurrence within the study area is provided for each species within the table notes as well as within the table itself, and is based on multiple scientific sources, all of which are listed in EIR/EIS Table 4.5-2. Merely because a specific marine species is known to occur within MBNMS, it is not necessarily present in the Study Area. MBNMS stretches between Rocky Point, located north of the Golden Gate to Cambria in San Luis Obispo County and 30 miles offshore, encompassing approximately a quarter of the California coast; the project study area encompasses less than 0.1 percent of MBNMS. Consequently, individual species may occur within MBNMS but not within the project study area. Employing scientifically established and documented natural life history and behaviors of an individual species, including geographic occurrence, is an acceptable and well-established methodology for determining the potential presence of an individual species to be present in a given location along the California coast. NOAA, CDFW and multiple universities and research institutes already extensively monitor the marine mammal population within MBNMS.

The studies and information presented in the EIR/EIS are referenced in Table 4.5-2 and demonstrate the scientific integrity of the analysis of species distributions. For example, MBNMS, 2016b, cited in the Table, explains that the Minke whales in Monterey Bay are typically observed inshore of 100 nautical miles and on occasion have been observed within 1.9 nautical miles (2.1 statute miles) of shore. They are normally observed as single individuals and not in groups. Typically, Minke whales are observed near and over natural hard bottom habitat where they typically feed on juvenile rockfish, which does not occur within the project study area. Although both resident and migrating Minke whales occur offshore in California, the only apparent sightings of resident Minke whales in Monterey Bay have been dozens of miles south of the project area along the Big Sur Coast. Sightings of Minke whales in Northern Monterey Bay by whale watching boats out of Santa Cruz occur less than 10 percent of the time, indicating limited presence in Northern Monterey Bay where the Project area is located. For all of these reasons, the determination that the likelihood of occurrence of a Minke whale in the project study area was assessed at Low to Moderate. Additional studies were not required for this EIR/EIS assessment. No changes have been made to the potential for any of the special status species listed in EIR/EIS Table 4.5-2 to occur within the study area.

Furthermore, any special status species with any potential to occur within the study area was included in the impact assessment, even if a specific species of fish, marine mammal, or reptile is identified as only having a low or moderate potential for occurrence in the Project Study Area, or not specifically cited in the text. The commenter correctly identified an inconsistency between Table 4.5-2 and the text on Draft EIR/EIS page 4.5-23; the text is in error and has been revised as follows:

> Chinook salmon, depending on the run, is State endangered or threatened, federally endangered or threatened and has a low to moderate ~~to high~~ potential to occur in the study area.

Finally, the commenter expressed concern about the EIR/EIS consideration of the white shark and tidewater goby in the impact assessment. Both species are presented in the EIR/EIS Table 4.5-2. The tidewater goby only occurs in Elkhorn Slough, Bennett Slough and the Salinas River, all of which are outside the designated project study area. Hence, its potential for occurrence in the context of the proposed project analysis alone would have been "not present." However, because the cumulative impact analysis included the DeepWater Desalination Project, which has elements within Moss Landing and the Elkhorn Slough, its potential for occurrence was increased to Low. As indicated above, all species with the potential to occur within the project study area were considered in the impact analysis, or in the cumulative analysis as applicable.

Marina-67 The commenter's assertion that the discharge of brine "will cause significant adverse impacts on the environment" is not consistent with the results of the extensive discharge modeling and analysis that is presented in EIR/EIS Section 4.3and

Appendix D1, and with the implementation of Mitigation Measures 4.3-4 and 4.3-5 which are also discussed in Section 4.3. The assertion that the project "would result in the decimation of 2,010 - 5,900 square meters of market squid habitat" is not a conclusion in the EIR/EIS. Examination of the text in question (Draft EIR/EIS pages 4.5-60 and 4.5-61) reveals no use of the word "decimation," and the impact analysis was based on brine discharge modeling, which found that brine >2 ppt above ambient salinity would not contact the seafloor. The calculation of the area greater than 2 ppt above ambient levels, as explained on Draft EIR/EIS page 4.5-61, was compared to the "area of suitable spawning habitat in Monterey Bay south of Monterey Submarine Canyon, ***which is the greatest focus of commercial fishing activities associated with spawning***" (emphasis added) and was intended to provide a worst-case assessment, should the area of brine >2 ppt above ambient happen to contact the seafloor, which the modeling demonstrated it would not. As explained on Draft EIR/EIS page 4.3-81, "The area where salinity exceeds the 2 ppt threshold under the worst case scenario (brine only) around each of the 129 outfall diffuser jets is a conical area with a volume on the order of 8.5 cubic feet (approximately 8 feet long by 2 feet in diameter), located approximately 2 feet above the seafloor (Figure 4.3-10)." Consequently, the conclusion that the proposed project would not violate water quality standards and would, therefore, be consistent with the MLMA, remains valid.

EIR/EIS Section 4.5.5.2 discusses the potential effects of elevated salinity from brine discharge, the potential effects of other brine discharge contaminants, and a discussion of the potential effects of brine discharge shear stress; all marine biological species were considered in the analysis. The public and decision-makers have been provided with a meaningful analysis (see response to comment Marina-61 regarding baseline) and have not been deprived of relevant information. As the EIR/EIS states in the conclusion of Impact 4.5-4, "Impacts on marine biological resources, including MBNMS resources, during operations of the proposed MPWSP would be less than significant."

Marina-68 The EIR/EIS conclusion that "… construction and operational impacts of the Project are not expected to result in the degradation of essential fish habitat within Monterey Bay" is supported with data and analysis. EIR/EIS Tables 4.5-3 and 4.5-4 list MSA managed fish species, and their potential to occur within the project study area in various life stages. EIR/EIS Figures 4.5-3 and 4.5-4 provide illustrations of rockfish conservation areas and designated EFH areas within Monterey Bay near the project study area. Additionally, EIR/EIS Section 4.5.1.3 presents the special status marine species and specifically discusses managed fish and invertebrate species. As designated special status species (Section 4.5.1.3), all the MSA listed species were considered in assessing Impacts 4.5-1 through 4.5-6, and 4.5-C (EIR/EIS Sections 4.5.5.1, 4.5.5.2 and 4.5.6).

Marina-69 Underwater noise levels measured in San Francisco Bay were not used in the EIR/EIS analysis. The only ambient underwater noise levels used in the analysis were those from a study located offshore Fort Ord and within the project study

area; the identified underwater ambient noise from these studies was on average 138 dB (see EIR/EIS Section 4.5.5.1, Impact 4.5-1).

The potential risk for discharge of drilling fluids into the marine environment was presented and evaluated in EIR/EIS Section 4.3.5.1 under Impact 4.3-2; the potential threat to marine biological resources would be negligible to non-existent because drilling fluids would consist of water, bentonite mud, and/or environmentally-inert biodegradable additives. Regardless, the use of any slant well drilling fluids would require mandatory compliance with NPDES Construction General Permit requirements that would involve the implementation of erosion and stormwater control measures so as to prevent substantial adverse effects on water quality during construction.

There was no underwater noise monitoring conducted during the test slant well drilling.

Marina-70 The EIR/EIR has been revised based on guidance from the CCC, and is based on the definition of primary habitat provided in the City of Marina's LCLUP and the definition of ESHA provided by the CCC and in other Local Coastal Plans (e.g., North County and City of Seaside). These revisions are consistent with the findings from the CCC staff report for the test slant well and assume that the entire subsurface slant well project area would be considered primary habitat by the City of Marina, and ESHA by the CCC.

Consistent with the comment, the EIR/EIS acknowledges that the project would result in impacts to primary habitat in Impacts 4.6-2 and 4.6-7. As described in these impact statements, impacts to primary habitat and ESHA would be reduced to less than significant with implementation of prescribed mitigation measures. The EIR/EIS adequately analyzes the proposed project's consistency with the City of Marina's LCLUP in Impact 4.6-4 and acknowledges, as the commenter describes, that the project would be inconsistent "with the City of Marina LCLUP policies governing protection of Primary and Secondary Habitats, a significant and unavoidable impact." See also response to comment Marina-94.

The EIR/EIS does not suggest that the project's conflict with the City of Marina's LCLUP would be circumvented by relying on Section 30260 of the Coastal Act. The EIR/EIS simply states that, for the test slant well, the CCC was ultimately able to approve the project consistent with the Coastal Act by relying upon Coastal Act Section 30260, which encourages coastal-dependent industrial uses and provides for resolution of conflicting Coastal Act policies where such development is concerned. CalAm will apply to the City of Marina for a Coastal Development Permit during the permitting process, which is separate from this CEQA/NEPA process. The City of Marina will need to decide whether or not to issue a Coastal Development Permit for this project. See EIR/EIS Section 3.5, Table 3-8. See also the response to MCWD-130 in Section 8.5.2.

Marina-71 As the commenter states, the Terrestrial Biological Resources study area includes a 50-foot buffer around the project area. The study area for the evaluation of Noise and Vibration impacts is described in EIR/EIS Section 4.12.2 as encompassing the project area and the nearest potentially affected sensitive receptors to the proposed facilities.

As stated in EIR/EIS Section 4.6.1.1, the Terrestrial Biological Resources study area was established as the anticipated area where direct and indirect impacts to sensitive biological resources may occur. The majority of the length of the project would include the installation of pipelines (approximately 6-inch to 42-inch in diameter) within a narrow linear work area. Due to the general duration, the project area, and the anticipated impacts, a 50-foot buffer of the project area was determined to provide an adequate analysis of existing conditions and to evaluate potential direct and indirect impacts on sensitive biological resources. Mitigation measures include pre-construction survey areas beyond 50 feet of the project area to ensure that indirect impacts to special-status species are avoided and/or minimized. For example, Mitigation Measure 4.6-1i requires that preconstruction "surveys shall cover all potential nesting sites within 500 feet of the project area for raptors and within 300 feet for other birds" and Mitigation Measure 4.6-1j requires a survey for American badger within 100 feet of the project area.

Marina-72 The electrical control panel and electrical control building at the slant well site at CEMEX are no longer part of the proposed project and were inadvertently mentioned in Impact 4.6-1. In response to this comment, the reference to these facilities in Impact 4.6-1 has been removed. This revision does not affect the impact analysis and conclusions, which remain relevant to the subsurface slant wells, and does not result in a need to recirculate the Draft EIR/EIS because it does not disclose a new or substantially more severe impact.

The EIR/EIS accurately describes the location of the proposed slant wells as mainly in the eastern side of the vegetated sand dunes. The majority of the wells would be located within largely unvegetated areas east of the heavily vegetated areas of the sand dunes. However, in response to this comment, the following text in Section 4.6.1.10, Sensitive Terrestrial Biological Resources in the Study Area has been clarified as follows:

> The <u>majority of the</u> remaining well clusters would be installed on the eastern side of the <u>heavily</u> vegetated <u>area of the</u> sand dunes.

Similarly, the following text in Impact 4.6-1 has been revised:

> The <u>majority of th</u>e remaining nine wells (Sites 2 through 6) would be installed on the eastern side of the <u>heavily</u> vegetated <u>area of the</u> sand dunes and constructed on concrete pads.

Although Impact 4.6-1 describes that some of the impacts of construction of the subsurface slant wells on western snowy plover and central dune scrub habitat would be temporary, such impacts are not "dismissed" because of the temporary nature of slant well construction. Rather, as indicated on Draft EIR/EIS pages 129 and 130, temporary loss of 8.0 acres and permanent loss of 1.0 acre of western snowy plover habitat, direct and/or indirect impacts on individual plovers, and several other construction-period impacts on special-status species, such as causing "temporary flight of breeding birds, nest abandonment, or nest failure," would be significant because of potentially lasting effects on nesting behavior in a particular area. These impacts have been qualified as temporary because the direct cause of the impacts (i.e., construction activities and disturbance of habitat) would be temporary, but for the reasons described in EIR/EIS Section 4.6.4 have been determined to be significant, because of the intensity and duration of the impact, rarity and context of the species, and susceptibility of the species to disturbance (i.e., including the potential for longer-term harm to result from temporary disturbance, such as in the event of nest failure). Impact 4.6-1 has been revised to clarify that construction-period impacts described above may have lasting effects on behavior that would be significant. This impact discussion analyzes these potential impacts and includes mitigation measures that would reduce such impacts to less than significant through implementation of avoidance and minimization measures, such as directing work to be done outside of the nesting season or requiring visual separation and/or noise reduction measures.

The terrestrial biological resources section of the Draft EIR/EIS states that portions of some project facilities may overlap with portions of other project facilities. The Draft EIR/EIS was structured so that potential impacts were analyzed for each project facility. However, discrete work limits for portions of these facilities that would overlap with each other have not been defined. During construction these overlapping work areas would not be divided into work areas for each project component, but would be treated as one work area. The Draft EIR/EIS quantifies the impact area of each project facility throughout the document. For example, Impact 4.6-2 on page 4.6-192, states "Earthmoving activities associated with installation of the Castroville Pipeline could result in the temporary loss of approximately 0.004 acre of central dune scrub, 0.15 acre of northern coastal scrub, and 0.06 acre of riparian woodland and scrub." The impact area and required mitigation for the entire project would be based on the total impact area within the entire project footprint, which would account for areas of overlap. Impacts 4.6-1, 4.6-2, 4.6-3, and Section 4.6.6, Cumulative Effects of the Proposed Project in the Final EIR/EIS have been revised to include the total acreage of sensitive biological resource habitat that would be impacted by the entire project.

Marina-73 Other than the portion that would be off-hauled (approximately 100 cubic yards), spoils returned from drilling the slant wells (approximately 1,600 cubic yards) would be composed of sand, and would form a layer less than 2 inches thick when spread within the 8-acre permanent disturbance area. Although this sand would

initially contain salts, the salinity of the sand spread within the construction disturbance area would be reduced after rains wash the salts from this layer, and would not permanently impact this area. Spoils would not be placed on top of the topsoil because topsoil would be salvaged and replaced after disturbance as required by Mitigation Measure 4.6-2b. Impact 4.6-1 in Section 4.6 has been revised to include this information; however, because this impact would be less than significant, this information does not trigger a need to recirculate the Draft EIR/EIS.

Marina-74 Impact 4.6-C does not conclude that the project's contribution to cumulative impacts on western snowy plover would be less than significant for the reasons that the commenter describes. Rather, Impact 4.6-C states that while the project's contribution would be significant, the residual effects of the project on western snowy plover after mitigation would not have a significant contribution because mitigation would avoid the potential impacts or minimize them to a degree that is not cumulatively significant. In response to this comment, Impact 4.6-C has been revised in the Final EIR/EIS to clarify the effects of the mitigation measures and how residual impacts would be minimized, as well as to describe the availability of western snowy plover habitat within the Monterey Bay Area. The cumulative impact analysis does account for the permanent, ongoing disturbance impacts related to project maintenance. Further, as described in Master Response 14, CEMEX Settlement Agreement, the closure of the CEMEX plant and planned restoration of the site now offers opportunities to implement compensatory mitigation for the project within adjacent, potentially high-quality habitat areas.

Marina-75 Impacts from slant well maintenance are evaluated in EIR/EIS Section 4.6.5.2. Slant well maintenance would disturb roughly 6 acres every 5 years (see Section 3.4.1). This would include access to and maintenance of the slant wells. Slant well operational impacts, including maintenance activities, are described in Impact 4.6-6 on Draft EIR/EIS page 4.6-235 and Impact 4.6-7 on Draft EIR/EIS page 4.6-244.

Marina-76 The biological resource information described in Section 4.6, Terrestrial Biological Resources, is based on surveys conducted by ESA, Arcadis, and AECOM between 2012 and 2016; see EIR/EIS Section 4.6.1.2.

Impact 4.6-6 explains that coast buckwheat, the host plant for Smith's blue butterfly, occurs at the site and that, "maintenance activities have potential to impact up to approximately 1.6-acre of Smith's blue butterfly habitat." The 1.6-acre impact area is the area of coast buckwheat mapped during surveys conducted by ESA, Arcadis, and AECOM between 2012 and 2016 within the slant well maintenance area. This impact assessment is based on multiple surveys conducted at the site and provides an accurate assessment of impacts based on baseline conditions.

Impact 4.6-6 identifies the mitigation measures that would be implemented and describes how they would ensure that operational impacts to sensitive biological resources are reduced to a less-than-significant level for each project facility. Mitigation Measure 4.6-1n states that CalAm shall develop and submit a Habitat Mitigation and Monitoring Plan (HMMP, not a Hazardous Materials Management Plan) to the appropriate resource agencies for approval. It will be up to each of the permitting agencies (i.e., CCC, CDFW, CCRWQCB, USACE, USFWS, MBNMS, local agencies) to determine if it expects the HMMP to be revised for each maintenance cycle or if one umbrella HMMP would suffice.

Marina-77 The mitigation measures cited in the comment are adequate and appropriate. Mitigation Measure 4.6-1c includes a list of several general measures that would be implemented to avoid and minimize impacts to sensitive biological resources, including a measure to remedy erosion. As described in Mitigation Measure 4.6-1a, a qualified biologist and/or qualified biological monitor would be onsite during all fencing and ground disturbance activities and would identify erosion as they monitor these activities. Mitigation Measure 4.6-1a also includes definitions of qualified biologist and qualified biological monitors. The term "qualified biologist" or "qualified Lead Biologist" for surveys is defined as an individual who shall possess, at a minimum, a bachelor's degree in biology, ecology, wildlife biology or closely related field and has demonstrated prior field experience using accepted resource agency techniques for the survey prescribed, and who possesses all appropriate USFWS, NMFS, and CDFW permits.

The term "biological monitor" or "qualified biological monitor" is defined as someone holding similar educational credentials to those of a qualified biologist and who has functioned as an environmental inspector or monitor on at least two construction projects within the preceding two years. This terminology is commonly employed in permits issued by the regulatory agencies; therefore, the use of it anticipates requirements that are likely to be incorporated into conditions of project approval. Erosion is a common term and a process familiar to those experienced with construction monitoring activities. A qualified biologist or qualified biological monitor has the capability to identify erosion, determine how the erosion shall be remedied, and to determine if it has been remedied.

Similarly, for Mitigation Measure 4.6-1j, a qualified biologist would conduct the preconstruction survey to determine whether the dens are inactive. As described in Mitigation Measures 4.6-1a, the qualified biologist would have the appropriate qualifications to conduct preconstruction surveys for badgers and to identify whether a den is inactive.

Regarding the use of the phrases "to the extent feasible" and "when feasible" in Mitigation Measure 4.6-2b and others, the mitigation measures include a two-tiered approach to mitigate impacts. If the first option is not feasible, then the mitigation measure provides a second option that would fully mitigate the impact. For

example, Mitigation Measure 4.6-1f, Avoidance and Minimization Measures for Smith's Blue Butterfly, states, "Construction of project elements shall be planned to avoid mapped host plants for Smith's blue butterfly whenever feasible" then "If it is not feasible to avoid disturbance to host plants during project construction, the following shall be implemented…" If it would not be feasible to avoid the host plant, then CalAm would implement measures to fully mitigate the impact.

In response to this comment, the Mitigation Measures 4.6-1c, 4.6-1e, 4.6-1h, 4.6-1i, 4.6-1k, 4.6-2b, and 4.6-6 have been revised to either include or to clarify this two-tiered approach.

Marina-78 Mitigation Measure 4.6-1i requires the implementation of avoidance and minimization measures for nesting birds. This measure requires that if work is conducted during the nesting season, then preconstruction surveys would be conducted within 14 days prior to site clearing and/or ground disturbance. In the response to comments from the California Department of Fish and Wildlife (CDFW), the measure has been revised from 14 days to 10 days. See the response to CDFW-6 in Section 8.4.2 for additional information. Mitigation Measure 4.6-1i follows the guidelines requested by CDFW, the agency responsible for enforcing California Fish and Game Code policies protecting special-status bird species. The measure adequately reduces impacts on nesting birds to less than significant for the purposes of CEQA and NEPA and follows the request by CDFW.

Similarly, Mitigation Measure 4.6-1 h, which requires implementation of avoidance and minimization measures for western burrowing owl, follows the guidelines established by CDFW in its Staff Report on Burrowing Owl Mitigation (CDFG, 2012). This report is the standard guidance report prepared and approved by CDFW to mitigate impacts to western burrowing owl. The measure adequately reduces impacts to western burrowing owl to less than significant for the purposes of CEQA and NEPA because it requires implementation of measures for avoidance of take, including establishing disturbance buffers and exclusion from burrows as outlined in standard CDFW guidance, and compensatory mitigation for loss of breeding and/or wintering habitat. See the response to comment Marina-77 regarding the commenter's statement that this measure is vague and fails to guarantee any effective mitigation.

In response to this comment, Mitigation Measure 4.6-6 has been revised to change "should" to "shall."

Marina-79 The Draft EIR/EIS did quantify the amount of permanent and temporary impact on special-status species habitat and sensitive natural communities for each facility throughout Impact 4.6-1 and Impact 4.6-2. For example, on page 4.6-132 of Impact 4.6-1, the Draft EIR/EIS states, "construction of the MPWSP Desalination Plant would result in the temporary loss of 10 acres and permanent loss of 15 acres of potential California red-legged frog and California tiger salamander upland

habitat." On page 4.6-189 of Impact 4.6-1, the Draft EIR/EIS states, "earthmoving activities associated with installation of the Source Water Pipeline could result in the temporary loss of approximately 6.7 acres of central dune scrub." Impacts 4.6-1, 4.6-2, and 4.6-3, and Section 4.6.6, Cumulative Effects of the Proposed Project have been revised to include the total project impact acreages. The amounts of permanent and temporary impact are reported in the Final EIR/EIS to the level of detail available at the preliminary design stage and include a reasonably conservative estimate of the extent of impacts. Further project refinements will occur, which are expected to reduce the impact area because preliminary estimates of areas impacted were intended to be conservatively large, and more detailed quantification of impact areas will be incorporated into the permitting process and implementation of mitigation measures, which provide that compensation acreage would be based on final design and construction specifications.

The commenter inaccurately states that "the HMMP is supposed to address the need for compensatory mitigation." Rather, Mitigation Measure 4.6-1n states that the HMMP would "outline measures to be implemented to, depending on the mitigation requirements, restore, improve, or re-establish special-status species habitat, sensitive natural communities, and critical habitat on the site." The HMMP itself would not address the need for compensatory mitigation. Compensatory mitigation requirements and ratios for permanent impacts on special-status species and sensitive natural communities are described in the species and sensitive natural community specific mitigation measures in Impact 4.6-1 and 4.6-2. The performance standards and monitoring duration are included in the revised special-status species and sensitive natural community-specific mitigation measures included at the end of this response. Mitigation Measure 4.6-1n states that the HMMP shall incorporate the performance standards described in the revised special-status species and sensitive natural community specific mitigation measures.

The project proponent is not required under CEQA or NEPA to already own or otherwise have rights to available mitigation lands to satisfy the requirements of proposed mitigation measures. Although proposed mitigation measures must be demonstrated to be feasible, at this time, the project or an alternative has not yet been approved, and mitigation measures for the project or an alternative have not yet been adopted or been required by any regulatory agency, that would result in the need for CalAm to acquire these lands. To confirm the feasibility of implementing measures requiring compensatory mitigation, ESA and AECOM biologists have spoken with Jacob Martin at USFWS and Kriss Neuman from Point Blue on July 20, 2017, to discuss potential lands that may be available and that would be suitable for mitigation. Representatives from CDFW were unavailable for the July 20, 2017 meeting. During that conference call, the existing CEMEX property, which will be required to end the mining operations in the near future (see Master Response 14, CEMEX Settlement Agreement), was identified as the most likely site that could be restored, enhanced, or preserved to provide appropriate compensatory mitigation for project impacts on coastal species.

Other potential specific lands identified by ESA biologists that may be available and suitable for compensatory mitigation land include Sparling Ranch Conservation Bank (for California tiger salamander and California red-legged frog) and the Monterey Regional Park District (special-status plants). CalAm would be held to any compensatory mitigation measures described in the Draft EIR/EIS and would be required to secure or acquire any necessary compensatory mitigation as a condition of project implementation.

In response to this comment, Mitigation Measures 4.6-1d, 4.6-e, 4.6-1f, 4.6-1h, 4.6-1m, 4.6-1n, 4.6-1o, 4.6-2b, and 4.6-3 have been revised to clarify mitigation ratios, methods for mitigating the impacts, and performance standards. These revised measures have been developed based on measures that are feasible, available, and typically included in CEQA/NEPA documents and in regulatory permit authorizations and that have been vetted by state and federal regulatory agencies with jurisdiction over the affected resources in the past. Therefore, no contingency measures are necessary given the evidence that the proposed measures are feasible and available and will be effective.

These revisions do not result in a need to recirculate the Draft EIR/EIS. As described in CEQA Guidelines Section 15088.5, "New information added to an EIR is not 'significant' unless the EIR is changed in a way that deprives the public of a meaningful opportunity to comment upon … a feasible way to mitigate or avoid such an effect … *that the project's proponents have declined to implement*" (emphasis added). Revised Mitigation Measures 4.6-1d, 4.6-e, 4.6-1f, 4.6-1h, 4.6-1m, 4.6-1n, 4.6-1o, 4.6-2b, and 4.6-3 do not disclose any new or more severe impacts and are not considerably different from those analyzed in the Draft EIR/EIS because they merely clarify or amplify the requirements of the measures analyzed in the Draft EIR/EIS, and the project proponent (CalAm) has not declined to implement these measures as revised (to the contrary, the Lead Agencies would enforce these measures if and when adopted in support of approval of the project or an alternative).

Marina-80 CEQA and NEPA do not require that mitigation measures refer to specific permits. The requirement to obtain an Incidental Take Permit is not required to be listed in Mitigation Measure 4.6-1o. Mitigation Measure 4.6-1o does state that "if California red-legged frog or California tiger salamander are observed within the construction area, a qualified biologist shall relocate the individual according to the relocation plan above and only with authorization from USFWS and CDFW." Authorization would include an Incidental Take Permit from CDFW for take of California tiger salamander as the commenter describes. EIR/EIS Section 3.5 explains that the proposed project would be subject to various regulations and could require discretionary permits from federal, state, and local jurisdictions. EIR/EIS Table 3-8 summarizes the permits and authorizations that would likely be required to build, operate, and maintain the proposed project, and includes the CDFW Incidental Take Permit.

Mitigation Measure 4.6-1a specifies that the qualified biologist that would implement surveys would possess all appropriate permits, including any CDFW permits that would be required of an ITP.

Mitigation Measure 4.6-1o was drafted to include conditions that would be consistent with CDFW's ITP requirements. In response to comments from CDFW, this measure has been revised. See the response to comment CDFW-8 in Section 8.4.2. If take of state listed species, including California tiger salamander, cannot be avoided, CalAm would apply for an ITP from CDFW prior to project implementation during the permitting process, which is separate from this CEQA/NEPA analysis.

In regard to Mitigation Measure 4.6-1g, the commenter correctly states that possession of a CDFW Scientific Collection Permit does not authorize an individual to capture and/or relocate sensitive species for CEQA compliance and, therefore, this measure does not adequately mitigate impacts to black legless lizard, silvery legless lizard, and coast horned lizard. However, Mitigation Measure 4.6-1g provides measures that describe survey methods and development of a relocation plan, in addition to the measure that the commenter lists, to adequately mitigate potential impacts to these lizards.

Marina-81 See the response to comment Marina-79.

Marina-82 Response to comment Marina-79 addresses the commenter's statement that the "Draft EIR/EIS fails to identify the lack of comparable areas suitable for compensatory mitigation …" and "fails to identify appropriate performance standards for 'success' or the duration of annual monitoring"

Impacts from periodic maintenance of the subsurface slant wells are analyzed in Section 4.6.5.2, Operational Facility Siting Impacts. As described in Impacts 4.6-6 and 4.6-7, continual disturbance of the approximately 6-acre slant well area every five years is considered a permanent impact loss of western snowy plover habitat and central dune scrub habitat. The compensatory mitigation requirement included in Mitigation Measures 4.6-1d, 4.6-1e, 4.6-1f, and 4.6-2b would only be applied once.

In response to this comment, Mitigation Measures 4.6-1d, 4.6-1e, 4.6-1f, and 4.6-2b have been revised to clarify this point.

Marina-83 As stated in Section 4.6.5.1 on Draft EIR/EIS page 4.6-171, "Mitigation Measure 4.6-1e applies to: the subsurface slant wells, MPWSP Desalination Plant, Source Water Pipeline and Source Water Pipeline Optional Alignment, New Desalinated Water Pipeline and New Desalinated Water Pipeline Optional Alignment, Castroville Pipeline and Castroville Pipeline Optional Alignments, Proposed ASR Facilities (ASR-5 and ASR-6 Wells, ASR Pump-to-Waste Pipeline, ASR Conveyance

Pipeline, and ASR Recirculation Pipeline), New Transmission Main and New Transmission Main Optional Alignment, Terminal Reservoir, Ryan Ranch-Bishop Interconnection Improvements, Main System–Hidden Hills Interconnection Improvements, and staging areas." This measure applies to all project components where special-status plant species have the potential to occur, as summarized in Table 4.6-6, and not just to the Terminal Reservoir. Mitigation Measure 4.6-2b addresses impacts to sensitive communities.

Marina-84 Compliance with regulations, statutes, ordinances, and the law is required of contractors, and is not optional. The relevant regulations are summarized in Section 4.7.2, Regulatory Framework, and contractors are legally required to know and comply with all details of the relevant regulations. Reprinting the entire text of the relevant regulations is not reasonable or necessary.

The source water pipeline would carry slant well feedwater, not potable water. The feedwater would not become potable until after treated at the desalination plant and then distributed through other pipelines not located adjacent to the outfall pipeline. Therefore, the placement of the source water pipeline near the MRWPCA outfall would not violate 22 CCR 64572.

In response to this comment, the Project Consistency with Plan, Policy, or Ordinance entry has been revised as follows:

> ~~Potentially Inconsistent~~ Consistent: Some of the project components would result in excavation in areas within the Former Fort Ord. Although cleanup activities have removed known contamination, previously-unknown contamination may be discovered. This issue is addressed in Impact 4.7-2, which requires compliance with relevant regulations.

As stated in Table 4.7-3, there would be no facilities within the City of Marina, including the slant wells, that would store hazardous materials. Further, the construction of the slant wells would not use hazardous materials, as defined in Chapter 6.5 of the California Health and Safety Code. In addition, City Municipal Code Section 8.12.070 exempts small quantities of less than 500 pounds or 55 gallons a month, whichever is less, of a hazardous material. The construction and maintenance of the slant wells would not use hazardous materials above reportable quantities. Therefore, this code would not apply.

Marina-85 EIR/EIS Section 4.7 (Hazards and Hazardous Materials), concludes in Section 4.7.3 that impacts related to hazards or hazardous materials will not impair the implementation of an adopted emergency response plan, during construction or operation. However, the analysis for potentially significant and unavoidable traffic and circulation impacts during project construction due to potentially concurrent construction of the project and other foreseeable cumulative projects is evaluated in EIR/EIS Section 4.9.6, Cumulative Effects of the Proposed Project. The analysis

notes that the schedules of the cumulative projects are unknown and it is not possible to determine whether a number of cumulative projects would occur at the same time and adversely impact traffic, thus resulting in the conservative conclusion that the cumulative impact could be significant and unavoidable. To address this, the EIR/EIS provides Mitigation Measure 4.9-C, Construction Traffic Coordination Plan, which would require CalAm to coordinate with the appropriate planning agency within each affected jurisdiction to develop and implement a Construction Traffic Coordination Plan to reduce the impact to less than significant. However, the conclusion of significant and unavoidable is retained because there is no guarantee that local agencies would participate in such coordination efforts during construction. While local and regional traffic and roadway capacity disruptions could contribute to a cumulative impact during construction, none of the roadways would be completely closed, the mitigation provides for alternative routes and this impact would therefore, not necessarily impair implementation of, or physically interfere with an adopted emergency response plan.

Marina-86 The analysis for encountering unknown hazardous materials sites is addressed in Impact 4.7-2. The text notes that "… although previous site cleanup activities have remediated known contamination at some sites, it is still possible that undiscovered contamination may be present, given the land use history in the project area." Implementation of Mitigation Measures 4.7-2a (Health and Safety Plan) and 4.7-2b (Soil and Groundwater Management Plan) would reduce this potential impact to less than significant. Because the potential for encountering unknown contamination has been addressed, no revisions were made to the EIR/EIS in response to this comment.

Marina-87 As explained in Impact 4.7-1, the well drilling methods would not use pressurized drilling techniques and frac-out events are not anticipated. Neither of the drilling methods would use fracking techniques or the chemicals used in fracking.

Marina-88 Mitigation Measures 4.7-2a and 4.7-2b do contain adequate performance standards. Mitigation Measure 4.7-2a, which is required by 29 CFR 1910.120 to include "a summary of all potential risks to construction workers and maximum exposure limits for all known and reasonably foreseeable site chemicals." The maximum exposure limits in accordance with 29 CFR 1910.120 are specifically designed to meet both public and construction worker safety standards.

Mitigation Measure 4.7-2b states that "CalAm or its contractor shall develop and implement a Soil and Groundwater Management Plan that includes a materials disposal plan specifying how the construction contractor will remove, handle, transport, and dispose of all excavated material in a safe, appropriate, and lawful manner." The RWQCB or Cal EPA human health screening levels are discussed in Section 4.7.2.2 in the subsection titled Screening Levels for Hazardous Materials in Soil or Groundwater. "Compliance in a lawful manner," as stated in Mitigation Measure 4.7-2b, includes using the cited screening levels.

Marina-89 Mitigation Measure 4.7-2b would not apply to the slant wells and the spreading of drilling spoils at the slant well location because, as discussed in EIR/EIS Section 4.7.1, there would be no hazardous materials sites at the slant well locations and none would be expected on this dune sand location. As discussed in Section 3.3.2.1, Subsurface Slant Wells, the sand-bentonite mud slurry generated during the drilling of the first 100 feet or so of the dry dune sands would be containerized and transported offsite for disposal as non-hazardous waste at a facility permitted to accept the material. The drilling spoils generated below the first 100 feet or so would consist of sand and seawater and possibly some potable water; no bentonite mud or other additives would be used to drill this portion of the slant wells. The water and sediment mixture generated during the lower portion of slant well drilling and construction would be placed in settling tanks, as necessary, to allow sediment to settle out. The volume of water produced during this drilling phase would be small enough that the construction contractor would dispose of the clarified effluent by percolating it into the ground at the CEMEX active mining area and not in sensitive dune areas. Drilling spoils generated during the lower portion of slant well drilling would consist of sand and would be spread within the construction disturbance area, not in sensitive dune areas, and would not require offsite disposal.

Marina-90 As discussed in EIR/EIS Section 4.7.1.1 in the subsection on Fort Ord Military Base Seaside Munitions Response Area (MRA), including Site 39 Inland Ranges and Former Fort Ord York School, most of the project components are located outside of MRAs and would not have the potential to encounter UXO. Those project components located within an MRA are located in areas that have already been cleared by the U.S. Army and are within areas disturbed after the closure of Fort Ord. The UXO has already been removed from the proposed areas of disturbance.

Marina-91 See response to comment Marina-90.

Marina-92 EIR/EIS Section 4.7.5.2 discusses the hazards associated with disinfection by products in the Seaside Basin, and presents the history of the ASR water quality analysis. The location of the old test injection well is not relevant since the recent and ongoing operation of the four existing ASR wells offers more contemporary information; see also response to comment USARMY-14 through -16 in Section 8.3.2. EIR/EIS Section 4.4.1 presents the Environmental Setting (see subsections titled Groundwater Quality in the Santa Margarita Sandstone and the Seaside Groundwater Basin, and Water Quality and the Existing ASR System), and Section 4.4.5 presents an analysis of the proposed injection of water into Wells ASR-5 and ASR-6 (see Impact 4.4-4, Impacts Associated with ASR Injection/Extraction Wells). The analysis evaluates the chemical reactions documented from the current injection of treated (and chlorinated) water and concludes that the continued injection of treated water would have the same short-term less than significant reaction. As explained in EIR/EIS Section 4.4.1.4, Pueblo Water Resources prepares annual Summary of Operations reports that document

the ASR system's well performance and water quality, and analyzes the water quality annually to monitor and re-evaluate the degradation rate of the disinfection byproducts every year. Therefore, no revisions were made to the EIR/EIS in response to this comment.

Marina-93 Impaired emergency access as a result of the proposed project is addressed in Section 4.9, Traffic and Transportation, Impact 4.9-4. Cumulative impacts on traffic and transportation, is addressed in Section 4.9.6. See response to comment Marina-85.

Marina-94 EIR/EIS Section 1.5.4.3 discusses other agencies' consideration of the EIR/EIS and identifies the City of Marina's authority in the issuance of a Coastal Development Permit for the slant wells, consistent with its certified local coastal plan. EIR/EIS Table 3-8 lists the anticipated permits and approvals required for the MPWSP and the City of Marina's responsibility under the Coastal Act (Cal. Pub. Res. Code §30000 et seq.) is shown on Draft EIR/EIS page 3-65.

EIR/EIS Section 4.8 addresses the potential impacts of the MPWSP on land use, land use planning and recreation. Section 4.8.2.2 presents the relevant state regulations, in this case the California Coastal Act; and Section 4.8.2.3 presents the local coastal program. The City of Marina's LCLUP is specifically presented on Draft EIR/EIS page 4.8-20, at which point Table 4.8-2 is introduced. Each resource section in EIR/EIS Chapter 4 includes a similar table that summarizes the pertinent regional and local land use plans, policies and regulations that were adopted for the purpose of avoiding or mitigating environmental effects, and indicates project consistency or inconsistency with such plans. Table 4.8-2 presents the applicable regional and local land use plans and policies relevant to land use and recreation from the City of Marina's Local Coastal Land Use Plan, and concludes the proposed project would be consistent with those land use and recreation policies. The text on Draft EIR/EIS page 4.8-29, however, identifies an inconsistency with a policy related to biological resources in Impact 4.6-4.

Impact 4.6-4, which begins on Draft EIR/EIS page 4.6-222, addresses the potential inconsistencies of the proposed project with the City of Marina LCLUP and concludes on page 4.6-224 that construction of the slant wells, the Source Water Pipeline, the new Desalinated Water Pipeline, the new Transmission Main and the staging area at Beach Road "would be inconsistent with the City of Marina LCLUP policies governing protection of Primary and Secondary Habitats, a significant and unavoidable impact." See also responses to comments Marina-70 and MCWD-150.

Marina-95 It would be premature to evaluate pre-project road conditions, and by extension to identify potential roadway rehabilitation measures, because the roads that would be used for project-related construction access and haul routes are not yet known. As stated in Mitigation Measure 4.9-6, "[t]he construction routes identified in the rehabilitation program must be consistent with those identified in the construction

traffic control and safety assurance plan developed under Mitigation Measure 4.9-1." And as stated in the second paragraph of Mitigation Measure 4.9-1, "[t]he traffic control and safety assurance plan shall be developed on the basis of detailed design plans for the approved project."

Marina-96 The commenter's point that the Walmart parking lot is privately-owned is noted, and Mitigation Measure 4.9-7 is revised as follows:

> **Mitigation Measure 4.9-7: Construction Parking Requirements.**
>
> Prior to commencing project construction, the construction contractor(s) shall coordinate with the affected jurisdictions (i.e., Monterey County, Cal State Monterey, and the cities of Marina and Seaside), and affected parties (i.e., the Walmart Superstore at 150 Beach Road), to design the staging areas to avoid or minimize parking impacts in the publicly used parking lots.

Marina-97 To further reduce construction exhaust emissions of NOx, Mitigation Measure 4.10-1a has been revised to identify construction equipment that meets Tier 4 standards as opposed to Tier 3 standards. In addition, Mitigation Measure 4.10-1a has been revised to include requirements for construction equipment powered by electricity or natural gas as well as for the use of other non-diesel powered equipment where feasible. See responses to comments MBARD-1, MBARD-3, and MBARD-4 in Section 8.5.3 for discussion of these revisions. In addition, Mitigation Measure 4.10-1e (Off-site Mitigation Program) has been added to the Final EIR/EIS to require CalAm to work with the Monterey Bay Air Resources District (MBARD) to put forth a good faith effort to fund an off-site mitigation program that would be contemporaneous with project construction to offset construction-related NOx (see response to comment MBARD-6).

Because the availability of high-tiered and non-diesel-powered construction equipment at the commencement of construction of the project is currently unknown, and the Lead Agencies cannot substantiate at this time that off-site mitigation in the form of emissions offsets is feasible (see response to comment MBARD-6), it is acknowledged that the mitigated emissions could be higher than those disclosed in the Draft EIR/EIS. To add clarity to this point, the discussion of Gaseous Criteria Pollutant Emissions in Impact 4.10-1 has been revised as follows (note that the change in mitigated pounds of NOx per day reflects the addition of the Brine Mixing Box and removal of Terminal Reservoir to/from the project subsequent to the release of the Draft EIR/EIS):

> Although the exact amount of mitigated emissions cannot be substantiated at this time due to the uncertainty in equipment availability and unknown feasibility of the off-site mitigation program, ~~F~~for ~~the~~ informational purposes ~~of estimating mitigated construction emissions of NO_x~~, if ~~it is assumed that~~ compliance with Mitigation Measure 4.10-1a would result in equipment emissions that would be equivalent to those that would be associated with

use of engines that comply with Tier 3 engine standards~~.~~ ~~.~~ ~~I~~mplementation of this mitigation measure would decrease maximum daily construction emissions of NO_x to approximately 316~~324~~ pounds per day, which would continue to result in a significant impact with respect to contributing to an exceedance of an ozone and/or NO_2 ambient air quality standard.

With regard to the City of Marina's mitigation suggestions associated with limiting the quantity and types of construction equipment, limiting construction hours of operation, and limiting fuel consumption, as well as the suggestion to undertake construction during the non-ozone season, such measures designed to reduce the daily NOx emissions to a less-than-significant level are infeasible because they would extend the construction period substantially. See response to comment MBARD-6. With regard to stationary sources of construction equipment (or other off-road exhaust emission sources), off-road construction equipment 50 horsepower or more would be covered with implementation of Mitigation Measure 4.10-1. Tier 4 emission standards are the most stringent standards available for off-road construction equipment; therefore, additional requirements to apply RACT or BACT to those sources are not warranted.

Marina-98 Implementation of Mitigation Measures 4.10-1a through 4.10-1c (revised to specify that replanted vegetation would be native, drought-tolerant) would reduce maximum daily construction emissions of PM10 to approximately 68 pounds per day, which would be below the MBARD PM10 significance threshold of 82 pounds per day. Therefore, with implementation of these mitigation measures, it can be concluded that short-term emissions associated with construction of the project would not contribute to an exceedance of a PM10 state or federal standard, and the associated impact would be mitigated to a less-than-significant level. As the impact would be less than significant with mitigation, inclusion of the additional suggested mitigation measures to control fugitive dust is not warranted.

Marina-99 Mitigation Measure 4.10-1c is referenced in Impact 4.10-3 due to its potential to control spore-containing dust from becoming airborne. The measure requires application of fugitive dust control measures to ensure that fugitive dust (which could contain coccidioides immitis spores) would be controlled to the maximum extent feasible.

Valley Fever-related less-than-significant impacts identified in the Draft EIR/EIS are discussed in terms of increased risk to public health in general (see Impact 4.10-3). It is acknowledged that people who have jobs where dirt and soil are disturbed, including construction workers that would be associated with the project, may have a higher risk of getting infected than others. It is important that workers understand the potential hazards related to their work and how to protect themselves. Employers also have responsibilities to control workers' exposure to hazardous materials, including spores that cause Valley Fever. Regulations governing Valley Fever protection and exposure are in the California Code of

Regulations regarding reporting work-connected fatalities and serious injuries, injury and illness prevention, control of harmful exposures, respiratory protection, and employer records-log 300 (8 Cal. Code Regs. §§342, 3203, 5141, 5144, 14300). Compliance with these requirements is compulsory, and failure to protect workers from exposure to spores that cause Valley Fever can result in enforcement actions.

Enforceable federal health standards also apply. The Occupational Safety and Health Administration (OSHA)'s Hazard Communication Standard (29 CFR §1910.1200) requires employees to be informed and trained about potential work hazards and associated safe practices, procedures, and protective measures. Requisite actions taken to comply with the Hazard Communication Standard could include, for example, training workers and supervisors on how to recognize symptoms of Valley Fever and identifying ways to minimize exposure, such as washing hands and changing clothes at the end of shifts. Washing facilities could be provided nearby for washing at the end of shifts. National Institute of Occupational Safety and Health (NIOSH)-approved respiratory protection with particulate filters could be made available to workers who request them. OSHA's respiratory protection standard describes the components of a comprehensive respiratory protection program (29 CFR §1910.134). Because as little as one spore may transmit the disease, the employer should assess the associated risk when potential exposure to dust is unavoidable and determine the level of respiratory protection needed based on the effectiveness of the various types of respirators for spores and particles of dusts. If a half-mask respirator with a particulate filter or a filtering face piece respirator is determined not to provide sufficient protection, e.g., because of a beard or other factor that prevents a close fit, loose-fitting powered air-purifying respirators could be an alternative.

Independent of worker safety laws, air districts also have authority to enforce compliance with air district rules and regulations that control dust and, thereby, have the effect of protecting workers and members of the public from dust-born concerns. The Antelope Valley Air Quality Management District, for example, issued notices of violation in 2013 for uncontrolled dust emissions from a construction project in a Valley Fever endemic area (Trabish, 2013). There is no indication that the MBARD would be any less aggressive in the monitoring and enforcement of the rules and regulations governing dust control in the project area.

Because these worker protection obligations are required, compliance with worker safety, health, and air quality requirements are enforceable independent of the CEQA and NEPA processes, and oversight agencies have demonstrated a willingness to enforce these obligations specifically with respect to exposure to spores that cause Valley Fever, the Lead Agencies have elected not to amend the project Health and Safety Plan to require specific avoidance measures.

Marina-100 See responses to comments Marina-97 and Marina-98, above.

Marina-101 See response to comment USEPA-4 in Section 8.3.5 for the text of the revised Mitigation Measure 4.11-1, which would require that CalAm achieve net zero GHG emissions from operational electricity use. As a result of these revisions, GHG-related impacts are reduced to a less-than-significant level as described in Section 4.11 of the Final EIR/EIS. Revisions to Mitigation Measure 4.11-1 address the comment's concerns about improper deferral by providing specific measures CalAm must take to achieve the GHG emissions performance standard outlined in the measure.

There is currently not enough project design information available to allow the Lead Agencies to describe in detail the carbon footprint for all operational components of the project in the EIR/EIS. Thus, the estimates provided in EIR/EIS Section 4.11 are based on best available information. However, Mitigation Measure 4.11-1 requires that a qualified professional prepare detailed carbon footprint information for project operation based on design specifications, and this would provide the basis for GHG emissions reductions and offsets required in this revised measure.

Marina-102 EIR/EIS Impact 4.12-4 addresses the proposed project's consistency with construction time limits established by the local jurisdictions and discusses the construction time limits allowed by local noise ordinances. This impact analysis explains that the cities of Seaside, Marina and Monterey all have ordinances that prohibit work outside of the allowable hours of construction and specifies the hours and conditions that apply for each jurisdiction. The Marina Municipal Code, Chapter 15.04, Section 15.04.055, limits outdoor construction activities that produce noise adjacent to residential uses, to the hours of 7:00 am to 7:00 pm. Project components in the city of Marina include subsurface slant wells, portions of the Source Water Pipeline, portions of the new Desalinated Water Pipeline, and portions of the new Transmission Main; portions of the new Transmission Main would be located in the city of Seaside. Mitigation Measure 4.12-4, Nighttime Construction Restrictions in Marina, specifically states that "[o]pen trench pipeline construction work within 500 feet to residential uses or transient lodging shall be restricted to the hours of 7:00 a.m. to 7:00 p.m. (standard time) Monday through Saturday, and 10:00 a.m. to 7:00 p.m. (standard time) on Sundays and holidays. During daylight savings time, construction hours may be extended to 8:00 p.m."

There are other project components (i.e. MPWSP Desalination Plant, Castroville Pipeline) that would require nighttime construction, but these components are not located within a jurisdiction with established construction time limits.

Marina-103 EIR/EIS Impact 4.12-4 addresses the proposed project's consistency with construction time limits established by the local jurisdictions and discusses the construction time limits allowed by local noise ordinances. As indicated in EIR/EIS Impact 4.12-4, no impact associated with conflicts with local construction time limits would occur from implementation of pipelines north of Reservation Road

because these components would not require nighttime construction and/or are not located within a jurisdiction with established construction time limits.

Marina-104 See response to comment USARMY-6 in Section 8.3.2.

Marina-105 See response to comment USARMY-6 in Section 8.3.2.

Marina-106 Mitigation Measure 4.12-1a states in part that, "The coordinator shall determine the cause of the complaint and ensure that reasonable measures are implemented to correct the problem." It does not include the phrase, "could be implemented." Methods of addressing noise complaints are discussed in Mitigation Measure 4.12-1b, General Noise Controls for Construction Equipment and Activities. The commenter's suggestion of providing an estimated response time for addressing noise complaints is acknowledged as reasonable, and Mitigation Measure 4.12-1a has been revised to include the following a response time requirement:

> CalAm and/or its contractor shall return all calls within 24 hours to answer noise questions and handle complaints. Documentation of the complaint and resolution shall be submitted to the CPUC weekly.

Marina-107 Mitigation Measure 4.12-1c addresses noise controls for nighttime pipeline construction and requires CalAm to submit a Noise Control Plan that "shall identify all feasible noise control procedures to be implemented during nighttime pipeline installation in order to reduce noise levels to the extent practicable at the nearest residential or noise sensitive receptor." Mitigation Measure 4.12-1c requires that at a minimum, "the Noise Control Plan shall require use of moveable noise screens, noise blankets, or other suitable sound attenuation devices be used to reduce noise levels during nighttime pipeline installation activities below 60 dBA L_{eq}." Consistent with CEQA Guidelines Section 15126.4(1)(B), Mitigation Measure 4.12-1c specifies a performance standard that would mitigate the significant effect of the project and which may be accomplished with "other suitable sound attenuation devices." The EIR/EIS does not need to specify why other controls have not been included.

The EIR/EIS contains all of the feasible mitigation measures suggested by the comment. Mitigation Measure 4.12-1d, Additional Noise Controls for ASR-5 and ASR-6 Wells, identifies that barrier blankets are available with a sound transmission class rating of 32, providing 16 to 40 dBA of sound transmission loss, depending on the frequency of the noise source (ENC, 2014). These barriers are also referred to as shrouds that are suggested by the comment. Additionally, see response to comment Marina-102 regarding Mitigation Measure 4.12-4, Nighttime Construction Restrictions in Marina.

Mitigation Measure 4.12-1b, General Noise Controls for Construction Equipment, requires muffled exhaust systems on all combustion engines for construction

equipment. Construction contractors are required to assure that construction equipment with internal combustion engines have sound control devices at least as effective as those provided by the original equipment manufacturer and no equipment is permitted to have an un-muffled exhaust. This measure also requires construction contractors to locate staging areas and stationary noise sources as far from nearby receptors as possible, and shall muffle and enclose them in temporary sheds, incorporate noise barriers, or implement other noise control measures, to the extent feasible.

Engine idling during construction is addressed in Mitigation Measure 4.10-1b, Idling Restrictions.

Electrically powered construction equipment is still in development and only a few equipment types are commercially available. Consequently, electrically powered construction equipment make up a negligible, if any portion of the contracting equipment fleet and are not considered to be a feasible mitigation strategy at present. Mitigation Measure 4.18-1 identifies specific measures that CalAm and its construction contractors would be required to implement as part of a Construction Equipment and Vehicle Efficiency Plan. The measures include a commitment to utilize existing electricity sources where feasible rather than portable diesel-powered generators.

See also response to comment USARMY-6 in Section 8.3.2.

Marina-108 A significant and unavoidable impact determination was identified with respect to construction and drilling activities associated with the ASR-5 and ASR-6 wells because, due to the proximity of sensitive receptors to this activity, it could not be demonstrated that attainment of a 60 dBA, Leq performance standard would be attainable using shielding techniques. As discussed in the response to comment USARMY-6, continuous 24-hour drilling is a requirement of constructing the ASR-5 and ASR-6 wells to prevent the borehole from potentially collapsing in on itself, filling the borehole with the surrounding geologic materials, and/or binding up the drill bit and trapping it in the borehole and seizing of the drill bit. Therefore, drilling during daytime hours only is not a feasible mitigation.

Marina-109 The closest sensitive receptors to the Desalination Plant site are residences on Neponset Road in unincorporated Monterey County; they are located 2,200 feet and 3,900 feet to the west. Construction of the Desalination Plant would be subject to the *Monterey County General Plan*. Monterey County General Plan Policy S-7.9 restricts evening construction activities within 500 feet of a sensitive land use. Because the nearest sensitive receptors are all greater than 500 feet away from the proposed Desalination Plant site, such construction activities would be consistent with Policy S-7.9. Consequently, construction activities at the Desalination Plant site would occur during times allowed by ordinance.

Marina-110 In response to this comment, the last sentence of Mitigation Measure 4.12-5, Stationary-Source Noise Controls, has been revised to specify that compliance monitoring would be based on post-construction operation of the stationary source and based on a single long-term (24-hour) measurement:

> … Once the stationary noise sources have been installed, the contractor(s) shall conduct a single long-term (24-hour) monitoring of noise levels to ensure compliance with local noise standards. CalAm shall submit a compliance monitoring report to the CPUC.

Marina-111 See responses to comments USARMY-6, Marina-106, and Marina-107.

Marina-112 Impact 4.13-2 addresses the potential for non-hazardous project construction waste to exceed landfill capacity or conflict with the California Integrated Waste Management Act provisions to reuse or recycle nonhazardous construction and demolition waste. Standard procedure for spoils disposal in the quantity that the proposed project is estimated to generate would involve coordination between CalAm or its contractor with the disposal site regarding soils testing for potential hazardous contamination. This requirement is discussed in Impact 4.7-2 in Section 4.7, Hazard and Hazardous Materials. Mitigation Measure 4.7-2b includes a requirement that CalAm or its contractor develop a Soil and Groundwater Management Plan, one required component of which is to "identify protocols for soil testing and disposal, identify the approved disposal site, and include written documentation that the disposal site will accept the waste. Contract specifications shall mandate full compliance with all applicable local, state, and federal regulations related to the identification, transportation, and disposal of hazardous materials, including those encountered in excavated soil or dewatering effluent." To provide clarification that Impact 4.13-2 addresses non-hazardous construction waste and Impact 4.7-2 addresses potentially hazardous construction waste, a cross-reference to Impact 4.7-2 has been added to the first paragraph under Impact 4.13-2.

Marina-113 The 10 constituents for which a compliance determination with the Ocean Plan water quality objectives cannot be drawn are listed in footnote 37 on Draft EIR/EIS page 4.3-101. The constituents are chlorinated phenolics, 2,4 dinitrophenol, tributyltin, aldrin, benzidine, bis(2-chloroethyl)ether, 3,3-dichlorobenzidine, 1,2-diphenylhydrazine, heptachlor, 2,4,6-trichlorophenol.

As stated on Draft EIR/EIS page 4.3-56, "the reported ambient water quality parameters and constituent levels described in Section 4.3.1.3… are considered to be representative of baseline concentrations; these are used, in part, to assess the proposed project's impacts on water quality." Section 4.3.1.3 describes the existing water quality setting and affected environment of the Monterey Bay, including salinity and temperature, dissolved oxygen, and other constituents such as pesticides, chemicals, and permitted point source discharges.

The proposed project is designed so that the MPWSP Desalination Plant would discharge brine through a multiport diffuser of the existing MRWPCA outfall and would be commingled with wastewater that is currently discharged through the outfall whenever the wastewater is available. As stated on Draft EIR/EIS page 4.3-27, the Ocean Plan requires an owner or operator of a desalination plant to first evaluate the availability and feasibility of diluting brine by commingling it with wastewater. Under Mitigation Measure 4.3-5, Implement Protocols to Avoid Exceeding Water Quality Objectives, the permittee shall complete a water quality assessment to ensure compliance with such Ocean Plan requirements and as part of the MRWPCA NPDES Permit amendment process (Order No. R3-2014-0013, NPDES Permit No. CA0048551), because in the absence of a water quality assessment, the brine may exceed water quality objective thresholds of the Ocean Plan. Implementation of Mitigation Measure 4.3-5 would ensure that data collection of source water and operational discharge quality are undertaken to establish compliance with the Ocean Plan and NPDES permit requirements. Implementation of Mitigation Measure 4.3-5 also would ensure that if the event arises where operational discharges do not meet the NPDES requirements, then operational discharges would not be released as proposed and additional design features, engineering solutions, and/or operational measures (such as additional pretreatment, additional treatment of discharge, retrofitting the existing outfall to increase dilution, and flow augmentation) would be implemented to reduce the concentration of non-conforming water quality constituents. See also response to comment Marina-41 and the discussion of the additional discharge and Ocean Plan Compliance modeling in Section 4.3.5.2 and Appendix D1.

Marina-114 As the owner and operator of the existing beach junction box and outfall, the MRWPCA was granted an Emergency Coastal Development Permit (EDCP No. G-9-16-0031, dated March 14, 2016) from the California Coastal Commission (CCC) to perform emergency protection work following the winter storms. See response to comment MRWPCA-4 in Section 8.5.9. MRWPCA sought approval from the CCC to leave the temporary protection measures in place to allow MRWPCA to conduct feasibility and alternatives analyses of a permanent protection solution (i.e., the Ocean Outfall Beach Erosion Protection Project). The permanent solution will be evaluated separately from this EIR/EIS (but included in the cumulative scenario relevant to the MPWSP; see Table 4.1-2) and would include an analysis of potential wave run-up/storm surge/coastal erosion. Studies conducted by Brown and Caldwell that were submitted by MRWPCA as comments on the Draft EIR/EIS indicate that the capacity of the outfall was not reduced as a result of the winter storms or emergency repairs.

The beach junction box relocation project would involve moving the junction box out of the surf zone and reinstalling it inland by approximately 650 to 1,000 feet. New, pre-lined 60-inch diameter outfall pipe would be installed on the westward side of the junction box, which would connect to the existing ocean outfall. The pipe diameter would match the existing outfall diameter of 60 inches, and the

overall length of the outfall pipeline would not change; therefore, the components would be sized to maintain the current outfall capacity of 81.2 mgd (Brown and Caldwell, 2017). The 2012 Trussell Technologies Outfall Capacity Evaluation is still an accurate assessment and the outfall would continue to be capable of supporting the proposed project's discharge when combined with instantaneous peak flows of wastewater effluent from the MRWPCA Regional Wastewater Treatment Plant. For these reasons, the replacement of the junction box and outfall would not change the siting or design of the proposed project.

Regarding the outfall's capacity to service the MPWSP and future wastewater flows, refer to response to comment Marina-151.

Marina-115 See response to comment Marina-114 regarding status of the beach junction box, and response to comment MRWPCA-5 for revisions to Impact 4.13-5 and Mitigation Measure 4.13-5a. The new junction box and outfall pipe segment would be pre-lined with material that would protect the components from corrosion. Therefore, the 2015 E2 Consulting Engineering evaluation of the junction box and the first 100 feet of the offshore portion of the outfall are outdated, but the conclusion that anaerobic conditions past the first 100 feet of the offshore outfall would preclude the introduction of oxygen into the concrete/steel interface of the outfall pipe, thereby preventing corrosion, remains accurate. However, as part of the *Beach Structure Evaluation and Protective Measures Technical Memorandum* (2017) Brown and Caldwell recommended that MRWPCA replace all of the WEKO seal clamps inside the nearshore area of the ocean outfall prior to the relocation of the junction box since the existing clamps could be susceptible to chloride corrosion (Brown and Caldwell, 2017).

Marina-116 In its comment letter on the Draft EIR/EIS, the MRWPCA provided additional studies on the condition of the outfall. The *Land Outfall Pipeline Evaluation and Protective Measures Technical Memorandum* (Brown and Caldwell, 2017) concluded that brine effluent would likely cause the land segment of the outfall to deteriorate and recommended the installation of a liner ahead of adding brine to the outfall. Two types of liners were recommended: a Vylon slip liner and a spiral wound HDPE liner. See response to comment MRWPCA-2 in Section 8.5.9, and the resulting revisions to Impact 4.13-5 and Mitigation Measure 4.13-5b.

Marina-117 The RUWAP Desalination Element is listed as cumulative Project No. 31, and the RUWAP Recycled Water Element is included as cumulative Project No. 35 in EIR/EIS Table 4.1-2. If the brine flow of about 1.5 mgd from the RUWAP Desalination Element were added to the 13.98 mgd of brine from the proposed MPWSP, the blended salinity would not be expected to change substantially, because according to the MCWD RUWAP Draft EIR (2004), the brine from the proposed RUWAP desalination process would have an estimated total dissolved solids (TDS) level of 47,600 mg/L, or 47.6 ppt salinity, which is lower than the estimated salinity of the brine that would be generated by the proposed MPWSP

(58.23 ppt, see EIR/EIS Table 4.3-11). As explained in response to comment MRWPCA-9, the dilution analyses presented in Appendix D1 of the Draft EIR/EIS were revised and expanded to include a wider array of flow scenarios. Discharge scenarios involving higher volumes of desalination brine were modeled to assess impacts on water quality and regulatory compliance. As noted in Final EIR/EIS Table 4.3-12, when the brine from the proposed project is blended with 0.1 mgd of trucked brine (see Note a in Table 4.3-10), the combined effluent would have a salinity of 58.1 ppt (Scenario No. 2). If an additional 2.3 mgd of desalination brine (58.23 ppt) was added to the flow (Scenario 15) the combined effluent (58.12 ppt) would increase in salinity by 0.02 ppt; not a substantial change.

As noted in Table 4.1-2, the GWR Project is currently proposed by MRWPCA to include 600 afy of advanced treated water for irrigation use on Fort Ord by MCWD. This 600 afy would replace some of the recycled water that would have been delivered by the RUWAP Recycled Water Element. The expanded GWR project, as currently proposed, has been considered in the cumulative analysis of Alternative 5a and 5b. See response to comment MRWPCA-14 in Section 8.5.9.

Final EIR/EIS Section 4.13.6.2, Cumulative Impacts during Project Operations, has been revised to include the clarifying information in this response.

Marina-118 EIR/EIS Section 4.14.1.2 explains that consideration of visual quality, visual sensitivity and landscape exposure yields a qualitative measure of the aesthetic resource value of a given area, and the meanings of these terms as they are used in the EIR/EIS are defined. EIR/EIS Section 4.14.1.2 explains that landscape units represent combinations of physical and cultural features that contribute to varying degrees of visual quality, and that landscape units are “aesthetic delineations” based upon factors such as land use, location, degree of urbanization, and boundaries of vegetation communities. The EIR/EIS does not use landscape units to represent parcel-specific characterization of land use. Hence, the landscape unit classifications do not necessarily, nor are they intended to “identify existing on-site land uses, visual characteristics, and existing levels of development” for each parcel.

The landscape units described in EIR/EIS Section 4.14.2.2 (titled Landscape Units) are general characterizations intended to describe the “regional landscape” of the project area. In comparison, EIR/EIS Section 4.14.2.3 (titled Visual Setting of the Project Area) presents the on-site land uses, visual characteristics, and existing levels of development of each proposed project facility site. These characterizations are supported by photographs, taken by the preparer of this section, of specific sites for which MPWSP components are proposed.

For example, the site of the desalination plant[3] is depicted in Figure 4.14-3a, Photograph 2, and described on Draft EIR/EIS page 4.14-13. The EIR/EIS explains the site's visual quality is low considering the industrial development surrounding the site (the Dole and Budweiser processing facility, the Monterey County landfill and the regional wastewater treatment plant and drying beds). The visual exposure is low because this site is only seen for short durations by travelers along Charles Benson Road and is screened by rows of trees to the south and west. The visual sensitivity of the site is also rated low, as the area is not located within a vista or view corridor and is not valued for recreational uses.

Further, as presented in EIR/EIS Section 4.14.5, the aesthetic resources analysis is based upon field observations conducted by the author in September 2013 and April 2016, along with a review of project maps and drawings, analysis of aerial and ground-level photographs, and a review of a variety of data available in public records. For these reasons, the visual setting and baseline conditions have been properly established, no changes have been made to the EIR/EIS in response to this comment and a need for recirculation of the Draft EIR/EIS has not been triggered.

Marina-119 EIR/EIS Figure 4.14-2 was previously presented in the April 2015 Draft EIR. The acronyms have not been identified on the figure, they do not add any value, and they have been removed from the Figure; their removal has no bearing on the analysis or impact conclusions. While not identical in each instance, the titles of the photographs in Figure 4.14-2 generally correspond with the landscape units used in Figure 4.14-1, and are sufficiently detailed to allow the reader to determine which photograph corresponds with which landscape unit or units. The similarities between photographs depicting similar landscape units is precisely due to the similarities in the landscape units the photographs are intended to represent.

EIR/EIS Section 4.14.2.2 explains that Figure 4.14-2 presents photographs that are "representative" of the landscape units shown in Figure 4.14-1. Further, EIR/EIS Section 4.14.2.3 notes that the Figure 4.14-2 photographs are intended to represent the "general setting" of the project area. EIR/EIS Section 4.14.2.3 notes that Figures 4.14-3a and 4.14-3b depict specific sites for which MPWSP components are proposed.

Marina-120 The first sentence in EIR/EIS Section 4.14.2.3 explains that "this subsection describes the existing visual character of the areas in which MPWSP components would be constructed." See the Project Area Boundary at the CEMEX property on EIR/EIS Figure 3-3a. The proposed components would be located within the disturbed area associated with prior sand mining activities within the 376-acre CEMEX site.

[3] Pursuant to CEQA Guideline Section 15096(d), in commenting on a Draft EIR, responsible agencies shall limit their comments to those project activities which will be subject to the exercise of power by the agency. The desalination plant is located in unincorporated Monterey County, and not within the City of Marina.

EIR/EIS Section 4.14.2.3 explains that "the visual quality of the Beaches and Coastal Dunes landscape unit is generally high but due to extensive alterations to the natural features at the CEMEX facility, the visual quality of the site is considered moderate. The site's visual sensitivity is high because of its location along the coast and proximity to Highway 1, which is an eligible state scenic highway. The visual exposure of the site is low, since the site is partially screened by dunes and trees and is mainly visible only from automobiles traveling along Highway 1 at speeds of 60 miles per hour. Based on the above-described factors, the site for the proposed subsurface slant wells has a moderate aesthetic resource value."

Figure 4.14-3a, Photo 1, is introduced in the Draft EIR/EIS on page 4.14-10, where it is said to represent the "Beaches and Coastal Dunes landscape unit at the CEMEX sand mining facility" which has high visual quality. The comment is correct to point out that Photo 1 was taken from within the CEMEX facility, as noted in the photo's caption. The second sentence of EIR/EIS Section 4.14.2.3 has been revised to read:

> "In addition, photographs taken from representative ~~public~~ vantage points portray~~s~~ the visual character of these locations."

See also the photo on the cover of the EIR/EIS of the southern portion of the CEMEX property, looking east, which includes the disturbed area inland of the vegetation that would be the location of the proposed slant wells. The existing test slant well is also visible on the cover photo.

Nothing in this response to comment triggers a need for recirculation of the Draft EIR/EIS.

Marina-121 See response to comment Marina-118.

Marina-122 See responses to comments Marina-118 and Marina-120.

Marina-123 EIR/EIS Figure 4.15-1, Culturally Sensitive Areas, points to the "Lapis Mining HD" and Section 4.15.2.3 clearly states that the direct and indirect Area of Potential Effects (APE) of the Source Water Pipeline would traverse the Lapis Sand Mining Plant Historic District. As noted on Draft EIR/EIS page 4.15-21, SWCA, as a consultant to the City of Marina in the evaluation of the test slant well (SWCA, 2014), recommended that the project be redesigned to avoid direct impacts on the Lapis Siding in adjacent areas that do not contain structures associated with the Lapis Sand Mining Plant. In order to avoid the Lapis Siding (see EIR/EIS Section 3.2.1.2), the proposed Source Water Pipeline would follow the CEMEX access road. Therefore, the Lapis Siding would not be impacted by the proposed project.

In addition, since publication of the Draft EIR/EIS, the California State Historic Preservation Officer (SHPO) has concurred with the finding of *No Adverse Effect*

to Historic Properties, including adverse effects to contributors to the Lapis Sand Mining Plant Historic District; see EIR/EIS Section 7.1.3.

Marina-124 In response to this comment, Section 4.16.1.1, Farmland Classifications, and Table 4.16-1, Monterey County Agricultural Land Summary and Conversion by FMMP Land Use Category, have been revised to reflect 2012-2014 agricultural conversion data for Monterey County rather than 2010-2012 data. Section 4.16.1.1 acknowledges that between 2012 and 2014, Monterey County experienced a net loss of Prime Farmland.

Marina-125 As stated in EIR/EIS Section 4.16, Agricultural Resources, the MPWSP Desalination Plant would be located on 25-acres of land that is zoned by the County of Monterey as Permanent Grazing and that is designated in FMMP maps as grazing land; however, the land has not been used for grazing or any other agricultural use since at least 1956, based on review of aerial photography of the site from 1956 through 2006, and confirmed in part based on an interview with a property manager with knowledge of the site dating to 1980 (RBF Consulting, 2012).

According to 2012-2014 California Department of Conservation Land Use Conversion data, 1,062,699 acres of grazing land were inventoried in Monterey County (CDC, 2014), and the removal of 25 acres would account for 0.0023 percent of such grazing land. In addition, a total of 739 net acres of grazing land were lost from 2012-2014, and the MPWSP Desalination Plant would account for only 3.38 percent of this net loss. For these reasons, the EIR/EIS correctly evaluated the potential impact in Impact 4.16-1, which assesses changes in the existing environment that, due to their location or nature, could temporarily disrupt agricultural activities or result in the permanent conversion of farmland to non-agricultural use, and correctly concluded that the conversion of 25 acres of grazing land for the MPWSP Desalination Plant would be a less-than-significant impact.

The 75-day public comment period for the Draft EIR/EIS provided ample opportunity for the public to review and comment on the proposed conversion. With respect to the gradual conversion of undeveloped, grazing, and/or agricultural lands that provide a buffer from more urbanized uses within the City of Marina and surrounding areas, the site of the proposed MPWSP Desalination Plant is located in unincorporated Monterey County, and is bordered on the west by agricultural fields, to the north by vacant land zoned for grazing, and to the south by Armstrong Ranch; to the east, the MRWPCA Regional Wastewater Treatment Plant and the MRWMD's landfill and recycling facilities are situated between the proposed desalination plant and the City of Marina. The 25-acre site does not act as a buffer from more urbanized uses within the City of Marina and surrounding areas.

Marina-126 The EIR/EIS adequately identifies the potential for proposed project operations to result in changes in the existing environment that, due to their location or nature,

could temporarily disrupt agricultural activities or result in the permanent conversion of farmland to non-agricultural use; see EIR/EIS Section 4.16.5.

Operational impacts related to groundwater resources are analyzed in Section 4.4, Groundwater Resources, under Impacts 4.4-3 and 4.4-4, which conclude that impacts on groundwater quantity and quality would be less than significant, which in turn means that agricultural users would not be significantly impacted by adverse effects on groundwater quality. As explained in Impact 4.4-4 on Draft EIR/EIS page 4.4-77, which relates to impacts on seawater intrusion, the MPWSP would incrementally contribute to redirecting or retarding the inland advance of seawater intrusion by capturing a portion of the seawater currently migrating inland. Figure 4.4-17 illustrates the anticipated reversal of seawater intrusion that would be due solely to the MPWSP. In addition, potential impacts on groundwater supply analyzed in Impact 4.4-3, on Draft EIR/EIS pages 4.4-57 through 4.4-68, are found to be less than significant because when desalinated water is returned to the basin, groundwater levels in the 400-Foot Aquifer underlying the Castroville Seawater Intrusion Project (CSIP) and Castroville Community Services District (CCSD) and adjacent areas would improve. Water levels could decline in the 180-FTE Aquifer by between 1 and 5 feet, but that would not expose screens, cause damage, or reduce yield in the existing, active groundwater supply wells.

Although potential impacts on groundwater supply are determined to be less than significant, the project applicant has proposed to expand the existing regional groundwater monitoring program to include the area where groundwater elevations are anticipated to decrease in the Dune Sand Aquifer, the 180-FTE Aquifer and the 400-Foot Aquifer. Applicant Proposed Measure 4.4-3 (Groundwater Monitoring and Avoidance of Well Damage), described on Draft EIR/EIS pages 4.4-74 through 4.4-75, is not required to reduce a potential impact to less than significant, but if it were determined that the project was causing groundwater levels to damage local active wells, this measure would ensure that active wells would be repaired or replaced.

In response to this comment, a cross-reference to Impacts 4.4-3 and 4.4-4 in Section 4.4, Groundwater Resources has been added to the Impact Conclusion subsection of Impact 4.16-2 in Section 4.16, Agricultural Resources, as follows:

> Impacts 4.4-3 and 4.4-4 in Section 4.4, Groundwater Resources describe the potential impacts on groundwater quality and quantity due to operation of the proposed project. As described therein, the proposed project would result in less-than-significant impacts on groundwater quality and levels. That analysis identifies less-than-significant impacts on existing users of wells that may be affected by the proposed project, including agricultural users. Because the proposed project would not affect groundwater quality or levels in a way that would adversely affect existing agricultural users, it would not result in a change in the existing environment that would indirectly result in

> the permanent conversion of Prime Farmland, Unique Farmland, or Farmland of Statewide Importance to non-agricultural use.

Regarding the topic of groundwater pumping from the basin, water rights issues are addressed in Section 8.2.2, Master Response 3, Water Rights.

Marina-127 As stated in Impact 4.16-1 in Section 4.16.5.1, Construction Impacts, the analysis assumes that agricultural land that is adjacent to, but outside of, the project area boundary would not be subject to construction disturbance. The impact analysis focuses on project facilities within the project area boundary that would require construction on agricultural land or parcels that are zoned for agricultural uses. Therefore, potential construction effects on 1.7 acres of Prime Farmland that are on the northern portion of the 46-acre parcel shared by the MPWSP Desalination Plant site are not included in the analysis of direct impacts because the Prime Farmland is not adjacent to and is not within the project boundary of the MPWSP Desalination Plant; there would be no impact.

As stated in Impact 4.16-3 in Section 4.16.5.2, Operational and Facility Siting Impacts, proposed development of the MPWSP Desalination Plant on the 25-acre upper terrace of the 46-acre parcel would be allowed with a use permit from Monterey County (Monterey County Zoning Code, Section 21.34.050). The use permit would not convert the entire 46-acre parcel to an industrial use, but would allow for a "public and quasi-public land use, including public utilities" on the 25-acre portion of the parcel. Therefore, siting and operation of the MPWSP Desalination Plant would not limit, constrain, and/or prevent any future agricultural uses within the 1.7-acre portion of the parcel that is designated as Prime Farmland.

Finally, CEQA and NEPA do not require an analysis of impacts on speculative future uses of a particular property. This parcel hasn't been used as productive farmland in several decades, and there is no evidence that suggests that the use of a portion of the parcel for the Desalination Plant would preclude the productive use of an unattached piece of Prime Farmland elsewhere on the parcel. It is inaccurate to state that this piece of land would "fallow" as a result of the project because it already has been uncultivated for decades independent of this project.

Marina-128 See response to comment Marina-125 and Marina-127. The entire 46-acre parcel, with the exception of the unconnected 1.7 acres of Prime Farmland that would not be affected by the proposed project, has not been used for grazing or any other agricultural use since at least 1956. In response to this comment, the following text has been revised in Impact 4.16-3, under the MPWSP Desalination Plant heading:

> Current and recent uses of a property can provide a practical measure of its suitability for agriculture. The 46-acre MPWSP Desalination Plant parcel is zoned for Permanent Grazing, but with the exception of the unconnected 1.7 acres of this parcel that form a portion of a neighboring farm and which

would not be affected by the proposed project, the property has ~~been idle for five or more years~~ not been used for grazing or any other agricultural use since at least 1956 (RBF Consulting, 2012). Section 21.34.050 of the Monterey County Zoning Ordinance allows for public and quasi-public land uses including public utilities on land zoned for Permanent Grazing (Monterey County, 2011). Therefore, the proposed development of the 25-acre upper terrace of the parcel for the MPWSP Desalination Plant site would be allowed with a use permit from Monterey County. The 200-foot buffer between farmland and new development that is required by the Monterey County Municipal Code has been accounted for in the preliminary site plan for the MPWSP Desalination Plant (see Figure 3-5b in Chapter 3, Description of the Proposed Project. Therefore, the proposed desalination facilities on the upper terrace would not conflict with the existing zoning for agricultural uses.

Marina-129 See response to comment USEPA-4 in Section 8.3.5 for revisions to Mitigation Measure 4.11-1, which would require the use of renewable energy, including from the LFGTE facility expansion if available, as a primary method of reducing or offsetting operational electricity demand. The City of Marina's comments regarding the necessity of the project to meet water demand (i.e., comments on Sections 2.1 through 2.5) are addressed in detail above. As described in Impact 4.18-2, while the proposed project would require a large amount of electricity each year to operate, it is necessary to provide drinking water to area residents to protect human health and safety. Further, the proposed project would not consume energy wastefully or inefficiently. The design and construction of the MPWSP Desalination Plant would incorporate various energy-efficient design elements into building support systems, electrical and treatment equipment, and process design that would reduce operational energy demand. Electricity consumed as a result of project operations would not be unnecessary, wasteful, or inefficient and the energy conservation impact related to the use of fuel and energy during project operations would be less than significant. CEQA does not require "inclusion of all feasible energy conservation technologies/measures," even for large projects, if no significant unnecessary, wasteful, or inefficient use of energy would occur.

Although not required to reduce an energy conservation impact, implementation of Mitigation Measure 4.11-1, GHG Emissions Reductions Plan, would require CalAm to have a qualified professional prepare a GHG Emissions Reduction Plan that must include a summary of state-of-the-art energy recovery and conservation technologies available for utility-scale desalination facilities and must include a commitment by CalAm to incorporate all available feasible energy recovery and conservation technologies; or, if CalAm finds that any of the technologies will not be feasible for the project, the Plan shall clearly explain why such technology is considered to be infeasible.

Regarding the specific suggested mitigation in the comment, the EIR/EIS addresses these as follows:

Construction

1. Mitigation Measure 4.10-1b already included a requirement to notify construction vehicle and equipment operators of State-required idling time limits in order to ensure enforcement of these requirements. Further, in response to comment CURE-Fox-15, the idling time limit for off-road diesel engines has been lowered from the State-required 5 minutes to 2 minutes.

2. See response to comment Marina-97 regarding the use of Tier 4 equipment.

3. Construction and demolition waste is addressed in Mitigation Measure 4.13-2: Construction Waste Reduction and Recycling Plan.

4. This suggestion is unrelated to the topic of energy conservation, and GHG emissions are addressed and mitigated in EIR/EIS Section 4.11.

5. The use of alternative fuels for construction equipment (including, as applicable, electric equipment) is addressed in Mitigation Measure 4.10-1a: Equipment with High-Tiered Engine Standards and would apply to generators used during construction.

6. The use of alternative fuels for construction equipment is addressed in Mitigation Measure 4.10-1a: Equipment with High-Tiered Engine Standards.

7. See response to comment Marina-97 regarding the use of Tier 4 equipment; which conform to the most stringent standards available for off-road construction equipment. It would be infeasible to require that the diesel equipment fleet exceed the current highest tier; such equipment cannot reasonably be expected to be available.

Operations

1. Senate Bill 743, which pertains to transit oriented infill projects, is not relevant to the proposed project.

2. It is unclear to what "jurisdiction-wide EV proliferation goals" the comment refers; none are known to apply to the proposed project.

3. Local (i.e., Monterey County) parking requirements are not relevant to the proposed project.

4. It is unclear whether the comment refers to vehicles of employees who may carpool to the site, carsharing services, or another type of "shared vehicle;" however, the small number of operational employees contributes only marginally to the anticipated operational energy use, and the Lead Agencies cannot compel project employees to share vehicles when accessing the site; therefore, the usefulness of providing parking for shared vehicles is speculative.

5. The proposed project does not include multi-family residential projects or non-residential projects.

6. Operation of the proposed project would not impact bicycle, pedestrian, or transit connections, and no such amenities would be applicable to operational employee access to the MPWSP Desalination Plant.

7. The use of on-site renewable energy production is addressed in Mitigation Measure 4.11-1.

8. The proposed project includes no wood-burning fireplaces or developments that may contain wood-burning fireplaces.

9. The proposed MPWSP Desalination Plant would not be located in an area that experiences urban heat island effect; therefore, measures designed to reduce such an effect are not relevant to the proposed project.

10. The use of on-site renewable energy production is addressed in Mitigation Measure 4.11-1.

11. Organic collection would not be relevant to operation of the proposed project.

12. The proposed project is not a new development and landscaping at project facilities would be minimal.

13. Operational energy performance targets are discussed in Mitigation Measure 4.11-1.

14. See Mitigation Measure 4.11-1 for a discussion of the GHG Emissions Reduction Plan that must include a summary of state-of-the-art energy recovery and conservation technologies available for utility-scale desalination facilities and must include a commitment by CalAm to incorporate all available feasible energy recovery and conservation technologies.

15. The proposed project does not include the design of bike lanes, nor do the Lead Agencies have the ability to require CalAm to develop bike lanes on Charles Benson Road, a private roadway.

16. Operation of the proposed project would not significantly alter drainage patterns; therefore, green infrastructure would not be a necessary mitigation measure for the proposed project.

17. The proposed project does not include public parking areas, and no such amenities would be applicable to operational employee access to the MPWSP Desalination Plant.

18. The proposed project is not a specific plan.

19. The proposed project would not create or be located near a major employment center.

20. No such amenities would be applicable to operational employee access to the MPWSP Desalination Plant.

21 through 23. The proposed project is not a residential development.

24. The small number of operational employees contributes only marginally to the anticipated operational energy use, and it would be speculative to assume energy use reductions could be achieved by requiring the provision of charging stations, because it cannot be known whether individual employees would own electric vehicles.

25. The proposed project is not on a park or public/quasi-public land.

26 and 27. The proposed project is not a residential development.

28 through 30. The proposed project is not a residential or commercial development.

31. See item 14, above.

32. The small size of the Desalination Plant parking lot would not create adverse energy impacts; therefore, tree cover would not be required.

33. See item 16, above.

34 through 36. See Mitigation Measure 4.11-1 for a discussion of the GHG emissions reduction plan and subsequent offsets of operational energy use.

Marina-130 Although Impact 4.18-3 would be less than significant independent of the implementation of Mitigation Measure 4.11-1, the measure would reduce energy consumption. Mitigation Measure 4.11-1 has been revised in the Final EIR/EIS to include measures that would further reduce the project's energy consumption and reduce GHG emissions. Therefore, PG&E's conclusion in the personal communication that it has adequate capacity and infrastructure to support the proposed project remains valid, even more so, since revised Mitigation Measure 4.11-1 would reduce energy consumption more than initially proposed in the Draft EIR/EIS. A written record of the communication with Jose Saldana at PG&E was included in the reference materials for the Draft EIR/EIS that were made available during the public review period.

Marina-131 See responses to comments Marina-129 and Marina-130. No significant impact related to energy consumption would occur during project operation; therefore, no mitigation is required. Nothing in these comments or responses triggers a need to recirculate the Draft EIR/EIS.

Marina-132 Both NEPA and CEQA requirements for analyzing environmental justice impacts are addressed in Section 4.20, Socioeconomics and Environmental Justice. This section also describes and cites CEQ's 1997 environmental justice guidance document.

With respect to impacts on coastal habitats and the coastal ecosystem in Marina, see responses to comments Marina-65 through Marina-83. With respect to impacts on coastal erosion in Marina, see responses to comments Marina-36 and Marina-37.

Responses to comments Marina-39 and Marina-113 address water quality impacts from brine discharge, and responses to comments Marina-5 through Marina-10 and Marina-45 through Marina-61 address groundwater impacts. Each of these categories of impacts would be less than significant, in some cases with implementation of mitigation measures. Thus, no "wide range of severe environmental impacts" as described in the comment would occur in relation to these resources; the conclusions in the EIR/EIS that no significant adverse impacts on these resources would occur is the basis for the Section 4.20 determination that no disproportionately high and adverse impacts related to these resources would occur. Similarly, cumulative impacts are analyzed based on the potential for the project to contribute to significant cumulative impacts; for these resources, the EIR/EIS found no potential for significant cumulative impacts that could result in disproportionately high and adverse environmental justice impacts. Sections 4.2 through 4.19 do not address environmental justice impacts.

Marina-133 As described in EIR/EIS Section 4.20, to determine whether there would be any proposed project environmental impacts that could disproportionately affect communities of concern, all of the individual resource issue area analyses in EIR/EIS Sections 4.2 through 4.19 were evaluated. Individual physical effects, cumulative effects, and potential aggregate or additive effects among different issue areas were reviewed. Only Section 4.10, Air Quality, described impacts that could result in a disproportionately high and adverse impact on minority and/or low-income populations.

In compliance with Federal Council on Environmental Quality (CEQ) guidance, the Lead Agencies have evaluated the land-based impacts in the context of environmental justice impacts; e.g., with respect to air pollutant emissions. As stated in EIR/EIS Section 4.20.4.2, the potential for disproportionately high and adverse impacts on minority and low-income populations was assessed applying USEPA's Guidance for Incorporating Environmental Justice Concerns in USEPA's NEPA Compliance Analysis (USEPA, 1988). EIR/EIS Section 4.20 identified and applied criteria for evaluating these air pollutant emissions in the context of environmental justice, including reference to maximum daily emissions scenarios and significance thresholds. Based on this analysis, EIR/EIS Section 4.20 concludes that the project would not result in a disproportionately high and adverse impact on minority and/or low-income communities. Section 4.20.6 also analyzed the potential for cumulative impacts with respect to environmental justice, and concluded that the potential cumulative impact in the identified regions would be less than significant.

The comment is unclear regarding what "multiple interrelated" project impacts it refers to or how the impacts discussed in response to comment Marina-132 might be additive. Consistent with CEQ guidance that requires consideration of cumulative or multiple adverse health or environmental hazard exposures (Council on Environmental Quality, 1997), the EIR/EIS considers those resource impacts

that could affect health issues such as air quality, GHG emissions, noise, and hazardous materials exposure. Review of these impact topics in Chapter 4 does not indicate that there would be a substantial aggregate effect of resource impacts or disproportionately high and adverse impacts on minority and/or low-income communities. The less than significant (and thus, not "high and adverse") impacts on separate types of resources identified in Chapter 4 would not combine with one another to result in greater impacts from an environmental justice perspective. For more information, see EIR/EIS Section 4.20, which considers the potential cumulative environmental justice impacts of emissions, project construction and siting, and water rates increases within the context of the cultural, social, historical, and economic factors in the Monterey District, and considers that these impacts would be less than significant.

The EIR/EIS does in fact quantify potential disproportionately high and adverse impacts spatially – see Table 4.20-6 which quantifies emissions near specific minority and low-income communities and compares them to emissions near specific communities not identified as minority or low-income, consistent with the approach suggested in the USEPA guidance document.

The environmental justice analysis is not segmented – EIR/EIS Section 4.20 includes a complete analysis of environmental justice issues, in compliance with federal requirements. The analysis necessarily relies on individual physical resource impacts identified in Chapter 4, but evaluates these impacts from the perspective of environmental justice issues, including assessment of aggregate effects.

Although all resource topics were considered in the analysis and determination of the environmentally superior/NOAA preferred alternative, the differing conclusions with respect to environmental justice impacts of alternatives (which are based on the air quality conclusions related to PM_{10} emissions) were inadvertently excluded in the discussion of the environmentally superior alternative in Draft EIR/EIS Section 5.6. This section has been revised to acknowledge that Alternatives 3 and 4 would have potentially significant and unavoidable impacts related to PM_{10} emissions, which could result in significant and unavoidable environmental justice impacts. This revision does not change the conclusions of the EIR/EIS, but simply restates conclusions in Section 5.6.

With respect to the comment that the EIR/EIS "dismisses without evaluation" potential depletion and degradation of Marina's water supply, see responses to comments Marina-5 through Marina-10, Marina-45 through Marina-61, Master Response 3, Water Rights (particularly Section 8.2.3.7) and Master Response 8, Project Source Water and Seawater Intrusion.

Finally, mitigation specific to environmental justice impacts is not required because appropriate mitigation already is provided in EIR/EIS Section 4.10, Air Quality, to

address potential disproportionately high and adverse impacts. See discussion in EIR/EIS Section 4.20.5.2. Also, there are many other mitigation measures in individual resource areas in Chapter 4 that reduce the overall physical impacts of the proposed project and therefore reduce the project's aggregate effects on communities of concern.

Marina-134 See responses to comments Marina-5 through Marina-10 and Marina-45 through Marina-61 and Master Response 8, Project Source Water and Seawater Intrusion. Because the proposed project would not exacerbate seawater intrusion or cause other adverse groundwater quality impacts, no socioeconomic effect is expected to stem from such physical impacts.

Marina-135 CEQA and NEPA require that an EIR/EIS analysis of cumulative environmental impacts focus on those impacts to which the project would contribute. Except with respect to emissions of criteria pollutants from pesticides, fertilizers, or other soil amendments (addressed below), the proposed project would not contribute to cumulative impacts related to use of pesticides, fertilizers, or other soil amendments from agricultural operations because it does not propose to use any of these materials. Additionally, the project would not contribute to impacts related to offensive odors (see EIR/EIS Section 4.10, Air Quality, Impact 4.10-5). Therefore, while the Lead Agencies acknowledge the concerns regarding existing environmental burdens caused by these impacts, the evaluation of the proposed project properly focuses on other types of impacts to which the project could or would contribute.

See Footnote 2 in Section 4.1, which states, "While a cumulative analysis includes past, present and reasonably foreseeable future projects, the category of past projects is captured within the existing setting, or baseline, against which impacts are judged throughout the EIR/EIS, including the cumulative analysis. However, where projects were implemented after 2012 (the baseline year), those projects are set forth within Table 4.1-2 and included in the cumulative analysis." Accordingly, air pollutant emissions from the existing Monterey Regional Water Pollution Control Agency (MRWPCA) facilities, existing Monterey Peninsula Regional Waste Management District (MPWMD) facilities, livestock ranching and other agricultural activities, and other facilities and activities that have existed in the Marina area since before 2012 are reflected in baseline conditions. Section 4.10, Air Quality, describes baseline criteria air pollutant concentrations based on data from the nearest ambient air quality monitoring station, which has not recorded any violations of the state or federal criteria air pollutant standards from 2011 through 2015.

In addition, as described in Section 4.10.6, in developing thresholds of significance for air pollutants, MBUAPCD considered the emission levels for which a project's individual emissions would be cumulatively considerable; therefore, if individual project emissions would exceed the identified significance thresholds, a significant cumulative air quality impact would occur and the project's contribution to the cumulative impact would be considered significant. Thus, it would be inappropriate

to quantify the emissions from baseline facilities and activities and cumulative projects and add these to the proposed project's emissions estimates to analyze cumulative effects, because there are no relevant numeric emissions thresholds that would apply to such a total.

In response to this comment, a description of the above-mentioned existing sources of air pollution in and near the City of Marina and other communities identified in the environmental justice analysis has been added to Section 4.20.6. Because the analysis already accounted for baseline air quality, and because project-level criteria air pollutant significance thresholds remain relevant to the proposed project's emissions regardless of other past, present, and reasonably foreseeable future projects, this information does not result in a change in the conclusions regarding the project's potential to contribute to cumulative impacts.

Relevant numeric emissions standards used in the Impact 4.20-2 analysis are provided in Table 4.20-6 and discussed in Impact 4.20-2.

Marina-136 The Lead Agencies acknowledge the City of Marina's concerns regarding its discretionary approval authority with respect to the Coastal Development Permit that would be required in order for the project to proceed. The Lead Agencies understand that certain City of Marina decisions under its Local Coastal Program may be appealed to the California Coastal Commission (CCC), potentially resulting in a CCC decision that is inconsistent with the City's decision and preference. Both CPUC and MBNMS will consider the City of Marina's comments in their respective decision-making processes. Specific concerns related to water supply, coastal resources, traffic, and noise are addressed in above responses.

Marina-137 See response to comment Marina-4.

Marina-138 See Master Response 8, Project Source Water and Seawater Intrusion, for more information on the capture zone, the cone of depression, seawater intrusion and project effects on groundwater resources. See Master Response 12, The North Marina Groundwater Model (v. 2016), for more information on the NMGWM. See also responses to comments Marina-55 through Marina-62 regarding the analysis of the proposed project's impacts on groundwater in the EIR/EIS. Contrary to the comment, the discussion of groundwater impacts was not dropped from the EIR/EIS analysis of alternatives in Chapter 5. EIR/EIS Table 5.6-1 presents the comparison of the impacts on groundwater resources for all alternatives, and concludes that the impacts for all alternatives would result in a decreased severity (shown by the down arrow) for operational groundwater impacts and the impact conclusions are either the same as the proposed project (less than significant) or No Impact (No Action alternative).

Marina-139 The EIR/EIS describes a total of eight alternatives, including the proposed project, the No Project alternative, and Alternatives 1 through 5b in EIR/EIS Section 5.4,

and evaluates these alternatives in Section 5.5. The extensively detailed screening of components is provided in EIR/EIS Section 5.3, and includes the screening and evaluations of 13 intake options, 7 outfall options, and 3 desalination plant site options in Sections 5.3.3, 5.3.4, and 5.3.5, respectively.

Marina-140 The commenter is incorrect that the EIR/EIS does not analyze an alternative of a size that would produce less water than the proposed project (the proposed project being either a 9.6 mgd desalination plant or a 6.4 mgd desalination plant that would be combined with a water purchase agreement whereby CalAm would procure water from the GWR project for its customers). Both Alternatives 5a and 5b are described in EIR/EIS Section 5.4 and are evaluated in EIR/EIS Section 5.5 with a 6.4 mgd desalination plant alone (at the CEMEX location and Potrero Road locations, respectively). Thus, the environmental impacts of these alternatives, as presented in the EIR/EIS and compared to the other alternatives, do not include effects of the GWR project. Alternatives 5a and 5b would produce approximately 3,500 afy less water than the proposed project; as such, each of these alternatives would produce only two-thirds the water of a 9.6 mgd desalination plant.

Clearly, the EIR/EIS analyzes alternatives that would avoid or minimize some of the project's environmental effects though they would impair attainment of the project objectives to some degree.[4] This is explained as to Alternative 5a, for example, in Section 5.4.7.3, Ability to Meet Project Objectives, where the EIR/EIS explains that implementation of Alternative 5a on its own and without the GWR project and associated water purchase agreement, would only partially meet the project objectives because the 6.4-mgd project would not develop enough supply to serve the existing land uses and water entitlements [12,845 afy] baseline or associated peak demands in CalAm's Monterey District. The 6.4 mgd desalination plant in combination with other existing sources (Carmel River legal entitlement, Seaside Basin, ASR, and Sand City Desalination) would achieve compliance with Order 95-10 and the Seaside Groundwater Basin Adjudication. However, Alternative 5a would not provide water supply reliability; and would not provide supply to fully serve Pebble Beach water entitlements or anticipated economic recovery at existing businesses. It would not provide enough supply to enable development of vacant legal lots of record. Assuming that the GWR Project is constructed (which is assumed in the cumulative analysis for this alternative), it would provide 3,500 afy of potable supply for the CalAm service area. Alternative 5a in combination with the GWR Project supply would meet the project objectives.

The GWR project is evaluated in the context of Alternatives 5a and 5b as a cumulative project. For further information on project objectives, see response to comment MCWD-2 in Section 8.5.2. Also see Master Response 13, Demand (Project Need) and Growth, concerning projected water needs in CalAm's service

4 Because the EIR/EIS does evaluate these two smaller-sized options, the cases cited by the commenter are inapplicable.

territory and to satisfy the project objectives. As explained in Master Response 13, if the Lead Agencies determine, based upon the evidence in the record, that project objectives could be satisfied with a lesser amount of water than would be supplied with either the proposed 9.6 mgd desalination plant or the 6.4 desalination plant, then the Lead Agencies could opt to approve a smaller project.

Marina-141 See response to comment Marina-11, MCWD-168, and MCWD-170 through MCWD-175.

Marina-142 See response to comment Marina-140 and MCWD-168. Alternatives 5a and 5b, at about two-thirds the size desalination plant as the proposed project, are designed to lessen or avoid environmental effects. While Alternatives 5a and 5b as to many resource areas have the same classification of impact as the larger plant (e.g., significant or less than significant), the EIR/EIS plainly sets forth the comparative volume or quantity of the effect, which is generally less than that of the proposed larger plant. For example, as to energy impacts, EIR/EIS Section 5.5.18.8 provides, "Alternatives 5a and 5b would have a decreased desalinated plant capacity; therefore, the total operational electricity demand would be reduced compared to the proposed desalination plant; approximately 3.7 MW, which is equivalent to approximately 63 percent of that for the proposed project."

Marina-143 See response to comment Marina-4 and Marina-140 and Master Response 13, Demand (Project Need) and Growth.

Marina-144 See response to comment Marina-123; the proposed project would not cause a significant impact to historic resources. See response to comments Marina-55 through MCWD-62 regarding the EIR/EIS analysis of the proposed project's impacts on groundwater resources.

As noted on Draft EIR/EIS page 5.5-83, "Proposed project slant well pumping would not exacerbate seawater intrusion because the slant wells would capture seawater as it crosses the coast and proposed project pumping is therefore, expected to retard future inland migration of the seawater intrusion front. The impact on seawater intrusion would be less than significant." But the EIR/EIS does not draw the same conclusion for alternatives with screened open water intakes. In fact, the EIR/EIS concludes that an alternative with an open water intake "would not extract source water from groundwater aquifers, and would not include in-lieu recharge of the 400-Foot aquifer because Salinas Valley return water would not be required; the open water intake would not deplete groundwater supplies or interfere with groundwater recharge. Operation of Alternative [. . .] would have no impact on local groundwater levels in the SVGB, a reduced potential for impact compared to the proposed project." See EIR/EIS Sections 5.5.4.5 for that conclusion about Alternative 2 (Open Water Intake at Potrero Road), Section 5.5.4.6 for Alternative 3 (DeepWater Desal) and Section 5.5.4.7 for Alternative 4 (People's Project). Thus, while some options would have a less than significant impact on groundwater resources, other options would have no impact on groundwater

resources. These comparative impacts will be taken into account in the decision-making process.

Marina-145 See response to comment Marina-4, regarding project objectives and purpose and need. EIR/EIS Section 5.6, provides 20 pages of discussion on the environmentally superior alternative, including an introduction, an overview of assumptions (Section 5.6.1.1), a summary of the significant impacts of the proposed project (Section 5.6.1.2), a discussion of the key differences between alternatives (Section 5.6.1.3) and a determination of the environmentally superior and NEPA-agency preferred alternative (Section 5.6.2); Table 5.6-1 provides an Alternatives Impact Summary.

The selection of the environmentally superior (CEQA) and environmentally preferred (NEPA) alternative did not downgrade any alternative with an open water intake because of permitting complexities and potential delays. The EIR/EIS explains in Section 5.6.1.3 that, "Three of the alternatives would use screened, open water intakes, which would reduce or avoid several proposed project impacts but result in new significant impacts." Section 5.6.1.3 further explains that the key differences in impacts pertaining to open water intakes include: the use of barges for construction and the placement of ballast rock on the seafloor within MBNMS which could result in temporary and permanent direct and indirect effects on marine habitat and associated marine biological resources, as well as historical resources (i.e., shipwrecks) in Monterey Bay; construction and operation of new facilities within a ravine of the Monterey Submarine Canyon could result in temporary and permanent effects due to unstable slopes; and the operation of screened open water intakes would result in long term effects on marine biological resources within MBNMS.

Two of the screened open water intake alternatives (Alternative 3, DeepWater Desal, and Alternative 4, People's Project) were determined not to be the environmentally superior alternative because, based on current information, each would produce more water than the proposed MPWSP and while they would each meet most of the project objectives and purpose and need, these alternatives would not generally reduce or avoid the potential significant environmental impacts of the proposed MPWSP. Alternative 2, the other open water intake alternative, was determined not to be the environmentally superior alternative because construction of the new intake structure would result in greater impacts on the seafloor than the proposed project, and operation of an open water intake would result in long-term marine biological impacts from impingement and entrainment. See EIR/EIS Section 5.6.2.

Marina-146 EIR/EIS Section 5.6.2 explains, "The impacts of the subsurface intakes at Potrero Road (Alternative 1), however, would have a greater impact on groundwater levels in the Dune Sands, 180- and 400-Foot aquifers, resulting in greater impacts on marine and terrestrial biological resources at Elkhorn Slough than pumping at CEMEX (proposed project). Therefore, neither Alternative 1 nor Alternative 5b

would offer overall environmental advantages over the proposed project or reduced-size alternative (Alternative 5a)." This conclusion is supported by the analysis in EIR/EIS Section 5.5.4.4 and Figure 5.5-2: "The extent of modeled drawdown in the Perched "A" Aquifer is almost twice the inland distance modeled at CEMEX for the proposed project because: 1) the Perched "A" Aquifer is not as thick as the Dune Sand Aquifer underlying the CEMEX site, and 2) the ocean water capture zone is restricted at Potrero Road to the Perched "A" Aquifer (the wells would not be screened in the 180/180-FTE Aquifers) because the underlying Salinas Valley Aquitard separates the Perched "A" Aquifer from the 180-Foot Aquifer."

EIR/EIS Section 5.5.4.4 further explains, "Modeling indicates that pumping under Alternative 1 would influence the Perched "A" Aquifer north of Potrero Road and the cone of depression would encompass the mouth of the Elkhorn Slough and about 1-mile inland up the slough (a portion of which is within MBNMS). This effect is shown by the 1-foot drawdown contour lines on Figures 5.5-2 and 5.5-3 and these results suggest a direct or indirect effect of project pumping at Potrero Road on the surface water/groundwater interaction in the Elkhorn Slough." Section 5.5.4.4 concludes that, "Alternative 1 would not impact groundwater levels in neighboring wells or contribute to seawater intrusion within the SVGB … and would result in the same impact conclusion as the proposed project, less than significant."

While minimal data are available for the Potrero Road site to assess the historical model calibration, borehole data collected at the Potrero Road site and at nearby Moss Landing helped confirm the modeled hydraulic conductivity in the Perched "A" Aquifer. EIR/EIS Appendix E2, Attachment 2, presents an Expanded Model which included Elkhorn Slough and the lower portion of the Pajaro Valley. The expansion was based on the USGS Pajaro Valley Hydrologic Model. The Expanded Model results indicate that the cone of depression due to slant well pumping at the Potrero Road site would extend northward into the Pajaro Valley by approximately one-half mile in the Perched "A" Aquifer, and approximately three-quarter mile for the 180-Foot/FTE Aquifer. While the amount of the groundwater that would otherwise flow into Elkhorn Slough cannot be quantified, the groundwater-surface water interaction at Elkhorn Slough is not speculative and a cone of depression from pumping at the well sites would have an effect on flows in Elkhorn Slough.

As described in Marine Biological Resources, EIR/EIS Section 5.5.5.4, based on the predicted areal extent of the drawdown, slant well pumping operations at Potrero Road could potentially adversely affect aquatic habitat in Elkhorn Slough due to reduced surface water flow and volumes. This would be an increased level of impact compared to the proposed project and because there is no method to mitigate for impacts on surface water flow and volumes in Elkhorn Slough, Alternative 1 would result in an ***increased impact conclusion*** on marine species,

natural communities or habitat, protected wetlands or waters, and critical habitats compared to the proposed project, significant and unavoidable.

As explained in Terrestrial Biological Resources, Section 5.5.6.4, Alternative 1 would also avoid the proposed project's impacts on steelhead habitat in the Salinas River and Tembladero Slough, but instead may affect steelhead habitat in Elkhorn Slough. "While the modeling cannot predict the amount of water diverted from Elkhorn Slough, it must be conservatively assumed, based on the predicted areal extent of the drawdown, that operations could potentially adversely affect steelhead habitat in Elkhorn Slough due to reduced surface water flow and volumes."

The comment criticizes the EIR/EIS for making conservative assumptions as to impact conclusions when the precise amount of the impact is not known. This approach, however, is typical in NEPA and CEQA analyses and consistent with the standard approach of the Lead Agencies.

Marina-147 The analysis of alternatives in EIR/EIS Section 5.5 includes a reduced sized desalination plant with fewer slant wells: Alternatives 5a and 5b. The selection of the environmentally superior alternative is presented in detail in EIR/EIS Section 5.6, and as stated therein, the smaller desalination plant in Alternative 5a would be the environmentally superior alternative; if the GWR project were implemented, this alternative would be the environmentally superior alternative that meets the basic project objectives. Otherwise, the proposed project would be the environmentally superior alternative for the reasons stated in EIR/EIS Section 5.6.2. Further, see responses to comments Marina-137 and Marina-138 through Marina-146 regarding the fully adequate, legal, and detailed analysis of alternatives provided in Chapter 5 of the EIR/EIS.

Marina-148 See responses to comments Marina-97 through Marina-100 (Air Quality), Marina-101 (Greenhouse Gas Emissions) and Marina-129 through Marina-131 (Energy Conservation). EIR/EIS Section 6.1 has been revised accordingly.

Marina-149 See responses to comments Marina-3 and Marina-4, as well as Master Response 13, Demand (Project Need) and Growth, regarding the estimates of existing annual demand and other service area demands proposed to be served by the project; available supplies; and water available for growth. See also Appendix L, which was prepared to test whether the project could be smaller if different supply and demand numbers were considered, and Section 8.2.13.5 of Master Response 13, which summarizes the results of that inquiry.

Marina-150 An essential purpose of the proposed project is to provide replacement water supply that would enable CalAm to cease diverting Carmel River water in excess of CalAm's water rights and to cease pumping from the Seaside Groundwater Basin in excess of CalAm's adjudicated right. Project implementation is, therefore, assumed to enable CalAm to "stop illegal pumping on the Carmel River and

Seaside Basin." The prospect that CalAm's adherence to its Carmel River water rights and adjudicated groundwater rights in the Seaside Groundwater Basin would result in greater use of the same resources by others to serve urban growth is speculative. The SWRCB's explicit concern expressed in Order 95-10 and the subsequent CDOs has been the effect of CalAm's unlawful diversions on *instream* beneficial uses of the Carmel River (see, e.g., Section 5 of Order 95-10).

As described in EIR/EIS Section 2.2.3, Order 95-10 established CalAm's legal rights to the Carmel River, and the SWRCB directed CalAm to take actions to terminate its unlawful diversions; one potential action specified in the order was to obtain appropriative rights to the Carmel River water that was being unlawfully diverted, and another was to contract with other agencies that had appropriative rights to divert and use water from the Carmel River. In the years since, other than SWRCB Water Right Permit 21330 to divert "Table 13" water (see EIR/EIS Section 2.4.6.1), CalAm has been unable to obtain appropriative rights and CalAm's ability to contract with others that have appropriative rights has been extremely limited (a contract with Malpaso Water Company and temporary forbearance agreement with the Trust for Public Land, described in EIR/EIS Section 2.4.6).

CalAm's use of water to which the Malpaso Water Company has rights is limited to the quantity of water not needed by Malpaso. CalAm's cessation of unlawful diversions would not change Malpaso's rights or the rate at which Malpaso is using them. Much of the Trust's land with water rights subject to the forbearance agreement will be converted to riparian habitat, and much of the water associated with that property is, therefore, expected to remain in the River. Other ways the Trust may use that water right are unknown to the Lead Agencies. The extent to which CalAm's adherence to the Carmel River rights established in Order 95-10 would allow increased diversions by others, such as those holding Carmel River water rights that are subject to minimum flow requirements, is not known; nor is it known whether the SWRCB would issue additional permits to water users listed in Table 13 of SWRCB Decision 1632 when CalAm's unlawful river diversions cease.

As noted above, the SWRCB's expressed concern about the unlawful diversions has been effects on instream uses, not potential constraints imposed by the unlawful diversions on existing or future water rights holders. It is also speculative to assume that any increased diversions by others, if they did occur when CalAm's unlawful diversions cease, would be used for urban development. The Seaside Groundwater Basin is an adjudicated basin. CalAm has been adhering to the schedule of decreasing pumping from the basin established by the Watermaster. Given that rights to the basin have been adjudicated, CalAm's adherence to its adjudicated right will not create new rights by others to basin groundwater.

Marina-151 As described in EIR/EIS Section 6.3.5.3, the amount of water provided by the MPWSP that would be available for growth is consistent with growth anticipated by the jurisdictions in CalAm's service area. EIR/EIS Section 6.3.6 identifies the impacts of growth based on impacts identified in the general plan CEQA documents of service area jurisdictions. No significant impacts have been identified related to increased wastewater flows from growth anticipated in CalAm's service area jurisdictions.

In addition, since these plans and CEQA documents were prepared, the Pure Water Monterey Groundwater Replenishment Project (GWR) was approved, in 2016, which will recycle more wastewater flows than MRWPCA already recycles for irrigation by users of the CSIP. Increasing the use of recycled water is expected to be a continuing trend, and is a stated goal of MRWPCA (MRWPCA, 2016); increased wastewater recycling will further reduce the outfall capacity used by wastewater discharges. In Draft EIR/EIS Comment MRWPCA-13, the MRWPCA states that the "[c]ost of potable water and increased conservation has been reducing overall sewage flow to the Regional Treatment Plant with a downward trend since 2002 resulting in less ocean discharge… [The Pure Water Monterey GWR project], currently out to bid, will further reduce ocean discharge, especially during the winter." Therefore, consistent with the findings of the General Plan CEQA documents reviewed for the EIR/EIS, the impact on outfall capacity of growth in service area jurisdictions is not expected to be significant.

Marina-152 EIR/EIS Section 6.3.6 and Table 6.3-9 summarize the environmental impacts of growth that water supply provided by the MPWSP would, to an extent, support. Also refer to the discussion under "Impacts of Growth" in Master Response 13, Demand (Project Need) and Growth. As stated on Draft EIR/EIS pages 6-40 to 6-41, Table J2 in Appendix J2 presents a more detailed summary of those impacts and summarizes the identified mitigation measures. As stated on page 6-26 under "Growth Trends and Projections in Jurisdiction Land Use Planning Documents, "[a]ll of the jurisdictions cite limited water supply as a key factor limiting planned development within their boundaries." This is confirmed in the individual city and county summaries presented in the same section. The EIR/EIS growth analysis is predicated upon the assumption that the MPWSP would indeed remove a constraint to growth.

In 2006, in consultation with service area jurisdictions, the MPWMD prepared a comprehensive assessment of water supply needs associated with growth anticipated in the jurisdictions' general plans (see Section 2.5.3.4, General Plan Buildout, and Section 6.3.5.3, Growth Trends and Planning Agency Projections). At the time, CalAm had proposed the Coastal Water Project. The EIR prepared for the Coastal Water Project also analyzed a Regional Project, the second phase of which included water to meet the future water needs identified in MPWMD's 2006 analysis (see EIR/EIS Section 1.4.1, The Coastal Water Project). The Regional Project was not constructed. As noted in EIR/EIS Section 1.4.2, CalAm withdrew its support for the Regional Project in 2012 and subsequently submitted an

application to the CPUC for the MPWSP. Thus, a water supply has yet to be developed to meet demand associated with general plan buildout identified by MPWMD. The limited amount of water supply available from the Malpaso Water Company to its subscribers in Carmel and the Carmel Valley area, discussed in EIR/EIS Section 2.4.6.2, does not change this conclusion. Since the MPWMD prepared its analysis, the estimates of some jurisdictions have been revised, reducing the total estimated demand from 4,545 afy to 3,526 afy, as discussed in EIR/EIS Section 2.5.3.4, General Plan Buildout, and shown in Table 2-5.

The 2nd column from the right in Table J2-1 in EIR/EIS Appendix J2, shows two levels of significance for the Monterey County General Plan EIR. As the column heading indicates, the significance levels shown are for general plan development "To 2030" and "To 2092." Table note "a" at this column heading explains: "The Monterey County General Plan EIR evaluated impacts anticipated to occur by the General Plan's 2030 planning horizon, as well as impacts anticipated to occur under full General Plan buildout, which is assumed to occur in 2092. The column shows both significance conclusions (impacts to 2030 are shown on the left and Impacts to 2092 on the right)." The table shows the significance level with mitigation.

Marina-153 The MPWSP has been proposed in response to SWRCB Order 95-10 and the revised 2016 Cease and Desist Order, which direct CalAm to terminate its unlawful diversions from the Carmel River. CalAm is obligated to comply with these orders as a matter of law, and EIR/EIS Section 4.6 concluded on Draft EIR/EIS page 4.6-2 that "since a primary purpose of the proposed project is to reduce pumping from the Carmel River to restore and increase flows, the effect of this project would be a beneficial effect on stream flows in the Carmel River and the river's aquatic and riparian biological resources." No infrastructure would be removed from the Carmel River, no decommissioning of facilities would be necessary and none is proposed. There is no reason to expect that implementation of the proposed MPWSP would result in any adverse impacts to the aquatic and riparian biological resources of the Carmel River.

8.5.1.2 Responses to Comments from City of Marina – Jacobson James & Associates Letter

Marina-JJ&A-1 The EIR/EIS did not rely only on the two-dimensional MCWRA maps to assess water quality degradation in the Dune Sand and 180-FTE Aquifer. Other sources included the water quality data obtained from the eight monitoring well clusters that CalAm installed to monitor the effects on the SVGB from test slant well pumping at CEMEX. These well clusters are screened discretely in the Dune Sand Aquifer, the 180-Foot/FTE Aquifer, and the 400-Foot Aquifer, and provide that "third dimension" needed to evaluate groundwater degradation, with depth and the vertical distribution of seawater intrusion in the underlying aquifers inland from the coast. In addition, the EIR/EIS used the pumping and water quality data obtained

from the test slant well to monitor aquifer response from pumping and changes in capture zone water quality. A description of the groundwater data reviewed and applied to the EIR/EIS groundwater analysis is provided in EIR/EIS Section 4.4.4, Approach to Analysis and in EIR/EIS Appendix E3. See also Master Response 9, Electrical Resistivity Tomography (ERT) and Airborne Electromagnetics (AEM); Mater Response 8, Project Source Water and Seawater Intrusion; and Master Response 12, The North Marina Groundwater Model (v. 2016).

Marina-JJ&A-2

EIR/EIS Section 4.4.5.2 presents the impacts of proposed project pumping on nearby production wells. Pursuant to significance criteria established by the Lead Agencies in Section 4.4.5, an impact is considered significant if the proposed project would lower groundwater levels in a nearby municipal or private groundwater production well enough to cause a substantial reduction in well yield, or to cause physical damage due to exposure of well screens and well pumps. The nearby production wells that could be affected by MPWSP pumping at the CEMEX site, including the MCWD wells, are shown on EIR/EIS Figure 4.4-14 and listed in Table 4.4-10. As noted in Table 4.4-10, the City of Marina's Wells 10, 11, and 12 are located over 2 miles to the southeast, and are screened in the 900-Foot/Deep Aquifer. The Ord Community Wells 29, 30, and 31 are located over 5 miles to the southeast and are screened in the lower 180-Foot and the 400-Foot Aquifers. See Master Response 3, Water Rights, Section 8.2.3.7, and Master Response 8, Project Source Water and Seawater Intrusion.

The transient North Marina Groundwater Model ($NMGWM^{2016}$) comprises eight different layers representing the depth distribution of aquifers and aquitards, and thus simulates three-dimensional groundwater flow (see Final EIR/EIS Appendix E2, Section 2.2, Model Construction). Model analyses assess the potential effects of changing vertical gradients between aquifers and across aquitards and were not limited to lateral flow within principal aquifers. For example, a range of values for the depth distribution of the relative volume of groundwater extracted by the slant wells from different aquifers was assessed as part of the sensitivity and uncertainty analysis. Analysis of potential impacts of vertical flow was implicit in the determination of water level changes in the 900-ft (Model Layer 8) and 400-ft (Model Layer 6) aquifers, which are reported together with model results for Model Layer 2 and Model Layer 4.; see Final EIR/EIS Appendix E2, Section 6, and Master Response 12, The North Marina Groundwater Model (v. 2016).

Marina-JJ&A-3

See Master Response 9; specifically, Section 8.2.9.1 discusses recent geophysical studies and Section 8.2.9.2 discusses correlation with actual subsurface data. Section 8.2.9.3 describes how the ERT/AEM data was used in the EIR/EIS. EIR/EIS Appendix E3, Section 3.1.8 discusses the evaluation of Stanford University's AEM data survey. In short, Dr. Knight's recent AEM survey provides data to help interpolate between control points provided by the MPWSP

monitoring network and confirms the work completed for the hydrogeologic investigation regarding the distribution of water quality in the MPWSP study area. See also EIR/EIS Section 4.4.1.4, Groundwater Quality.

Marina-JJ&A-4 See Master Response 9, Electrical Resistivity Tomography (ERT) and Airborne Electromagnetics (AEM). EIR/EIS Section 4.4.1.4 and Table 4.4-4 explain that both the Dune Sand Aquifer and the 180-FTE Aquifer in this area already contain highly brackish groundwater. All data collected to date (see EIR/EIS Appendix E3) confirm that the Dune Sand Aquifer contains very transmissive materials and directly overlies and is in hydraulic continuity with the underlying 180-FTE Aquifer in the project area. Contrary to the comment and consistent with evidence in the EIR/EIS, the 400-Foot Aquifer in the project area is confined and the 180/400-Foot Aquitard, although shown as inferred within dashed lines on EIR/EIS Figure 4.4.3, is most certainly present and restricts flow from the 180-FTE aquifer above it. The assertion that movement of seawater intruded groundwater from the 180-FTE Aquifer to the 400-Foot Aquifer is likely to continue and be exacerbated by the MPWSP is inconsistent with the analysis in EIR/EIS Section 4.4.5, and Appendix E2 (see also Master Response 12, The North Marina Groundwater Model (v. 2016)). The 400-Foot Aquifer in the CEMEX area is already intruded with seawater as shown by the TDS concentrations on EIR/EIS Figure 4.4.3. The proposed slant wells would only draw groundwater from the Dune Sands Aquifer and the 180-FTE Aquifer. As discussed in EIR/EIS Section 4.4.5.2, the only drawdown response from the slant well pumping in the 400-Foot Aquifer would occur with 0 and 3 percent return water with current sea level conditions, but this would not result in a significant impact. The 6 and 12 percent return water scenarios with current sea level conditions would cause groundwater levels to increase in the 400-Foot Aquifer and after 63 years, there would be no drawdown response in the 400-Foot Aquifer. In response to the comment's assertion that the EIR/EIS did not consider the entirety of Dr. Knight's work in its analysis, see EIR/EIS Section 4.4.1.4, and Master Response 9, Electrical Resistivity Tomography (ERT) and Airborne Electromagnetics (AEM).

Marina-JJ&A-5 See Master Response 9, Electrical Resistivity Tomography (ERT) and Airborne Electromagnetics (AEM), for a discussion of the use and applicability of the May 2017 AEM survey data in the EIR/EIS; see also EIR/EIS Appendix E3.

Marina-JJ&A-6 The inland movement of groundwater is driven by regional recharge and pumping patterns. EIR/EIS Section 4.4.1.3 describes the groundwater flow and occurrence in the SVGB, and describes how groundwater in the Pressure and East Side Areas flows northwest from the upper reaches of the SVGB until it reaches the city of Salinas, at which point groundwater in both the 180-Foot and 400-Foot Aquifers flows towards a groundwater depression north of the city; see EIR/EIS Figures 4.4-5 and 4.4-6, as well as Figures 3-1 through 3-4 in the 2015 State of the Salinas River

Groundwater Basin report (Brown and Caldwell, 2015). Along the coast, flow in both the 180-Foot and 400-Foot Aquifers is towards the east, or landward, and has resulted in seawater intrusion; see EIR/EIS Figures 4.4-10 and 4.4-11.Local conservation efforts implemented near the coast cannot alone reverse the effect of these regional inland gradients; to be successful and to place this concept in perspective, local conservation efforts would have to provide sufficient recharge to mitigate the inland pumping that is responsible for the historical overdraft and seawater intrusion. For example, ongoing groundwater enhancement programs in the SVGB (including the Castroville Seawater Intrusion Project (CSIP) and the Salinas Valley Water Project (see EIR/EIS Section 4.4.1.3), have been effective at reducing groundwater extraction in those areas. However, the objective of SVWP Phase 1 was to stop (not reverse) seawater intrusion and to provide adequate water supplies and flexibility to meet current and future (year 2030) needs (MCWRA, 2001, Section 3.0).

As reported in Brown and Caldwell 2015, Section 4.3.1, groundwater flows out of the Pressure Subarea into the East Side Subarea because of large groundwater elevation declines in the East Side Subarea that have reversed the natural groundwater head gradient. The large storage declines that have occurred in the Basin in the past, especially in the East Side Subarea, have created a significant landward groundwater head gradient that must be reversed before seawater intrusion can be halted. Pumping would have to be decreased by about 30 percent in the Pressure and East Side Subareas to decrease seawater intrusion to about 8,100 afy after 20 years. Specifically, based on 2012 actual extractions, pumping would have to decline from about 114,000 afy to 80,000 afy in the Pressure Subarea and from about 96,000 afy to 67,000 afy in the East Side Subarea. This would be a total pumping reduction of about 63,000 afy in both Subareas affected by seawater intrusion.

Phase II of the SVWP would put to beneficial use the water right allocated to MCWRA by Water Right Permit #11043[5] by further developing surface water resources that will be used to offset groundwater pumping in the Pressure Area and East Side. However, see response to comment Beech 3-3 and Beech 3-4 regarding the status of Water Right #11043. Both SVWP Phase I and Phase II are addressed in the cumulative impacts analysis in EIR/EIS Section 4.4.6. Actions that may be developed or required as a function of SGMA are too speculative to opine about in the EIR/EIS. Nonetheless, as demonstrated above, substantial actions would be needed merely to arrest seawater intrusion, without consideration of more dramatic actions that would be needed to reverse such intrusion.

The inland gradient imposed on the NMGWM[2016] is based on real-world measurements and is not artificial. As outlined in Final EIR/EIS Appendix E2, Section 5.3, the average observed regional gradient (0.0007) represents Fall 2015

5 Available online at http://www.co.monterey.ca.us/home/showdocument?id=19020.

groundwater elevations based on water level contour maps provided by Geoscience Support Services, Inc. (2016). As part of sensitivity testing of the NMGWM^{2016} (see EIR/EIR Appendix E2, Section 5.4), average regional gradients of 0.0004 and 0.0011 were also superimposed on the superposition model. If the inland regional hydraulic gradient decreases over time as a result of successful actions by MCWRA or as a result of actions resulting from SGMA, the capture zone would be slightly larger and would more resemble that from the minimum gradient examined for this analysis (0.0004), shown in Final EIR/EIS Appendix E2, Figure 5.6. However, the expectation that the groundwater depression on the East Side will be resolved within a reasonable timeframe and the inland gradient would be dramatically decreased is speculative for the reasons explained above, and the impact conclusion on groundwater resources remains unchanged.

Marina-JJ&A-7

See response to comment Marina-JJ&A-06 regarding the potential capture zone. The assumption in the comment that future groundwater conditions will cause reduced or flat gradients fails to recognize that sea level is projected to rise, continuing to exacerbate the difference between coastal water levels and inland water levels. Therefore, any increases in inland groundwater elevations would be partially offset by future sea level rise. Sea level is one of the inputs for which a range of values was used to assess NMGWM^{2016} uncertainty and was reported in Final EIR/EIS Appendix E2. See Master Response 8, Project Source Water and Seawater Intrusion; Figures 8.2.8-1 and Figure 8.2.8-2 show the modeled capture zone for the Dune Sands Aquifer and the 180-FTE Aquifer, respectively, and resemble the commenter's Figure 6a.

The water transmitting properties of the aquifer materials inland near the coast are insufficient to supply the majority of the water extracted by the slant wells. For example, the modeled horizontal conductivities of the inland A-Aquifer (2-4 ft/d), are one to two orders of magnitude smaller than the modeled Dune Sand Aquifer that would be tapped by the slant wells (150-625 ft/d); see EIR/EIS Appendix E2, Figure 3.4a. The water supplied to the slant wells in Model Layer 2 would, therefore, originate more readily from the Dune Sand Aquifer at the coast and beneath the ocean, than from inland. The combination of this contrast in hydraulic conductivity and ample recharge available from the ocean make it implausible for the inland gradients to reverse and "strand" the project.

Marina-JJ&A-8

See Master Response 7, The Deeper Aquifers of the Salinas Valley Groundwater Basin, for a discussion of the deep aquifer system (inaccurately referred to as the 900-Foot Aquifer). The text in EIR/EIS Section 4.4.1.2 and Section 4.4.5.2 has been revised to provide additional information on the deeper aquifers of the SVGB and to clarify the discussion of the impact of the MPWSP on those aquifers.

Marina-JJ&A-9 See response to comment Marina-JJ&A-8. Final EIR/EIS Appendix E2, Figure 3.3a shows that the horizontal hydraulic conductivity specified for Model Layer 8 (the 900-Foot/Deep Aquifer) falls at the midpoint of reported values from other sources, and therefore, the NMGWM^{2015} values were reasonable and not modified in the NMGWM^{2016}. Moreover, hydrographs for four 900-Foot Aquifer wells with historical water level data from 1979 to 2011 are reported in Appendix E2 Figure 4.1, and show good agreement between measured and model-calculated water levels. All of the model runs reported in Appendix E2 show a substantially decreasing cone of depression with depth, confirming that uncertainty in model results attributed to uncertainty in parameter values (for example, variable values for horizontal and vertical conductivity) becomes less significant for the deeper model layers.

Marina-JJ&A-10 See responses to comments Marina-JJ&A-2, Marina-JJ&A-8 and Marina-JJ&A-9. See also Master Response 7, The Deeper Aquifers of the Salinas Valley Groundwater Basin. Analysis of potential impacts of vertical flow was implicit in the determination of water level changes in the 900-Foot/Deep (Model Layer 8) and 400-Foot (Model Layer 6) aquifers, which are reported together with model results for Model Layer 2 and Model Layer 4 in Final EIR/EIS Appendix E2, Figures 5.3, 5.4, 5.9 and 5.10. The model results that consider return water also included all four model layers. Hydrographs presented in Final EIR/EIS Appendix E2, Figure 4.1, show the water-level declines ranging from 10 to 50 feet associated with seasonal pumping in Model Layer 8 (the 900-Foot Aquifer). As noted in EIR/EIS Section 4.4.1.3, Groundwater Flow and Occurrence, there is a groundwater divide along the north side of the SGB separating groundwater flow paths between the SGB and the SVGB in both the shallow and deep aquifers, as illustrated on Figures 4.4-7 and 4.4-8. Impacts on the SGB are described in EIR/EIS Section 4.4.5.2.

Marina-JJ&A-11 The proposed length and placement of the MPWSP slant wells are described in EIR/EIS Section 3.2.1.1 and in Table 3-1, and are shown on Figure 3-3a; the City of Marina City Limits and Mean High Water are both shown on the figure. EIR/EIS Table 3-1 explains that the slant wells would draw water "from groundwater aquifers that extend beneath the ocean floor (the Dune Sands Aquifer and the 180-Foot-Equivalent Aquifer of the Salinas Valley Groundwater Basin) for use as source water for the MPWSP Desalination Plant."

EIR/EIS Table 3-2 presents the total length of each slant well extending seaward of the 2020 MHW line, and EIR/EIS Figure 3-3b presents an Illustrative Cross-Sectional View of the Subsurface Slant Wells, so the distances onshore and offshore are fully disclosed. Contrary to Footnote 11 in the comment, the design details of the proposed slant wells that are noted in Footnote 79 on page 28 of Appendix EIR/EIS

were made publicly available with all of the other references cited in the EIR/EIS: see https://tinyurl.com/MPWSPRefs.

The notes in EIR/EIS Table 3-2 reference Appendices C1 (Coastal Water Elevations and Sea Level Rise Scenarios) and C2 (Analysis of Historic and Future Coastal Erosion with Sea Level Rise). The basis for determining the 2020 mean high water line is provided in the Coastal Erosion Study (EIR/EIS Appendix C2), and it is discussed in EIR/EIS Section 4.2.5.4. Appendix C2 examined coastal processes to determine the likelihood for the slant wells and their well heads to become exposed before the end of their usable lifespan. The study estimated coastal retreat both laterally and vertically. The lateral extent of erosion was evaluated using coastal erosion hazard zones; the vertical extent was evaluated using coastal profiles. As explained in EIR/EIS Section 4.2.4.5, the future vertical profile is the current profile eroded at the historic rate, with added erosion caused by sea level rise. The lower profile envelope represents a highly eroded condition, which could occur from a combination of localized erosion (rip currents), a large winter storm, and seasonal changes.

As explained in EIR/EIS Section 3.3.1.1, the nine new permanent slant wells would be approximately 900 to 1,000, while keeping the well screen above the 180/400-Foot Aquitard. Based on EIR/EIS Table 3-2 and Figure 3-3b, the commenter's calculation that an average 82 percent of the individual well casing lengths would be landward of the projected 2020 MHW line in the City of Marina is not unreasonable. As explained in EIR/EIS Appendix E3, while placement of production well screens closer to or under the ocean may achieve the maximum ocean water percentage (OWP) in the first few months and a very slight increase in the medium-term, a difference of a few hundred feet in screen placement relative to the ocean boundary would have minimal overall effect on OWP.

Marina-JJ&A-12

As explained in Final EIR/EIS Appendix E2, Section 1, the NMGWM was developed in 2008 to evaluate proposed groundwater extraction projects for the Monterey Peninsula area. The NMGWM was updated for the April 2015 Draft EIR (herein referred to as $NMGWM^{2015}$) and again for the current EIR/EIS (herein referred to as $NMGWM^{2016}$). See Master Response 12, The North Marina Groundwater Model (v. 2016), for more information.

As of this writing, the U.S. Geological Survey (USGS) model for the Salinas Valley (i.e., the Salinas Valley Integrated Hydrologic Model, or SVIHM) is not available nor has a release date been published. The initial hydraulic conductivity and storage values implemented in the SVIHM were also taken from the SVIGSM and refined based on sub regions (USGS, 2016), similar to the EIR/EIS Appendix E2 analysis where the Fort Ord layering and parameters were modified to better match the smaller-scale conceptual model, and to be consistent with the available data for these model inputs.

The NMGWM^{2016} is a more accurate representation of the hydro-stratigraphic framework in the Fort Ord area than SVIGSM and the NMGWM^{2015}, since it includes the "A-Aquifer" and "Fort Ord Salinas Valley Aquitard" ("FO-SVA"). The inclusion of these geologic features is consistent with, but was implemented independently from, the Lawrence Berkeley National Laboratory (LBNL) peer review of NMGWM^{2015} and recommendations; see EIR/EIS Appendix E1.

Marina-JJ&A-13 As explained in EIR/EIS Appendix E2, Section 1, the NMGWM was developed in 2008 to evaluate proposed groundwater extraction projects for the Monterey Peninsula area (Footnote 12 in the comment letter is a link to the April 2015 Draft EIR) and was updated for the current EIR/EIS (see response to comment Marina-JJ&A-12). Contrary to the comment, EIR/EIS Appendix E2 does not claim on page 7 – or anywhere – that the NMGWM was developed to evaluate regional scale impacts. In fact, Appendix E2, Section 2.2 explains that the SVIGSM represents the entire Salinas Valley Groundwater Basin, whereas the NMGWM represents only a 149 square mile portion of the over 650 square mile SVIGSM area. The NMGWM^{2016} was employed to calculate the water level decline (drawdown) and changes in groundwater flow directions in response to proposed project pumping. See Master Response 12, The North Marina Groundwater Model (v. 2016), for more information.

Marina-JJ&A-14 Slant well pumping effects on the inland movement of saltwater was assessed using the NMGWM^{2016} and MODPATH. As explained in EIR/EIS Appendix E2, Section 5.4, the MODFLOW computer code post-processer MODPATH was employed to simulate groundwater-flow paths. MODPATH utilizes the output from MODFLOW simulations to simulate paths for "particles" of water moving through the modeled groundwater system. In addition to delineating particle paths, MODPATH computes the time-of-travel for the simulated particles to reach their ending locations. The superposition NMGWM^{2016} was utilized without the regional gradient to isolate changes in saltwater movement due solely to slant well pumping.

The spatial resolution of the NMGWM^{2016} is sufficient for its intended purpose – to estimate the area where the difference between pumping and non-pumping water levels (the drawdown) are greater than or equal to one foot. EIR/EIS Appendix E2 reports that, "Under 2012 sea level conditions, the maximum distance from the well field to the 1-foot drawdown contour in Model Layer 2 is about 15,000 feet, and in Model Layer 4 the distance is about 20,000 feet." To place these distances in perspective relative to model resolution, there are 75 to 100 model cells between the well field and the 1-foot contour. If the distance to the 1-foot contour were actually one model cell further than estimated by the model, it would represent an error of 1 percent at most. Additionally, any error in the distance to the 1-foot contour owing to uncertainty in aquifer parameter values, sea level, pumping rate,

and so forth is much greater than the error introduced by model discretization and is, therefore, rigorously quantified and accounted for by the model sensitivity analysis. See EIR/EIS Appendix E2, Section 6, and Master Response 12, The North Marina Groundwater Model (v. 2016), for more details.

Marina-JJ&A-15 EIR/EIS Section 4.4.3, Evaluation Criteria, explains that implementation of the proposed project would have a significant impact on groundwater resources if it would substantially deplete groundwater supplies or interfere substantially with groundwater recharge such that there would be a net deficit in aquifer volume or a lowering of the local groundwater table level, or violate any groundwater quality standards or otherwise degrade groundwater quality. EIR/EIS Section 4.4.4 explains that four primary sources of data and information were used to guide the impact analysis: 1) information obtained through subsurface investigations commissioned by CalAm; 2) groundwater modeling; 3) the SWRCB Final Review of CalAm's MPWSP; and 4) CalAm operating rules for injection and extraction of desalinated water by ASR.

EIR/EIS Section 4.4.4.2 explains that groundwater modeling was a primary analytical tool used to evaluate proposed project impacts on groundwater resources, which are summarized in EIR/EIS Table 4.4-9 and evaluated in EIR/EIS Section 4.4.5.1 and 4.4.5.2. The $NMGWM^{2016}$ was employed to estimate the cone-of-depression, which is defined in EIR/EIS Section 4.4.4.2 as the area where the difference between pumping and non-pumping water levels (the drawdown) would be greater than or equal to one-foot. The model was also utilized to provide insight into the change in groundwater-flow directions in response to pumping. Overlying jurisdictional or political boundaries were not considered. The model employs eight layers to represent the depth distribution of water-bearing and non-water-bearing sediments in the basin and the 149-square-mile model domain includes the City of Marina. Model Layer 8 represents the 900-Foot/Deep Aquifer (see Master Response 7, The Deeper Aquifers of the Salinas Valley Groundwater Basin, regarding the name of this aquifer and for more information about the deeper aquifers of the SVGB), which is one of the source aquifers for the City of Marina water supply. Therefore, while the degradation of groundwater quality in the City of Marina (or any overlying jurisdiction) resulting from the MPWSP was not an explicit objective of the groundwater modeling, the model evaluates the potential for drawdown and changes to groundwater flow (and quality) within the City of Marina. See Master Response 12, The North Marina Groundwater Model (v. 2016), for more details.

Marina-JJ&A-16 EIR/EIS Section 4.4.5.2, Impact 4.4-3 addresses groundwater supplies and groundwater levels, and explains that the first step in the analysis was to determine the pumping scenario that would have the most profound aquifer response surrounding the slant wells at the CEMEX site in order to conservatively judge

potential impacts. EIR/EIS Figure 4.4-13 shows the cone of depression and the extent of pumping influence in the 180-FTE Aquifer; it assumes that no water would be returned to the SVGB, and sea level would be consistent with current levels. Since this scenario would generate the most pronounced cone of depression with the largest area of influence because groundwater would not be returned to the basin, and because current sea level would not increase groundwater levels and gradients at the coast, this scenario is used to represent the maximum area of pumping influence. In other words, Figure 4.4-13 depicts the improbable worst case aquifer response from the proposed project. The proposed project was appropriately modeled using the superposition approach because drawdown due solely to project pumping is independent of other stresses in the basin (including variations in weather patterns) and depends primarily on the pumping rate, and the water transmitting and storage properties of the aquifers.

EIR/EIS Section Impact 4.4.5.2, Impact 4.4-4 addresses changes in water quality, and explains that water quality considerations associated with the project operations include the exacerbation of seawater intrusion and the potential for the proposed project to cause new contamination, or to extend the limits of existing groundwater contamination through pumping at the subsurface intake system. The impact analysis considers the effect of continuous pumping at the CEMEX site on local groundwater quality in the Dune Sand and 180-FTE Aquifer. See Also response to comment Marina-JJ&A-14.

The cumulative drawdown is determined from the superposition results; the superposition results depicting the change resulting from the project's contribution to cumulative effects are simply added to the drawdown determined for other projects. The resulting total represents the overall cumulative effects and then the project's incremental contribution to the total is judged as to level of significance as warranted; see EIR/EIS Appendix E2, Attachment 1, and response to comment LWMC-15.

Marina-JJ&A-17

EIR/EIS Section 4.4.4.2 acknowledges that the MPWSP pumping will never be the only stress on the aquifers in the vicinity of the proposed project, and the effects from proposed project pumping would be additional to the effects from the other stresses on the basin such as seasonal climate and agricultural pumping trends, other pumping wells, injection wells, land use, or contributions from rivers. However, the superposition modeling approach simplified the complex problem of quantifying groundwater level changes and fluxes due to geographically and temporally varying recharge and discharge processes occurring within the Salinas Valley Groundwater Basin since the CEQA/NEPA analysis is required to evaluate the change in these groundwater elevations and fluxes as a result of a new stress – groundwater extraction by the proposed slant wells – against baseline conditions. Rather than employ a model to simulate the complex problem (i.e., attempt to quantify the effects of all recharge and discharge processes occurring within the

basin and then subtracting the effects of the other stresses to isolate the effects of the proposed project to comply with CEQA/NEPA), superposition is employed to determine the incremental drawdown against baseline, due solely to the proposed groundwater extraction by the proposed slant wells. In other words, superposition is employed to isolate the expected change in groundwater levels and fluxes due solely to the slant wells and these impacts are presented in EIR/EIS Section 4.4.5.2. These changes would be additive to future changes that occur as the net result of all other recharge and discharge processes in the basin.

See response to comment Marina-JJ&A-14 (regarding the migration of degraded water quality) and response to comment Marina-JJ&A-15 (regarding impacts to Marina); see also Master Response 3, Water Rights, Section 8.2.3.7.

EIR/EIS Section 4.1.7.1 explains the approach to the analysis of cumulative impacts. For each resource or issue considered, the cumulative effects analysis identifies the relevant geographic area and time period within which cumulative effects could occur and then considers existing conditions (which are the combination of natural conditions and the effects of past projects) and describes the effects of other past, present and reasonably foreseeable future projects in combination with the effects of the proposed project. EIR/EIS Section 4.4.6 evaluates the cumulative effects of the proposed project in combination with other stress factors on groundwater resources.

Marina-JJ&A-18 See responses to comments Marina-JJ&A-6 and Marina-JJ&A-7.

Marina-JJ&A-19 See responses to comments Marina-JJ&A-1 and Marina-JJ&A -2 regarding the NMGWM and seawater intrusion. See also response to comment Marina-JJ&A-14 regarding the EIR/EIS analysis of slant well pumping effects on the inland movement of saltwater. The model does include system heterogeneity by using spatially varying conductivity zones. For example, Model Layer 2 represents the shallow water-bearing sediments referred to as Dune Sand Aquifer, A-Aquifer, Perched Aquifer, Perched ‘A’ Aquifer, 35-Foot Aquifer, and -2-Foot Aquifer. Similarly, Model Layer 4 represents the 180-Foot Aquifer, 180-FTE Aquifer, Upper and Lower 180-Foot Aquifer, and Pressure 180-Foot Aquifer.

Marina-JJ&A-20 The Fort Ord SVA and the transition zone west of the Fort Ord SVA are shown on EIR/EIS Appendix E2, Figures 3.2b, 3.2c, and 3.2f. However, Model Layer 3 is thin relative to Model Layer 2 and Model Layer 4, and not easily viewable in the cross sections.

Marina-JJ&A-21 EIR/EIS Appendix E2, Section 4.1 explains that "steep vertical gradients" refer to vertical gradients that are greater than 1.0 (see Footnote 67) and indicative of perched groundwater conditions (Belitz and Heimes, 1990). Perched groundwater occurs when an unsaturated zone separates an upper saturated zone from a deeper saturated zone. Vertical groundwater movement between upper and lower saturated zones must pass through the unsaturated zone. Water movement between saturated and unsaturated zones is referred to as flow under "variably saturated" conditions. MODFLOW simulates groundwater flow under saturated conditions only; it does not simulate water movement in unsaturated or variably saturated conditions. Hence, MODFLOW is limited for simulating steep vertical gradients. See Master Response 12, The North Marina Groundwater Model (version 2016), for more details.

EIR/EIS Appendix E2, Table 3.1 presents the modifications implemented in the $NMGWM^{2016}$; model layers were modified from $NMGWM^{2015}$, but model layers were not added.

Marina-JJ&A-22 The acceptance or rejection of a model depends not only on the evaluation of model error but also the intended application for which the model was created. The $NMGWM^{2016}$ does include system heterogeneity; see the second part of response to comment Marina-JJ&A-19.

The model employs eight layers to represent the depth distribution of water-bearing and non-water bearing sediments; see the second part of response to comment Marina-JJ&A-15. Finally, model-calculated drawdown due to test slant-well pumping was compared to measured drawdown and validated model predictions (EIR/EIS Appendix E2, Figure 4.6 shows measured versus model calibrated drawdown in CEMEX monitoring wells during slant well pumping). The $NMGWM^{2016}$ is capable of adequately supporting the impact conclusions in EIR/EIS Section 4.4.5 and 4.4.6 for the reasons explained in response to comment Marina-JJ&A-12 through Marina-JJ&A-22. See also Master Response 12, The North Marina Groundwater Model (v. 2016), for more details.

Marina-JJ&A-23 The $NMGWM^{2016}$ was not constructed or employed to calculate changes in water quality and water density due to the mixing of ocean water and groundwater. As noted by the comment, EIR/EIS Appendix E2, Section 4.3, presents the comparisons between MODFLOW (constant density model) calculated water level changes and calculations using SEAWAT (variable density model) and indicates only slight differences in calculated water levels. Slant well pumping effects on the inland movement of saltwater was assessed using the $NMGWM^{2016}$ and MODPATH, as noted in response to comment Marina-JJ&A-14. Response to comment Marina-JJ&A-2 explains that an analysis of potential impacts of vertical

flow was implicit in the determination of water level changes in the 900-ft (Model Layer 8) and 400-ft (Model Layer 6) aquifers, which are reported together with model results for Model Layer 2 and Model Layer 4. See Master Response 12, The North Marina Groundwater Model (v. 2016).

Marina-JJ&A-24 Downward vertical gradients are addressed in response to comment Marina-JJ&A-2. The model represents the various hydrogeologic features using spatially varying conductivity zones; see the second part of response to comment Marina-JJ&A-19. The reliability of the specified aquifer parameters for these zones was determined by comparing NMGWM^{2016} values to the measured or estimated values for similar materials. These comparisons indicated general agreement with values from previous hydrogeological and model studies (see EIR/EIS Appendix E2, Section 3.3, Aquifer Parameter Zones). The model employs eight layers to represent the depth distribution of water-bearing and non-water bearing sediments; see the second part of response to comment Marina-JJ&A-15.

See also response to comment Marina-JJ&A-19 regarding parameterization of hydraulic conductivity, and Master Response 12, The North Marina Groundwater Model (v. 2016), for more information on the assignment of hydraulic conductivity values to the model layers.

Marina-JJ&A-25 The model employs eight layers to represent the depth distribution of water-bearing and non-water bearing sediments; see the second part of response to comment Marina-JJ&A-15 for further explanation. See also response to comment Marina-JJ&A-9 for a discussion of the zone approach for the deeper aquifers. See response to comment JJ&A-26 concerning model calibration.

Marina-JJ&A-26 EIR/EIS Appendix E2 explains that the model layering and parameterization of the NMGWM^{2015} was revised based on new borehole data and analysis of the test slant well data. Additionally, the A-Aquifer, FO-SVA, and clay transition parameter zones were added and their parameter values based on reported aquifer tests. The resulting NMGWM^{2016} did not need to be recalibrated because the reliability of the specified aquifer parameters for these zones was determined by comparing NMGWM^{2016} values with the measured or estimated values for similar materials. Model error was assessed using six (6) tests widely used and accepted within the groundwater modeling community. The acceptance or rejection of a model depends on the evaluation of model error and also the intended application for which the model was created (in this application, the model is employed to calculate drawdown and changes in groundwater flow directions). Model-calculated drawdown due to test slant well pumping was compared to measured drawdown and validated model predictions and the adequacy of model parameterization and parameter values (EIR/EIS Appendix E2, Figure 4.6, shows measured vs. model

calibrated drawdown in CEMEX monitoring wells during slant well pumping). See also Master Response 12, The North Marina Groundwater Model (v. 2016).

Marina-JJ&A-27 Automated parameter estimation was not used to update the $NMGWM^{2015}$ to the $NMGWM^{2016}$ and, therefore, is not discussed in EIR/EIS Appendix E2. Parameter sensitivity identifies the parameters that have the greatest influence on model calculations. In model calibration, the sensitivity analysis identifies the parameters that have the greatest influence on the comparisons between model-calculated and measured values (parameter calibration sensitivity). As noted in response to comment MarinaJJ&A-26, the $NMGWM^{2016}$ was not re-calibrated. When employing a model to predict future conditions, the sensitivity analysis identifies the parameters that have the greatest influence on the predictions (parameter prediction sensitivity).

EIR/EIS Appendix E2, Section 6.0, Uncertainty, explains that both sensitivity to assumed project operations and sensitivity to modeled aquifer parameters were considered. In the case of modeled aquifer parameters, the sensitivity assessment used "extreme values relative to the calibrated values and values reported by other sources, and therefore, using these values essentially brackets the range in possible drawdowns." Extreme values were employed to test uncertainty in the conceptual model and choice of parameters and provided a conservative answer to the question "would the model predictions change so as to change the conclusions regarding proposed slant well operation?" See Master Response 12, The North Marina Groundwater Model (v. 2016), for more details.

Marina-JJ&A-28 The model was employed to estimate the cone of depression and changes in groundwater flow directions; see responses to comments Marina-JJ&A-15 regarding the $NMGWM^{2016}$ spatial resolution approach to assessing impacts to groundwater quality. Model heterogeneity is addressed in response to comment Marina-JJ&A-19, and model calibration is addressed in response to comment Marina-JJ&A-27.

Marina-JJ&A-29 As stated in EIR/EIS Appendix E2, Section 7, "[d]ue to the complex nature of simulating recharge and discharge processes in the Salinas Valley Groundwater Basin, *and identified problems with specified initial water levels and boundary conditions that were derived from SVIGSM results* (emphasis added), we employed the theory of superposition to remove these deficiencies. We converted the $NMGWM^{2016}$ into a superposition model and ran 34 future scenarios representing variable project operations and sea levels (2012 and 2073)." The use of superposition is well documented in the scientific literature and, as explained in EIR/EIS Appendix E2, is a logical and technically valid approach for determining the effects of slant-well pumping and it overcomes the influence of deficiencies in

quantifying initial conditions, pumping and recharge inherent in the SVGSM. The superposition approach provides substantial benefit in terms of reliability over the calibrated version of the model. As noted in response to comment MCWD-GeoHydros-16, a key advantage of the superposition approach is the simulation of effects of one stress when other stresses are not well quantified. Thus, superposition is a superior approach because the simulation of these other stresses is unnecessary and the superposition approach can provide reliable information about the effects due solely to project pumping. See Master Response 12, The North Marina Groundwater Model (v. 2016), for more details. The use of superposition and the approach to cumulative drawdown effects are addressed in responses to comments Marina-JJ&A-16 and Marina-JJ&A-17. Model results at the CEMEX site of potential effects of proposed project pumping on the capture zone and seawater intrusion are presented in EIR/EIS Appendix E2, Section 5.4

Marina-JJ&A-30 It is not necessary to correct the SVIGSM because the use of superposition removed the dependency of the NMGWM^{2016} on the SVIGSM. Additionally, superposition is a more efficient approach for calculating drawdown and changes in groundwater flow directions due to proposed slant well pumping. See also Master Response 12, The North Marina Groundwater Model (v. 2016).

Marina-JJ&A-31 See response to comment Marina-JJ&A-12 regarding the availability of the USGS model for the Salinas Valley.

Marina-JJ&A-32 The use of superposition is well documented in the scientific literature and, as explained in EIR/EIS Appendix E2, is a logical and technically valid approach for determining the effects of slant-well pumping. It also overcomes the influence of deficiencies in quantifying initial conditions, pumping and recharge inherent in the SVIGSM. The superposition approach provides substantial benefit in terms of reliability over the calibrated version of the model. The technical approach to evaluating the MPWSP's impacts on groundwater impacts has been thoroughly documented in EIR/EIS Section 4.4 and Appendix E2. Specifically:

- EIR/EIS Section 4.4.5.2, Impact 4.4-3 addresses groundwater supplies and groundwater levels.
- EIR/EIS Section Impact 4.4.5.2, Impact 4.4-4 addresses changes in water quality, and explains that water quality considerations associated with the project operations include the exacerbation of seawater intrusion and the potential for the proposed project to cause new contamination, or to extend the limits of existing groundwater contamination through pumping at the subsurface intake system. Slant well pumping effects on the inland movement of saltwater was assessed using the NMGWM^{2016} and MODPATH.

- Appendix E2 summarizes and provides extensive technical detail about the $NMGWM^{2016}$ in relation to the hydrogeology, model construction, assessment of model inputs and output, revisions to the $NMGWM^{2015}$ and its application to calculate drawdown using superposition.
- Model inputs are based on thorough scientific review of available data.
- The applicability of the equivalent fresh-water heads is well documented in Appendix E2, Master Response 12, The North Marina Groundwater Model (v. 2016), and the scientific literature.
- Comparisons between MODFLOW (constant density model) calculated water level changes and calculations using SEAWAT (variable density model) indicated slight differences in calculated water levels.
- The model adequately simulates measured water levels and seasonal trends, which demonstrates scientific validity.
- The model adequately simulates measured drawdown in response to test slant well pumping, which demonstrates its scientific validity.
- RMSE comparisons and evaluation of other model performance criteria demonstrate that the $NMGWM^{2016}$ is an improvement relative to the $NMGWM^{2015}$ and model errors and uncertainty minimally influence model output.
- The use of sensitivity analysis to provide a range of water-level drawdown is well documented and based on extensive data for hydraulic conductivity.

8.5.2 Responses to Comments from Marina Coast Water District

By letter dated March 29, 2017, the Marina Coast Water District (MCWD) provided comments on the Draft EIR/EIS. Responses to comments from MCWD are provided in Section 8.5.2.1. Attached to the MCWD letter, were comment letters from Hopkins Groundwater Consultants (MCWD-HGC, dated March 29, 2017), GeoHydros (MCWD-GH, dated March 27, 2017), EKI (MCWD-EKI, dated March 28, 2017), and IntakeWorks (MCWD-IW, dated March 28, 2017). Responses to these comments are provided in Sections 8.5.2.2 through 8.5.2.5. With its comment letter, MCWD submitted a flash drive containing voluminous materials (e.g., the April 2015 MPWSP Draft EIR and 2017 Draft EIR/EIS reference documents, and PRA-requested materials). The Lead Agencies reviewed and considered all such data in responding to comments and preparing the Final EIR/EIS. Due to the substantial volume of documents on the flash drive (25 GB), they are not reprinted within the Final EIR/EIS, but a copy of the flash drive will be made available upon request to either of the Lead Agencies.

Subsequent to the close of the Draft EIR/EIS comment period, MCWD sent the Lead Agencies additional information to consider in the MPWSP environmental review process. By letter dated November 9, 2017, the MCWD provided the following; a Preliminary Interpretation of SkyTEM Data Acquired in the MCWD (Gottschalk and Knight, June 16, 2017); a memo report by Hopkins Groundwater Consultants titled, Monterey Peninsula Water Supply Project Return Water (MCWD-HGC2, dated September 29, 2017), and; a memo report by EKI titled, Groundwater Remedial Actions and Establishment of Remedial Goals at Fort Ord MCWD, CA (MCWD-EKI2, dated June 22, 2017). Responses to MCWD-HGC2 and MCWD-EKI2 are provided in Sections 8.5.2.6 and 8.5.2.7, respectively. Gottschalk and Knight (2017) presents a preliminary interpretation of the Airborne Electromagnetic (AEM) imaging data that was conducted for the MCWD, and is referred to by MCWD, HGC and others in the comments. See also Master Response 9, Electrical Resistivity Tomography (ERT) and Airborne Electromagnetics (AEM) as well as EIR/EIS Appendix E3.

8.5.2.1 Responses to Comments from MWCD – Main Letter

MCWD-1 Consistency with regulations, plans and policies is addressed in each relevant topic area in EIR/EIS Chapter 4, Environmental Setting (Affected Environment), Impacts, and Mitigation Measures. As explained in EIR/EIS Section 4.1.5, Project Consistency Analysis, the EIR/EIS includes a discussion of any inconsistencies between the project and applicable general plans, specific plans, and regional plans and any conflicts between the project and applicable plans, policies, and regulations of agencies with jurisdiction over the project adopted for the purpose of avoiding or mitigating an environmental effect (CEQA Guidelines §15125 and Appendix G). Also, per NEPA, the analysis includes a discussion of the possible conflicts between the proposed project and the objectives of federal, regional, state, and local land use plans and policies for the area concerned that are imposed for the protection of the environment (40 CFR §1502.16(c) and 40 CFR §1508.27(b)(10)).

The Sustainable Groundwater Management Act (SGMA) is described in EIR/EIS Section 4.4.2.2 and also in Master Response 6, The Sustainable Groundwater

Management Act. The MCWRA Agency Act is described in EIR/EIS Section 2.6.3, Section 4.4.2.3 and Master Response 4, The Agency Act and Return Water. The Federal and State Endangered Species Acts are discussed in EIR/EIS Sections 4.6.2.1 and 4.6.2.2, respectively, of Section 4.6, Terrestrial Biological Resources. The Coastal Act is addressed in multiple places in the EIR/EIS, as is the City of Marina's Local Coastal Land Use Plan (LCLUP) (see Final EIR/EIS Chapter 9, Index). The City of Marina's LCLUP is specifically addressed in Section 4.6, Terrestrial Biological Resources, in Section 4.6.5.2, which identifies a project conflict with the Marina LCLUP. Therefore, Impact 4.6.4 is determined to be significant and unavoidable. Monterey County Code of Ordinances Section 10.72.030(B) is addressed in the land use regulatory discussion in EIR/EIS Section 4.8.2.3. Water rights are addressed in EIR/EIS Section 2.6 and Master Response 3.

MCWD-2 The project that is proposed by CalAm, and described in Appendix H of its March 14, 2016 Amended Application to the CPUC (CalAm, 2016a), is the 9.6 mgd project, described in EIR/EIS Chapter 3, Description of the Proposed Project, and analyzed in Chapter 4, Environmental Setting (Affected Environment), Impacts, and Mitigation Measures. EIR/EIS Section 1.1, Introduction, explains that the Amended Application for the proposed project also includes a second option that would meet the project objectives by combining a reduced-capacity desalination plant (6.4 mgd) with a water purchase agreement for 3,500 acre-feet per year (afy) of advanced treated water from another source, the Pure Water Monterey Groundwater Replenishment (GWR) project. This second capacity option in CalAm's application is reflected in Alternative 5a. While both of these options were proposed by CalAm (in an "either/or" fashion) and thus represent the project proposed by the applicant, the larger desalination plant was selected to be analyzed as the "Proposed Project" in Chapter 4 of the EIR/EIS since it is larger and thus was expected to have greater impacts than the smaller capacity option.

Chapter 5, Alternatives Screening and Analysis, provides detailed descriptions of two reduced-sized alternatives (Alternatives 5a and 5b, see Sections 5.4.7 and 5.4.8, respectively) and Section 5.5, Alternatives Impact Analysis, presents an analysis of the environmental impacts of all alternatives, including Alternatives 5a and 5b. See response to comment Marina-140 concerning the EIR/EIS's evaluation of the smaller desalination plant options in Alternatives 5a and 5b. Under CEQA and NEPA, an alternative need not be analyzed unless it would meet most of the basic objectives of, or the purpose and need for, the project. See CEQA Guidelines Section 15126.6(a) and 40 CFR 1502.13 and 1508.9(b). The primary objective of the proposed project is to supply in a timely manner water for CalAm customers to replace certain existing supply sources, such that a smaller desalination plant than those considered in the EIR would not meet the basic project objectives. However, see Master Response 13, Demand (Project Need) and Growth, concerning demand and supply assumptions and the possible consideration of alternate scenarios in which lessened demand would allow for a smaller desalination plant. The Lead Agencies will consider all evidence in the record concerning demand and supply prior to acting upon the project, and may conclude that a smaller desalination plant (or some other alternative) would indeed satisfy the basic objectives of the project.

MCWD-3 As noted in EIR/EIS Section 1.1, this EIR/EIS has been prepared in accordance with CEQA (Cal. Pub. Res. Code §21000 et seq.) and the CEQA Guidelines (Cal. Code Regs., Tit. 20, Div. 6, Ch. 3, §15000 et seq.), and with NEPA (42 U.S.C. §4321 et seq.,) and its implementing regulations (40 CFR Parts 1500-1508). The potential effects that the proposed project (described in Chapter 3) and Alternatives (described in Section 5.4) may have on the environment are evaluated and disclosed in EIR/EIS Sections 4.2 through 4.20 (proposed project), and in Section 5.5 (Alternatives Impact Analysis). EIR/EIS Chapter 5 provides a robust and comprehensive alternatives analysis. As stated EIR/EIS Section 5.1.1, Alternatives Analysis – CEQA/NEPA Requirements, the selection of alternatives followed CEQA Guidelines Section 15126.6 and NEPA requirements in 40 CFR Sections 1502.13 and 1502.14, including identifying the feasibility of the various alternatives selected for analysis; see response to comments MCWD-168, below, and Marina-140, in Section 8.5.1. Furthermore, as stated in EIR/EIS Section 5.1.1, CEQA Guidelines Section 15126.6(a) acknowledges that an EIR need not consider every conceivable alternative to a project; see response to comment MCWD-170.

The federal actions proposed by MBNMS are presented in EIR/EIS Section 1.3.2 and consist of: 1) authorization of a Coastal Development Permit to be issued by the City of Marina for CalAm to drill into the submerged lands of the Sanctuary to install a subsurface intake system; 2) authorization of a Central Coast Regional Water Quality Control Board (RWQCB) issued National Pollutant Discharge Elimination System (NPDES) permit or other discharge authorization to allow for the discharge of brine into the Pacific Ocean and MBNMS via an existing ocean outfall pipe; and 3) issuance of a special use permit to CalAm for the continued presence of a pipeline[1] transporting seawater to a desalination facility in MBNMS.

Responses to comments from Hopkins Groundwater Consultants (HGC), GeoHydros, EKI, and Intake Works have been provided following responses to MCWD's main letter. EIR/EIS Chapter 3 presents a detailed description of the proposed project (see response to comments MCWD-78 through MCWD-85); Chapter 4 presents the environmental baseline (setting), impacts, mitigation and cumulative effects of the proposed project (see response to comments MCWD-86 through MCWD-167); and Chapter 5 provides a robust and comprehensive alternatives analysis (see response to comments MCWD-168 through MCWD-185).

See response to comments MCWD-2 regarding the 9.6 mgd versus the 6.4 mgd project.

[1] The Applicant proposes to use subsurface intakes (slant wells) to supply the desalination plant with source water. The well casings, or pipes, would extend seaward of MHW and would require a special use permit to be present within MBNMS.

MCWD-4 Response to comment MCWD-HGC1-3 and Master Response 6, Sustainable Groundwater Management Act, Section 8.2.6.2, discuss the "Marina Subarea" and the "Pressure Area."

MCWD-5 EIR/EIS Section 1.4 presents the project setting and background, and describes the water supply challenges facing CalAm and its Monterey District Service Area customers; Section 1.4.1 presents the history of the Coastal Water Project (CPUC Proceeding A.04-09-019), the CPUC approval of implementation of the Regional Project alternative in Decision D.10-12-016 as well as the CPUC decision to close Proceeding A.04-09-019 in Decision D.12-07-008. The SWRCB orders are introduced in EIR/EIS Section 1.3 and are further explained in Section 2.2.3. The Sustainable Groundwater Management Act (SGMA) is discussed in EIR/EIS Section 4.4.2.2 and SGMA's relationship to the proposed project is further clarified in Master Response 6. Climate change, sea level rise and coastal erosion are discussed in EIR/EIS Section 4.2.4.5 (Coastal Retreat Study) and Appendices C1 and C2. Assembly Bill 1182[2] (Keely) is discussed in EIR/EIS Sections 5.2.2 and 5.2.3.

MCWD-6 It is correct that one of the actions required for the project is an authorization by MBNMS; see EIR/EIS Section 1.3.2. However, there is not a specific regulation requiring MBNMS to consider public versus private ownership prior to issuing an authorization, and ownership is not specifically addressed in the MBNMS Desalination Guidelines. The reference to consideration of ownership comes from MBNMS Management Plan Desalination Action Plan Strategy 1, which lists numerous activities including: "In collaboration with the California Coastal Commission, consider the ramifications of public versus private ownership of desalination facilities."

In 2006, MBNMS staff partnered with the Association of Monterey Bay Area Governments (AMBAG) in comprehensively identifying the potential environmental, economic, and social impacts, both positive and negative, associated with seawater desalination, if conducted in the Monterey Bay area. The Desalination Guidelines and the Desalination Feasibility Study for the Monterey Bay Region (AMBAG, 2006) were intended to address Desalination Action Plan Strategies 1 and 2 in the Management Plan. The MBNMS Desalination Guidelines (NOAA, 2010) were developed to specifically address the potential impacts that were identified during this initial investigation. As noted in the introduction to the MBNMS Desalination Guidelines, the guidelines were developed by MBNMS staff, in close collaboration with staff from the California Coastal Commission, the Central Coast Regional Water Quality Control Board, and NOAA's National Marine Fisheries Service (NMFS). During this collaborative process, many factors were considered, including private versus public ownership. Furthermore, the

[2] The state legislature passed Assembly Bill 1182 in 1998, ordering the CPUC to identify alternatives to the Carmel River Dam which was the subject of CPUC Proceeding A.97-03-052.

EIR/EIS considers both private and public alternatives in Sections 5.4 and 5.5. See Section 6.4 regarding compliance with the MBNMS Desalination Guidelines.

Regarding the MBNMS Guideline stating that desalination plants should only be pursued when other economically and environmentally preferable alternative water sources are infeasible and should be sized not to induce growth, the EIR/EIS fully evaluates alternatives in Section 5.5, Alternatives Impact Analysis, including the No Project alternative (described in EIR/EIS Section 5.4.2) and reduced size desalination facilities (described in Sections 5.4.7 and 5.4.8). EIR/EIS Section 5.2, Alternatives Not Evaluated in Detail, considered other supply alternatives, but determined that these other alternatives were not feasible to achieve the project objectives. The purpose, need and objectives for the proposed project are established in EIR/EIS Section 1.3. Growth inducement is discussed in Section 6.3 and in Master Response 13, Demand (Project Need) and Growth.

The obligations of the Lead Agencies in the decision-making process is described in EIR/EIS Section 1.5.4. If the CPUC certifies the Final EIR/EIS, it will then decide whether or not to grant the Certificate of Public Convenience and Necessity (CPCN) for the MPWSP, as proposed or modified, or an alternative. In addition to environmental impacts addressed during the CEQA/NEPA process, the CPCN process will consider any other issues that have been established in the record of the proceeding, including but not limited to economic issues, social impacts, the need for the project, the SWRCB Orders on the Carmel River, and any and all current laws and regulations.

MCWD-7 See responses to comments MCWD-4 and MCWD-84. The locations of MCWD's water supply wells are presented in EIR/EIS Section 4.4.5.2 in Table 4.4-10, which explains that MCWD's wells are too far from the project capture zone to be affected by the proposed project pumping. The City of Marina's Wells 10, 11, and 12 are over 2 miles to the southeast, and are screened in the 900-Foot Aquifer and the Ord Community Wells 29, 30, and 31 are located 5 plus miles to the southeast and are screened in the lower 180-Foot and the 400-Foot Aquifers. See also Master Response 8, Project Source Water and Seawater Intrusion, and Master Response 3, Water Rights, specifically, Section 8.2.3.7.

The "Marina Subarea" has not been the only source of water that MCWD has used since its founding to serve its ratepayers. Between early 1997 and February 2003, MCWD operated a 300-afy desalinated plant at its facility on Reservation Road for its Central Marina customers; the plant has remains idle.

MCWD-8 The Regional Project is described in EIR/EIS Section 1.4.1 and the decision to close Proceeding A.04-09-019 (D.12-07-008) is discussed in Section 1.4.2. This current environmental review process, however, is *different* in several key respects to the prior MPWSP and the prior Regional Project; EIR/EIS Section 1.4.3 provides context for the environmental review of the currently proposed project

and the environmental review associated with this EIR/EIS, while Section 1.4.4 describes the revisions made in this EIR/EIS, and distinguishes between the current EIR/EIS and the prior April 2015 Draft EIR.

MCWD-9 See Master Response 3, Water Rights.

MCWD-10 The text quoted in the comment is in the introduction to EIR/EIS Section 5.2. Section 5.2.1 provides an overview of the alternatives not evaluated in detail, and Sections 5.2.2 through 5.2.6 provide a summary of five different projects (including the Coastal Water Project, see Section 5.2.4) that were considered and rejected in earlier environmental review documents because the projects were determined to be politically, legally, economically, or technically infeasible; others are concepts that were speculative or technically or economically infeasible.

The discussion of the Coastal Water Project, and therefore the North Marina Project and the Regional Desalination Project in Section 5.2.4, explains the history of the Coastal Water Project, and the CPUC's closing of proceeding A.04-09-019 with Decision D-12-07-008, and explains that certain elements of the three projects evaluated in the Coastal Water Project EIR (e.g., intake, plant location and brine discharge components) have been carried into the alternatives analysis presented in this EIR/EIS. The EIR/EIS does not explicitly call out the Regional Project as infeasible; rather the EIR/EIS explains the evolution of the MPWSP, of which the Regional Project was an earlier configuration. Yet, ongoing litigation and disputes between the two former proponent/partner parties over the Regional Project may well make it infeasible, and besides, it would not appear to have environmental advantages so as to lessen any significant effects of the proposed project. See also response to comment MCWD-4 which addresses the Marina Subarea, and Master Response 9, Electrical Resistivity Tomography (ERT) and Airborne Electromagnetics (AEM), which addresses the availability and use of ERT/AEM data for assessing aquifers.

MCWD-11 See Master Response 4, The Agency Act and Return Water.

MCWD-12 Vertical wells were not considered in the EIR/EIS Section 5.3 component screening and evaluation; see responses to comments MCWD-172 and MCWD-IW-6 for details on why this component was eliminated from full analysis. The Regional Project did propose vertical wells; six wells pumping 2,800 gallons per minute (gpm) (equivalent to 4 mgd per well[3]) would have been located at least 500 feet apart along the coast in an area approximately 0.25 mile wide (starting on the inland side of the coastal dunes) by 3 miles long (an area south of the Salinas River and north of Reservation Road) and the water pumped from the wells would have included

[3] This is an unrealistic pumping rate. As noted in Draft EIR/EIS Appendix I1 on page I1-4, source water yield from a vertical well typically ranges between 0.1 and 1.5 mgd (Hunt, 2008). The 300 afy Sand City Desalination Plant utilizes two vertical wells (and two on standby). In order to supply 24 mgd of feedwater for a 9.6 mgd desalination plant, the project would need 24 vertical wells, not six. To provide 15.5 mgd of feedwater for a 6.4 mgd desalination plant, the project would need approximately 16 vertical wells.

approximately "15 percent of intruded groundwater from the SVGB" (Coastal Water Project Final EIR, SCH No. 2006101004, Section 5.2.2.1, page 5-21). The reliability of modeling slant wells is no different from modeling vertical wells because all groundwater models simulate subsurface water movement in porous media. They are approximations because a model cannot quantify exactly the spatially variable properties that exist in the real world; see Master Response 12, The North Marina Groundwater Model (v. 2016), Section 8.2.12.2.

MCWD-13 Groundwater modeling was conducted for the Coastal Water Project EIR (which included the Regional Project as well as the North Marina Project; see EIR/EIS Section 5.2.4) prior to approval of that project, not after its approval. The January 2009 CWP Draft EIR and the October 2009 CWP Final EIR both included an Appendix E titled "North Marina Ground Water Model Evaluation of Potential Projects," prepared for CalAm by Geoscience Support Services, dated July 25, 2008 (Geoscience, 2008). The July 2008 groundwater modeling concluded that "after 56 years of operating the Regional Project, the inland groundwater elevations in the 180-Foot Aquifer would be higher than under No Project conditions. The area around the Project wells would have lower groundwater elevations due to the trough developed by continuous pumping. Groundwater flow directions would be similar to normal hydrologic year flow directions."

As noted in D.10-12-016 at Findings of Fact 175: "Based on the analysis of hydrology and groundwater modeling in the FEIR, we are persuaded that the volume of water available for desalination and delivery to CalAm will not be diminished, although the water that originates from the Salinas Valley Groundwater Basin may well become purer, because pumping the wells (whether vertical or slant wells) will not only draw seawater towards the coast, but the saline-intruded groundwater will also be drawn towards the coast, which in essence reverses the seawater intrusion dynamic, and reduces the salinity of the groundwater portion of the intake supply but does not change the volume." (CPUC Decision D.10-12-016)

A version of the groundwater model that was used to evaluate the Regional Project was also used in the April 2015 Draft EIR to evaluate the proposed MPWSP. That 2015 version of the model (referred to as $NMGWM^{2015}$) was peer reviewed by Lawrence Berkeley National Laboratories, and HydroFocus independently advanced and revised the model for use in the current EIR/EIS, as $NMGWM^{2016}$. See Master Response 5, The Role of the Hydrogeologic Working Group and its Relationship to EIR/EIS, Section 8.2.5.6.

The $NMGWM^{2016}$ employs eight layers to represent the depth distribution of water-bearing and non-water bearing sediments in the basin. The 149-square-mile model domain includes the City of Marina, and Model Layer 8 represents the 900-Foot/Deep Aquifer. Hence, the model clearly evaluates the potential for drawdown and changes to groundwater flow within the City of Marina. See Master Response 12, The North

Marina Groundwater Model (v. 2016), for more details, including the manner in which the test well data was indeed used in the modeling effort.[4]

Model-calculated drawdown due to test slant well pumping was compared to measured drawdown and was used to validate model predictions. EIR/EIS Appendix E2, Figure 4.6 shows measured versus model calibrated drawdown in CEMEX monitoring wells during slant well pumping.

Superposition is employed to isolate the expected change in groundwater levels and fluxes due solely to the proposed slant well pumping. These changes would be additive to future changes that occur as the net result of all other recharge and discharge processes in the basin. Therefore, the project drawdown is added to the drawdown determined for other cumulative projects and the results represent the overall cumulative effects; see EIR/EIS Section 4.4.6.

Conducting the modeling as part of the EIR/EIS process, and making the modeling results (as well as the model itself) available for public review, provides the public with ample opportunity to review and make comments, resulting in a transparent process that provides for full and open disclosure. Applicant Proposed Measure 4.4-3, Groundwater Monitoring and Avoidance of Well Damage, proposes to expand the existing regional groundwater monitoring program to include the area where groundwater elevations are anticipated to decrease in the Dune Sand Aquifer, the 180-FTE and the 400-Foot Aquifer as a result of project pumping, and would, therefore, be included in the Mitigation Monitoring and Reporting Plan that gets adopted with any project approval decision. Therefore, any further MPWSP evaluation, testing, and modeling for groundwater impacts would proceed within a regulatory framework that would be open to full public scrutiny, consistent with CEQA, NEPA, the Public Utilities Code and due process.

MCWD-14 SGMA is discussed in Master Response 6, The Sustainable Groundwater Management Act.

MCWD-15 As demonstrated in Master Response 13, Demand (Project Need) and Growth, CalAm's objective of meeting peak demands of existing customers means meeting peak monthly demands, which are approximately 30 percent greater than average, not the 10 percent referenced in the comment; see the discussion of "Supply for Peak Demands" in Section 8.2.13.3 of Master Response 13.

See Master Response 13 Sections 8.2.13.1 and 8.2.13.2 regarding the demand and supply assumptions underlying the proposed MPWSP. Note that the supply sources CalAm has historically used were reduced by the Seaside Groundwater Basin

[4] The comment includes Footnote 4, which introduces litigation initiated by MCWD against the CCC with respect to the test slant well, and refers to an attached brief filed as part of that case. Indeed, MCWD has brought three lawsuits challenging aspects of the test slant well for the Project. See Response to Comment MCWD-89.

adjudication as well as by State Water Board orders on the Carmel River. Please see Marina-140, in Section 8.5.1, concerning Alternatives 5a and 5b.

Regarding alternative supply sources, the consideration and evaluation of numerous project alternatives over the years, described in EIR/EIS Section 5.2, Alternatives Not Evaluated in Detail, supports the conclusion that viable alternatives have not been identified that would supply sufficient water without a desalination plant. Indeed, an alternative source suggested in the descriptions of "Scenarios A and B" (see response to comment MCWD-31 through 42) includes a "small desalination plant." Refer to responses to comments MCWD-42 through MCWD-49 regarding alternative sources of supply. MCWD's contention that adequate alternative sources are available also relies on an arguably unrealistic assumption that demand in 2016 represents service area demand in non-drought periods (discussed under "Existing Annual Service Area Demand" in Master Response 13, Section 8.2.13.2) and further supposes that the other demands that the project proposes to serve need not be served.

See also the discussion in "Supply Provided by the Desalination Plant" in Master Response 13, Section 8.2.13.3, and "Alternative Supply and Demand Scenarios" in Section 8.2.13.4, which explains that the desalination plant could be operated at a somewhat lower capacity if long-term demand were to decline, and explores the potential to reduce the size of the desalination plant under alternative demand and supply scenarios, respectively. As described in EIR/EIS Section 1.5.4, the CPUC will consider any other issues that have been established in the record of the proceeding, including but not limited to economic issues, social impacts, and the need for the project.

MCWD-16 The CPUC has properly exercised independent judgment under Public Resources Code section 21082.1(c)(3). A lead agency has the discretion to adopt materials that it chooses, such as those drafted by the applicant or its consultants, so long as the lead agency independently reviews, evaluates, and exercises judgment over that documentation and issues it raises and addresses. (*Friends of La Vina v. County of Los Angeles* (1991) 232 Cal.App.3d 1446; Pub. Resources Code, §21082.1, subd. (c); Cal. Code Regs., tit. 14, §15084, subd. (e).) The lead agency also has the discretion to resolve factual issues and to make policy decisions. As an example, "[i]f the determination of a baseline condition requires choosing between conflicting expert opinions or differing methodologies, it is the function of the agency to make those choices based on all of the evidence." (*Save Our Peninsula Committee v. Monterey County Board* (2001) 87 Cal.App.4th 99, 120; citing *Barthelemy v. Chino Basin Municipal Water District* (1995) 38 Cal.App.4th 1609, 1617.) Even if an entire study or technical document is initially prepared by the project applicant or a third party (such as the NMGWM^{2015} prepared by Geoscience as CalAm's consultant) and subsequently adopted by the lead agency, that does not mean that the lead agency failed to exercise its independent judgement. (*City of Poway v. City of San Diego* (1984) 155 Cal.App.3d 1037, 1042.) Under NEPA regulations, materials

may also be prepared by the applicant or a third-party contractor as long as the agency independently evaluates the information submitted and the agency is responsible for its accuracy (40 CFR §1506.5).

See also Master Response 5, The Role of the Hydrogeology Working Group and its Relationship to EIR/EIS, Section 8.2.5.5. The CEQA/NEPA consultants, under contract to the CPUC, prepared the EIR/EIS independent from the HWG, using professional judgment in evaluating the information provided by the HWG. The CEQA/NEPA consultants considered and incorporated information and data generated by the HWG to inform the EIR/EIS, only as appropriate. The EIR/EIS impact analysis conclusions and mitigation measures prepared by the CEQA/NEPA consultants were not shared or discussed with the HWG prior to publication of the Draft EIR/EIS.

Extensive documentation in EIR/EIS Appendix E2 (Section 3) demonstrates the reliability, authenticity, and genuineness of the NMGWM^{2016}. Responses to model-related comments provided by Hopkins, GeoHydros, EKI, and Dr. Abrams further demonstrate the soundness of the modeling approach and trustworthiness. See Master Response 12, The North Marina Groundwater Model (v. 2016), for more details. See responses to comments MCWD-168 through MCWD-174 for responses to comments addressing the CEQA/NEPA approach to alternative intake technologies and alternatives that was performed by the EIR/EIS preparers.

See also Master Response 5, The Role of the Hydrogeology Working Group and its Relationship to EIR/EIS, where the HWG members are discussed in Section 8.2.5.3 and the potential conflicts of interest are addressed in Section 8.2.5.6.

MCWD-17 EIR/EIS Section 1.5.4 describes the CPUC decision making process for the MPWSP; it is identical to the processes employed by the CPUC for other projects subject to CEQA. Before making a decision on the project, the Commission will consider all of the evidence in its record (including parties' testimony and briefs, all evidentiary hearings and the entire CEQA/NEPA review record, including the Final EIR/EIS). On the basis of all such evidence, the Commission will reach a decision on whether to issue a Certificate of Public Convenience and Necessity, all in accord with the Public Utilities Code and due process.

MCWD-18 The Lead Agencies appreciate the unique position of the commenter. Each comment presented in the comment letter and attachments has been addressed in this set of responses. See responses to comments MCWD-HGC, MCDW-GeoHydros, MCWD-EKI and MCWD-Intake Works, which follow these responses to MCWD's main letter.

MCWD-19 This comment is addressed in Master Response 6, The Sustainable Groundwater Management Act.

MCWD-20 The EIR/EIS preparers independently considered the reasonableness of the proposed demand, supply, and operations assumptions submitted by CalAm for its Monterey District Service Area, in the context of other water supply planning projections; Section 2.3 thoroughly describes the CalAm service area demand assumptions, and the "other demand" assumptions included in project sizing, while Section 2.4 describes the available supplies. EIR/EIS Section 6.3.5.1 evaluates the demand and supply assumptions to determine if the provision of water proposed by the project appears reasonable, and if it would directly or indirectly induce growth, and concludes that supply not used to meet existing demand, demand of existing business customers under more robust economic conditions, or the SVGB return water obligation would be available to support new development. New development might include improvement of existing vacant lots of record. Water supply capacity to serve new development would remove water supply limitations as an obstacle to such development and would be considered growth-inducing under CEQA and NEPA.

CalAm is under SWRCB orders to manage its current water supplies as efficiently as possible; the MPWMD presents monthly water supply reports and CalAm production reports at its monthly Board of Directors meetings and these reports are available at the MPWMD website.[5] Table 8.2.13-2 in Master Response 13, Demand (Project Need) and Growth, presents typical monthly operations to meet project demands assuming a 9.6 mgd desalination plant and 6 percent Salinas Valley Groundwater Basin (SVGB) return water obligation; see also EIR/EIS Appendix L. The comments about the relative complexity of CalAm's current and future water supply portfolio and similarities between operating an electric utility and a water utility are noted. Regarding peak demand, see the discussion under "Supply for Peak Demands" in Section 8.2.13.2 of Master Response 13.

MCWD-21 The information provided regarding reserves required of electric utilities and the comment about CalAm's objective of meeting peak demand are acknowledged. As stated in EIR/EIS Section 1.3.1, the fourth primary objective of the proposed project is to "[d]evelop a reliable water supply for the CalAm Monterey District service area, accounting for the peak month demand of existing customers." Peak demands ("reserve margins") are discussed in EIR/EIS Section 2.3.2, Peak Demands. Also see the discussion under "Supply for Peak Demands" in Master Response 13, Section 8.2.13.3.

MCWD-22 The reduction in CalAm's Carmel River supply pursuant to SWRCB orders is a key driver of the proposed MPWSP (see EIR/EIS section 2.2.3), as is the Seaside Groundwater Basin (SGB) Adjudication (see EIR/EIS section 2.2.4). EIR/EIS Table 2-1 presents the SGB adjudicated operating and natural safe yields, including CalAm's pre-adjudicated production, while Table 2-4 presents the legal and/or contractual limits of the portfolio of water supply sources available to CalAm's

5 http://www.mpwmd.net/who-we-are/board-of-directors/bod-meeting-agendas-calendar/

Monterey District, with the proposed MPWSP. Table 2-4 presents available supplies assuming construction of the proposed 9.6 mgd desalination plant or a 6.4 mgd plant combined with purchase of GWR Project water (Alternative 5a). As used in the EIR/EIS, in lieu replenishment of the Seaside Groundwater Basin – to replenish the amount of groundwater CalAm has pumped in excess of its adjudicated right – would occur when CalAm pumps only 774 afy of its 1,474 afy adjudicated right from the Basin, leaving the other 700 afy in the ground, as discussed in EIR/EIS Section 2.2.4. See also response to comment MCWD-28.

Since the SGB has been adjudicated, the amount of groundwater CalAm can pump from the Basin is limited by court order, as discussed in EIR/EIS Section 2.2.4 and presented in Table 2-1; this represents supply available under the No Action Alternative, and would not change with the proposed project. Under the adjudication, CalAm is able to augment storage, and withdraw water that it puts into the SGB via aquifer storage and recovery; the MPWSP proposes to enhance and increase ASR in the Seaside Basin. If purchased GWR water were added to CalAm's supply portfolio, CalAm would also be able to withdraw its portion of GWR that had previously been put into the Basin. The EIR/EIS subtracts the service area demand presented in EIR/EIS Table 2-3 from the available total supplies presented in Table 2-4, to determine how much supply provided by the proposed MPWSP would be in excess of current uses and would, therefore, be available for other uses (i.e., growth). Water produced by the proposed project in excess of CalAm's needs is assumed to induce growth, and the indirect impacts of that growth are evaluated in EIR/EIS Section 6.3.

An EIR/EIS is required to evaluate the effects of a proposed project against baseline (existing) conditions and not against a future scenario of demand and supply in 2022 – the environmental setting will normally constitute the baseline physical conditions by which a lead agency determines whether an impact is significant (CEQA Guidelines 15125(a)). Sections 8.2.13.2 and 8.2.13.3 of Master Response 13 summarize the EIR/EIS demand and supply assumptions, respectively, and document why they are reasonable. However, questions have been raised as to whether the proposed project is necessary or could be smaller if one considered different supply and demand assumptions.

EIR/EIS Appendix L was prepared to test that possibility by considering different supply and demand numbers. The primary consideration is whether facts exist to support a smaller desalination plant (e.g., having one or more fewer reverse osmosis [RO] units) such that either a smaller plant or a phased plant could be approved for the 9.6 mgd proposed project or the 6.4 mgd Alternative 5a. The results of this sensitivity analysis could inform and affect the ultimate project decision.

Regarding existing annual service area demand, see Master Response 13, Section 8.2.13.2. As stated in response to comment MCWD-20, Table 8.2.13-2 in Master Response 13 shows typical monthly operations to meet project demands; as

discussed there, this table was provided to the EIR/EIS preparers by CalAm, but it was independently reviewed and subsequently revised by the EIR/EIS preparers. The table shows that available supplies from the multiple sources would be used to meet demand that varies each month over the course of the year. The table shows that operations would meet the supply and demand related objectives for the project. The first page of the table shows when and how much of the injected desalinated water would be extracted from the ASR system each year. As the table shows, this water would be injected in wetter months and withdrawn in drier months. The second page of the table shows how supplies provided by the desalination plant would be distributed.

EIR/EIS Appendix L presents a sensitivity analysis to test the possibility that the proposed project could be downsized, and examines whether the proposed project is necessary or could be smaller if one considered different supply and demand numbers that some commenters believe are more reasonable than those used in the Draft EIR/EIS. The Lead Agencies will consider all evidence in the record concerning demand and supply prior to acting upon the project, and may conclude that a smaller desalination plant (or some other alternative) would indeed satisfy the primary objectives of the project.

MCWD-23 See the discussion under "Existing Annual Service Area Demand" in Master Response 13, Section 8.2.13.2; see also the discussion of Pebble Beach Entitlements, which are considered part of existing demand, under "Other Demands." Master Response 13, Section 8.2.13.2 explains that two other factors that influenced demand in recent years were the recession that began in late 2007 to early 2008 and the recent five-year drought.

MCWD-24 EIR/EIS Section 2.4.3 describes CalAm's supply sources; see also Master Response 13, Section 8.2.13.3. Regarding the use of 2016 demand to represent annual service area demand, see the discussion of Existing Annual Service Area Demand in Master Response 13, Section 8.2.13.3. An average of 3,500 afy of GWR Project water would be available to CalAm, assuming the GWR Project is constructed and becomes operational, as also discussed in Section 8.2.13.3. Regarding the ASR system yield and CalAm's water rights permits to divert water to aquifer storage and recovery, see response to comment MCWD-30. EIR/EIS Section 5.4.2.4, Ability to Meet Project Objectives, includes a discussion on the ability of the No Project Alternative to meet project objectives assuming implementation of the GWR Project.

MCWD-25 The CalAm Monterey District Service Area overlies a small portion of the Seaside Groundwater Basin, as shown in EIR/EIR Figure 3-1, but MCWD's Ord Community overlies a substantial portion of the Basin. While CalAm used to pump upwards of 4,000 afy from the Seaside Basin CalAm's adjudicated allocation from the Seaside Groundwater Basin is 1,474 afy, as explained in EIR/EIS Section 2.2.4 and Table 2-1. As explained in response to comment USARMY-16, the volume of

water that CalAm could inject into the ASR system in a given year could be a combined maximum of about 7,426 acre-feet from all sources.

See also response to comment MCWD-22. Since the Seaside Basin Adjudication Decision (Monterey County Superior Court, 2007) Section II.C.2 acknowledges that " . . . the public interest is served by augmenting the total yield of the Seaside Basin through artificial groundwater recharge, storage, and recovery," and since CEQA Guideline Section 15126.2 states that " . . . an EIR shall identify and focus on the significant environmental effects of the proposed project," the EIR/EIS did not analyze the synergistic benefits of the increased groundwater storage in the Seaside Groundwater Basin because it would be a benefit, and not a potentially adverse significant impact. However, given that NEPA does consider beneficial effects, it is acknowledged that the enhanced ASR aspect of the project could provide beneficial effects to the groundwater resources within the Seaside Basin.

MCWD-26 EIR/EIS Chapter 3 provides a general description of the technical and environmental characteristics of the proposed facilities, consistent with CEQA Guidelines Section 15124(c). On March 23, 2017, CalAm provided to MCWD an assessment of estimated pipeline capacities, including pressure assumptions, for proposed uses of the MCWD-CalAm joint pipeline in General Jim Moore Boulevard, including future supply from CalAm's proposed desalination facility (CalAm, 2017). The assessment shows there would be ample capacity in the joint pipeline for projected future uses: up to 11,081 gallons per minute (gpm) on an average day, and up to 9,996 gpm at peak hour. Since the shared pipeline is part of a pressurized system, whatever source water that is permitted to use the pipeline would become blended in the pipeline. Regardless of the source or the destination, appropriate volumes associated with each source would share the pipeline during different times of the year. See also responses to comment MCWD-27 and MCWD-157.

MCWD-27 The purpose and need for the expansion of the existing Seaside Groundwater Basin ASR system is described in EIR/EIS Section 3.2.4. As noted in that section, the ASR expansion would provide additional injection/extraction capacity for both desalinated product water and Carmel River supplies in order to increase system reliability. The proposed new ASR injection/extraction wells would be used to inject Carmel River supplies and desalinated water into the Seaside Groundwater Basin for storage, and during periods of peak demand, the stored water would be extracted and delivered to customers; see EIR/EIS Table 3-1. As shown in Table 8.2.13-2 in Master Response 13, the MPWSP desalinated supplies would be extracted from the Seaside Groundwater Basin and delivered to customers between May and October. As proposed, the 2,100 afy of desalinated water that would be injected each winter into the Seaside Groundwater Basin when customer demands are lower means that CalAm would be able to extract that amount in the summer months when demands are higher, thus meeting a primary objective (see EIR/EIS

Section 1.3.1) of developing a reliable water supply for CalAm's Monterey District service area, accounting for the peak month demand of existing customers.

In addition, as discussed in EIR/EIS Section 2.2.4, CalAm is entitled to 1,474 afy from the Seaside Groundwater Basin as a result of adjudication but has agreed with the Seaside Groundwater Basin Watermaster to leave 700 afy of its entitlement in the Seaside Groundwater Basin for 25 years, as repayment for its previous overdrafting. Both the stored desalinated water and the Seaside Groundwater Basin water are assumed to be available supplies to meet the peak month demand. See Master Response 13.

MCWD-28 The GWR Project water to which MCWD is entitled would provide an in-lieu recharge of the adjudicated Seaside Groundwater Basin if there were subscribers/irrigators/customers who would use the water in exchange for the potable water they currently receive, or pump directly from the Seaside Groundwater Basin themselves. If the Bayonet and Blackhorse Golf Courses were to receive GWR Project water in exchange for their current use of an equal amount of groundwater from the Seaside Groundwater Basin, 400 to 500 afy of water could remain in the Seaside Groundwater Basin. If an additional 200-300 afy of GWR Project water could also be provided to other Seaside Groundwater Basin users in exchange for their existing use of potable water from the Seaside Groundwater Basin, and if CalAm could affect such an agreement to do so with the Watermaster, the court and other stakeholders, then that 700 afy (0.625 mgd) would not be required to be produced at the desalination plant. Since each desalination treatment module is sized at 1.6 mgd, this 700 afy reduction would represent less than one-half of a treatment module and would not alone be enough of a savings to justify downsizing the project. This and other possible reductions in demand will be considered by the Lead Agencies in their decision-making process. The magnitude of any potential adverse impacts resulting from the implementation of a desalination plant that is reduced in size from Alternative 5a and 5b would be reduced from what was evaluated for Alternatives 5a and 5b in EIR/EIS Section 5.5. However, it is expected that the classifications of all such impacts would remain the same as set forth in the EIR/EIS, as would the suggested mitigation measures. An average of 3,500 afy of GWR water (as opposed to 3,700 afy noted in the comment) would be available to CalAm from MRWPCA; see Master Response 13, Section 8.2.13.3.

MCWD-29 See Master Response 13, Demand (Project Need) and Growth, Section 8.2.13.3, regarding supply assumed to be available to CalAm from the Sand City desalination plant. EIR/EIS Section 5.4.2 has been revised to clarify that 230 afy represents supply assumed to be available to CalAm from the Sand City plant at the end of the Cease and Desist Order (CDO) extension period, and that CalAm's eventual, longer term supply from that desalination plant would be 94 afy. CalAm has a long term right only to the 94 afy so the Lead Agencies cannot reasonably assume any greater number would be available for CalAm's use. For the No Project Alternative, the estimate of 230 afy was assumed in order to characterize

available supply at the end of the CDO extension period; at that time, a portion of Sand City's share of Sand City desalination plant production is assumed to not yet be needed by the City and therefore would continue to be available to CalAm. Over time, it is assumed that Sand City will need more of its 206 afy share of the plant's production to serve Sand City development, and supply available to CalAm will be reduced to CalAm's long term share of 94 afy. The third bullet under "Supply Shortages" in EIR/EIS Section 5.4.2.3 has been revised as follows:

> Continued use at the end of the Revised CDO extension period of approximately 230 afy provided by Sand City's existing desalination plant (*eventually decreasing to CalAm's long term supply from the Sand City desalination plant of 94 afy, same as proposed project*) . . .

MCWD-30 SWRCB-issued water rights permits for diversion of Carmel River supplies are discussed in EIR/EIS Section 2.4.3, Section 3.4.2, and Section 4.4.2.2. The combined diversion limits of the two permits (20808A and 20808C) is set at 5,326 afy (2,426 afy and 2,900 afy, respectively) and is contingent upon hydrology/rainfall and, therefore, meeting certain instream flow requirements based on NMFS 2002 recommendations and the physical attributes of the wells; the permits do not, as the comment states, include an estimated annual average yield. Nor does the MPWMD website describing the ASR project "report" average yields; rather the website explains that "[t]he Phase 1 ASR project *entails* [emphasis added] a maximum diversion of 2,400 afy from the Carmel River and an average yield of about 920 afy" and further explains that "[t]he average yield of the Phase 2 ASR project is *estimated* [emphasis added] at approximately 1,050 AFY of additional water supplies." (http://www.mpwmd.net/water-supply/aquifer-storage-recovery/). As noted by SWRCB Order WR 2016-0016, the ASR project diverted just over 1,110 afy of water in Water Year 2009-2010 and Water Year 2010-2011, and between 0 and 210 afy in the drier water years from Water Year 2011-2012 through Water Year 2014-2015. The 1,920 afy and 1,970 afy estimates cited in the comment are just that, whereas the historical values cited in Order 2016-0016 represent actual diversions that have been available as a result hydrology/rainfall.

In its comments on the EIR/EIS, the MPWMD provided Attachment 1 (see comment MPWMD-14, in Section 8.5.7), which calculates the ASR project yield with the new Monterey Pipeline (which is under construction) to be 1,600 afy under "normal" hydrology, compared to 918 afy without the new Monterey Pipeline in the same water year type. Taking all water year types into consideration, the estimated annual yield from ASR with the capacity of the new Monterey Pipeline would average 1,641 afy. The EIR/EIS is using 1,600 afy as a long-term average and not the 1,920 afy or 1,970 afy estimates, because the 1,600 is a more current and realistic value that has been provided by MPWMD, the agency formed under California Water Code with a mission "to promote or provide for a long-term sustainable water supply, and to manage and protect water resources for the benefit of the community and the environment." See also Master Response 13.

MCWD-31 The recycled water supplies anticipated by MCWD from the Regional Urban Water Augmentation Project (RUWAP) Recycled Water Project are described in EIR/EIS Table 4.1-2 as a cumulative project (Project No. 31), as is the Pure Water Monterey GWR (Project No. 59), through which MCWD will now receive the recycled supplies identified by the RUWAP Recycled Water Project. The full size of the GWR project, regardless of who administers or serves the supply (MCWD or MRWPCA), is fully considered in the cumulative analysis of Alternative 5a and 5b in Section 5.5. See also response to comment MCWD-28 regarding the use of GWR water and Seaside Basin in-lieu recharge.

MCWD-32 In assessing the No Project alternative, the Lead Agencies used a different set of supply assumptions from what is presented in the No MPWSP Option cited in the comment; see the first five rows of EIR/EIS Table 2-4, which are based on the best available information. For example, the Carmel River supply is not available equally in all months due to instream flow requirements (see EIR/EIS Section 2.2.3); the available Seaside Basin supplies are dictated by the adjudication and an agreement between CalAm and the Watermaster (see EIR/EIS Section 2.2.4); long term supply from the Sand City desalination plant is only 94 afy (see EIR/EIS Section 2.4.4); ASR is reliable at 1,600 afy (except in drought years when the yield would be zero, see EIR/EIS Section 2.4.3); and GWR will only supply CalAm with 3,500 afy -- the additional 200 afy is a drought reserve. Also see responses to comments MCWD-27 through MCWD-30 and Master Response 13, Demand (Project Need) and Growth, Section 8.2.13.3. See Master Response 13, Section 8.2.13.2, regarding EIR/EIS demand assumptions. EIR/EIS Section 5.4.2.4, Ability to Meet Project Objectives, includes a discussion on the ability of the No Project Alternative to meet project objectives assuming implementation of the GWR Project.

MCWD-33 The EIR/EIS utilized a different supply assumption than the commenter's No MPWSP Option Scenario A. For a discussion of supplies available to CalAm, see responses to comments MCWD-27 through MCWD-30, MCWD-32, and Master Response 13, Section 8.2.13.3. Regarding existing annual service area demand, see Master Response 13, Section 8.2.13.2.

MCWD-34 For a discussion of supplies available to CalAm, see responses to comments MCWD-27 through 30, MCWD-32, and Master Response 13, Section 8.2.13.3. For an explanation of existing annual service area demand used for sizing the proposed project, see EIR/EIS Section 2.3.1 and Master Response 13, Section 8.2.13.2; the EIR/EIS does not assume 2016 demand. Regarding the ability of the No Project Alternative to meet project objectives, see EIR/EIS Section 5.4.2 and response to comment MCWD-37. The analysis presented by the comment assumes an annual average demand and supply scenario when, in fact, the demand of customers and the availability of supplies varies by month; customer demand in the peak summer months is approximately 130 percent of normal, and supplies in a drought (specifically, water stored in ASR) may not be available. See also EIR/EIS Appendix L.

MCWD-35 The underlying supply and demand assumptions included in the commenter's No MPWSP Option Scenario A are not supported by the EIR/EIS. For a discussion of supplies available to CalAm, see responses to comments MCWD-27 through 30, MCWD-32, and Master Response 13, Section 8.2.13.3. Regarding existing annual service area demand, see Master Response 13, Section 8.2.13.2.

MCWD-36 The underlying supply assumptions regarding the commenter's No MPWSP Option Scenario B are not supported by the EIR/EIS. For a discussion of existing annual service area demand and other demands the project proposes to meet, see EIR/EIS Section 2.3.1, and Master Response 13, Section 8.2.13.2. See also the discussion of "Alternative Supply and Demand Scenarios" in Master Response 13, Section 8.2.13.4, which explores the potential to reduce the size of the desalination plant under alternative demand and supply scenarios; see also EIR/EIS Appendix L. Regarding the ability of the MPWSP No Project Alternative to meet project objectives, see response to comment MCWD-37.

MCWD-37 The conclusions presented in the comment about the No MPWSP Option Scenario B assumes an annual average demand and supply scenario, when in fact, the demand of customers and availability of supplies varies by month; customer demand in the peak summer months is approximately 130 percent of normal, and supplies in a drought (specifically, water stored in ASR) may not be available. See also EIR/EIS Appendix L.

EIR EIS Section 5.4.2.4 describes the ability of the No Project Alternative to meet project objectives, with and without the GWR Project. The EIR/EIS analysis concludes that the No Project Alternative would achieve compliance with the Revised CDO and the Seaside Groundwater Basin adjudication but would not provide sufficient supply to allow for replenishment of water that CalAm previously pumped in excess of its adjudicated rights from the Basin; would not provide water supply reliability; and would not provide supply for the development of vacant legal lots of record or supply to meet demand resulting from economic recovery of the hospitality industry. See also responses to comments MCWD-15 and MCWD-27.

MCWD-38 The supply assumptions presented in the commenter's No MPWSP Option Scenario A and Scenario B are not supported by evidence presented in this EIR/EIS. See responses to comments MCWD-32 through MCWD-37, MCWD-39, and Master Response 13.

MCWD-39 See the discussion under "Existing Annual Service Area Demand" in Master Response 13, Section 8.2.13.1 regarding CalAm's estimate of existing service area demand, consistent with project objective number 4. Refer to the discussion of Pebble Beach Entitlements under "Other Demands" in Master Response 13, Section 8.2.13.1 regarding CalAm's obligation to serve properties with these entitlements. Meeting existing demand, existing obligations to supply water, and

demand of existing customers under improved economic conditions, and having the capacity to serve existing lots of record is consistent with the objective of providing a reliable water supply.

CalAm's March 2016 amended Project Description states, regarding the project variant (a 6.4 mgd plant combined with GWR water purchase), that the "primary objectives of the MPWSP Variant are the same as those for the proposed project [which are to provide additional water supplies] to meet the estimated total annual demand in the Monterey District of 15,296 afy…." That total, originally provided in CalAm's January 2013 supplemental testimony, includes the demand components described in EIR/EIS Chapter 2 and Section 6.3. The more specific objectives described in the EIR/EIS are consistent with the scope of the more general objectives stated in the project description of the amended application, including "diversify and create a reliable drought-proof water supply" and "protect the local economy from the effects of an uncertain water supply." The more specific objectives described in EIR/EIS Section 1.3.1 were indeed provided by CalAm, the project applicant; this information was presented in testimony and similar formal submittals during the CPUC's application proceedings. The existing annual demand assumed in the EIR/EIS was revised to 12,270 afy in supplemental testimony provided by CalAm in April 2016 (Svindland, 2016). The CEQA project objectives set forth in the EIR/EIS were compiled by the CPUC to reflect CalAm's application and other submittals.

MCWD-40 EIR/EIS Section 4.20.5.1 addresses socioeconomic impacts of the proposed project, and Section 4.20.5.2 addresses the environmental justice issues pursuant to NEPA requirements. As noted in EIR/EIS Section 4.20.2.2, and consistent with CEQA Guidelines Section 15131(a), "Economic or social effects of a project shall not be treated as significant effects on the environment" and the focus of the analysis in the EIR/EIS was on the physical changes caused by the proposed project. As noted in EIR/EIS Section 1.5.4, ". . . the Certificate of Public Convenience and Necessity process will consider any other issues that have been established in the record of the proceeding, including but not limited to economic issues, social impacts . . . and the need for the project."

MCWD-41 Regarding existing annual demand, other demands, and supplies available to CalAm, refer to responses to comments MCWD-32 through MCWD-40 and Master Response 13; regarding the proposed ASR wells, see response to comment MCWD-27; regarding the commenter's suggested alternative to replenishing the Seaside Groundwater Basin, see response to comment MCWD-28.

Contrary to the comment, the EIR/EIS does not use the 690 afy as a return water obligation. As discussed in EIR/EIS Section 2.5.1, Salinas Valley Groundwater Basin Return Water, groundwater modeling simulated operating scenarios with return water obligations representing 0, 3, 6, and 12 percent of the source water (see Section 4.4, Groundwater Resources). EIR/EIS Table 5.5-19 shows the

amount representing 6 percent return water for the larger 9.6 mgd project (1,620 afy) and Table 5.5-24 shows the amount representing 6 percent return water for the smaller 6.4 mgd project (1,042 afy), and neither discussion makes a distinction or an assumption as to whether it is delivered to CCSD or the CSIP. See Master Response 4 regarding the Agency Act and SVGB return water. Because EIR/EIS Section 4.4 concluded the impacts of proposed project pumping at the CEMEX property on groundwater resources would be less than significant, there is no obligation to mitigate for environmental, groundwater, and SGMA direct, indirect, and cumulative impacts from slant well pumping; see also Master Response 6, The Sustainable Groundwater Management Act.

MCWD-42 Regarding alternative supply sources, see response to comment MCWD-15 and responses to comments MCWD-43 through MCWD-49. Regarding existing annual demand, including the suggestion of using 2015 or 2016 as a reliable estimate of service area demand, see the discussion of Demand Assumptions in Master Response 13, Section 8.2.13.2. See also the discussion of Alternative Supply and Demand Assumptions in Master Response 13, Section 8.2.13.4. Regarding the ability of the commenter's proposed No MPWSP Option Scenario A and Scenario B to meet project objectives, see response to comment MCWD-38.

MCWD-43 The Interlake Tunnel project is described in EIR/EIS Section 5.2.5 and has been under consideration by Monterey County Water Resources Agency (MCWRA) since the late 1970s. But the recent drought renewed interest in this project, which would involve building a tunnel between the Nacimiento Reservoir, and the larger capacity San Antonio Reservoir, to preserve approximately 50,000 afy of water that would otherwise spill from Nacimiento Reservoir because it is too small to capture all the watershed drainage. The project would provide additional flood control and water supply benefits to existing users and beneficiaries of the MCWRA Zone 2C, and would be funded through a Proposition 218 assessment of Zone 2C property owners; however, CalAm's service area is not within Zone 2C and, therefore, CalAm customers would not be direct beneficiaries of the Interlake Tunnel project.

A new Salinas River diversion and conveyance facility to convey water to near Salinas is proposed under the unexercised SWRCB-issued water right referenced in the comment; but the SWRCB issued a Notice of Proposed Revocation of Water Right Permit #11043 in 2010. The future availability of water under Permit #11043 is extremely uncertain. See response to comment Beech3-3 in Section 8.7.2.

It would be speculative to assume a Salinas River surface water right could be obtained and would be a component of a reliable water supply portfolio; without it, and considering the implementation concerns described in this response below, this scenario would not meet the project objectives. However, if a project could secure a water right to appropriate and divert 10,000 to 20,000 afy when there are excess surface water flows in the Salinas River, then:

1. The existing diversion facility (rubber dam) could be expanded to move the surface water to an expanded advanced water treatment facility (e.g., Pure Water Monterey) and then conveyed to the Seaside Groundwater Basin. If the treated surface water were blended with other GWR source waters, either during treatment or conveyance, additional injection/extraction wells would need to be constructed in the Seaside Groundwater Basin so the water could be stored and "polished" in the ground (retention time) before it is made available for extraction in the high demand months.

2. The surface water could be treated in a desalination plant, although it would be more cost-effective to use a standard surface water treatment plant. However, the excess stormwater would only be available for diversion and treatment in the winter months, and not the high demand months of summer, so storage would be necessary.

3. Under the scenario described by the comment, Salinas River flows would be available for diversion from November through March. Groundwater recharge in the Castroville area would need to occur through injection and not in-lieu recharge, because winter demands would be low. The CSIP was developed as an initial response to stopping seawater intrusion by raising groundwater levels at the coast through in-lieu recharge, and the implementation of SVWP Phase I met the objective of stopping seawater intrusion. However, the groundwater depression on the east side of Salinas persists; SVWP Phase II was meant to provide water to fill the depression and would have utilized new Salinas River diversions and conveyance facilities to deliver water from Water Right Permit #11043 to do so. See response to comment Beech3-4.

4. It is not clear how any portion of the excess Salinas River water stored at the Armstrong Ranch would help meet any of the objectives of the proposed project.

The Salinas Valley Basin Groundwater Sustainability Agency (SVBGSA) will decide what projects get implemented to remedy the critically overdrafted SVGB. The implementation of a Salinas River Excess Flow Capture project would be speculative for the reasons presented in this response.

MCWD-44 See response to comment MCWD-27 and 28.

MCWD-45 Since MCWD does not represent the agricultural community within the Salinas Valley, it is not clear whether such growers are concerned over the GWR project. Indeed, the GWR Project will provide an additional 1,000 afy to the growers who subscribe to the CSIP. See response to comment MCWD-43 for a discussion on stormwater capture/groundwater recharge.

MCWD-46 An analysis of the increased availability of ASR water as of January 1, 2022 has not been conducted because the Phase I and Phase II ASR projects correspond to MPWMD and CalAm's existing Water Rights Permits 20808A and 20808C, which authorize and limit the diversion of up to 2,426 afy for ASR Phase I, and up to 2,900 afy for ASR Phase II; see also response to comment MCWD-30. Carmel

River water in excess of CalAm's legal right to 3,376 afy would stay in the River when the CDO expires in 2022, and would not be available for diversion to use, or storage by CalAm.

Response to comment MPWMD-14 in Section 8.5.7 includes a table prepared by the MPWMD that presents the increased storage capacity of ASR, resulting from the increased conveyance capacity provided by the new Monterey Pipeline. The analysis by the MPWMD indicates that, in a normal precipitation year, an additional 682 af could be available for storage in ASR with the new Monterey Pipeline, and this EIR/EIS is using that assumption; in an above normal precipitation year, that incremental increase could be 1,016 af.

MCWD-47 See responses to comments MCWD-43 and MCWD-44. If MCWD has an unused entitlement of 727 afy from the GWR Project for use in the Ord Community, it is not clear why MCWD would need 1,000 afy from a Salinas River Water Treatment Plant; furthermore, it does not seem reasonably foreseeable that MCWD would build a 5,000 afy water treatment plant, of which MCWD would make 4,000 afy available to CalAm.

MCWD-48 As stated on Draft EIR/EIS page 4.4-89, Table 4.1-2 explains it is not reasonably foreseeable that MCWD would build a 2,700 afy desalination plant at its Armstrong Ranch[6] property if the MCWD need for Ord Community water is only 973 afy (unless some of the GWR Project entitlement were sold to CalAm). As noted by MCWD in response to a California Public Records Act request, the water source for a MCWD desalination facility has not been determined, but it could be seawater-intruded groundwater from the 180-Foot Aquifer, or it could be seawater from shallow wells located along the coast (MCWD, 2016). However, neither the timing or the capacity of a MCWD-proposed desal project would meet the objectives of the proposed project. Horizontal wells had not previously been mentioned or proposed, but have been addressed in response to comment MCWD-171.

MCWD-49 See response to comments MCWD-15, MCWD-39, and MCWD-43 for information on supply and demand.

MCWD-50 See responses to comments MCWD-HGC, Master Response 3, Water Rights, Master Response 4, The Agency Act and Return Water, and Master Response 6, The Sustainable Groundwater Management Act; the source water that originated in the SVGB is not required to be returned to the Marina Subarea. See also EIR/EIS Appendix E3; the return water percentage is likely to be no more than 10 percent within the first 2 years of project slant well pumping, decreasing to no more than 5 percent within 6 months to roughly 3 years. Longer term, it appears that the return water percentage would be between 1 percent and 4 percent, well within the

6 It is unclear how a desalination plant of this size at the Armstrong Ranch and a groundwater recharge and augmentation project at the same general location would operate or what the inter-relationship would be. Neither project is well defined nor appears to be reasonably foreseeable.

0 to 12 percent range studied in the EIR/EIS. Because EIR/EIS Section 4.4 concluded the impacts on groundwater resources from proposed project pumping at CEMEX would be less than significant, there is no obligation to provide return water to mitigate for impacts to the Marina Subarea.

EIR/EIS Table 5.5-19 shows water supplies that would be available with the MPWSP, compared with the service area demands shown in Table 5.5-18, as well as two estimates of the SVGB return water obligation associated with operating the proposed 9.6-mgd desalination plant. Table 5.5-19 illustrates available and surplus supply (or deficit) during the SGB replenishment period, assuming a 6 percent or 12 percent return water obligation. As shown, under either of these return water scenarios, the available supply would meet demand associated with existing land uses and water entitlements (12,845 afy), with a surplus of 209 or 1,829 afy depending on the return water obligation. EIR/EIS Tables 5.5-20 through 5.5-24 present similar analyses for Alternative 1 through Alternative 5, respectively. See also response to comment MCWD-IW-11 (regarding HDD wells) and MCWD-IW-12 (regarding Ranney wells).

The EIR/EIS assumed an alternative that did not include a Salinas Valley Return Water commitment (i.e., one that would utilize an open water intake) would result in more water available for growth; see EIR/EIS Section 5.5.21.5 (Alternative 2), Section 5.5.21.6 (Alternative 3), and Section 5.5.21.7 (Alternative 4).

MCWD-51 See Master Response 3, Water Rights, Section 8.2.3.7, Effect on MCWD.

MCWD-52 See Master Response 3, Water Rights, and responses to comments MCWD-53 and MCWD-56.

MCWD-53 The EIR/EIS analyzes the subject of water rights to be sure the decision-makers are reasonably informed as to the feasibility of the project in order to minimize the possibility that they approve a project that cannot, in the end, be implemented. There is no legal imperative concerning this feasibility issue, and thus no legal standard is required to be applied. See Master Response 3, Water Rights, Section 8.2.3.1.

MCWD-54 See Master Response 3, Water Rights, and response to comment MCWD-53.

MCWD-55 See Master Response 3, Water Rights.

MCWD-56 CalAm's right to use water for the project would be an appropriative right. The EIR/EIS text referred to by the comment concerning use of water beyond the boundaries of the CEMEX property pertains to overlying rights, not to appropriative rights. See EIR/EIS Section 2.6, Water Rights, and Master Response 3, Water Rights, for additional details.

MCWD-57 See EIR/EIS Section 2.6, Water Rights, and Master Response 3, Water Rights.

MCWD-58 The locations of MCWD's water supply wells are presented in EIR/EIS Table 4.4-10 in Section 4.4.5.2, which explains that MCWD's wells are too far from the capture zone to be affected by the proposed project pumping. See Master Response 8, Project Source Water and Seawater Intrusion, Sections 8.2.8.1 and 8.2.8.2, for a description of the capture zone. While the MPWSP would draw water from the sediments of the Dune Sand Aquifer and the 180-Foot Aquifer (referred to locally as the 180-FTE Aquifer), the capture zone would be recharged primarily by seawater and would not extend inland to impact inland groundwater users.

MCWD-59 See Master Response 3, Water Rights, Master Response 4, The Agency Act and Return Water, Master Response 8, Project Source Water and Seawater Intrusion, and responses to comments MCWD-50 and MCWD-HGC.

MCWD-60 The onsite technical information sought by the SWRCB has been provided in EIR/EIS Section 4.4 and is supported by Appendices C3 and E3. See also responses to comments MCWD-59, MCWD-87, MCWD-EKI and MCWD-GeoHydros.

MCWD-61 See Master Response 2, Source Water Components and Definitions. This EIR/EIS uses 500 mg/L total dissolved solids (TDS) as the fresh water standard consistent with the recommended standard in 22 Cal. Code Regs. 64449, in Table 64449-B. Furthermore, the cited portion of the Basin Plan excepts groundwater from being suitable for municipal or domestic water supply where water exceeds 3,000 mg/l TDS and the area is not reasonably expected by the regional water board to supply a public water system. Monitoring well data concerning existing TDS levels within the area of the capture zone for the proposed project indicates that groundwater already greatly exceeds 3,000 mg/L TDS. In addition, there is no indication that the seawater-intruded portion of the SVGB is reasonably expected by the regional water board to supply a public water system.

MCWD-62 See Master Response 6, The Sustainable Groundwater Management Act, regarding the "Marina Subarea," which is not a DWR-recognized groundwater basin.

The comment refers to California Water Code section 10780, the Groundwater Quality Monitoring Act, but that act does not apply to the proposed project. Rather, its purpose was to establish and implement groundwater monitoring and oversight for well stimulation treatment activities in areas of oil and gas operations. (Wat. Code § 10783.) Since the project does not propose to engage in any well stimulation treatment activities for oil and gas operations, the Groundwater Quality Monitoring Act does not apply to the proposed project.

The commenter also cites to 40 CFR section 144.3(a) for the definition of "Underground Source of Drinking Water," and criticizes the State Board Report for not addressing it. The Lead Agencies did not author the State Board Report. SWRCB is the expert agency concerning water in California so presumably took

federal law and regulations into account in preparing the Report. In addition, to the extent that such federal regulations pertain to the project, CalAm would be required to comply with them. Even if the SVGB were classified as an Underground Source of Drinking Water under federal regulations, that would not appear to preclude CalAm from having rights to the project source water under the common law "developed water" legal construct addressed in the State Board Report.

MCWD-63 See responses to comments MCWD-61 and MCWD-62.

MCWD-64 See response to comment MCWD-60, and Master Response 3, Water Rights, for a discussion of the potential injury to legal water users resulting from the proposed MPWSP. See also Master Response 6, Sustainable Groundwater Management Act, which explains that the "Marina Subarea" is not a DWR-recognized groundwater basin.

MCWD-65 See Master Response 8, Project Source Water and Seawater Intrusion, and Master Response 3, Water Rights.

MCWD-66 See Master Response 8, Project Source Water and Seawater Intrusion, Master Response 4, Agency Act and Return Water, and Master Response 3, Water Rights.

MCWD-67 See Master Response 4, Agency Act and Return Water, and Master Response 3, Water Rights.

MCWD-68 See Master Response 3, Water Rights, Section 8.2.3.8, Effect of Annexation Agreement.

MCWD-69 See Master Response 3, Water Rights.

MCWD-70 See Master Response 3, Water Rights, and Master Response 4, The Agency Act and Return Water.

MCWD-71 See Master Response 3, Water Rights.

MCWD-72 See Master Response 4, The Agency Act and Return Water, Sections 8.2.4.1 and 8.2.4.2 for clarification on the Agency Act, MPWSP compliance with the Act, and the relationship between the proposed project and return water. As discussed in the EIR/EIS Section 4.4.5.2, the EIR/EIS did not identify significant impacts on groundwater resources from the proposed slant well pumping. See Master Response 8, Project Source Water and Seawater Intrusion, Sections 8.2.8.1, 8.2.8.2, and 8.2.8.4 for additional clarification on the MPWSP effects on groundwater resources at the CEMEX site and in the SVGB.

MCWD-73 This comment is addressed in Section 8.2.6 of Master Response 6, The Sustainable Groundwater Management Act.

MCWD-74 This comment is addressed in Master Response 6, The Sustainable Groundwater Management Act.

MCWD-75 See Master Response 3, Water Rights, and responses to comments MCWD-61 and MCWD-62.

MCWD-76 See Master Response 3, Water Rights, and Master Response 6, The Sustainable Groundwater Management Act.

MCWD-77 EIR/EIS Section ES.8 addresses private (versus public) ownership of the desalination plant, specifically Monterey Country Health and Safety Code Section 10.72.030. EIR/EIS Table 3-1 lists the Monterey County Health Department Permit to Construct a Desalination facility as an anticipated permit or approval.

With respect to the Monterey County Code provisions governing desalination plants, including a requirement that they be publicly owned, on October 25, 2012, the CPUC issued a decision (Decision 12-10-030) with a ruling summarized as follows:

> This decision determines that the authority of the Commission in regard to this application preempts Monterey County Code of Ordinance, Title 10, Chapter 10.72, concerning the construction, operation and ownership of desalination plants. This decision further determines that the findings, conclusions and orders herein are an exercise of jurisdiction that is paramount to that of a county Superior Court concerning the same subject.

The Coastal Commission report referred to by the comment does state that the issue of whether a proposed desalination plant is owned by a public versus private entity is a factor to be considered and addressed by the Coastal Commission because privately owned facilities would be subject to less government oversight and different economic incentives. Of course, given that CalAm is a regulated utility, albeit an investor-owned private entity, there is a layer of oversight by virtue of the CPUC requirements that would not apply to a purely private entity. The Coastal Commission report notes that there may need to be additional conditions of approval placed upon privately owned plants in order to ensure coastal resource protection. No doubt, the factors noted in the Coastal Commission report will be considered and applied as warranted if the project is approved by the Lead Agencies and CalAm seeks a coastal development permit. Similarly, MBNMS can consider the effect of public versus private ownership in its action on the MPWSP. See also response to comment MCWD-6.

MCWD-78 The EIR/EIS discloses the proposed project's technical, economic and environmental characteristics of all proposed project components, facilities and any and all anticipated activities. The useful life of each component is usually considered in the amortization of project costs (see CDM, 2014, Table 2-2) and with a routine maintenance schedule, the useful life can be exceeded and is not necessarily a reason

alone for decommissioning. Components of large-scale infrastructure projects are typically decommissioned when a lease expires on the property (e.g., a solar project on federally owned property) or when the resource is exhausted (e.g., mining of aggregate ore) or when technology becomes obsolete (e.g., San Onofre Nuclear Generating Station). In this case, CalAm owns the property at the desalination plant and will have a deeded easement on a portion of the CEMEX property, the seawater resource is not finite, and the EIR/EIS discloses the impacts associated with a potential range of Salinas Valley Return Water volumes. The EIR/EIS provides project description information that allows for the evaluation and review of the potential environmental impacts of the proposed project, and nothing in this comment or response meets a threshold in CEQA Guidelines Section 15088.5 that would trigger a need to recirculate the Draft EIR/EIS. See responses to comments MCWD-79 through MCWD-85, below, for specific responses to the desalination plant, slant wells, and the return water obligation.

MCWD-79 Not unlike most large, capital-intensive infrastructure projects (e.g., the MCWD RUWAP, the Sand City Desalination Plant, the Salinas Valley Water Project, the MCWD 300 af Desalination Project, or the Pure Water Monterey GWR Project), the MPWSP EIR/EIS did not include a temporal length of the proposed project components, because the operational impacts of a capital project of this magnitude are assumed to occur indefinitely. There is no anticipated or planned end to the project. The analysis of GHGs conservatively used a 40-year project lifetime to amortize the project construction emissions (see EIR/EIS Section 4.11.4.1), but all other topical sections evaluated and disclosed the ongoing impacts resulting from maintenance activities described in EIR/EIS Section 3.4.1, particularly at the slant wells. See response to comment Marina-25 in Section 8.5.1.

MCWD-80 CalAm proposes as part of the project to forego decommissioning the test slant and to convert the test slant well into a project slant well. The EIR/EIS examines that proposal. Special Conditions 6 and 17 of the Coastal Development Permit (CDP), which address decommissioning of the test slant well and posting a bond to ensure that it is carried out, do not foreclose the possibility of CalAm converting the test slant well to a permanent well (see Master Response 11, CalAm Test Slant Well, Section 8.2.11.8, for general information regarding this proposed conversion). Notably, in its Summary of Staff Recommendation included on page 2 of the CDP Staff Report, the CCC stated:

> If the data collected from this proposed test well demonstrates that this well design and location would provide the necessary amount of water and not cause unacceptable adverse effects, CalAm may choose to apply for additional coastal development permits to convert the test well to a production well and/or construct additional similar wells, subject to certification of an Environmental Impact Report ("EIR") by the California Public Utilities Commission, which is preparing the document for the above-referenced water supply project.

Further, in its Findings and Declarations included on page 16 of the CDP Staff Report, the CCC stated:

> These Findings, and any coastal development permit issued pursuant to these Findings, apply only to the proposed test slant well and its associated monitoring wells and do not authorize development that may be associated with long-term use of the well, including converting the well to use as a water source for the separately proposed MPWSP. Any such proposal will require additional review and analysis for conformity to relevant Local Coastal Programs and the Coastal Act and will be conducted independent of any decision arising from these Findings. Further, the Commission's decision regarding these Findings exerts no influence over, and causes no prejudice to, the outcome of those separate future decisions.

Accordingly, and as described in EIR/EIS Table 3-8, CalAm intends to apply for a Coastal Development Permit(s) for the proposed project (including conversion of the test well) from the City of Marina and/or CCC, as applicable.

Finally, the EIR/EIS is not tiering from the CCC CEQA-equivalent analysis; the EIR/EIS independently evaluates the conversion of the test slant well to a permanent well, as described in EIR/EIS Section 3.2.1.1 in Table 3-1. See Master Response 11, CalAm Test Slant Well, Section 8.2.11.2.

MCWD-81 The test slant well is being operated under a CDP that was issued by the CCC (see Master Response 11, Section 8.2.11.2) and its ongoing operation under that permit is not part of the proposed project; the conversion of the test slant well to a permanent well is part of the proposed project and is described in EIR/EIS Section 3.2.1.1; see also Master Response 11, Section 8.2.11.7, and response to comment MCWD-80.

MCWD-82 EIR/EIS Section 3.4.1 describes the 5-year maintenance schedule for the proposed intake system and Impact 4.2-10 describes the potential for the intake wells to be influenced by coastal erosion. As noted in response to comment MCWD-78, the useful life of a component is not a reason alone for decommissioning. For clarification and consistency of terms, however, the text at page 4.2-70 has been revised as follows,

> The proposed slant wells would not be exposed during the ~~operational~~ useful life of the slant production wells (anticipated to be 20 to 25 years) and would not contribute to further coastal erosion or changes in the beach environment.

Slant wells are indeed a new, evolving technology[7] and the test slant well at CEMEX appears to be demonstrating that the technology does work at this location, under the pertinent hydrogeologic conditions, for this application. As shown in EIR/EIS

[7] See response to comment Marina-11. See also Master Response 11, Section 8.2.11.8 for a discussion of the Dana Point slant well and the feasibility of evolving slant well technology.

Figure 4.2-7, coastal erosion could expose the test slant well in a 100-year storm event by the year 2060 and Mitigation Measure 4.2-10 is a Slant Well Abandonment Plan. Mitigation Measure 4.2-10 has been revised in the Final EIR/EIS and now includes additional details within the measure, as well as the identification of secondary impacts resulting from implementation of Mitigation Measure 4.2-10. All of the other proposed slant wells would be located further inland of the 2060, 100-year flood event envelope as shown on Figure 4.2-8. If CalAm needs to replace a slant well, it will need to apply for a Coastal Development Permit to do so.

MCWD-83 See Master Response 4, The Agency Act and Return Water, Section 8.2.4.3 for clarification on the Agency Act and the quantity of return water. See also EIR/EIS Appendix E3.

MCWD-84 There is no requirement that water be returned to the "Marina Subarea." See Master Response 6, Sustainable Groundwater Management Act, Section 8.2.6.2, for a discussion of SGMA Basin designations. The Agency Act requires that no groundwater from the Salinas Basin may be exported for any use outside the Basin, but makes no specific mention of subdivisions in the Basin. EIR/EIS Section 4.4.4.2 describes the return water considerations and CalAm et al, 2016b, is the Return Water Settlement Agreement that includes the proposed formula for calculating the actual annual return water obligation, and explains "the volume of Annual Return Water Obligation shall be determined by the [Monterey County Water Resources] Agency based on the methodology set forth in Exhibit A" to the Agreement; see also Master Response 4, The Agency Act and Return Water, Section 8.2.4.3.

MCWD-85 The Final EIR/EIS will allow for informed decision-making to occur because the scope of the proposed project and the associated environmental consequences of the proposed project have been fully disclosed. Nothing in these comments or responses meets a threshold in CEQA Guidelines Section 15088.5 that would trigger a need to recirculate the Draft EIR/EIS.

MCWD-86 The potential impacts on the groundwater resources of SVGB are fully evaluated and presented in Section 4.4. See also response to comments MCWD-87 through MCWD-90.

MCWD-87 The onsite technical information sought by the SWRCB has been provided in EIR/EIS Section 4.4 and is supported by Appendices C3 and E3. The Dune Sand and 180-Foot Aquifers are described in EIR/EIS Section 4.2.1.1 (geologic setting), Section 4.4.1.2 (local and regional hydrogeology), Section 4.4.1.3 (groundwater flow and occurrence), and Section 4.4.1.4 (groundwater quality), as well as in EIR/EIS Appendix C3, Section 4.4.4 (regional geologic setting), Section 4.6.6 (hydrostratigraphy), Section 5.2 (groundwater quality, CEMEX area), and EIR/EIS Appendix E3, Section 1.2 (hydrogeologic conceptual model).

See Master Response 11, CalAm Test Slant Well, Section 8.2.11.4 (monitoring wells and baseline report), Section 8.2.11.5 (long-term pump test) and Section 8.2.11.6 (use of the test well data in the EIR/EIS). How "extracted fresh water is replaced" is addressed in EIR/EIS Section 3.2.3.7 (Castroville Pipeline) and Section 4.4.4.2 (groundwater modeling).

EIR/EIS Appendix E2 Section 5.3 explains that slant well pumping effects on the inland movement of saltwater was assessed using the NMGWM^{2016} and MODPATH. Particles were placed along the edge of the inferred 2013 seawater intrusion front in the 180-FT Aquifer (Model Layer 4) and 400-FT Aquifer (Model Layer 6), as reported by MCWRA. Forward particle-tracking was then employed to show the change in front location after 63 years of slant well pumping. Without slant well pumping, the particles representing saltwater would continue to migrate inland. With slant well pumping, the movement of saltwater would be in response to the regional background gradient and drawdown created by slant well pumping. The superposition NMGWM^{2016} was thus used without the regional gradient to isolate changes in saltwater movement due solely to slant well pumping. The change in particle locations initially placed at the seawater intrusion interface represent the change in saltwater location relative to its inland location due to continued background recharge and pumping (e.g., the acceleration or retardation of existing saltwater intrusion).

EIR/EIS Appendix E2 Section 4.3 explains that the NMGWM^{2016} was developed using the MODFLOW computer code, which does not consider variable density effects. The NMGWM^{2016} employed equivalent freshwater heads to simulate the density contrast between seawater and the underlying groundwater. Comparisons between MODFLOW calculated water level changes and calculations using a variable density flow model (SEAWAT) indicated slight differences in calculated water levels (approximately one foot). These differences exist nearest the coast, where there is a measured difference in groundwater salinity ranging from seawater to freshwater. Near the coast, and where density effects are greatest, slant well pumping would have a much greater influence on water level changes and flow than the spatial differences in salinity and water density. However, as the salinity concentration decreases with increasing distance from the coast, the differences in model calculated water levels would diminish and become insignificant. The effects of variable density flow on NMGWM^{2016} model results were therefore considered negligible and a dual density model is not necessary.

See response to comment MCWD-HGC, and MCWD-GH-26 through MCWD-GH-30, and; Master Response 12, The North Marina Groundwater Model (v.2016) and EIR/EIS Appendix E3.

MCWD-88 The data from the test slant well was indeed used in the groundwater modeling, as explained in EIR/EIS Appendix E2, Sections 3.2 and 4.2. The comment misrepresents the capabilities of a superposition model; see Master Response 12,

The North Marina Groundwater Model (v. 2016), Section 8.4.12.4. See also responses to comments MCWD-HGC and MCWD-GeoHydros.

MCWD-89 See response to comment MCWD-88 and Master Response 11, CalAm Test Slant Well, Section 8.2.11.6. The Lead Agencies for the EIR/EIS agree with the CCC statement provided in the comment that, "… pumping and water quality testing to be conducted during the slant well test is necessary to inform the design of a potential full-scale facility. Other actions, such as drilling additional boreholes or conducting additional modeling, would not be sufficient to characterize the site and its potential to provide source water."

The comment refers to litigation initiated by MCWD against the CCC with respect to the test slant well, and refers to an attached brief filed as part of that case. Indeed, MCWD has brought three lawsuits challenging aspects of the test slant well for the Project. A summary of the lawsuits and their status as of publication of the EIR/EIS is as follows:

1. *Marina Coast Water District v. California Coastal Commission*, Santa Cruz County Superior Court Case No. CISCV180839, California Court of Appeal, Sixth District, Case No. H042742.

In this action filed December 11, 2014, MCWD challenged the CCC's approval of Coastal Development Permit ("CDP") Nos. A-3-MRA-14-0050 and 9-14-1735 allowing CalAm to construct and operate the test slant well and associated infrastructure and development, MCWD alleged that approval of the two CDPs violated procedural and substantive requirements of the CEQA and the California Coastal Act. Following a hearing on the merits on July 23, 2015, the Honorable Judge Rebecca Connolly of the Santa Cruz County Superior Court denied MCWD's petition in its entirety. A judgment in favor of the CCC and CalAm was entered on August 24, 2015. MCWD appealed the judgment to the Sixth Appellate District of the California Court of Appeal. On October 26, 2016, the Court of Appeal affirmed the Superior Court's decision in full in an unpublished decision. On November 22, 2016, the Court of Appeal denied MCWD's petition for rehearing of that decision. On December 5, 2016, MCWD filed a Petition for Review in the California Supreme Court, which was denied on January 11, 2017. On January 12, 2017, the Court of Appeal issued its remittitur, closing the case.

2. *Marina Coast Water District v. California State Lands Commission*, Santa Cruz County Superior Court Case No. CISCV180895

In this action filed January 15, 2015, MCWD challenges the California State Lands Commission's (CSLC) approval of a lease to allow CalAm to construct and operate a portion of the test slant well on State-owned land. MCWD alleges that CSLC's approval of the test well lease violated procedural and substantive

requirements of CEQA. On September 29, 2015, the Honorable Judge Rebecca Connolly of the Santa Cruz County Superior Court approved a stipulation staying all proceedings in this action until issuance by the Sixth Appellate District of its remittitur in the appeal of Marina Coast Water District v. California Coastal Commission, Case No. CISCV180839. This case remains pending before the Superior Court.

3. *Marina Coast Water District v. California Coastal Commission*, Santa Cruz County Superior Court Case No. 15CV00267

In this action filed November 5, 2015, MCWD challenges the Coastal Commission's October 6, 2015, approval of a permit amendment to CDP Nos. A-3-MRA-14-0050 and 9-14-1735 to clarify how certain operational performance standards are applied to the test well. MCWD alleges that the CCC's approval of the CDP permit amendment violated procedural and substantive requirements of CEQA and the California Coastal Act. On February 19, 2016, CalAm moved to stay the suit pending appeal of *Marina Coast Water District v. California Coastal Commission*, Superior Court Case No. CISCV180839, Sixth Dist. Court of Appeal Case No. H042742 (discussed above). Two of MCWD's four causes of action were heard on the merits by the Honorable Judge Paul Burdick in Santa Cruz County Superior Court on September 20, 2016. At the hearing, the Superior Court denied MCWD's petition as to those two causes of action. The remaining two causes of action were heard on August 30, 2017. The Superior Court denied the remaining two causes of action at a hearing on October 3, 2017. A judgment in favor of the CCC and CalAm on all causes of action was entered on January 11, 2018.

On January 12, 2018, MCWD appealed the Superior Court's judgment to the Sixth Appellate District of the California Court of Appeal. That appeal is pending.

MCWD-90 See responses to comments MCWD-HGC, MCWD-EKI, and MCWD-GeoHydros. See also responses to comments MCWD-92 through MCWD-106 regarding baseline, consistencies with applicable laws and regulations, the analysis of impacts on groundwater resources and cumulative impacts.

MCWD-91 Response to comment MCWD-HGC, and Master Response 6, The Sustainable Groundwater Management Act, Section 8.2.6.2, explain that the "Marina Subarea" is not a DWR-recognized groundwater basin. See Master Response 10, Environmental Baseline under CEQA and NEPA. EIR/EIS Section 4.2.1.1 presents the existing regional geology and describes the geologic units of the Salinas Valley Groundwater Basin and the area around North Marina. EIR/EIS Section 4.4.1 presents the setting/affected environment for groundwater resources and includes a discussion of terminology and concepts (Section 4.4.1.1), local and regional hydrogeology (Section 4.4.1.2), groundwater flow and occurrence (Section 4.4.1.3), and

groundwater quality (Section 4.4.1.4). See also response to comments MCWD-92 through MCWD-99.

MCWD-92 EIR/EIS Section 4.4.1.2 presents the local and regional hydrogeological conditions in the SVGB, including a description of the Dune Sands Aquifer. The 13-year old citation on Draft EIR/EIS page 4.4-8 represented the best available information on the Dune Sands Aquifer until CalAm started drilling boreholes in 2015, and began sampling water quality from the monitoring wells. The latest CalAm data has been incorporated into the conceptual model of the groundwater basin as well as into the NMGWM^{2016} and EIR/EIS Section 4.4; therefore, the more contemporary data was included and considered in the EIR/EIS analysis. The text in Section 4.4.1.2 has been revised to explain that,

> ". . . most of the water in the Dune Sand Aquifer along the coast has been intruded by seawater and is considered saline to brackish (Kennedy/Jenks, 2004 and Appendix C3 Section 5.2)."

General water quality conditions are discussed in EIR/EIS Section 4.4.1.4 and water quality results from test slant well sampling is presented in Table 4.4-4; see also EIR/EIS Appendix C3, Table 5-3.

The EIR/EIS sections present a description of the Dune Sand Aquifer, which has been developed and agreed upon by experts in hydrogeology with specific knowledge of the SVGB. The environmental setting for hydrogeology fulfills the requirements of CEQA/NEPA and was developed through subsurface investigations, review of available literature, data from groundwater monitoring wells and an evaluation of test slant well data (see EIR/EIS Section 4.4.4). As discussed in EIR/EIS Section 4.4.5.2, the proposed slant wells would be extracting water from the coastal region in an area with documented seawater intrusion and the impacts on neighboring production wells and water quality would be less than significant. See Master Response 8, Project Source Water and Seawater Intrusion, Section 8.2.8.1, 8.2.8.2, and 8.2.8.4 for clarification regarding the MPWSP source water capture zone, its water quality conditions, and potential impacts on inland water users. Also refer to response to comment MCWD-HGC, which responds to claims made by HGC on the water quality of the Dune Sands Aquifer and 180-Foot Aquifer.

MCWD-93 The environmental setting description of the 180-Foot/180-FTE Aquifer presented in EIR/EIS Section 4.4.1 fulfills the requirements CEQA/NEPA and was developed through subsurface investigations, review of available literature, data from groundwater monitoring wells, and an evaluation of test slant well data (see EIR/EIS, Section 4.4.4).

The NMGWM^{2016} simulates the 180-FTE aquifer (Model Layer 4) as confined. However, beneath the CEMEX site, well logs from monitoring well borings do not

show a confining clay bed above the 180-FTE Aquifer. The degree of confinement within the 180-FTE Aquifer, therefore, varies spatially with distance inland and away from the coast. In the NMGWM[2016], the modeled vertical conductivity decreases over seven orders of magnitude at the coast to areas less than 2 miles inland (see EIR/EIS Appendix E2, Figure 3.3b). The text in the EIR/EIS Section 4.4.1 has been revised to provide additional clarity regarding the degree of confinement in the 180-FTE Aquifer underlying the CEMEX site relative to the inland portions of the aquifer. The added text does not represent new information that would change the conclusions of the impact analysis presented in the Draft EIR/EIS.

See Master Response 8, Project Source Water and Seawater Intrusion, Section 8.2.8.2, and response to comment MCWD-HGC for additional information and discussion regarding water quality in the capture zone of the proposed MPWSP slant wells and the purported areas of "fresh" groundwater near the project site.

MCWD-94 The description of the 400-Foot Aquifer presented in EIR/EIS Section 4.4.1 provides the necessary basis for conducting an analysis of impacts, and is sufficient to fulfill the environmental setting/affected environment requirements of CEQA and NEPA. See response to comment MCWD-HGC regarding the purported "fresh" groundwater present in the 400-Foot Aquifer underlying the project site. See also Master Response 10, Environmental Baseline under CEQA and NEPA.

MCWD-95 EIR/EIS Section 4.4.1.3 discussing Groundwater Elevations and Flow Direction has been updated based on supplemental groundwater flow data provided through CalAm's recent hydrogeologic investigation for the MPWSP; see EIR/EIS Appendix E3, TM-2. Contrary to the comment, groundwater in the Dune Sands Aquifer flows inland from the Monterey Bay, as discussed in response to comment MCWD-HGC.

MCWD-96 The EIR/EIS uses water quality data provided by MCWRA and applicable groundwater data from CalAm's hydrogeologic investigation to represent the current effects on seawater intrusion. These sources were considered the best available information at the time the EIR/EIS was prepared. The EIR/EIS is designed to report information to the public, and by law should not mislead the public. The EIR/EIS has been updated to reflect current information on groundwater quality; see EIR/EIS Appendix E3. See response to comment MCWD-HGC regarding inconsistencies in the use of the monitoring data and areas of purported "fresh" groundwater in the MPWSP project area. As discussed in EIR/EIS Section 4.4.1.4 and Master Response 8, Project Source Water and Seawater Intrusion, the California Secondary MCL for TDS is 500 mg/L and as explained in response to comment MCWD-61, this EIR/EIS uses 500 mg/L TDS as the fresh water standard consistent with the recommended standard in 22 Cal. Code Regs. § 64449, in Table 64449-B.

MCWD-97 EIR/EIS Section 4.4.4.1 explains that, "Special Condition 11 of the Coastal Development Permit, Protection of Nearby Wells, requires the MPWSP HWG to establish baseline water and TDS levels prior to commencing the long term pumping tests." The Draft Technical Memorandum, Baseline Water and Total Dissolved Solids Levels, Monterey Peninsula Water Supply Project Area, April 15, 2015, [8] is referenced in EIR/EIS Section 4.4 as Geoscience, 2015b, and continues to be publicly available with all of the other EIR/EIS references. EIR/EIS Section 4.4.4.1 explains that the long-term pumping test began in mid-April 2015, and results (of the long-term pump test, not the baseline report) are available at http://www.watersupplyproject.org/#!test-well/c1f1l. See also Master Response 11, CalAm Test Slant Well, Section 8.2.11.4, for a discussion of monitoring wells and the baseline report.

The Geoscience technical memorandum was prepared in compliance with this provision of Special Condition 11, and included the results of five weekly monitoring reports. Chapter 6.0 of the Geoscience technical memorandum presents baseline water levels and TDS concentrations for the period from February 19, 2015 to April 10, 2015; the baseline water and TDS levels are shown on Figures 2-1 through 2-5 and 3-1 through 3-5, respectively. As discussed in Master Response 11, Section 8.2.11.4, the test slant well was shut down because, as required of CalAm by Special Condition 11, groundwater levels were approaching the maximum allowable water level decrease of 1.5 feet. The CCC then recommended that CalAm develop a proposed amendment to Special Condition 11 that better incorporated the local and regional trends in water levels and salinity. Special Condition 11 was revised in October 2015. The revised Special Condition 11 stated that if drawdown exceeds 1.5 feet at Monitoring Well-4 (MW-4) from *regional groundwater elevation trends*, or if TDS levels increase more than two thousand parts per million *from regional TDS level trends*, CalAm would shut down the slant well. Special Condition 11 also required CalAm and HWG to review weekly monitoring data and prepare a monthly report to document the regional/background groundwater elevation trends and TDS level trends. Long term pumping of the Test Slant Well resumed on October 27, 2015. Since that time, CalAm has collected and publicly reported groundwater level and water quality (TDS) data from the Test Slant Well and Cal Am monitoring wells. These data integrate the regional groundwater levels trends and thereby establish both water levels and water quality baseline.

The EIR/EIS relied upon the baseline water level and water quality data that have been collected from the test slant well and CalAm monitoring wells since October 2015. The CalAm clustered monitoring wells are screened across the Dune Sands,

8 The Draft EIR/EIS references Geoscience, 2015b, which is the Draft Geoscience *Technical Memorandum Baseline Water and Total Dissolved Solids Levels, Monterey Peninsula Water Supply Project Area,* dated *April 15, 2015*. In that draft document, Section 6.0 was titled, "*Recommended Monitoring of Baseline and TDS Levels,*" which is incorrect and was subsequently revised in the final version of the document with the correct heading of "*Summary of Baseline and TDS Levels.*" The correct heading for Chapter 7.0 is "*Recommended Monitoring of Baseline and TDS Levels."* The EIR/EIS has been revised to cite the final version of Geoscience's *Technical Memorandum Baseline Water and Total Dissolved Solids Levels, Monterey Peninsula Water Supply Project Area, April 20, 2015.*

180-Foot/180-FTE Aquifer, and the 400-Foot Aquifer to provide groundwater levels in the discrete water bearing zones. As these water level and water quality data consider the regional pumping and climatic trends and have been collected for over 2 years, they were considered viable baseline for the analysis of groundwater draw down and water quality impacts.

In regard to refining the groundwater models, groundwater levels from the monitoring wells at the CEMEX site were used to determine measured drawdown in response to test slant well pumping, and the measured drawdown was compared to model-calculated drawdown for test slant well pumping. See EIS/EIS Appendix E2 Section 4.2, Figure 4.6 which shows improvement of the $NMGWM^{2016}$-calculated water levels compared to those of the $NMGWM^{2015}$, indicating that modifications to the aquifer parameter zones and conductivity values improved model performance at the CEMEX site.

MCWD-98 See response to comment MCWD-97. EIR/EIS Impact 4.4-4 explains the approach to, and impact of, the proposed project on groundwater quality within the slant well pumping area of influence, and presents the impact on seawater intrusion. Appendix E2 Section 5.3 explains that slant well pumping effects on the inland movement of saltwater was assessed using the $NMGWM^{2016}$ and MODPATH. Baseline water levels for the aquifers are presented in the April 15, 2015 report titled *Baseline Water and Total Dissolved Solids Levels*. However, water quality measured as TDS was not used to refine the $NMGWM^{2016}$ because the model was not constructed or employed to calculate changes in water quality and water density due to the mixing of ocean water.

MCWD-99 See response to comment MCWD-87 regarding studies recommended by the SWRCB, and Master Response 8, Project Source Water and Seawater Intrusion, regarding the source water capture zone and the existing brackish to saline groundwater within that zone. The MPWSP would not extract potable groundwater, but would extract brackish-to-saline ambient groundwater at first, which would be replaced by seawater infiltrating through the coastal sediments. See response to comment MCWD-HGC for a discussion of the purported "fresh" groundwater in the Dune Sands, 180-FTE and 400-Foot Aquifers. Contrary to HGC's claims, it is unlikely that any large volume of low TDS (usable) water exists in the area that would be impacted (the capture zone) by the MPWSP slant wells. As discussed in response to comment MCWD-97, baseline water elevations and groundwater quality have been established based on over two years of groundwater monitoring data that includes regional pumping and climatic trends. See Master Response 4, The Agency Act and Return Water, Section 8.2.4.3, for clarity on the projected ocean water percentage and return water requirement. See response to comment MCWD-HGC for a discussion of the Dune Sands Aquifer and its role as an alleged "protective layer against seawater intrusion." See Master Response 3, Water Rights, Section 8.2.3.3 and 8.2.3.5, for additional discussion of the beneficial use of the groundwater.

MCWD-100 EIR/EIS Section 4.4.2.4 refers to Table 4.4-7 for regional and local land use plans and regulations, not state regulations. As explained in EIR/EIS Section 4.1.5, the analysis of project consistency with federal and state regulations and plans, such as the Basin Plan (see EIR/EIS Section 4.4.2.2) and the Agency Act and Ordinance 3709 (see EIR/EIS Section 4.4.2.3), are addressed in the Regulatory Framework subsection of each topical section rather than in the table that occurs at the end of each Regulatory Framework subsection, which is reserved for regional and local plans and policies. See Master Response 4, The Agency Act and Return Water, regarding consistency with the Agency Act and MCWRA Ordinance 3709.

MCWD-101 See response to comment Marina-44.

MCWD-102 HydroFocus used the best available data to quantitatively represent the water transmitting and storage property values of the water-bearing and non-water bearing units represented by the model (parameter values). The sensitivity analysis evaluated the uncertainty in model results to the potential variability in the specified parameter values. The analysis demonstrated reasonable and acceptable levels of uncertainty in model outputs, and provided conservative estimates of possible error (in other words, using extreme values, the sensitivity analysis identified similarly extreme estimates of error). Hence, whether the uncertainty is "tolerable" is irrelevant, and what is relevant is that the effect of that uncertainty was quantified and thus made transparent to analysts and reviewers, thereby allowing the information to be considered as part of their assessments. See EIR/EIS Appendix E2, Section 6.0, Uncertainty.

Prior modeling efforts (i.e., the $NMGWM^{2015}$) were not abandoned. Rather, the prior modeling effort was improved by using new information to update the model (i.e., the $NMGWM^{2016}$), and EIR/EIS Appendix E2 shows that the performance of the updated model is superior to the prior modeling effort. As described in Master Response 12, The North Marina Groundwater Model (v. 2016), Section 8.2.12.3, the "superposition model" is not a different model, but rather an application of the $NMGWM^{2016}$. The superposition approach calculated the information required to analyze the impacts of project pumping directly – the changes in water levels and flow – and, therefore, is actually more transparent rather than an attempt to "mask problems." Indeed, GeoHydros employed the same approach of superposition to calculate changes in water levels and flow; however, its analysis was flawed as described in Section 8.2.12.3 in Master Response 12 (see "Water Levels" subheading).

Superposition does not preclude identification of the source of feedwater for the MPWSP slant wells. The $NMGWM^{2016}$ was employed to calculate the water level decline (drawdown) in response solely to proposed project pumping. Drawdown due solely to proposed project pumping is dependent primarily on the pumping rate, the water transmitting and storage properties of the aquifer, and any change in groundwater recharge or discharge that occurs solely as a result of that drawdown.

For example, if pumping causes coastal water levels to decline below sea level, ocean water will percolate into the underlying aquifer and move inland to replace the extracted water. This increase in ocean water recharge induced by the new pumping reduces the drawdown relative to that which would have occurred in the absence of the ocean-water recharge. EIR/EIS Appendix E2, Figures 5.6 and 5.12, show the ocean capture zones that would be created by slant well pumping and its effect on recharge from the ocean. These capture zones reveal the likely source water extracted by the wells. See also Figures 8.2.12-1 and 8.2.12-2 in Master Response 12.

Further, superposition model results do not preclude prediction of measurable groundwater elevations associated with the proposed slant well pumping. Model-calculated drawdown due to slant well pumping can be compared to measured drawdown. For example, EIR/EIS Appendix E2, Figure 4.6, shows how the drawdown from measured water levels is compared with the drawdown calculated by the model using the superposition approach. See Master Response 12, Section 8.2.12.3. for more detail describing why superposition helps validate future drawdown projections compared to other methods.

The NMGWM^{2016} provides substantial benefits over the NMGWM^{2015}: it resolves discrepancies with initial water levels, boundary conditions, and uncertainties in predicted future background recharge and pumping. Further, the approach is more efficient because it calculates the change in water levels and drawdown directly, rather than relying on two model runs and performing a subtraction to isolate the change. The superposition approach described in EIR/EIS Appendix E2 is, therefore, more transparent.

The cone of depression is defined as the area where groundwater levels change as a result of a new stress; see Master Response 8, Project Source Water and Seawater Intrusion, Section 8.2.8.1. In this analysis, it is the area where the water level change is more than 1 foot in response to proposed slant well pumping. As explained in detail above, this area is calculated most directly and reliably using superposition.

MCWD-103 The text in the EIR/EIS has been revised to clarify the degree of confinement in the 180-Foot Aquifer. The NMGWM^{2016} simulates the “180-FTE Aquifer” (Model Layer 4) as confined, as discussed in response to comment MCWD-93. The NMGWM^{2016} therefore addresses the “180-FTE Aquifer” semi-confinement by the absence of a clay layer at the CEMEX site and the addition of the transition zone between the site and the mapped extent of the FO-SVA.

Regarding the comment’s assertion that the EIR/EIS does not recognize the “protective water levels” in the Dune Sands Aquifer along the coast, see response to comment MCWD-HGC.

The groundwater in the capture zone of the proposed MPWSP slant wells would be a combination of highly brackish groundwater and seawater, well above the 3,000 milligrams per liter of TDS beneficial use standard in the California RWQCB Basin Plan for the Central Coast; see response to comment Marina-44, in Section 8.5.1. For this reason, and because brackish groundwater outside the MPWSP capture zone would not be impacted, there is no need to consider this threshold when determining production from the MPWSP slant wells.

Neither CalAm nor the Lead Agencies have proposed returning water to the basin as a mitigation measure needed to reduce a significant groundwater impact under CEQA or NEPA; rather, it is proposed by CalAm to ensure compliance with the Agency Act. This is discussed in detail in Master Response 4, The Agency Act and Return Water, Sections 8.2.4.1 and 8.2.4.2.

Applicant-Proposed Measure 4.4-3 would expand the current groundwater monitoring program by including nearby active production wells and new wells to monitor changes in groundwater elevations, and ensures that if neighboring groundwater production wells are damaged or made unusable due to the project, they would be repaired or replaced by CalAm. However, it should be noted that implementation of this measure is not necessary to address a significant environmental impact. Applicant-Proposed Measure 4.4-3 would provide continued verification that the MPWSP does not negatively impact water quality or water levels to such a degree that wells are damaged or made unusable. This mitigation measure adequately fulfills (indeed, goes above and beyond given the finding that impacts are not significant) the requirements of CEQA and NEPA because it provides a mechanism to regularly monitor groundwater levels, and if drawdown occurs in a nearby well that damages or otherwise renders the well unusable, CalAm would restore or replace the supply.

MCWD-104 Refer to Master Response 12, North Marina Groundwater Model (v. 2016), Section 8.2.12.2, for further information on the construction and capabilities of the NMGWM. As stated in response to comment MCWD-HGC, the $NMGWM^{2016}$ was not constructed or employed to calculate changes in water quality and water density due to the mixing of ocean water and groundwater. The use of equivalent freshwater head to represent seawater, and the constant groundwater density assumption to calculate the drawdown extent is a reasonable and appropriate approach because the error these approximations introduce is small relative to the uncertainty in other more influential factors like the specified pumping rates, return water volumes, projected sea levels, aquifer parameter values, and the relative contributions of multiple aquifers to total slant well production (see EIR/EIS Appendix E2, Section 6.0 “Uncertainty”).

The NMGWM’s consideration of the groundwater confinement of the Dune Sand Aquifer and 180-FTE/180-Foot Aquifer is discussed in response to comment MCWD-93.

Mitigation Measure 4.4-4 does not defer mitigation. As discussed in the EIR/EIS Section 4.4.5.2, Mitigation Measure 4.4-4 provides an adequate mechanism to monitor changes in groundwater levels near the Fort Ord remediation plumes and to reduce groundwater quality impacts by requiring CalAm to take necessary actions to ensure that the plumes do not expand or change direction due to groundwater flow by MPWSP. As described in Mitigation Measure 4.4-4, CalAm would incorporate groundwater elevation monitoring at the two plumes into its well monitoring program. This would provide continuous groundwater monitoring data, which CalAm would make available to the public and the U.S. Army. In response to the comment, the text of Mitigation Measure 4.4 has been revised to clarify that CalAm would continuously coordinate with the U.S. Army during the groundwater data evaluation stages. See also responses to comments from the U.S. Army in Section 8.3.2.

MCWD-105 See responses to comments MCWD-92 through MCWD-104.

MCWD-106 See responses to comments LWMC-14 through LWMC-19 for discussion of the approach to the cumulative analysis of groundwater resources.

MCWD-107 See response to comment Marina-71. Response to comment MCWD-108 and 109 explain that the project area boundary did not extend under the area of drawdown from project pumping because the groundwater effects would be isolated from surface water wetlands and other waters, such as ponds and streams, due to the depth of groundwater accessed by the slant wells and the lack of hydraulic connectivity between those aquifers and surface waters. As a result, the ecosystems are not groundwater dependent.

MCWD-108 EIR/EIS Figures 4.4-13 and Figures 8.2.8-3 and 8.2.8-4 in Master Response 8, Project Source Water and Seawater Intrusion show the area where operation of the slant wells would result in drawdown of the Dune Sand Aquifer and the 180-FTE Aquifer (see also response to comment MCWD-141). The analysis demonstrates that these effects would be isolated from surface water wetlands and other waters, such as ponds and streams, due to the depth of groundwater accessed by the slant wells and the lack of hydraulic connectivity between those aquifers and surface waters. As indicated by the groundwater level measurements of the groundwater underlying the CEMEX area (see Appendix E3), the brackish groundwater in the Dune Sand Aquifer that would contribute to the MPWSP slant well feedwater is 20 to 35 feet below the surface of the dunes. The perched freshwater that supports shallow wetland features is not hydraulically connected to the Dune Sands Aquifer, and water surface fluctuation in the aquifer would not translate to the upper perched freshwater.

MCWD-109 The EIR/EIS provides a thorough analysis of the proposed project's effects on groundwater and concludes that no effects on shallow groundwater would result from the project (see EIR/EIS Figures 4.4-13 and Figures 8.2.8-3 and 8.2.8-4 in

Master Response 8, Project Source Water and Seawater Intrusion; see also response to MCWD-141). The analysis does demonstrate project effects on the Dune Sands Aquifer and the deeper 180-FTE Aquifer, which are not hydraulically connected to surface water features, such as the jurisdictional wetlands and other waters regulated by state and federal agencies (see EIR/EIS Section 4.4.4). For coastal wetlands and other waters to be affected by drawdown of these two aquifers, there would need to be an unconfined hydraulic connection between the surface water wetlands and other waters, and the aquifer that would be accessed by the slant well intakes; the groundwater analysis in the EIR/EIS shows that not to be the case. In the absence of effects on coastal wetlands and other waters, the proposed project would not conflict with the relevant portions of the guidelines for desalination plants in the Monterey Bay National Marine Sanctuary.

MCWD-110 See response to comment Marina-71.

MCWD-111 Responses to comments MCWD-115 through MCWD-129, MCWD-131, and MCWD-134, below, describe in detail how the existing measures do not defer mitigation, or how mitigation has been revised in the Final EIR/EIS to ensure that mitigation would not be improperly deferred.

MCWD-112 See response to comment Marina-77.

MCWD-113 Responses to comments MCWD-115 through MCWD-129, MCWD-131, and MCWD-134, below, describe in detail how the existing measures do not rely on future agency coordination or permits, or how mitigation has been revised in the Final EIR/EIS to ensure that mitigation would not rely on future agency coordination or permits.

MCWD-114 For each proposed facility that would result in less-than-significant impacts on terrestrial biological resources with incorporation of mitigation, the EIR/EIS identifies all applicable mitigation measures and includes a discussion of how the mitigation measures would reduce the impact to less than significant. For example, on Draft EIR/EIS page 4.6-131 in Impact 4.6-1, the Draft EIR/EIS lists the applicable mitigation measures and then describes in detail how the measures would reduce impacts on special-status species (e.g., by requiring installation of exclusion fencing to ensure special-status species do not occur within the construction area). The explanation of the effects of specific mitigation measures on reducing specific impacts follows the list of applicable mitigation measures.

MCWD-115 CPUC and MBNMS, as the Lead Agencies, will have oversight responsibilities to ensure that the project is implemented as disclosed in the CEQA/NEPA documents, including by way of a Mitigation Monitoring and Reporting Plan (MMRP) and the National Marine Sanctuaries Act (NMSA) permit process that would be adopted along with approval of the project or an alternative. Although CalAm would be responsible for hiring the Lead Biologist, Mitigation Measure 4.6-1a identifies the

minimum requirements of a Lead Biologist: an individual who shall possess, at a minimum, a bachelor's degree in biology, ecology, wildlife biology or closely related field and has demonstrated prior field experience using accepted resource agency techniques for the survey prescribed, and who possesses all appropriate USFWS, NMFS, and CDFW permits. CalAm would be required to hire a Lead Biologist that meets those minimum requirements and who would therefore have the experience and capability to oversee and/or implement the proposed mitigation measures, and as noted in the measure "[t]he Lead Biologist, qualified biologists, and qualified biological monitors shall be subject to approval by resource agencies with jurisdiction over the special-status species with potential to occur at the project site (and local agencies, if required)."

Further, the monthly monitoring reports will be submitted to the regulatory agencies upon request. The CPUC and/or MBNMS, and not the public, will be responsible for overseeing and ensuring successful implementation of the mitigation measures by CalAm and/or its designee(s). Consistent with its pattern and practice, the CPUC Energy Division will contract with an independent third-party construction monitoring provider to ensure that a neutral third party will oversee the Applicant's implementation of all mitigation measures. Further, any monitoring reports that are submitted to the CPUC and/or MBNMS will be public records and will be accessible to the public upon request.

Moreover, while Mitigation Measure 4.6-1a states, "[t]he monthly report shall also document the effectiveness and practicality of the prescribed avoidance and minimization measures and recommend modifications to the measures if needed," it does not suggest that the mitigation measures might not be practical or effective. This statement does not undermine the effectiveness of the measures; rather, it ensures that any ineffective or impractical measures and suggested modifications to the measures are documented, and that further actions are taken to ensure that the performance standards are met.

MCWD-116 Mitigation Measure 4.6-1c does not include language that allows for improper deferral or diminishes the effectiveness of the measure. This measure limits work to the delineated construction boundary, and any work outside of the area will be prohibited unless approved by the Lead Biologist. The comment states that the measure needs to include performance standards to determine what activity could occur outside of the construction boundary and require that an impact assessment is conducted in these areas. The experienced and qualified Lead Biologist will be able to discern whether any work implemented outside of the project boundary would impact sensitive biological resources and, per Mitigation Measure 4.6-1a, would oversee compliance with the proposed mitigation measures.

Due to the size of the project area and varying site conditions, it is impractical to describe the exact type or method of best management practices (BMPs), referenced in Subpart 5, that would be employed. As Subpart 5 of Mitigation

Measure 4.6-1c requires, CalAm will implement the BMPs that would be required to prevent loss of habitat due to erosion caused by project related impacts. The Lead Biologist would oversee compliance with this measure. See also See response to comment Marina-77.

MCWD-117 Mitigation Measure 4.6-1d does describe under what circumstances the USFWS might approve work during the breeding season and describes the steps to obtaining USFWS approval during the breeding season in subpart 3. In response to this and other comments, this measure has been revised to clarify the performance standards that CalAm must meet to implement this measure. The revised measure includes enforceable criteria to be implemented if nests are discovered and stipulates that work may proceed, subject to USFWS approval, if the work would not cause an adult to abandon an active nest or young or change an adult's behavior so it could not care for an active nest or young, or as allowed within the take provisions authorized by USFWS. With respect to wintering plovers, the revised measure clarifies that the appropriate performance standard is to ensure that wintering plovers are not directly impacted by construction activities.

Additionally, in response to this and other comments, Mitigation Measure 4.6-1d has been revised to include performance standards for restored habitat. The revised measure no longer includes the option of contributing to an "in lieu" fee program or a mitigation bank. See the response to Marina-72 for the full text of the revised measure. See the response to MCWD-127 regarding the timing for preparation of the Habitat Mitigation and Monitoring Plan required under Mitigation Measure 4.6-1n.

MCWD-118 Although Mitigation Measure 4.6-1e describes that project facilities shall be sited to avoid impacts on special-status plants if feasible, the measure then describes what would be required if avoidance is not feasible. See response to comment Marina-77 for additional discussion.

In response to this comment, Mitigation Measure 4.6-1e subpart 2 has been revised to include the success criterion to be used to ensure that the site would be returned to pre-construction conditions. The exact methods by which the site would be returned to pre-construction conditions cannot be determined at this time because the project is still in the preliminary design phase. Once the plans have progressed beyond the preliminary design phase, and focused botanical surveys for special-status plants have been completed per the requirements in Mitigation Measure 4.6-1e, then the appropriate methods would be determined and the success criterion used to ensure the site is returned to pre-construction conditions.

EIR/EIS Impact 4.6-1 acknowledges that direct impacts, which would include take, would result in a significant impact. This is described for the subsurface slant wells on Draft EIR/EIS page 4.6-124. The EIR/EIS concludes that implementation of the entire Mitigation Measure 4.6-1e, not just obtaining an Incidental Take Permit as stated in subpart 3, would reduce impacts to less than significant. The measure

discloses that an Incidental Take Permit may be required and provides several measures to reduce impacts to special-status plant species to less than significant.

In response to this comment, this measure has been revised to clarify the applicable success criterion and compensation ratios in subpart 5. The HMMP describing this compensation and success criteria is required in Mitigation Measure 4.6-1n.

See response to comment CDFW-4 regarding Mitigation Measure 4.6-1e.

MCWD-119 Mitigation Measure 4.6-1f does not "only" require that construction activities avoid impacts where feasible. Although the measure describes that construction activities shall be planned to avoid host plants for Smith's blue butterfly, the measure then describes what would be required if avoidance is not feasible, including the implementation of pre-construction surveys and relocation of host plants outside of the project area. See response to comment Marina-77 for additional discussion.

The mitigation measure does not improperly defer development of a relocation plan, including the scope of the survey area and identification of appropriate relocation sites, until after the project has been approved. It is impractical to develop a relocation plan at this time because the project is still in the preliminary design phase. Once the design has progressed beyond the preliminary design phase, then the study area would be determined. Additionally, a floristic botanical survey would need to be conducted, as required in Mitigation Measure 4.6-1f, during project design and prior to project implementation to document the location of Smith's blue butterfly host plants within or adjacent to the project area. The exact impacts, and thus the exact location and dimension of appropriate relocation sites would be determined once the project has progressed beyond the preliminary design phase and required surveys have been conducted.

In response to the comment regarding the performance standards and compensation ratio in subpart 5, Mitigation Measure 4.6-1f has been revised. See the response to Marina-79 for additional discussion.

MCWD-120 Mitigation Measure 4.6-1g does not improperly defer mitigation. It is impractical to prepare this relocation plan at this time because the project is currently in the preliminary design phase. Once the design has progressed beyond the preliminary design phase, the exact area of black legless lizard, silvery legless lizard, and coast horned lizard habitat that would be impacted would be determined. Once that area is determined, the potential relocation sites can be determined. Mitigation Measure 4.6-1g requires that surveys be conducted at the relocation sites prior to relocation, and includes a performance standard that only relocation sites that are not overpopulated and that have suitable habitat conditions (e.g., soils, moisture content, vegetation, aspect) shall be used to ensure relocation is feasible. There are large expanses of central dune scrub, which provide suitable habitat for these species, located in the vicinity of the proposed project area and lizards may be

relocated to these areas as long as relocation performance standards have been met. Mitigation Measure 4.6-1g has been revised to change the use of the word "should" to "shall."

Obtaining a Scientific Collecting Permit from CDFW would not authorize an individual to relocate black legless lizard, silvery legless lizard, and coast horned lizard. Obtaining a Scientific Collecting Permit from CDFW for these species would demonstrate that an individual has knowledge and experience with these species, which is necessary to implement this measure.

MCWD-121 Mitigation Measure 4.6-1h does not improperly defer mitigation. This mitigation measure requires development of a Burrowing Owl Exclusion Plan and, if compensatory mitigation is necessary, a Burrowing Owl Habitat Mitigation Plan that would be incorporated into the Habitat Mitigation and Monitoring Plan. It would be impractical to develop either of these plans at this time because the project is still in the preliminary design phase; the exact project area, and impacts on suitable burrowing owl habitat and potential areas where owls may need to be excluded can't be determined until the design has progressed The elements that would be included in and performance standards for the Burrowing Owl Exclusion Plan are described in Mitigation Measure 4.6-1h. The Burrowing Owl Habitat Mitigation Plan would detail the required compensatory mitigation. Compensatory mitigation would be required if burrowing owls are found on-site, which according to Mitigation Measure 4.6-1h would be determined during protocol surveys and pre-construction surveys of the project area. The compensatory mitigation requirements would not be determined until these surveys have been conducted, so the Burrowing Owl Habitat Mitigation Plan cannot be prepared at this time; however, Subpart 9b of Mitigation Measure 4.6-1h specifies the performance standards that conservation lands must meet.

Subparts 5 and 6 of Mitigation Measure 4.6-1h state that a minimum buffer distance, as included in Table 4.6-8, shall be maintained unless otherwise authorized by CDFW. In response to this comment, the measure has been revised to include a performance standard to ensure that even if the buffer is reduced, it shall be sufficient to avoid significant impacts on burrowing owls (with authorization from and as determined by CDFW). CalAm and CDFW may agree to modify the buffer depending on site conditions where an owl is observed and the type of construction activities, so the exact buffer cannot be determined at this time.

Mitigation Measure 4.6-1h provides buffer distances to be established based on the level of disturbance. Table 4.6-8 in this measure includes the buffer distance depending on the time of year and level of disturbance. As included in the table footer, this information was derived from the Staff Report on Burrowing Owl Mitigation prepared by the California Department of Fish and Game in March 2012, which, as stated in the Staff Report, "is designed to provide a compilation of the best available science for Department staff, biologists, planners, land managers,

California Environmental Quality Act (CEQA) lead agencies, and the public to consider when assessing impacts of projects or other activities on burrowing owls." This document is the guiding document for determining mitigation for western burrowing owl. As described in Mitigation Measure 4.6-1a, the Lead Biologist would oversee this measure and implement it in consultation with CDFW to determine the level of disturbance.

Subpart 8 of Mitigation Measure 4.6-1h requires that "site monitoring shall be conducted prior to, during, and after exclusion of burrowing owls from their burrows sufficient to ensure take is avoided." Contrary to the comment, this measure does not state that take is a threshold of significance for impacts on burrowing owls. Subpart 8 is just one measure that would be implemented in Mitigation Measure 4.6-1h. Implementation of all measures in Mitigation Measure 4.6-1h would reduce impacts to less than significant.

In response to this comment, the measure has been revised to remove qualifying language such as "if feasible" and to change the use of "should" to "shall."

MCWD-122 Mitigation Measure 4.6-1i does not improperly defer mitigation. The measure stipulates a no-disturbance buffer for nesting birds, but allows for the buffer to be modified as determined in consultation with CDFW. In response to this comment, this measure has been revised to include performance standards to ensure that even if the buffer is modified, it would not cause significant impacts to nesting birds. The buffer may be modified depending on the exact location of the nest, species sensitivity to construction disturbance, and the type of construction, so the exact buffer cannot be determined at this time. Additionally, in response to comment CDFW-6 in Section 8.4.2, Mitigation Measure 4.6-1i has been revised to incorporate CDFW recommendations to monitor behavior before and during the project, consult with CDFW, and use a 250-foot no disturbance buffer around active nests of non-listed bird species and a 500-foot no disturbance buffer around the nests of unlisted raptors.

As described in EIR/EIS Section 4.6.18, special-status species include species protected by the federal Migratory Bird Treaty Act and Fish and Game Code. The Migratory Bird Treaty Act protects any part, nest, or egg, or any migratory bird, California Fish and Game Code 3503 protects nests or eggs of any bird, and California Fish and Game Code 3503.5 protects hawks, owls, and their nests and eggs. Mitigation Measure 4.6-1i addresses impacts on nesting birds protected under these regulations, not non-nesting birds, so the measure does not include pre-construction surveys or avoidance measures for non-nesting birds. Subpart 10 of Mitigation Measure 4.6-1c addresses impacts to special-status species that are within the work area to avoid and minimize direct impacts to these species.

MCWD-123 In response to this comment, Mitigation Measure 4.6-1j has been revised to include a buffer distance of 200 feet from an active natal badger den. CalAm and CDFW

may agree to reduce this buffer as long as it continues to meet the performance standard of ensuring that construction does not alter the behavior of the adult or young in a way that would cause injury or death to those individuals. The buffer was selected based on the biological requirements and sensitivity of the species, best professional judgement, and a review of typical buffer distances that have been included in other CEQA documents. This buffer distance would ensure that the project would not result in injury or death to badgers, which would reduce potential impacts to badgers to less than significant. The impact analysis, as described in EIR/EIS Section 4.6.4, is based on the rarity and context of the resources and magnitude of the impact, among other criterion. Based on the status of the American badger, a species of special concern, and the magnitude of impact, it was determined that the proposed mitigation would be sufficient to reduce impacts to less than significant. All temporarily impacted areas would be returned to pre-construction conditions, as required in Mitigation Measure 4.6-1c, and no additional compensatory mitigation has been proposed.

MCWD-124 In response to this comment, subpart 3 of Mitigation Measure 4.6-1k has been revised to include a minimum 50-foot buffer. The buffer was selected based on the biological requirements and sensitivity of the species, best professional judgement, and a review of typical buffer distances that have been included in other CEQA documents.

In response to this comment, subpart 4 of Mitigation Measure 4.6-1k has been revised to remove "to the extent feasible" and to add an effective and enforceable measure to implement when young woodrats are encountered in the nest.

MCWD-125 In response to this comment, Mitigation Measure 4.6-1l has been revised to clarify that bat roosts that begin during construction would be unaffected by the continuation of the same type of construction.

The EIR/EIS acknowledges in Impact 4.6-1 that direct impacts, which would include take, would be a significant impact. Mitigation Measure 4.6-1l states that "take of individual bats will be avoided." This measures provides for the avoidance of take as well as several other required measures, such as removing trees or structures when bats are active, and if this is not feasible, to remove trees and structures in a manner that would avoid and/or minimize impacts on roosting bats. Implementation of the all of the measures in Mitigation Measure 4.6-1l, including the measure for take avoidance, would ensure that impacts on special-status bats are reduced to less than significant.

MCWD-126 See the response to comment Marina-77 which describes the use of "to the extent feasible." Additionally, the commenter notes that performance standards must be established in the measure. In response to this comment, Mitigation Measure 4.6-1m has been revised to include a performance standard that replacement trees shall have a minimum of 70 percent survival in the fifth monitoring year to ensure success.

MCWD-127 See the response to comment Marina-79. Mitigation Measure 4.6-1n does not include compensatory mitigation requirements and performance standards, but the HMMP would summarize the compensatory mitigation requirements and performance standards from the revised special-status species and sensitive natural community specific mitigation measures in Mitigation Measures 4.6-1d, 4.6-1e, 4.6-1f, 4.6-1h, 4.6-1m, 4.6-1o, and 4.6-2b. These measures have been revised and/or clarified to include compensatory mitigation requirements and performance standards. The revised special-status species and sensitive natural community measures do not include an "in lieu" fee program option for compensation.

It is impractical to prepare the HMMP at this time. The HMMP would include a summary of special-status species and sensitive natural community compensation requirements. The project is currently in the preliminary design phase. Once the design has progressed beyond the preliminary design phase, the exact area of special-status species and sensitive natural community habitat that could be impacted would be determined. Once this area is determined, then the exact amount, location, and type of appropriate mitigation would be identified. Additionally, the HMMP would outline a planting plan and identify appropriate planting material, which would be determined closer to restoration and enhancement implementation and based on site needs and the availability of local container stock at that time. Further, this plan would need to be approved by all appropriate agencies (*i.e.*, CCC, CDFW, CCRWQCB, USACE, USFWS, and local agencies that require a habitat mitigation and monitoring plan), which would be done as part of the permitting process, separate from this CEQA/NEPA analysis.

MCWD-128 In response to this comment, Mitigation Measure 4.6-1o has been revised to include performance standards for restoration or compensation sites. It is impractical to prepare this relocation plan at this time. The project is currently in the preliminary design phase. Once the design has progressed beyond the preliminary design phase, then the exact area of California red-legged frog and California tiger salamander habitat that would be impacted would be determined. Once that area is determined, then suitable "nearby" relocation sites, as required in the measure, can be determined. Mitigation Measure 4.6-1a has been revised to include a performance standard that states that the animal would be relocated to a similar or better type of habitat. There are large expanses of grassland and other suitable habitat types for California red-legged frog and California tiger salamander in the project vicinity and individuals may be relocated to these areas as long as relocation performance standards have been met.

The California red-legged frog is a federal listed species and California tiger salamander is both a federal and state listed species. CalAm will need to obtain take authorization from the USFWS for take, including relocation, of both California red-legged frog and California tiger salamander from CDFW for take, including relocation, of California tiger salamander; see EIR/EIS Table 3-8. If either of these species is within the work area, the agencies would likely stipulate

relocation out of harm's way rather than authorize injury or death of an individual. This is a typical provision of Biological Opinions and Incidental Take statements that are issued to authorize projects where there is potential for take.

See the response to comment CDFW-8 for a response to the CDFW's comment on Mitigation Measure 4.6-1o.

MCWD-129 In response to this comment, Mitigation Measure 4.6-1q has been revised to include a performance standard to avoid frac-outs, and if a frac-out occurs it is properly cleaned-up. It is impractical to prepare the frac-out plan at this time. The project is currently in the preliminary design phase. Once the design has progressed beyond the preliminary design phase, with locations and construction methods at crossings of wetlands or streams specified, then the frac-out plan can be prepared as part of the permit process.

MCWD-130 EIR/EIS Section 4.6.1.8 describes that various habitat areas "may" be considered primary or secondary habitat areas by the City of Marina's LCLUP and Environmentally Sensitive Habitat Areas (ESHA) by the CCC because a formal determination of the extent of primary and secondary habitat in the project area has not been made by the City of Marina and a formal determination of the extent of ESHA in the project area has not been made by the CCC. The extent of these areas would be determined as part of the permitting process, which is separate from this CEQA/NEPA analysis. In the absence of a formal determination from the City of Marina and the CCC, the EIR/EIS includes a conservative assumption that these areas would be considered primary habitat within the City of Marina's LCLUP jurisdiction, and ESHA in the project area for the purposes of the impact analysis.

The City of Marina defines primary habitat to include "habitat for all identified plant and animal species which are rare, endangered, threatened, or are necessary for the survival of an endangered species. These species will be collectively referred to as 'rare and endangered.'" The LCLUP (City of Marina, 1982) includes "preliminary" maps of habitat for rare and endangered plants "to provide a guide to the locations where more intensive study is required." The LCLUP includes a policy that "before any use or change in use, areas identified as potential habitat for rare and endangered plant or animal species shall be investigated by a qualified biologist to determine the physical extent of the primary habitat areas for the specific rare and endangered plants and animals on that site." So while these areas have been preliminarily mapped, they require site specific surveys to confirm these boundaries. The extent of these areas need to be confirmed by the City of Marina.

ESA and AECOM biologists met with staff from the CCC and a biologist from SWCA contracted to the City of Marina at the proposed project site on May 19 and July 19, 2017, to review and confirm the boundaries of ESHA and primary and secondary habitat within the project area. While the boundaries were not confirmed during these meetings, the CCC provided guidance that the approach taken in the

EIR to analyzing primary and secondary habitat was likely too conservative and that additional areas of non-sensitive habitat (i.e. dune topography, even where currently covered with iceplant) may also be considered ESHA. In response to this guidance, and based on the definition of primary habitat provided in the City of Marina's LCLUP and the definition of ESHA provided by the CCC and in other local coastal plans, the EIR/EIS has been revised to assume that all undeveloped areas within the coastal zone would be considered primary habitat (within the City of Marina's LCLUP jurisdiction) and ESHA in all other jurisdictions. Although the limits of these jurisdictional boundaries have changed in the Final EIR/EIS, the impact conclusions remain the same as in the Draft EIR/EIS. The new areas that are now assumed to be primary habitat and/or ESHA are areas that are largely ruderal or dominated by non-native plant species such as iceplant and their general function and value (as low quality, non-sensitive vegetation communities) has not changed since publication of the Draft EIR/EIS. See also the response to comment Marina-70.

MCWD-131 The EIR/EIS does analyze impacts from construction of the subsurface slant wells, including conversion of the temporary test slant well to a production well; see EIR/EIS Section 3.2.1, Table 3-1 and Section 4.6.1.10. As described on Draft EIR/EIS page 4.6-70, "the subsurface slant wells include ten subsurface slant wells (the converted test slant well and nine new wells)." The EIR/EIS does state that the exact limits of primary habitat would be determined through the Coastal Development Permit (CDP) process, but does not defer consideration of these impacts to the CDP application process. The EIR/EIS fully evaluates potential impacts to ESHA, including primary habitat as defined by the City of Marina's LCLUP, in Impacts 4.6-2 and 4.6-7. The response to comment MCWD-130 describes why the EIR/EIS includes conservative assumptions for the limits of ESHA and primary habitat in the absence of formal determinations by the CCC and City of Marina.

The EIR/EIS does not rely on conformance to Coastal Act policies to ensure impacts to ESHA are reduced to less than significant. The EIR/EIS states that implementation of Mitigation Measure 4.6-2a, as well as other measures such as Mitigation Measure 4.6-2b would ensure that if ESHA is affected by the proposed project, then this impact would be reduced to less than significant.

In response to the comment, Mitigation Measures 4.6-2a has been revised to state that the project would conform to ESHA policies or other policies of the Coastal Act, instead of only ESHA policies. Although the project would result in a less than significant impact on ESHA, as discussed in Impacts 4.6-2 and 4.6-7, the project would have a significant and unavoidable impact as it would be inconsistent with the City of Marina's LCLUP, as discussed in Impact 4.6-4. These findings are not inconsistent as they are both describing impacts to different resources. Impacts 4.6-2 and 4.6-7 evaluate impacts to ESHA as a sensitive natural community and Impact 4.6-4 evaluates the project's consistency with local plans

and policies. Although the project would mitigate impacts to the ESHA, it would still conflict with a local plan or policy.

In regards to the test slant well, this structure currently exists at the project site and impacts from installation of the test slant well were evaluated in the CEQA document for the test slant well project. Its installation and operation as a test slant well is not a part of the proposed project. See Master Response 11, CalAm Test Slant Well, Sections 8.2.11.2, 8.2.11.3, and 8.2.11.7

Consistency with the policies in the City of Marina's LCLUP, and consistency with these policies protecting biological resources, is evaluated in Impact 4.6-4 under the heading "City of Marina LCLUP."

Each impact statement includes an explanation for how the mitigation measures would mitigate impacts to a less than significant level. See the response to MCWD-114.

In response to the comment regarding Mitigation Measure 4.6-2a, see the response to MCWD-130. Additionally, as described in Impact 4.6-2 and Impact 4.6-7, CalAm would be required to implement Mitigation Measure 4.6-2a, as well as other mitigation measures, including Mitigation Measure 4.6-2b, to reduce impacts to less than significant. The EIR/EIS does not rely solely on implementation of Mitigation Measure 4.6-2a to reduce impacts to less than significant.

See the response to comment Marina-77 in response to the "to the extent feasible" language in Mitigation Measure 4.6-2b. In response to this comment, this measure has been revised to include performance standards and clarify compensatory mitigation requirements.

The EIR/EIS evaluates the potential impacts of the proposed project on ESHA as a sensitive natural community in accordance with CEQA requirements. Impact 4.6-2 and Impact 4.6-7 describe potential impacts of the proposed project on ESHA and proposed mitigation measures to reduce the potential impacts to less than significant. Nonetheless, it is acknowledged that Section 30240 of the Coastal Act states that ESHA shall be protected against any significant disruption of habitat values, and only uses dependent on those resources shall be allowed within those areas. However, Section 30260 of the Coastal Act does encourage coastal-dependent industrial uses provided, among other measures, that adverse environmental effects are mitigated to the maximum extent feasible.

MCWD-132 See responses to comments MCWD-117, MCWD-121, and MCWD-122, as well as responses to comments CDFW-6 and CDFW-7.

MCWD-133 The EIR/EIS' analysis of impacts on federal wetlands, federal other waters, and/or waters of the state evaluates the potential for direct or indirect effects on these features as a result of construction activities. See response to comment Marina-71 for

explanation of the study corridor that was evaluated. CEQA and NEPA require analysis of reasonably foreseeable effects; for wetlands and other waters, reasonably foreseeable effects are confined to resources within proximity to the proposed project. Furthermore, federal and state laws regulate the placement of fill within wetlands and other waters, which was considered as a potential direct effect of the project at locations where that would occur within the project study area. While state laws also regulate indirect effects on fish and wildlife habitat (California Fish and Game Code Section 1600 et seq.) and beneficial uses (Porter Cologne Water Pollution Control Act), the EIR/EIS concludes that the project would not result in lowering of groundwater such that wetlands and other waters would be adversely affected (see responses to comments MCWD-108 and MCWD-109).

MCWD-134 A formal delineation of waters of the U.S. has not been verified by the U.S. Army Corps of Engineers (USACE) and a delineation of waters of the State has not been verified by the Regional Water Quality Control Board (RWQCB) and the CCC. These formal determinations are not required for the CEQA/NEPA analysis. The EIR/EIS used the best available knowledge based on surveys conducted within the study area. As described in EIR/EIS Section 4.6.1.6, wetlands or waters potentially regulated by the USACE, RWQCB, and/or CCC were mapped in the project's study area during field surveys. A wetland delineation report, based on some of these field surveys, has been prepared and is referenced in the Final EIR/EIS. In the absence of a formal determination by these agencies, the EIR/EIS conservatively assumes that areas mapped during field surveys, included in the wetland delineation report, and included in the USFWS National Wetland Inventory, would be considered potentially jurisdictional by these agencies. Impacts to wetlands and waters were evaluated in Impact 4.6-3 and Impact 4.6-8 based on these assumptions. In response to this comment, Mitigation Measure 4.6-3 has been revised and clarified to include performance standards and compensatory mitigation requirements.

In response to this comment, and to clarify the assumptions in the EIR/EIS, the following text has been added to Section 4.6.1.6, Wetlands and Other Waters:

> <u>In the absence of a verified wetland delineation by the USACE, RWQCB, and CCC, this document assumes that all potential jurisdictional features identified in the surveys described above and by the NWI may be considered jurisdictional by the USACE, RWQCB, and CCC.</u>

MCWD-135 As described in EIR/EIS Section 4.6.5.2 on Draft EIR/EIS page 4.6-234, "because the location, nature, and extent of disturbance associated with future pipeline repairs cannot be predicted, it would be too speculative to analyze the potential site-specific adverse effects associated with future pipeline repairs at this time. However, certain pipeline repairs may be subject to future CEQA/NEPA review. For these reasons, only known, reasonably foreseeable, operational impacts are evaluated below." The EIR/EIS evaluates known, reasonably foreseeable impacts.

There is no possible way to predict the location or extent of work that may be required for possible future pipeline repairs and therefore no possible way to evaluate impacts on this unknown level of work. However, as the EIR/EIS states, certain pipeline repairs may be subject to future CEQA/NEPA review, which would be separate from this analysis, but many of the pipeline repairs would result in impacts similar to pipeline construction; those impacts and associated mitigation measures are addressed in this EIR/EIS, and the impacts would be less than significant.

MCWD-136 The analysis of potential impacts on western snowy plover in Impact 4.6-6 acknowledges that noise or disturbance from maintenance activities could significantly impact wintering plovers. The discussion of the nature of such impacts was provided in the subsection titled "Overview of Potential Construction Effects on Wildlife" in Impact 4.6-1 (see Draft EIR/EIS page 4.6-123). In response to this comment, the referenced text in Impact 4.6-6 has been revised to clarify that detailed discussion of the types of impacts that could result from maintenance-related noise and disturbance is provided under Impact 4.6-1.

MCWD-137 In response to this comment, Mitigation Measure 4.6-6 has been revised to change "should" to "shall."

As described in Impact 4.6-6, "Although it is unlikely that many birds would become sick or die at the brine storage basin annually, over the life of the project, some migratory waterfowl could become sick or die from use of the brine storage basin, a significant impact." As demonstrated at the adjacent MRWPCA Regional Wastewater Treatment Plant, use of bird deterrents has deterred most birds from its ponds. As described in Mitigation Measure 4.6-6, CalAm would be required to implement a monitoring and adaptive management approach to deter most birds from the Brine Storage Basin. If during monitoring, bird or wildlife deaths are detected at the Brine Storage Basin, then the type of bird deterrent shall be modified to ensure most birds are deterred from the Brine Storage Basin and thus the risk of death to migratory waterfowl is reduced to less than significant.

MCWD-138 In response to this comment, Mitigation Measure 4.6-1c has been revised to prohibit the use of photodegradable and other plastic mesh erosion control products. See the response to comment CDFW-9; also see response to Marina-77, in Section 8.5.1, for the revised mitigation measure.

MCWD-139 See responses to MCWD-108 and MCWD-109 and response to comment CURE-Owens-19 in Section 8.6.2.

MCWD-140 Responses to comments on the adequacy of the mitigation measures in Section 4.6 are provided in the responses to comments MCWD-111 through MCWD-113, MCWD-115 through MCWD-128, MCWD-131, MCWD-134, MCWD-137, and MCWD-142.

See the response to comment MCWD-114 regarding where the EIR/EIS describes how specific mitigation measures would reduce impacts to less than significant.

MCWD-141 As discussed in EIR/EIS Section 4.4.5.2, the slant wells proposed at the CEMEX site would draw groundwater levels down in the Dune Sand Aquifer and in the underlying 180-FTE Aquifer. The drawdown would be greatest (up to 29 feet) close to the coast surrounding a zone of groundwater capture created by pumping (see EIR/EIS Figures 4.4-13 and Figures 8.2.8-3 and 8.2.8-4 in Master Response 8, Project Source Water and Seawater Intrusion) and would be less pronounced (1 to 5 feet) in the area of influence that is projected to extend inland up to 3 miles beyond the capture zone (see EIR/EIS Figures 4.4-14 and 4.4-15). In order for the drawdown induced by MPWSP pumping to impact jurisdictional surface water features or wetlands, the groundwater in either the Dune Sand Aquifer or the 180-FTE Aquifer would have to interact with the ground surface such that a change in the groundwater level induces a response in the surface water feature/wetland.

The Dune Sand Aquifer is the unconfined, uppermost water-bearing unit and is the aquifer with the greatest likelihood of a hydraulic connection with the surface, while the 180-FTE Aquifer is deeper and semi-confined with water levels at even lower elevations. A groundwater-surface water interaction with the Dune Sand Aquifer would be evident if a surface water feature was created as an expression of the groundwater surface. This condition does not exist in the study area as evidenced by groundwater levels in eight Dune Sand and 180-FTE Aquifer monitoring wells measured by Cal Am since early 2015 (see EIR/EIS Section 4.4.4). If a groundwater-surface water interaction did exist with the Dune Sand Aquifer, water levels in the monitoring wells would be at or slightly below the ground surface. Nearly two years of groundwater monitoring has revealed that the groundwater surface of the Dune Sand Aquifer ranges in depths between 10 and 43 feet below the ground surface, with an average depth to water of 26 feet, depending on the location. Water levels in the 180-FTE Aquifer are consistently lower than those in the Dune Sand Aquifer. These groundwater surface depths only fluctuate by a few feet throughout the year. Lithologic logs of the monitoring well borings verify that there is a defined vadose (unsaturated) zone composed of sand and/or silty-clayey sand between groundwater of the Dune Sand Aquifer and the ground surface. EIR/EIS Appendix E3 provides water levels monitoring data and lithologic logs of monitoring well borings.

Hydrogeologic conditions demonstrate that the surface water features and wetlands of concerns are clearly perched at or just below the ground surface and likely fed, not by groundwater in the Dunes Sand Aquifer, but by sources of surface water that include precipitation, fog drip, surf spray, irrigation runoff, or seepage from locally perched saturated lenses in the younger sand dunes. Therefore, the Dune Sand and 180-FTE Aquifers are not in hydraulic connection with surface water features and the degree of their separation precludes direct surface drawdown effects and water quality changes (i.e., increased salinity in the capture zone) near the CEMEX site and throughout the area projected to be influenced by MPWSP pumping.

MCWD-142 According to the Fort Ord Reuse Authority (FORA) website, the HCP was expected to be released for public review by the end of 2017. At the time of publication of the Final EIR/EIS, the Installation-Wide Multispecies Habitat Conservation Plan (HCP) is currently in a draft form, and has not yet been released or adopted. Impact 4.6-8 analyzes whether the proposed project would "be inconsistent with the provisions of an adopted Habitat Conservation Plan, natural community conservation plan, or other approved local, regional, or state habitat conservation plan during construction or operations." The EIR/EIS is not required to analyze whether the project would be inconsistent with a draft document. It is unknown exactly what measures would be included in the HCP once it is finalized and adopted, so it would be speculative to analyze potential inconsistencies with a document that has not been finalized and adopted.

Mitigation Measure 4.6-8 only applied to the Terminal Reservoir. Since the Terminal Reservoir has been removed from the proposed project, this comment is no longer applicable and Mitigation Measure 4.6-8 has been deleted.

MCWD-143 As explained in EIR/EIS Section 4.1.7.1, Approach to the Analysis of Cumulative Effects, the EIR/EIS engaged in a two-step process. The first step describes the effects of other past, present and reasonably foreseeable future projects in combination with the effects of the proposed project. Where the analysis finds that the cumulative effects of past, present and future projects plus the proposed project would be significant and adverse, the second step of the cumulative impact process identifies whether the proposed project's contribution to the overall adverse effect would be of a considerable nature (referred to as a "cumulatively considerable contribution" under CEQA) such that the project's contribution to cumulative effects in that area is deemed significant. In essence, it is only if the answer is affirmative in both steps of the analytical process that the project's contribution to the overall significant and adverse cumulative effect is deemed a significant effect associated with the project.

In response to this comment, Impact 4.6-C has been revised to clarify that, with implementation of the proposed mitigation measures, the residual project impacts would be minimal and would not be cumulatively considerable. The only exception is that the proposed project would conflict with the City of Marina's LCLUP, which would be a significant and unavoidable contribution to a significant cumulative impact.

The adequacy of the proposed mitigation measures is described in responses to comments MCWD-115 through MCWD-129, MCWD-131, and MCWD-134.

MCWD-144 As the commenter states, the Reclamation Plan for the CEMEX site requires reconstruction and revegetation of the "southerly slopes." Portions of the subsurface slant well site may result in temporary or permanent impacts to a small portion of the southern slope revegetation area. The EIR/EIS describes the majority

of this area as central dune scrub, a sensitive natural community, and the entire subsurface slant well site as primary habitat as defined by the City of Marina's LCLUP. As described in Impact 4.6-2 and 4.6-7, impacts to sensitive natural communities and primary habitat will be reduced to less than significant by implementing various mitigation measures including Mitigation Measure 4.6-2b. The revised Mitigation Measure 4.6-2b requires that any temporarily impacted areas are restored to pre-construction conditions and any permanent impacts are compensated at a 2:1 ratio. With implementation of this measure, any areas that have been reclaimed and would be impacted would either be restored to their current condition or mitigated at an offsite location to ensure no net loss of this habitat.

MCWD-145 The list of cumulative projects described in EIR/EIS Section 4.1.7.2 includes projects for which detailed descriptions and expected impacts are known, as well as projects that have less defined impacts but may contribute to regional impacts. Therefore, the exact acreage and extent of all cumulative projects is unknown. In response to this comment, Impact 4.6-C has been revised to include a general description of the amount of sensitive habitat that may be disturbed by the cumulative projects. This analysis is based on a review of the environmental documents that have been prepared for some of the cumulative projects. Additionally, Impact 4.6-C has been revised to include the total acreage of impacts that the proposed project may have on sensitive habitat types.

MCWD-146 No citation or reference was provided to support the comment's assertion that the rate of erosion at the coastline at the CEMEX facility nearly doubled from 2014 to 2016 from 220,000 to 380,000 cubic yards per year. Nonetheless, as explained in EIR/EIS Section 4.2.1.3, Section 4.2.4.5, and Appendix C2, Sections 1 and 2, the rate of erosion varies each year and is the net result of seasonal changes, localized erosion (rip currents), long-term erosion, and sea level rise, relative to the annual sand supply (sand supplied from inland sources by rivers and streams and sand supplied from ocean sources during surges, which both supply the coastal sand drift). As explained in Appendix C2 on page 4, the modeling used a conservative approach that applied historic erosion rates, anticipated sea level rise and a 100-year storm event. The historic erosion rates used in the model input are linear erosion rates, not volume rates. This is because the modeling was conducted to estimate the year when the coastline is anticipated to have retreated back towards the well, not the volume of sand removed. The results are provided as erosion profiles showing the cross sectional view of coastal profiles at various times in response to coastal retreat. Over the modeled time period from 2012 to 2073, the annual *linear* rate of erosion varies from 7 to 9 feet per year.

The commenter asked if the 15 feet of scour observed around the outfall pipe during the winter storm surge in early March 2016 is consistent with the 2014 coastal retreat projections. It is important to note that the 15 feet of scour is an individual winter event *with a solid object (the outfall pipe) exposed on the beach,*

followed by some backfill of the beach once the storm had passed. It is more important to note that the amount of scour was exacerbated because the outfall pipe was exposed. The presence of a solid object on the beach causes scour to increase as wave forces are concentrated around the solid object. As shown on EIR/EIS Figures 4.2-7 and 4.2-8, the amount of scour due to a 100-year storm event *without a solid object exposed on the beach* ranges from about 8 to 14 feet. The 15 feet of scour is not consistent with the modeled coastal retreat because of the presence of the outfall pipe.

In addition, the coastal retreat projections are the accumulation of the previously discussed multiple causes of coastal retreat. The existing test slant well head and the proposed slant well heads are located further inland behind the existing sand dunes. As discussed in Section 4.2.1.3, and in Appendix C2, the scour experienced at a given location is the result of several causes with a net result also controlled by the sand supply. Nonetheless and as shown on Section 4.2 Figure 4.2-7, coastal retreat is not anticipated to reach the test slant well until about 2060; the other proposed slant well locations would not be reached until well after 2060. Therefore, because Mitigation Measure 4.2-10 would result in monitoring coastal retreat and decommissioning of the well prior to exposure on the beach, the well would never be exposed to scour and would not exacerbate or accelerate coastal erosion.

The commenter states the coastal retreat modeling did not use "available computer-aided modeling as identified in Appendix C2." The commenter is referring to text on Page 7 of Appendix C2 that states: "Alternative estimates could be developed by computer-aided modeling of sand transport. For example, XBEACH and other available software can provide estimates of storm-induced profile erosion (USGS, 2009). Also, GENESIS and other available software can provide estimates of future shoreline positions. Such further analysis may enhance the ability to assess the likelihood of shore recession estimates presented herein."

However, as stated on Appendix C2, Page 4: "The potential inland shoreline retreat caused by sea level rise and the impact from a large storm event was estimated using the geometric model of dune erosion originally proposed by Komar et al (1999) and applied with different slopes to make the model more applicable to sea level rise (Revell et al, 2011). This method is consistent with the FEMA Pacific Coast Flood Guidelines (FEMA, 2005)."

While other modeling methods are available, the modeling method is consistent with FEMA guidelines. Furthermore, the model uses a conservative approach that maximizes the potential coastal retreat. As explained on Page 4 of Appendix C2, the representative coastal profiles conservatively used "…an extremely eroded profile (lower envelope) for each future time horizon."

In addition, to be conservative, the accretion of sand on to the beach was not included in the model, as noted on Page 6: "The overall linear regression shows

accretion, but the shorelines have fluctuated historically, and the most recent shoreline (spring 2010) is more eroded than the spring 1998 post-El Nino LiDAR. For this reason, we conservatively do not include the accretion signal" and "North of the Salinas River, the shore is accreting and dune growth appears to be occurring but accretion was neglected in these locations as well."

In other words, an acceptable model was used with conservative input parameters to maximize the potential amount of coastal retreat.

MCWD-147 EIR/EIS Figure 4.2-7 accurately represents that the well head for the test slant well is about 30 feet above Mean Lower Low Water (MLLW) of the intertidal zone. Figure 4.2-8 shows the proposed slant well location at Profile 4b, which would pass just north of the well head for Proposed Slant Well Site WS-2 (see Figure 3-3a); Slant Well Sites WS-2 through WS-6s would all be located about the same distance from the shoreline. As discussed in EIR/EIS Section 4.2, Impact 4.2-10, the test slant well location would be the most likely to be affected by coastal retreat.

MCWD-148 The coastal retreat modeling described in EIR/EIS Section 4.2.4.5 was conducted to estimate the year when the coastline is anticipated to have retreated back towards the wells, and the potential for the exposed wells to exacerbate scour of the beach. The results are provided as erosion profiles showing the cross-sectional view of coastal profiles at various times in response to coastal retreat; see EIR/EIS Figures 4.2-7 and 4.2-8. The analysis indicates the test slant well could become exposed on the beach sometime around the year 2060; that would be about 45 years after the well was installed. Therefore, while 20 to 25 years as useful life for the slant wells may be inconsistently used in the EIR/EIS, the useful life of the slant wells is not relevant to Impact 4.2-10 and has no bearing on the significance conclusion. See also responses to comments MCWD-78, MCWD-79 and MCWD-82.

MCWD-149 Impact 4.2-10 explains that based on projections of sea level rise and anticipated coastal retreat, abandonment procedures are anticipated to begin prior to 2060 for the converted test slant well and after 2060 for the other nine slant wells, but would occur as needed based on monitoring required under Mitigation Measure 4.2-9, Slant Well Abandonment Plan. The implementation of this mitigation measure would eliminate, not merely reduce any erosion impact, by ensuring the slant well(s) would be decommissioned prior to exposure.

Mitigation Measure 4.2-9 has been revised to include annual reporting of the erosion rate to the agency that issues the Coastal Development Permit. The mitigation measure, and therefore, the annual reporting requirement, would be enforced by the CPUC as a component of its Mitigation Monitoring and Reporting Plan (MMRP) that the CPUC would adopt if and when it approves a project or alternative that includes slant wells (CEQA Guidelines Section 15091(d)). Thus, the revised mitigation measure and the third-party monitoring of the MMRP by the CPUC will provide for the appropriate public reporting requirements.

Special Condition 6 of the test slant well CDP states that the "Permittee shall cut off, cap, and bury the slant well head at least 40 feet below the ground surface, and shall completely remove all other temporary facilities approved by this coastal development permit." Since EIR/EIS Figure 4.2-7 accurately represents that the well head for the test slant well is located at 30 feet above MLLW, this permit condition requires the well to be cut off 10 feet below MLLW.

With the implementation of Mitigation Measure 4.2-9, the section of well casing and pipelines at risk of exposure would be cut and removed to a depth of 5 feet below the 2060, 100-year lower profile envelope as determined by the 2014 Coastal Erosion Study (Appendix C2). Since the 2060, 100-year lower profile envelope would be at 10 feet below MLLW (see EIR/EIS Figure 4.2-7), that would require the casing to be removed to a depth of 15 feet below MLLW or 45 feet below the ground surface. This is consistent with, and in fact more aggressive than the Special Condition 6 that was placed on the test slant well by the CDP. See also Master Response 14, CEMEX Settlement, Section 8.2.14.2; with the closure of the Lapis Sand Plant in 2020 as a result of the Settlement Agreement, ongoing coastal erosion at this location is expected to slow compared to erosion rates that have occurred with sand mining. Therefore, the erosion profiles in the EIR/EIS likely overestimate the rate of future shoreline change, and the test slant well is likely to be exposed later than the EIR/EIS projects. The analyses and conclusions related to coastal erosion in the EIR/EIS have not been revised, and instead have been retained as conservative estimates of potential erosion-related impacts.

MCWD-150 EIR/EIS Section 4.1.5 explains the approach taken to the project consistency analysis. See response to comment Marina-94.

The Draft EIR/EIS concludes on page 4.6-224 that construction of the slant wells, the Source Water Pipeline, the new Desalinated Water Pipeline, the new Transmission Main and the staging area at Beach Road "would be inconsistent with the City of Marina LCLUP policies governing protection of Primary and Secondary Habitats, a significant and unavoidable impact." As further explained on Draft EIR/EIS page 4.6-224, the CCC reached a similar conclusion in its review of the test slant well Coastal Development Permit application, on appeal. The CCC staff report noted that development of the test slant well in the proposed location would conflict with Coastal Act policies related to protection of ESHA (Coastal Act Section 30240). The CCC staff report for the test slant well states: "Although the project is proposed to be located in portions of the CEMEX site that have been subject to disturbance, the entire area in which the project would be located is primary habitat and ESHA under the LCP. The proposed project is not a resource dependent use, so it cannot be approved consistent with the LCP's habitat protection policies." (CCC, 2014)

The CCC was ultimately able to approve the project consistent with the Coastal Act, however, by relying upon Coastal Act Section 30260, which encourages

coastal-dependent industrial uses and provides for resolution of conflicting Coastal Act policies where such development is concerned.

EIR/EIR Table 4.8-3 presents a summary of land use and recreation impacts, and Impact 4.8-1 states, "Consistency with applicable plans, policies, and regulations *related to land use and recreation* that were adopted for the purpose of mitigating an environmental effect" (emphasis added). As stated in the second paragraph under Impact 4.8-1, "This section evaluates overall project consistency with applicable plans, policies, and regulations *pertaining to land use and recreation*" (emphasis added). Therefore, to be consistent with Table 4.8-3 and with the intent of the analysis in this section, the impact statement on Draft EIR/EIS page 4.8-34 has been revised as follows:

> **Impact 4.8-1: Consistency with applicable plans, policies, and regulations <u>related to land use and recreation</u> that were adopted for the purpose of mitigating an environmental effect.**

As noted above, the required analysis has disclosed that the proposed project, because it would be inconsistent with the City of Marina LCLUP policies governing protection of Primary and Secondary Habitats, would result in a significant and unavoidable impact. Nothing in this response to comment has triggered a need to recirculate the Draft EIR/EIS.

MCWD-151 As listed in EIR/EIS Table 4.7-1, there are no known active hazardous materials sites that are directly beneath any of the proposed project components. Nonetheless, the discussion in EIR/EIS Section 4.7.1 notes that the area has a long history of chemical use from commercial, industrial, agricultural, and military land uses, and various investigations and cleanups have been undertaken to address the releases. Consequently, although not expected, it is recognized that previously undiscovered chemical releases could be present and construction activities might encounter hazardous materials of previously undetected chemicals at unknown concentrations.

To address this possibility, Mitigation Measures 4.7-2a, Health and Safety Plan, and 4.7-2b, Soil and Groundwater Management Plan were identified in the EIR/EIS. Together, these mitigation measures are clear, enforceable and include appropriate performance standards as they would ensure that workers are apprised of the potential for soil and groundwater contamination, trained in the recognition of such possible contamination, and trained in the use of personal protective equipment and decontamination procedures, as needed. Further, upon discovery of contamination construction workers are required to stop work and notify the Monterey County Department of Environmental Health, followed by the retention of a qualified environmental firm to perform sampling and remediation. Construction workers would not perform the cleanup; cleanup would be conducted by environmental professionals trained to investigate, manage, and remediate hazardous materials. The environmental professionals would conduct sampling to identify risks, respond with

the appropriate safety procedures and protective equipment, and remediate the site using screening levels, as discussed in EIR/EIS Section 4.7.2.

As discussed above, the specific kinds and concentrations of hazardous materials of previously undiscovered hazardous materials, if any, obviously remain unknown until construction activities uncover their presence. Because the known hazardous materials sites in the region have previously been cleaned up, construction activities are not expected to encounter contaminated soil or groundwater, or unexploded ordnance (UXO). However, the previous investigations and cleanups have identified the overall nature of historical chemical and hazardous materials used in the regional area, which is known to have included fuels, lubricants and oil, solvents, various volatile organic compounds (e.g., carbon tetrachloride, trichloroethene), pesticides and herbicides, metals (e.g., cadmium, chromium, copper, nickel, and lead), wood preservatives (e.g., creosote and less commonly copper, chrome, arsenic, and pentachlorophenol), or UXO. Consequently, the Health and Safety Plan and the Soil and Groundwater Management Plan would include procedures to address these specific hazardous materials.

Upon certification of the EIR/EIS and the approval of the various permits, CalAm would commence construction of the proposed project. Contractors engaged in work that would disturb soil or conduct dewatering of excavations would be required to prepare a Health and Safety Plan and the Soil and Groundwater Management Plan relevant to the work they are contracted to perform. The contract specifications would mandate full compliance with all applicable local, state, and federal regulations related to the identification, transportation, and disposal of hazardous materials, including those encountered in excavated soil or dewatering effluent. This compliance would include notifying the appropriate regulatory agency of the release and acquiring the agency's concurrence that the newly discovered hazardous materials have been remediated to their satisfaction before work would continue in the affected location.

MCWD-152 The analysis under Impact 4.7-4 does not simply state; it explains that the risk of a release of hazardous materials near a school would be low, *because of the performance standards* imposed by the permitting requirements on the construction activities, *as discussed under Impact 4.7-1* [emphasis added]. EIR/EIS Section 4.7.2.2 addresses the Hazardous Materials Release Response Plans and Inventory Act - Health and Safety Code, Section 25500 et seq. Section 25532 of the Health and Safety Code (Pub. Resources Code, § 21151.4) states that: "An environmental impact report shall not be certified or a negative declaration shall not be approved for any project involving the construction or alteration of a facility within one-fourth of a mile of a school that might reasonably be anticipated to emit hazardous air emissions, or that would handle an extremely hazardous substance or a mixture containing extremely hazardous substances in a quantity equal to or greater than the state threshold quantity specified pursuant to subdivision (j) of Section 25532 of the Health and Safety Code, that may pose a health or safety

hazard to persons who would attend or would be employed at the school… .” The code continues by providing conditions and exemptions. Hazardous air emissions are toxic air contaminants identified by the California Air Resources Board. Construction would result in the short-term emissions of diesel particulate matter (DPM), a toxic air contaminant, within 0.25 mile of schools. The risk of the handling or emissions of hazardous materials near a school or any other site is analyzed for Impact 4.7-4; based on a screening-level analysis discussed in EIR/EIS Section 4.10, Air Quality, DPM emissions would be less than the Monterey Bay Unified Air Pollution Control District’s increased cancer risk threshold. Therefore, the proposed project would be in compliance with this code.

MCWD-153 As discussed above, Mitigation Measures 4.7-2a and 4.7-2b are not improperly deferred mitigation and adequately address the potential to encounter previously unknown soil and/or groundwater contamination. As discussed in Impact 4.7-C, cumulative projects would be subject to the same regulatory requirements as the MPWSP. These regulations would require cumulative projects that would include soil excavation and/or dewatering to prepare and implement health and safety plans, and soil and groundwater management plans to address the potential to encounter hazardous materials. These plans would be similar to the plans required under Mitigation Measures 4.7-2a and 4.7-2b, and would be subject to the same regulatory action levels. Implementation of these plans would reduce the risks from encountering hazardous materials to less than significant. No revisions were made in response to this comment.

MCWD-154 See response to comment USEPA-4 for the text of the revised Mitigation Measure 4.11-1, which would require that CalAm achieve net zero GHG emissions from operational electricity use. As a result of these revisions, GHG-related impacts are reduced to a less-than-significant level as described in Section 4.11 of the Final EIR/EIS. Revisions to Mitigation Measure 4.11-1 address the comment’s concerns about improper deferral by providing specific measures CalAm must take to achieve the GHG emissions performance standard outlined in the measure, including the potential purchase and retirement of carbon offsets. With regard to MCWD comments on Mitigation Measure 4.18-1, see responses to comments MCWD-164 and MCWD-167.

MCWD-155 As explained in EIR/EIS Section 4.1.7.2 and Table 4.1-2, Project No. 31, RUWAP Desalination Element, it is speculative to assume that MCWD will implement a 2,700 afy desalination facility, or what the size, timing or configuration of that facility would be. Therefore, the EIR/EIS does not generally include the RUWAP Desalination Plant in the cumulative analysis. Making conservative assumptions, however, EIR/EIS Section 4.4.6 does analyze the development of a 1,000 afy desalination plant on MCWD land as a cumulative project, in the event that such an option is chosen to make up the shortfall needed to provide water to support the FORA Base Reuse Plan.

Regarding the comment that modeling based upon best available information is needed, see response to comment MCWD-102. As discussed in EIR/EIS Impact 4.4-4, the MPWSP would have a less-than-significant impact on groundwater quality, with regard to salinity, since the slant well pumping would retard the inland migration of the seawater intrusion front. This is further presented in EIR/EIS Figure 4.4-17. In addition, Table 4.4-10 presents the known active supply wells within vicinity of the proposed MPWPS slant wells. The table includes the MCWD municipal wells, but only in mention because the Wells 10, 11, and 12 are over 2 miles to the southeast, and are screened in the 900-Foot Aquifer, and the Ord Community Wells 29, 30, and 31 are located 5 plus miles to the southeast and are screened in the lower 180-Foot and the 400-Foot Aquifers. While the proposed location of the RUWAP Desalination Element wells is speculative at this time, EIR/EIS Section 4.4.6, discusses the potential cumulative groundwater effects if MCWD were to construct a 1,000 afy desalination plant. In this scenario, the MCWD wells would be located south of the CEMEX site at the MCWD property at Reservation Road. Groundwater at this location is already degraded by seawater intrusion/high salinity. The EIR/EIS concludes that if the MPWSP and RUWAP Desalination Element were to operate concurrently, there would be no significant cumulative impact to groundwater quality and the two projects could in fact, contribute to a beneficial effect to reduce seawater intrusion. Overall, the proposed project would not cause increased salinity levels at the proposed RUWAP Desalination Element wells, nor would it cause MCWD to install additional infrastructure for the treatment of source water or increased energy requirements.

MCWD-156 EIR/EIS Section 4.13, Table 4.13-4, includes average monthly flows of treated wastewater effluent from the MRWPCA Regional Treatment Plant, which includes treated effluent from MCWD's vested usage of the facility. Table 4.13-4 shows that the brine stream from the MPWSP when combined with the highest monthly effluent flows from the MRWPCA would be an estimated 34 mgd. The MRWPCA outfall has an overall capacity of 81.2 mgd, therefore there would be ample capacity for proposed discharges from a 1,000 afy RUWAP Desalination Element. In addition, the MPWSP would not adversely affect the 2009 Memorandum of Understanding between the MRWPCA and MCWD for the Planning for Use of MRWPCA Outfall for Brine Disposal, which provides priority right to the MCWD for the use of unused outfall capacity of up to 25 mgd of brine.

MCWD-157 See response to comment MCWD-26. Per the 2009 Wheeling Agreement between CalAm and MCWD, CalAm is permitted to use a portion of the capacity of MCWD's water conveyance facility for CalAm's ASR Project. The subject of the agreement is the conveyance that extends southwards from the inter-tie location within General Jim Moore Boulevard just south of Coe Avenue and includes all appurtenant devices and fittings on the main transmission pipe itself. The Wheeling Agreement is intended to provide the terms and conditions for construction, financing, operation and maintenance, scheduling, quality requirements, term, priorities, and fair compensation for CalAm's joint use of the Subject Facility. The

Subject Facility is the same pipeline that the New Transmission Main would connect to in order to convey MPWSP water to CalAm's existing water supply distribution system. The Wheeling Agreement would need to be revised to include MPWSP water. Pursuant to Water Code Sections 1810 through 1813, CalAm and MCWD are to determine the unused capacity required and available capacity in the Subject Facility for CalAm's and MCWD's proposed uses. On March 23, 2017, CalAm provided to MCWD an assessment of estimated pipeline capacities, including pressure assumptions, for proposed uses of the Subject Facility, including future supply from CalAm's proposed desalination facility. The assessment shows that there is ample capacity in the Subject Facility for projected future uses (CalAm, 2017). The Subject Facility is a pressurized system, in which all the water that is permitted to use the facility would mix and reach the intended destinations, regardless of the location of the source.

In response to this comment, EIR/EIS Table 3-1 has been revised to include the following description of the New Transmission Main:

> "This pipeline would convey desalinated water between the new Desalinated Water Pipeline at Reservation Road, crossing U.S. Army-owned property along General Jim Moore Blvd. to the existing Phase I ASR Facilities <u>where it would connect to CalAm's existing water supply distribution system at the General Jim Moore Boulevard/Coe Avenue intersection</u>."

In addition, EIR/EIS Section 3.2.3.4, New Transmission Main, has also been revised:

> "The new Transmission Main would continue east along Lightfighter Drive for approximately 0.4 mile to General Jim Moore Boulevard, turn south along the east side of General Jim Moore Boulevard to Normandy Road. South of Normandy Road the pipeline would be located along the west side of General Jim Moore Boulevard <u>for approximately 1.9 miles</u>, ending at the existing Phase I ASR Facilities ~~near General Jim Moore/Coe Avenue~~ (see **Figures 3-7** through **3-9a**) <u>where it would connect to CalAm's existing water supply distribution system at the General Jim Moore Boulevard/Coe Avenue intersection</u>."

MCWD-158 EIR/EIS Section 4.13, Impact 4.13-1 states that construction of the MPWSP could damage or interfere with existing water, sewer, stormwater drainage, natural gas, electric, or communication utility service lines, and construction could require the permanent relocation of these utility lines, potentially interrupting service if the relocation could not be avoided. Such impacts on utilities and utility services during project construction would be potentially significant. Therefore, implementation of Mitigation Measures 4.13-1a (Locate and Confirm Utility Lines), 4.13-1b (Coordinate Final Construction Plans with Affected Utilities), 4.13-1c (Safeguard Employees from Potential Accidents Related to Underground Utilities), 4.13-1d (Emergency Response Plan), 4.13-1e (Notify Local Fire

Departments), and 4.13-1f (Ensure Prompt Reconnection of Utilities) are required to reduce the impact to a less-than-significant level. Such impacts and mitigation measures would apply to any existing/planned MCWD utilities that may be within the MPWSP project area.

MCWD-159 As described in EIR/EIS Section 4.18.3, the evaluation criteria used to determine if the proposed project would result in a significant impact related to energy conservation are based on Appendix F of the CEQA Guidelines. The remainder of this introductory statement summarizes comments on the EIR/EIS energy conservation analysis conducted for the proposed project. Responses to MCWD-160 through MCWD-167 are provided below.

MCWD-160 EIR/EIS Mitigation Measure 4.11-1 for greenhouse gas (GHG) emissions has been revised to require CalAm to achieve net zero GHG emissions from operational electricity use through adherence to a specific loading order of four options, the first of which is to secure renewable energy from on-site solar photovoltaic (PV) panels and/or the adjacent Monterey Regional Waste Management District (MRWMD) landfill-gas-to-energy (LFGTE) facility (see response to comment USEPA-4, in Section 8.3.5, for the revised text of Mitigation Measure 4.11-1). Implementation of this revised mitigation measure would ensure that renewable energy resources are incorporated into the design of the project to the extent feasible.

For consistency with revised Mitigation Measure 4.11-1, EIR/EIS Section 4.18.4.3, *Landfill-Gas-to-Energy Option*, has been revised as follows:

4.18.4.3 Landfill-Gas-to-Energy Option

~~Information regarding the potential use of methane gas as an alternative energy source is provided here for informational purposes only; t~~This EIR/EIS conservatively assumes that all proposed operational power requirements would be met via the existing PG&E power grid. ~~Although not evaluated in this EIR/EIS~~However, CalAm is actively pursuing a renewable energy source option with Monterey Regional Waste Management District (MRWMD) that would allow CalAm to meet a portion of the MPWSP Desalination Plant operational energy requirements with methane gas from the existing MRWMD landfill-gas-to-energy (LFGTE) facility located adjacent to the MPWSP Desalination Plant site. The MRWMD LFGTE facility produces 5.07 Megawatts (MW) of continuous electricity that is sold to PG&E. MRWMD plans to increase the electric generation capacity of the LFGTE facility by 3.2 MW in two stages; the first phase of improvements would increase the capacity by 1.6 MW, followed by an additional 1.6-MW increase in six to eight years. Once the expansion is complete, the total generation capacity of the LFGTE facility would be 8.27 MW (ESI, 2014).

> If this renewable energy source option is implemented, about half of the MPWSP Desalination Plant operational energy requirements could be met with methane gas from the LFGTE facility~~; the remainder would come from the local PG&E grid~~. Overhead powerlines, electrical transformers, metering devices, and switchgear would be needed to connect the MRWMD LFGTE facility with the MPWSP Desalination Plant. Implementation of this option and the construction of the associated interconnection improvements would require separate environmental review ~~and are not evaluated in this EIR/EIS~~.

MCWD-161 In the context of the EIR/EIS Energy Conservation analysis, indirect energy use refers to the energy used for extraction, manufacturing, and transportation of raw materials to make construction materials that would be used for the project (refer to the first paragraph of EIR/EIS Impact 4.18-1). Evaluation of these energy sources is outside the scope of this CEQA/NEPA review because the types, amounts, and processes associated with those energy sources is unknown. Nonetheless, the fourth paragraph of the EIR/EIS Impact 4.18-1 discussion contained an error in that it should not have indicated that the amounts of indirect energy that would be used associated with the extraction, manufacturing, and transportation of raw materials to make the construction materials for the project would not be expected to be substantial because information to make that determination is not available. However, compared to the direct energy consumption that would occur under the project, electricity use during construction would not be expected to be substantial because electric powered equipment would be a small fraction of the overall equipment used to construct the project. Therefore, the fourth paragraph of the EIR/EIS Impact 4.18-1 discussion has been revised as follows:

> The amount of electricity ~~and indirect energy~~ consumption that would be associated with construction of the project is unknown and cannot be estimated as it would be too speculative given existing data; however, the amount~~s~~ would not be expected to be substantial.

MCWD-162 The energy usage associated with the Monterey Main System, Aquifer Storage and Recovery, Sand City Coastal Desalination Plant, and the Subsurface Intake System components of the proposed project were estimated by multiplying energy use factors [kilowatt-hours/acre-feet (kWh/af)] by the average annual water production (afy). It should be noted that CalAm also provided additional detailed data regarding how the energy use factor for the Monterey Main System was estimated. Those data showed a slightly lower average annual energy use factor of 913 kWh/af compared to 915 kWh/af as shown in the power table spreadsheet. Since the energy use factor is used to estimate both the existing conditions and future with project conditions, and the existing conditions involve a higher water production rate than future with-project conditions for the Monterey Main System, the lower energy use factor was used for a more conservative analysis. This explains why the energy usage disclosed in the EIR/EIS for the project is slightly higher than shown in the power table spreadsheet (i.e., CalAm, 2016b) referenced

in the comment. That spreadsheet, which was available for review along with all materials referenced in the Draft EIR/EIS during the public comment period, includes notes that describe how the energy use factors were estimated.

MCWD-163 As described in Impact 4.18-2, while the proposed project would require a large amount of electricity each year to operate, it is necessary to provide drinking water to area residents to protect human health and safety. Further, the proposed project would not consume energy wastefully or inefficiently. The design and construction of the MPWSP Desalination Plant would incorporate various energy-efficient design elements into building support systems, electrical and treatment equipment, and process design that would reduce operational energy demand (e.g. variable speed pumps, energy recovery devices). Electricity consumed as a result of project operations would not be unnecessary, wasteful, or inefficient and the energy conservation impact related to the use of fuel and energy during project operations would be less than significant.

Although not required to reduce an energy conservation impact, implementation of Mitigation Measure 4.11-1, GHG Emissions Reductions Plan, would require CalAm to have a qualified professional prepare a GHG Emissions Reduction Plan that shall include a summary of state-of-the-art energy recovery and conservation technologies available for utility scale desalination facilities and shall include a commitment by CalAm to incorporate all available feasible energy recovery and conservation technologies; or, if CalAm finds that any of the technologies will not be feasible for the project, the Plan shall clearly explain why such technology is considered to be infeasible.

For discussion of the project's potential use of electricity from the LFGTE expansion, refer to response to comments MCWD-160 and USEPA-4.

MCWD-164 Mitigation Measure 4.18-1 requires CalAm to prepare a Construction Equipment and Vehicle Efficiency Plan. The mitigation measure identifies several specific performance standards for the measures that CalAm and its construction contractors must implement to increase the efficient use of construction equipment to the maximum extent feasible and to ensure that construction activities are conducted in a fuel-efficient manner (see EIR/EIS Section 4.18, Impact 4.18-1). Therefore, Mitigation Measure 4.18-1 is not deferred mitigation. See also response to CURE-Fox-123. The amount of electricity and indirect energy consumption that would be associated with construction of the project is currently unknown and cannot be estimated as it would be too speculative given existing data (see Draft EIR/EIS, p. 4.18-15). More important, the precise plan of construction as to timing of elements, sequencing, and the precise exact types of construction equipment to be employed, etc., cannot be known until the project is approved, a contractor is hired, and construction-level plans are available. Therefore, although it is premature to prepare a fully-developed construction equipment efficiency plan at this time, preparation of the plan prior to implementation of construction would be

feasible and implementation of the approved plan would ensure construction activities are conducted in a fuel-efficient manner for construction equipment and vehicles.

Since implementation of Mitigation Measures 4.18-1 and 4.10-1b, which limits equipment idling, would increase the efficient use of construction equipment to the maximum extent feasible and would ensure that construction activities are conducted in a fuel-efficient manner, the impact would be mitigated to a less-than-significant level. In addition, Mitigation Measure 4.10-1a has been revised to identify construction equipment that meets Tier 4 standards as opposed to Tier 3 standards (refer to response to comment MBARD-6). Tier 4 emission standards are the most stringent and efficient standards available for off-road construction equipment.

MCWD-165 As described in the Impact 4.18-2, the amount of gasoline and diesel required to fuel vehicles and equipment during operation and maintenance of the project would be relatively small. The vehicle trips would be necessary to support operation and maintenance of the proposed project and would be equivalent to approximately 0.01 percent of the total amount of gasoline and 0.02 percent total diesel fuel sold in Monterey County in 2012 (see Section 4.18.1.2, *Local Energy Systems*). The overall transportation energy use requirements during operation and maintenance would not be significant relative to the overall sales of transportation fuels in the county. Regardless, Mitigation Measure 4.18-1 has been revised to include a requirement that CalAm provide options for worker carpooling.

MCWD-166 Operation of the proposed project would rely on electrical power supplied from Pacific Gas and Electric Company (PG&E)'s existing regional power grid. It is generally not possible to determine the exact generation source(s) of electricity on the power grid that would supply the proposed project regardless of its location relative to existing power generation plants, or whether or not the electricity would even be generated within Monterey County. Therefore, it is not reasonable to assume that the electricity required for the project would be generated at Moss Landing Power Plant.

The personal communication referred to in the comment was a phone call that occurred on September 9, 2016, between a PG&E Project Manager with Distribution Services, and the Environmental Science Associates EIR/EIS Energy Analyst. During that call, PG&E indicated that it is moving forward in its planning to service CalAm with 6 megawatts (MW) of electricity for the MPWSP. The project would be serviced by nearby distribution circuits and no electrical transmission upgrades would be needed. PG&E does not consider the MPWSP to be a large electrical load, and a "large load process" would not be necessary for PG&E to service the project. The large load process is designed to determine how PG&E customers with large energy requirements will be fed electricity. When asked if there is a specific MW threshold that triggers the large load process, the PG&E representative said that there is not and that it is based on the project

location and what infrastructure is available to support the project in the area. From the perspective of serving electricity to the MPWSP, PG&E considers the MPWSP to be a "typical new service." Therefore, implementation of the proposed project could be accommodated by the existing local and regional energy supplies and the impact would be less than significant.

MCWD-167 As described in EIR/EIS Impact 4.18-C, Mitigation Measures 4.18-1 (Construction Equipment and Vehicle Efficiency Plan) and 4.10-1b (Idling Restrictions) would be implemented to ensure construction activities would be conducted in a fuel-efficient manner. Even if project construction were to occur simultaneously with other cumulative projects, the cumulative use of energy resources during construction would be consistent with normal construction practices and would comply with efficiency- and conservation-related policies and codes intended to address cumulative energy consumption statewide, such as the California Integrated Energy Policy and the California Green Building Standards Code (refer to EIR/EIS Section 4.18.2.2). As explained in EIR/EIS Section 4.1.7.1, Approach to the Analysis of Cumulative Effects, the EIR/EIS engaged in a two-step process. If the first step of the analysis finds that the cumulative effects of past, present and future projects plus the proposed project would be significant and adverse, the second step identifies whether the proposed project's contribution to the overall adverse effect would be of a considerable nature such that the project's contribution to cumulative effects in that area is deemed significant. Therefore, after mitigation, project construction would not have a cumulatively considerable contribution to a significant cumulative impact on the supply and/or availability of these fuel sources during construction. Further, Mitigation Measure 4.18-1 is not deferred mitigation (see response to comment MCWD-164).

EIR/EIS Impact 4.18-C also discloses that the anticipated increase in electricity consumption for the proposed project would represent approximately 2 percent of Monterey County's annual usage, and an even smaller percentage of PG&E's overall service area usage (0.05 percent). And given that PG&E purchases wholesale electric energy and capacity from generators and suppliers and periodically conducts solicitations / requests for offers for additional supplies of conventional and renewable electricity, in the event that many other cumulative projects would be high demand electricity users and would request electrical service from PG&E, additional wholesale electric energy may need to be purchased by PG&E and it would be received through its existing electricity grid. There may need to be local distribution line upgrades to connect some of the cumulative projects to the electricity grid (e.g. DeepWater Desal), but any such upgrades would be minor. Therefore, the proposed project would not have a cumulatively considerable contribution to a significant cumulative impact associated with the unnecessary, wasteful, or inefficient use of energy during operation, and the operational cumulative impact would be less than significant.

MCWD-168 See responses to comments MCWD-2 and Marina-140. As stated in EIR/EIS Section 5.1.1, the selection of alternatives followed the CEQA Guidelines Section 15126.6 and NEPA requirements in 40 CFR Sections 1502.13 and 1502.14, including identifying the feasibility of the various alternatives selected for analysis, as defined in CEQA Guidelines Section 15126.6(f) as alternatives capable of being accomplished in a successful manner within a reasonable period of time, taking into account economic, environmental, legal, social, and technological factors. An extensively robust and detailed screening of components was provided in EIR/EIS Section 5.3, and included the screening and evaluation of intake, outfall, and desalination plant site options in Sections 5.3.3, 5.3.4, and 5.3.5, respectively. The EIR/EIS also evaluates a total of eight whole alternatives, including the proposed project, the No Project Alternative, and Alternatives 1 through 5b in EIR/EIS Section 5.5.

With the revisions to GHG Mitigation Measure 4.11-1 (see response to comment USEPA-4, in Section 8.3.5), and the related revision to the conclusion of Impact 4.11-1 (incremental contribution to climate change from GHG emissions) to less than significant with mitigation, the EIR/EIS does not identify any unavoidable significant impact for any resource that would require inclusion of a downsized alternative as mitigation. See also response to comment Surfrider-6.

MCWD-169 No new significant impacts or substantially more severe significant impacts have been identified as a result of these comments or the associated responses that would trigger a requirement to recirculate the Draft EIR/EIS.

MCWD-170 EIR/EIS Chapter 5 provides a robust and comprehensive alternatives analysis. See response to comment MCWD-168. CEQA Guidelines Section 15126.6(a) acknowledges that an EIR "need not consider every conceivable alternative to a project. Rather it must consider a reasonable range of potentially feasible alternatives that will foster informed decision making and public participation."[9] Here, EIR/EIS Section 5.2 first considers alternatives not evaluated in detail, including the New Los Padres Dam and Reservoir, Plan B, the Coastal Water Project, the Interlake Tunnel, and Pure Water Monterey GWR. EIR/EIS Section 5.3 then discusses and considers intake, discharge and plant location options. As noted in Section 5.3.3, thirteen intake options were identified and screened for fatal flaws; six of the thirteen were not carried forward. The seven intake options that were determined to be feasible were carried forward for evaluation (see EIR/EIS Section 5.3.3.14). The next step in the alternatives process (see EIR/EIS Section 5.3.6) compares the impacts of each intake option against the proposed slant wells at CEMEX to determine if any adverse impacts would be reduced. Of the seven intake options evaluated, for reasons

[9] The point behind the case holding cited by the commenter, *Watsonville Pilots Assn. v. City of Watsonville* (2010) 183 Cal. App. 4th, 1059, 1087, is that even if an alternative considered in an EIR is ultimately determined by the decision-makers to be infeasible, that alternative may still be counted as within the reasonable range of alternatives required by CEQA to be included in an EIR. Thus, the case does not advance the commenter's position or undermine the validity of the EIR/EIS alternatives analysis.

described in Table 5.3-4, two intake options -- Option 3, Slant Wells at Potrero Road, and Option 9, Open-water Intake at Moss Landing -- were carried forward into the development of whole alternatives that are described in Section 5.4 and analyzed in Section 5.5.

The Lead Agencies did not use the scoping process to narrow the range of potential alternatives. While additional intake options were originally considered, EIR/EIS Appendix I2 describes the facts and rationale for rejected component options.

MCWD-171 The EIR/EIS Appendix I explains that horizontal wells were not evaluated further for the reasons cited by the comment. Nothing in this comment letter or the associated responses has caused the Lead Agencies to revise that conclusion. No revisions were made to the conclusion in EIR/EIS Appendix I1 regarding HDD wells.

CEQA Guidelines Section 15126.6(a) states "there is no ironclad rule governing the nature or scope of the alternatives to be discussed." Furthermore, CEQA Guidelines Section 15126.6(f) states: "The range of alternatives required in an EIR is governed by a 'rule of reason' that requires the EIR to set forth only those alternatives necessary to permit a reasoned choice. The alternatives shall be limited to ones that would avoid or substantially lessen any of the significant effects of the project." Furthermore, Lead Agencies do not need not to consider every conceivable alternative to a project and this EIR/EIS provides a robust and comprehensive analysis of component options as well as whole alternatives, as described in response to comment MCWD-170.

However, as noted by the Huntington Beach Independent Scientific Technical Advisory Panel (HB ISTAP, 2014): "The performance of the HDD systems will be suboptimal in granular materials (sands) as opposed to lithified strata (limestone) . . . and . . . [t]here is inadequate data on the long-term reliability and maintainability of the HDD wells/drains at this time. This subsurface intake design option is considered technically infeasible at the Huntington Beach site because of a high performance risk. There is too great uncertainty that a system could be constructed that would reliably provide the required water volume over the operational life of the desalination facility." The HB ISTAP 2014 further explains that "The largest capacity system in Spain is currently not operating at its original design capacity."

See also response to comment MCWD-IW-9, MCWD-IW-10 and MCWD-IW-11. Note that the possible use of HDD wells was not dismissed on the basis of comparative cost concerns. While cost was mentioned in the EIR/EIS, HDD wells were eliminated on other feasibility grounds, including technological, ability to meet the project objectives and failure to reduce significant impacts.

MCWD-172 Vertical wells were not considered in the EIR/EIS Section 5.3 component screening and evaluation. Because vertical wells would have to be located at the same location or farther inland than the proposed slant wells at CEMEX to avoid

coastal erosion, they would likely have a greater effect on SVGB water quality and groundwater levels than the proposed slant wells, given the more inland locations of the well screens within the aquifers. Furthermore, while the CPUC approved vertical wells as part of the Regional Project, see response to comment MCWD-12, specifically, Footnote 2 which explains that 24 vertical wells would be needed over a linear distance of at least one mile to support a 9.6 mgd desalination plant, and 16 vertical wells would be needed over a linear distance of almost one mile to support a 6.4 mgd desalination plant. The reverse osmosis system proposed by CalAm, described in EIR/EIS Section 3.2.2.2, would be modular and would comprise six active and one standby module, each capable of producing 1.6 mgd of desalinated water. The EIR/EIS did not identify any impacts that would need to be lessened or avoided by using packaged desalination systems.

MCWD-173 While the Huntington Beach ISTAP Phase 1 Feasibility Report (HB ISTAP, 2014) concluded that an infiltration gallery was a feasible subsurface option, the Phase II Feasibility Report (HB ISTAP, 2015) concluded that the beach infiltration gallery is infeasible at the Huntington Beach location and several factors led to that conclusion. First, the additional engineering design assessment concluded that a substantially larger gallery would likely be required compared to the considerations in Phase 1. Second, the ISTAP further considered the periodic beach re-nourishment schedule, which means that the surf zone migrates following nourishment cycles, reducing the effectiveness of the intake filtration through the sand. Third, construction of a larger-than-anticipated gallery would require many years to construct due to construction constraints on a highly used public beach.[10]

In Monterey, the concern is exacerbated. EIR/EIS Appendix I1 explains that approximately 222,000 square feet (or about 5 acres) of the seabed in Monterey Bay would need to be excavated at a depth of 6 to 8 feet to install an active infiltration bed for the 9.6 mgd desalination plant; a 6.4 mgd plant would require approximately 145,000 square feet or about 3.3 acres. An infiltration gallery would have a greater impact on marine biological resources in MBNMS than slant wells. Based on the extent of temporary and permanent disturbance that an infiltration gallery would have on the sand dunes and marine habitat in MBNMS, this technology is considered infeasible at this location. Furthermore, the EIR/EIS concludes that the project would not have significant impacts on groundwater resources, including the SVGB, so no such option is necessary to ensure less than significant groundwater impacts.

MCWD-174 Slant wells are indeed a new, evolving technology. See response to comment Marina-11 and Master Response 11, CalAm Test Slant Well, Section 8.2.11.7. The HB ISTAP's 2014 conclusions were made for subsurface intake technologies at the

[10] On October 4, 2017, the CA State Lands Commission issued a Notice of Availability and Intent to Consider Certification of the Final Supplemental EIR for the Seawater Desalination Project at Huntington Beach. The Final EIR considered a lease modification that would allow Poseidon to install wedgewire screens on an existing open water intake that would provide almost 107 mgd of feedwater.

Huntington Beach site for a potential 100 to 127 mgd desalination project. The test slant well at CEMEX today is demonstrating the technology works at this location under these conditions for this application. See EIR/EIS Appendix E3.

The CPUC does not have a representative on the HWG; Dr. Williams and Geoscience represent CalAm; see Master Response 5, The North Marina Groundwater Model (v. 2016), Section 8.2.5.2. Both the HB ISTAP 2014 and Geosciences 2012 reports were included as references to the EIR/EIS.

See responses to comments MCWD-HGC. The commenter presents a speculative condition predicated on unsubstantiated risk that speaks to the project's feasibility and not an environmental impact of the proposed project. CEQA Guidelines Section 15370 defines mitigation as avoiding, minimizing, rectifying, reducing or eliminating, or compensating for impacts, and the EIR/EIS found no impacts from operation of the slant wells that would require the mitigation described in the comment. The project includes the return water component as an integral element of the project; thus, even if the MPWSP were less efficient than expected, the fresh water component of the source water would be subject to return. See also response to comment MCWD-82. Alternatives to slant wells are discussed in EIR/EIS Section 5.3.6.1.

MCWD-175 EIR/EIS Section 5.2.1 explains that the MPWSP is the result of a multi-year planning effort. Since 1989, various entities have proposed several options intended to meet the water supply needs of the Monterey Peninsula and address the impacts on the Carmel River that are underlying SWRCB Order 95-10. Several of those options generated their own environmental review documents, which in turn contained many alternatives, some of which are still relevant here. As part of the 2009 Coastal Water Project EIR, the CPUC reviewed these previously prepared documents, including the Monterey Peninsula Long-Term Water Supply Contingency Plan (Plan B) Component Screening Report and the CPUC Carmel River Dam Alternative Plan B Project Report (see Section 5.2.1 for citations of these reports), to determine what projects and alternatives had already been considered and eliminated since SWRCB Order 95-10 was issued. The conclusion that no viable alternatives have been identified that would supply water without a desalination plant is consistent with the history of the multi-year planning effort.

The Coastal Water Project, a prior iteration of the MPWSP, is discussed in EIR/EIS Section 1.4. See also responses to comments MCWD-5, MCWD-10, and MCWD-170.

MCWD-176 See responses to comments MCWD-5, MCWD-10, MCWD-12, and MCWD-170; Master Response 3, Water Rights; and Master Response 4, The Agency Act and Return Water. See also EIR/EIS Section 4.4.5.2 for Applicant Proposed Measure 4.4-3, Groundwater Monitoring and Avoidance of Well Damage.

MCWD-177 See response to comment MCWD-15 regarding CalAm's objective of meeting peak monthly demand. See also response to comments MCWD-20 through MCWD-49 for a discussion of alternatives and project objectives.

EIR/EIS Section 5.2.6 explains that the CPUC authorized CalAm to enter into a Water Purchase Agreement in Decision 16-09-021 on September 15, 2016, which provides that the MRWPCA will sell purified water from its advanced treated Pure Water Monterey GWR Project to the MPWMD, which in turn will sell it to CalAm for distribution to ratepayers in the Monterey District service area. The GWR Project is also, therefore, included in the No Project/No Action alternative described in EIR/EIS Section 5.4 because it is not reliant upon approvals considered in this EIR/EIS and could (and likely would) become operational under the No Project/No Action alternative. Essentially, the comment advocates consideration of the No Project/No Action Alternative, which is indeed thoroughly evaluated in the EIR/EIS. The GWR Project would not be relevant in the context of the proposed project or any alternative that includes a 9.6 mgd or greater desalination plant (i.e., Alternatives 1, 2, 3, and 4) because, if the GWR Project is implemented, CalAm would not need to construct a 9.6 mgd desalination plant (the proposed project); instead, it would propose to construct the 6.4 mgd plant as described in Alternatives 5a and 5b, or enter into a purchase agreement with an alternative desalinated water provider for an amount equivalent to the output of a 6.4 mgd plant (i.e., under Alternatives 3 or 4). Therefore, the analysis of a 9.6 mgd desalination plant is predicated on an assumption that the GWR Project would not be successfully implemented and, therefore, this water would not become available to CalAm. The Lead Agencies acknowledge that as the GWR Project progresses in its implementation, this scenario will become more remote. The analyses of Alternatives 5a and 5b in combination with the GWR Project adequately address the increasingly likely outcome that the GWR Project will deliver water for CalAm use. See also EIR/EIS Table 5.5-1 and Master Response 15, Alternative Desalination Project – Status, Information Sources, and Cumulative Scenario, Section 8.2.15.3.

MCWD-178 EIR/EIS Appendix I2 evaluated Intake Option #11, Ranney Wells in Seaside/Sand City because this intake option was included in public comments received during the MPWSP EIR scoping process, requesting that the CPUC consider subsurface intakes located outside of the Salinas Valley Groundwater Basin; the Monterey Peninsula Water Management District 95-10 Project Constraints Analysis (referred to herein as the 2008 Constraints Analysis) (ICF et al., 2008) was attached to the comment.

As explained in Appendix I2, the "preferred" wells identified in the 2008 Constraints Analysis are located within the Salinas Valley Groundwater Basin, since they are located north of the northernmost extent of the divide between the Seaside and Salinas Valley Groundwater Basins. Since the former Fort Ord Wastewater Treatment Plant site and former Stillwell Hall site are both located in

the Salinas Valley Groundwater Basin, the investigation focused on the Bunker site, to be true to the scoping comment, because the Bunker site is located in the Seaside Groundwater Basin.

Subsurface investigation of the Bunker site (ICF et al., 2008) revealed the presence of clay layers in some of the borings and not in others. Low-permeability strata encountered were discontinuous and occurred at differing elevations. The investigation concluded that even if there were evidence of an extensive low-permeability layer between the shallow aquifer system and the underlying aquifers, the siting constraints of both the CCC and the CA State Parks, combined with the relatively low-permeability sands at this site, limit the potential amount of feedwater that could be developed from a subsurface intake at the Bunker site to about 2,000 afy (Feeney, 2009). Therefore, Intake Option #11 was eliminated from further consideration.

EIR/EIS Section 5.3.3 did consider Ranney Wells at CEMEX. As described in EIR/EIS Section 5.3.3.13, each caisson would be 12 feet in diameter, and would be buried approximately 50 feet into the sand, with the top of the caisson flush with the beach surface. Each of the four Ranney wells would be equipped with five screened laterals that would draw groundwater from the shallow Dune Sands Aquifer, and not from the deeper aquifers as claimed by the comment. EIR/EIS Table 5.3-4 provides preliminary environmental impacts comparisons of the intake alternatives that were carried forward, against the proposed project slant wells. EIR/EIS Section 5.3.6.1 concludes that, "Ranney wells (Intake Option 13) were shown to result in similar environmental effects compared to the proposed slant wells, resulting in neither increased or decreased impacts; Ranney wells do offer an opportunity to replace slant well technology at either the CEMEX or the Potrero Road site if necessary."

See also response to comment MCWD-170 and MCWD-IW-12.

MCWD-179 The EIR/EIS does analyze the potential effects of the No Project Alternative based on what is reasonably expected to occur. See, for example, Sections 5.5.3.3 and 5.5.6.3, which describe the beneficial effects of increased streamflows in the Carmel River. The decommissioning of the test slant well would be a reasonably foreseeable occurrence under this scenario, but already has been analyzed in the separate CEQA and NEPA documents prepared for the test slant well. The EIR/EIS did not revise its conclusion about Stage 4 Water Rationing not being needed if the No Action Alternative with GWR meets 89 percent of estimated demand, because as stated in Section 5.4.2.4 and reiterated in the comment, the No Action alternative could meet "89 percent of estimated demand after implementation of foreseeable demand management and offset programs described in Section 5.4.2.3, ***including*** [emphasis added] Stage 3 Water Conservation, and possibly Stage 4 Water Rationing to meet the supply shortfall. Master Response 13, Demand (Project Need) and Growth, Section 8.2.13.3 explains the GWR Project will make 3,500 afy

available to CalAm, not 3,700 afy. Therefore, the total with the GWR Project supply under the No Project Alternative would be 9,880 afy, as stated in the EIR/EIS, and not 10,080 afy as claimed in the comment. See Master Response 13 regarding the demand that needs to be met by feasible project alternatives.

MCWD-180 Alternative 1 (Slant Wells at Potrero Road) is described in detail in EIR/EIS Section 5.4.3, which explains, as does Table 5.4-1, that Alternative 1 would produce the same amount of desalinated water as the proposed project, 9.6 mgd. The conclusion in EIR/EIS Section 5.4.3.4 that Alternative 1 would not provide sufficient supplies to serve existing legal lots of record is described in EIR/EIS Section 5.5.21.4: In the event that the return water obligation is determined to be 12 percent (the highest return value simulated), after meeting existing demand and entitlements, only 209 afy would be available for other uses, and, therefore, Alternative 1 would not fully meet the project objective/need for water, some of which was to support limited growth (e.g., legal lots of record).

The analysis of impacts on groundwater resources from slant wells located at Potrero Road is provided in Section 5.5.4.4and provides a summation of the groundwater modeling results from operation of the slant wells and figures of the resulting cone of depression predicted by the NMGWM^{2016}. Details of the modeling approach and results are presented in EIR/EIS Appendix E2. See Master Response 12, The North Marina Groundwater Model (v. 2016), for more information on the adequacy of the NMGWM.

As stated in the analysis, the operation of Alternative 1 could result in drawdown in the SVGB aquifers so as to require the return of up to 12 percent of the source water that originated in the SVGB, to the SVGB. Different drawdown areas were shown for the three aquifers on EIR/EIS Figures 5.5-2 through 5.5-4, based on the amount of return water and sea level rise. While the cone of depression is much larger for Alternative 1 than for the proposed project, the impact conclusion would be the same as the proposed project impact on groundwater: less than significant. In addition, as stated in EIR/EIS Section 5.5.4.4, Alternative 1 would include Applicant-Proposed Measure 4.4-3 (Groundwater Monitoring and Avoidance of Well Damage) to provide continued verification that project pumping would not adversely impact neighboring wells or contribute to seawater intrusion within the SVGB. However, the cone of depression associated with Alternative 1 would extend to Elkhorn Slough, unlike the proposed project's cone of depression that does not intersect either the Salinas River or the Tembladero Slough. Potential impacts on marine biological resources in Elkhorn Slough that could result from Alternative 1 and Alternative 5b are presented in EIR/EIS Sections 5.5.5.4 and 5.5.5.8, respectively. Potential impacts on terrestrial biological resources in Elkhorn Slough that could result from Alternative 1 and Alternative 5b are presented in EIR/EIS Sections 5.5.6.4 and 5.5.6.8, respectively.

MCWD-181 As explained in EIR/EIS Section 5.4.7.1, CalAm is seeking authorization to implement Alternative 5a (reduced size desalination system) if it becomes clear that the GWR Project will be completed and on line in a timeframe that can supply water to meet the proposed project's objectives. If the GWR Project cannot supply water within that timeframe, then CalAm seeks authorization to implement the proposed project. The other 9.6 mgd-equivalent alternatives analyzed in Chapter 5 also could be downsized (e.g., through a smaller water purchase agreement from the DeepWater Desal Project under Alternative 3) if GWR Project water becomes available. Presenting two alternatives as environmentally superior under these possible outcomes provides the decision-makers with options to choose from during the project approval process. The presentation of two reasonable environmentally superior alternatives, the choice between which is reliant on actions not within the scope of this EIR/EIS (i.e., successful implementation of the GWR Project), is not inconsistent with CEQA or NEPA.

In addition, CalAm's project application was submitted, and the EIR/EIS was begun, long before the GWR Project was approved by MRWPCA and the associated Water Purchase Agreement for CalAm to secure GWR water was subsequently approved by the CPUC. The framing of the EIR/EIS structure and alternatives analysis was reasonable and logical at the outset, and remains so in light of continued uncertainties and to ensure flexibility for the decision-makers.

MCWD-182 See responses to comments Surfrider-6, MCWD-171 (HDD wells) and MCWD-178 (Ranney wells).

MCWD-183 See response to comment MCWD-180.

MCWD-184 See response to comment Surfrider-6. Response to comment MCWD-HGC and Master Response 6, The Sustainable Groundwater Management Act, Section 8.2.6.2, explain that the "Marina Subarea" is not a DWR-recognized groundwater basin. See also Master Response 3, Water Rights, and Master Response 4, The Agency Act and Return Water. See responses to comments MCWD-168 through MCWD-173 regarding alternative components, response to comment MCWD-171 regarding HDD wells, and response to comment MCWD-178 regarding Ranney wells. No alternatives were deemed infeasible solely on the basis of cost. Response to comment MCWD-150 explains the inconsistency of the proposed project with Marina's LCLUP and how the CCC was ultimately able to approve the slant test well project by relying upon Coastal Act Section 30260, which encourages coastal-dependent industrial uses and provides for resolution of conflicting Coastal Act policies where such development is concerned; the Marina LCLUP did not need to be amended. Response to comment MCWD-190 addresses the issue of recirculation.

MCWD-185 This comment offers the commenter's opinion and preference, and does not address the adequacy of the EIR/EIS. Decision-makers will consider this comment during the project approval process.

MCWD-186 Master Response 13, Demand (Project Need) and Growth, Section 8.2.13.2 provides a discussion of Supply for Peak Demands. The analysis in EIR/EIS Section 5.5 assumes that both the 6.4 mgd desalination plant and the GWR project would be implemented under Alternatives 5a or 5b; see response to comment MCWD-15. MBNMS is the NEPA Lead Agency for this EIR/EIS, consistent with actions identified in the MBNMS Final Management Plan, to ensure opportunity for input from local jurisdictions and the interested public regarding implementation of desalination plants and facilitating assessment and analysis of the potential growth inducing impacts of desalination plants, among other actions described under Strategy DESAL-1: Develop and Implement Regional Desalination Program in Section 2, Coastal Development, of the Management Plan. EIR/EIS Section 6.3 evaluates the impacts of growth that would be induced by the proposed project. See also Master Response 13, Section 8.2.13.3. As described in EIR/EIS Section 6.3, the impacts of growth have been evaluated in the general plan CEQA documents of jurisdictions in CalAm's service area. Those jurisdictions located in the coastal zone have also adopted local coastal program land use plans to guide development in coastal areas. Growth provided for in general plans would be required to be consistent with provisions of local coastal programs and plans. The demand estimates provided by CalAm and others throughout this CEQA/NEPA process have been independently reviewed and assessed by the Lead Agencies. Spreadsheet models of various supply and demand scenarios have been prepared and are included in the Final EIR/EIS as Appendix L.

MCWD-187 EIR/EIS Section 4.4.5.2, Impact 4.4 provides an analysis of the potential water quality effects that could impact or harm other groundwater users, otherwise degrade groundwater resources, and exacerbate seawater intrusion; the impacts were determined to be less than significant. The analysis employed groundwater modeling particle tracking to assess changes to the MCWRA-defined seawater intrusion front. Results of the modeling indicate that slant well pumping would retard the migration of saltwater into the southern portion of 180-Foot Aquifer that would have otherwise contributed to the advancement of the seawater intrusion front; slant well pumping would have little to no effect on future saltwater intrusion in the 400-Foot Aquifer. Supplemental discussion of the hydrogeological characteristics, graphic representation of the slant well capture zone, and supplemental discussion of water quality impacts are provided in Master Response 8, Project Source Water and Seawater Intrusion. See also response to comment MCWD-141. Response to comment MCWD-HGC and Master Response 6, The Sustainable Groundwater Management Act, Section 8.2.6.2, explain that the "Marina Subarea" is not a DWR-recognized groundwater basin. See also response to comment MCWD-EKI.

EIR/EIS Section 6.4, the assessment of project conformity with guidelines for desalination plants in MBNMS, accurately summarizes the Guidelines for Entrainment and Impingement contained in Section D.3, page 6 of the Guidelines for Desalination Plants in the MBNMS (NOAA, 2010). The conclusion that the proposed project would be consistent with this guideline has not changed.

MCWD-188 See response to comment MCWD-6 regarding the issue of public versus private ownership. EIR/EIS Section 6.4 lists the NOAA Guideline (page 4 of the MBNMS Desalination Guidelines) stating that, "Desalination plant proponents should pursue collaborations with other water suppliers and agencies currently considering water supply options in the area to evaluate the potential for an integrated regional water supply project," and it has been determined to be addressed by the scope of the overall EIR/EIS analysis. Furthermore, the CalAm project would be considered regional because it addresses the needs of multiple cities and has been coordinated with other agencies (MRWPCA). The MBNMS Management Plan (see page 82) refers to the CalAm project as a "larger multi-city regional project."

The comment does not include the full NOAA Guideline (from page 4), which states that proponents "should include an evaluation of other potential desalination locations and alternatives, as well as other forms of water supply." EIR/EIS Sections 5.1 through 5.3 screen and analyze a thorough selection of intake, outfall, and desalination plant options and include analyses of several different intake locations, desalination plant locations, larger projects and reduced project sizes (see also EIR/EIS Section 5.4). Each alternative, regardless of whether the intakes and desalination plant would be operated by CalAm, would provide water to CalAm's service area, and in some instances, would provide water to an extended regional water supply area (e.g., see Alternative 3 in EIR/EIS Section 5.4.5). Furthermore, Alternatives 5a and 5b would include a reduced capacity desalination plant of 6.4 mgd, with an additional 3,500 afy of recycled water from the GWR Project purchased by CalAm. These alternatives represent collaboration with other water suppliers; furthermore, Alternative 5a was determined to be the Environmentally Superior Alternative/Preferred Alternative in the EIR/EIS. Thus, the EIR/EIS has considered more than just the CalAm "go-it-alone" or open water intake.

MCWD-189 Figure 5.1 in Appendix E2 represents the cells of the $NMGWM^{2016}$ that were modified to include the re-distribution of constant head values associated with sea level rise, and is not presented to indicate impacts from flooding; EIR/EIS Figure 4.3-3 presents the areas subject to flooding from sea level rise in the year 2100. See also response to Shriner-6.

MCWD-190 As noted in several responses, nothing in the Final EIR/EIS represents significant new information that would trigger recirculation of the Draft EIR/EIS. As noted in Master Response 6, The Sustainable Groundwater Management Act, Section 8.2.6.2, for example, the Marina Subarea is not a DWR-recognized designation, and the hydrogeological conditions do not justify this designation. See response to comment MCWD-84.

The commenter refers to CEQA's requirements to recirculate a draft EIR for an additional round of public review and comment, and urges that the Draft EIR/EIS be recirculated. While some new information has indeed been added to the EIR/EIS in order to amplify or clarify the data within the Draft EIR/EIS, none of such new

data implicates new or substantially more severe significant environmental impacts than were shown in the Draft EIR/EIS, nor does it indicate that there are feasible alternatives or mitigation measures available that would minimize significant effects but that the project proponent declines to embrace. In addition, the Draft EIR/EIS was comprehensive and robust, and the Lead Agencies do not believe that it was fundamentally flawed in any way. For these reasons, recirculation of the Draft EIR/EIS is not required. Furthermore, the Draft EIR/EIS was itself a revised, updated and enhanced version of the Draft EIR that was published by the California Public Utilities Commission for the MPWSP in April, 2015. The environmental review for the MPWSP has entailed a lengthy process with multiple opportunities for public review and comment.

MCWD-191 See all the previous responses to comments MCWD-1 through MCWD-190 that address the comment.

8.5.2.2 Responses to Comments from MWCD – Hopkins Groundwater Consultants (HGC)

These responses address comments provided by Hopkins Groundwater Consultants, Inc. (HGC) on the Groundwater Resources section of the MPWSP EIR/EIS, dated March 29, 2017. Due to the organization and format of the HGC Technical Memorandum, and the amount of repetition in the HGC comments, these responses have been arranged thematically based on several primary topic areas. The HGC-identified comment numbers that pertain to the topic area, are listed within the response to each relevant topic area.

MCWD-HGC-1 ***Water Rights, Return Water, SGMA***

HGC submitted several comments on CalAm water rights, return water, Agency Act, the method that return water was calculated, and the Ocean Water Percentage (OWP) in the feedwater. Supplemental information to clarify these topics has been prepared and is available in several Master Responses and in EIS/EIR Appendix E3, as listed below:

- **Master Response 3, Water Rights,** among other topics, addresses comments regarding the legal framework of return water, harm and injury, effects of the proposed MPWSP on MCWD, the Annexation Agreement, Agency Act/Ordinance 3709, surplus water, and legal considerations regarding the quality of basin water. Pertains to HGC comments 1, 2, 4-6, 8-10, 12, 24, 30, and 40;
- **Master Response 4, The Agency Act and Return Water,** provides further clarification regarding the Agency Act and location of return water, return water quantities, the Ocean Water Percentage (OWP) calculations, and legal aspects of the return water. Pertains to HGC comments 3, 4, 10, 11, and 22;
- **Master Response 6, The Sustainable Groundwater Management Act (SGMA)**, provides clarification regarding the SGMA and its application to

the MPWSP. Pertains to HGC comments 1, 7, 8, 22, 27, 35, 36, 39, and 42, and;

- **EIR/EIS Appendix E3, Hydrogeologic Investigation Report**, provides a description and technical justification for the calculation of the OWP as it applies to return water. Pertains to HGC comments 1, 3, 9, 22, and 29**.**

MCWD-HGC-2

Existing Seawater Intrusion in the Salinas Valley Groundwater Basin (SVGB)

Pertains to HGC comments 3, 16, 20, 29, and 41. HGC repeatedly asserts that the EIR/EIS mischaracterizes the existing seawater intrusion in the SVGB that was identified in the 1940s and has been monitored for many years by the Monterey County Water Resources Agency (MCWRA). Contrary to HGC's assertion (Page 2 of HGC TM), the EIR/EIS does not suggest that "the shallow aquifers along the coastline around the CEMEX site are fully intruded by seawater and the groundwater in the project area of the SVGB consists almost entirely of highly saline seawater that extends up to 8 miles inland." EIR/EIS Section 4.4.1.4 describes current seawater intrusion in the coastal area of the SVGB and explains that brackish to saline groundwater can contain concentrations of total dissolved solids (TDS) that range from 33,500 milligrams per Liter (mg/L) at the coast to 500 mg/L near the inland seawater intrusion front and that brackish water in the 180-FTE aquifer near the proposed MPWSP ranges from 5,000 mg/L to 29,000 mg/L. These ranges of TDS concentration do not describe "fully intruded" shallow aquifers with "highly saline seawater that extend up to 8 miles inland." The analysis of seawater intrusion in the EIR/EIS is based on the annual MCWRA monitoring program and resulting seawater intrusion maps that show the inland advance of the seawater intrusion front. These maps are provided in the EIR/EIS as Figures 4.4-10 and 4.4-11. The analysis recognizes that localized areas of lower TDS concentrations would be expected in areas predominantly intruded by seawater due to the heterogeneity of the water transmitting and storage properties of the sediments. EIR/EIS Section 4.4.5.2, correctly concludes that the MPWSP would extract primarily seawater and a smaller volume of brackish groundwater from a zone that has been degraded by seawater intrusion (over 23,000 mg/L) and therefore, would not be suitable as a potable supply due to the high salinity. This topic is discussed further in the section below that discusses the purported areas of fresh groundwater in the Dune Sand and 180-FTE Aquifer.

Additional clarification of this topic is in Master Response 8, Project Source Water and Seawater Intrusion, which discusses the water chemistry in the feedwater capture zone. Master Response 9, Electrical Resistivity Tomography (ERT) and Airborne Electromagnetics (AEM), Section 8.2.9.3, provides additional discussion regarding the findings from the May 2017 AEM survey conducted for MCWD by Stanford University's Dr. Rosemary Knight. AEM survey results help interpolate between control points provided by the MPWSP monitoring network and confirms the work completed for the MPWSP hydrogeologic investigation. EIR/EIS

Appendix E3, Hydrogeologic Investigation Report, Section 1.4.5, provides additional discussion of the seawater intrusion and use of intruded groundwater as feedwater for the MPWSP slant wells.

MCWD-HGC-3

"Marina Sub Area"

MCWD and HGC make repeated references to the "Marina Subarea." HGC acknowledges in its comment letter that this is not a DWR-recognized designation but claims that the hydrogeological conditions justify such designation for their discussion purposes: while the physical boundaries of the "Marina Subarea have not been mapped, in MCWD's characterization, it is the combined area that includes portions of the 180-Foot and 400-Foot Aquifer Subbasin (DWR Basin 3-004.01) located south of the Salinas River and the northwest portion of the Salinas Valley Monterey Subbasin (Basin 3-004.10)." MCWD and HGC claim that the "Marina Subarea" is the coastal subarea north of the over-drafted SVGB and the area that would be directly impacted by the MPWSP slant well pumping. However, the hydrogeological conditions of the area potentially affected by the MPWSP, as described in EIR/EIS Section 4.4, Groundwater Resources, do not justify or support this designation. The term "Marina Subarea" as defined by HGC is not based on or consistent with the accepted definitions of basins in the SVGB and its identification as a distinct groundwater basin appears to have originated with HGC. In a hydrogeologic sense, the area identified as the Marina Subarea is simply part of a continuous, hydraulically connected portion of the 180/400-Foot Aquifer subbasin of the SVGB. The "Marina Subarea" and its relationship to the MPWSP project are discussed further in Master Response 6, The Sustainable Groundwater Management Act.

MCWD-HGC-4

Slant Well Screen Length

Pertains to HGC comments 11, 12, 14, and 23. HGC asserts that the proposed MPWSP slant wells would need to extend under the ocean to be effective at extracting a high percentage of seawater. HGC attributes the length of the test slant well, which was shorter than planned, to drilling problems. Both assertions are incorrect. The well screens beneath the beach would be as effective in extracting a high percentage of seawater as wells screened a couple of hundred feet further under the ocean. As explained in EIR/EIS Appendix E3, while placement of production well screens closer to or under the ocean may achieve the maximum OWP in the first few months and a very slight increase in the medium-term OWP, a difference of a few hundred feet in screen placement relative to the ocean boundary would have minimal overall effect on OWP because of the volume of seawater at the recharge boundary. The proposed MPWSP slant wells would extend as far offshore as possible, while keeping the well screen above the 180/400-Foot Aquitard; see EIR/EIS Section 3.2.1.1, Table 3-2 and Figure 3-3b. In the Dune Sand Aquifer, the slant wells would be placed at 14 degrees below

horizontal through a vertical saturated thickness of 60 feet and would penetrate about 250 lineal feet. Assuming a well efficiency of 70 percent and a drawdown of 35 feet below static level, the Dune Sand Aquifer screen interval should produce 600 to 1,000 gallons per minute (gpm). The proposed MPWSP slant well screens in the 180-FTE Aquifer would transect a vertical thickness of approximately 100 feet in the 180-FTE Aquifer, achieving a completion length of over 400 feet, with an anticipated production rate of 1,200 gpm at a 70 percent well efficiency (HWG, 2017). This is discussed in detail in EIR/EIS Appendix E3, Section 4.0.

CalAm initially proposed to drill the test slant well a total length of 1,000 lineal feet at an angle of 19 degrees below the horizontal. The drilling methodology selected was appropriate and capable of reaching the target depth. A decision was made by CalAm to end the pilot hole drilling at a final target length of 724 feet, to allow enough time to complete well construction and development before equipment was required to be removed prior to the Snowy Plover nesting season. It is important to note that at 724 feet, the dual-rotary drilling and casing advancement was proceeding smoothly and could have continued, barring environmental permit scheduling constraints (EIR/EIS Appendix E3). Details of the test slant well permitting, construction and operation are provided in Master Response 11, CalAm Test Slant Well.

MCWD-HGC-5

"Protective" Groundwater Flows

Pertains to HGC comments 5, 15, 16, 18, 24, and 29. Inherent in the comments presented by HGC is the claim that the MPWSP would interfere with and negatively impact the ability of "fresh" groundwater to continue to "protect" the Dune Sand and 180-Foot Aquifers from seawater intrusion. HGC proposes the theory that shallow perched/mounded "freshwater" that flows atop the Fort Ord-Salinas Valley Aquifer and waterfalls into the Dune Sands Aquifer and 180-Foot Aquifer provides fresh groundwater that protects these aquifers from seawater intrusion. However, this is unsupported because these freshwater flows from the shallow perched/mounded aquifers have been occurring for many years and seawater intrusion has continued to advance inland, regardless. Secondly, the shallow groundwater perched/mounded in the Fort Ord area is high in Total Dissolved Solids (TDS), high in nitrate, and is in limited quantity in terms of water supply. Furthermore, the claim by HGC that the proposed MPWSP pumping at the CEMEX site would hinder the ability of this "protective flow" to reduce seawater intrusion is unfounded because the area where these freshwater flows enter the Dune Sand Aquifer and/or the 180-FTE Aquifer is 1.5 miles inland of the MPWSP slant wells; too far inland to be affected by the slant well capture zone of the proposed MPWSP. See Master Response 8, Project Source Water and Seawater Intrusion.

MCWD-HGC-6

Conservation and Restoration Efforts in 180-Foot Aquifer

Pertains to HGC comments 3 and 29. HGC refers to conservation and groundwater restoration efforts in the 180-Foot Aquifer in what it refers to as the "Marina Subarea" (discussed above) and suggests that groundwater quality has been restored with protective groundwater levels due to the "prohibition of pumping along the coastal portion of the SVGB." Ceasing groundwater pumping in the 180-Foot Aquifer and transferring MCWD pumping to the deeper aquifers was done out of necessity (see Master Response 7, Deep Aquifers of the SVGB, Section 8.2.7.1) and was not, as HGC suggests, a deliberate effort by MCWD to restore that aquifer. MCWD began pumping the 180-Foot Aquifer, but stopped when those wells became intruded by seawater. It then tapped into and pumped from the 400-Foot Aquifer until those wells became intruded by seawater. MCWD was then forced to explore the water bearing sediments of the deeper aquifers to find a fresh groundwater source (Feeney and Rosenberg, 2003). The proposed MPWSP would extract highly brackish to saline water from the slant well capture zone at the coast, which would be recharged by seawater infiltrating through the coastal terrace deposits. The slant wells would not draw groundwater from inland groundwater sources beyond its capture zone.

MCWD-HGC-7

Cone of Depression versus the Capture Zone

Pertains to HGC comments 5-7, 15, 29, 30, 34, and 36. HGC incorrectly compares water quality impacts of the MPWSP with the area exhibiting groundwater level changes within the cone of depression (also referred to as the area of influence), as projected by the NMGWM^{2016}. The cone of depression created by the proposed slant well pumping, as discussed in EIR/EIS Section 4.4.5.2, is the area delimited by groundwater level draw down of 1-foot or more. There is a considerable difference between the cone of depression and the "capture zone" of the project, as explained in Master Response 8, Project Source Water and Seawater Intrusion, Section 8.2.8.1. Groundwater level impacts depend on the size and geometry of the cone of depression, while groundwater quality impacts are dependent on the capture zone. The MPWSP would be drawing source water through the slant wells from an area close to the coast. The extent of the capture zone would be confined to an area adjacent to the coast of Monterey Bay (generally west of Highway 1), as discussed in Master Response 8 and shown in Figures 8.2.8-1 and 8.2.8-2. No negative groundwater quality impacts would occur within the portion of the cone of depression that is beyond and inland of the capture zone because incoming seawater would be providing the majority of the feedwater to the MPWSP slant wells.

HGC incorrectly suggests that drawdown in the onshore portion of the aquifer beyond and inland of the MPWSP slant well capture zone would be a cumulative effect that would contribute to a greater onshore gradient and increase the seawater

intrusion into those portions of the SVGB. The North Marina Groundwater Model version 2016 ($NMGWM^{2016}$) particle-tracking results presented in EIR/EIS Appendix E2, Figure 5.7 and Figures 8.2.8-1 and 8.2.8-2 presented in Master Response 8, show that onshore drawdown has the opposite effect; it reduces the onshore gradient beyond the capture zone, which retards the inland movement of the saltwater intrusion front. In other words, particle tracking results indicate that, in relation to present-day conditions, gradients would decrease east of the capture zone, eastward moving groundwater would slow, and the rate of seawater intrusion would decrease as a result of proposed project pumping. It is important to note that the capture zones shown in Figure 5.6 of Appendix E-2 include a range of inland gradients based on measured water levels. These capture zones consider the inland gradient, and, therefore, delineate that area along the coast where seawater intrusion would be intercepted and captured by the pumping wells.

MCWD-HGC-8

Characterization of Dune Sand Aquifer

Pertains to HGC comments 16-18, 37, and 38. As discussed in the EIR/EIS Appendix E3, Section 2.1.7, there are important distinctions between the Dune Sand Aquifer and its equivalents (-2-Foot Aquifer encountered in the Monterey Peninsula Landfill area and the "Perched A' in the Salinas Valley), described in the EIR/EIS, Section 4.4.1.2, as opposed to the 35-Foot Aquifer in the Monterey Peninsula Landfill area and the A-Aquifer in the Fort Ord Area (hereafter referred to as the shallow perched/mounded aquifers). The shallow perched/mounded aquifers in the Fort Ord area overlie the Fort Ord-Salinas Valley Aquitard (FO-SVA). Wells from the Dune Sand Aquifer and its equivalents cannot be considered correlative with wells from the shallow perched/mounded aquifers because these are two separate and disconnected aquifers. The shallow perched/mounded aquifer is of limited extent, which results in the water from that aquifer flowing over the edge of the underlying clay layer (similar to a waterfall) into the deeper Dune Sand Aquifer and equivalents, or the 180-Foot Aquifer, depending of the hydrostratigraphy at the particular location. This effect is the same as described in the *Protective Groundwater Flows* section above. However, this occurs about 1.5 miles inland of the coast and, therefore, would not be affected by the proposed MPWSP pumping.

HGC apparently interprets the local hydrogeology at monitoring well MW-5S by inferring that the Dune Sand Aquifer is perched on a regional clay layer and that MW-5S is screened in the Dune Sand Aquifer. But monitoring well MW-5S is screened in a perched aquifer and not the Dune Sands Aquifer; it is screened in a localized water bearing zone underlying the Monterey Peninsula Landfill, referred to as the 35-Foot Aquifer. MW-5S was completed in the uppermost saturated unit but, at that location, the uppermost saturated unit is at a higher elevation and is not correlative with the shallow interval in the other MPWSP monitoring wells. That is why monitoring well MW-5S is identified as MW-5S(P), with the "P" indicating that the well is monitoring an upper perched/mounded aquifer.

HGC states that CalAm's monitoring well MW-5S has a water surface of approximately 35 feet above sea level. However, it is not possible for seawater intrusion to flow uphill at that location. This statement confirms the argument that any fresh water from the shallow perched/mounded aquifer in the Fort Ord A-Aquifer or the 35-Foot Aquifer at the landfill would not be impacted by MPWSP pumping and would continue unimpeded to its final destination.

HGC prepared a groundwater elevation contour map of the Dune Sand Aquifer as Figure 6 in the March 27, 2017 TM. In preparing the groundwater contour map, HGC apparently combined groundwater elevation data from the Dunes Sand Aquifer (MW-1S, MW-3S, MW-4S, MW-7S, MW-8S, and MW-9S), its equivalents (-2-Foot Aquifer encountered in the Monterey Peninsula Landfill area and the "Perched A' in the Salinas Valley), the 35-Foot Aquifer in the Monterey Peninsula Landfill area, and the shallow perched/mounded aquifers. The contour map produced by combining these data points implies that the Dune Sand Aquifer and the perched aquifers form one single aquifer mounded on the FO-SVA and that groundwater flows out toward the Monterey Bay to the west and the Salinas River to the east. Proper contouring using corresponding groundwater elevation data would result in accurate contours that show groundwater in the Dune Sand Aquifer flowing inland from the Monterey Bay. The HGC contour map misrepresents the available groundwater data and appears contrary to the hydrogeologic conceptual model for this area, developed and agreed upon by the community of hydrogeologists, including the experts in the Hydrogeologic Working Group.

MCWD-HGC-9

Purported Existence of Fresh Water in "Marina Subarea"

Pertains to HGC comments 3-5, 9, 10, 15, 16, 18, 19, 22, 29, 34, and 36. HGC asserts that the EIR/EIS inaccurately characterizes the groundwater quality in the area affected by the proposed MPWSP slant wells. HGC contends that there are areas of "fresh" groundwater within what is referred to as the "Marina Subarea" (discussed above), which the proposed MPWSP would impede upon and degrade. HGC relies on groundwater chemistry data CalAm collected from its eight groundwater monitoring wells in February 2015. This section addresses HGC's apparent misconception that lower chloride and TDS concentrations identified in CalAm's wells can be equated with the areas of "freshwater," as shown in Figures 1 and 2 of the HGC Technical Memorandum, dated March 29, 2017. HGC appears to have been selective in using the groundwater quality data points from five groundwater well locations spaced a mile or more apart, and randomly extrapolated regions claiming there are areas of "fresh" groundwater without any consistent correlation to the available groundwater quality data. These regions of purported "fresh" groundwater are located between Highway 1 and the Salinas River on Figures 1 and 2 of the HGC TM and are labelled as "Areas of [Dune Sand Aquifer]/[180-Foot Aquifer], Filled With Freshwater." As explained below, HGC characterization of areas of "freshwater" is inaccurate and misrepresents the available groundwater quality data.

Accurate interpretation of groundwater chemistry data for characterization of seawater intrusion requires an understanding of the changes that occur to chloride, sodium, and calcium concentrations in the groundwater. Seawater contains high concentrations of chloride and elevated or steadily increasing chloride concentrations are a common indicator of the onset of seawater intrusion. However, at low chloride concentrations, trends must be considered as well as absolute concentrations because it is a prolonged process and takes time for chloride concentrations to increase and trends to be recognizable (HydroMetrics, 2016). Seawater contains more sodium than calcium. During the early stages of seawater intrusion, the concentrations of calcium can increase because sodium attaches to the geologic materials in the aquifer and replaces calcium (a process called cation exchange), thereby removing sodium from the groundwater. The exchange of sodium for calcium lowers the sodium/chloride ratio as the seawater front progresses inland. Therefore, low concentrations of chloride may not necessarily indicate groundwater that has not been intruded with seawater, but could indicate incipient seawater intrusion as the front approaches. The latter is the case in the MPWSP project area.

HGC chose to use CalAm monitoring well clusters MW-5, MW-6, MW-7, and MW-8 as indicator wells to establish the areas of "fresh" groundwater. The monitoring well locations are shown in EIR/EIS Figure 4.4-9. HGC also used two Monterey Regional Water Pollution Control Agency (MRWPCA) wells as a data point representing water quality in the 180-Foot Aquifer. HGC reported average concentrations of chloride in the shallow and mid-range monitoring wells in each cluster. The chloride concentrations used by HGC to support "fresh" groundwater range from 67 milligrams per Liter (mg/L) in monitoring well MW-6S to 387 mg/L in the monitoring well MW-7S. Chloride data was not available for the MRWPCA well. As discussed in EIR/EIS Section 4.4.1.4 and Master Response 8, Project Source Water and Seawater Intrusion, the California Secondary Maximum Contaminant Level (MCL) for chloride is 250 mg/L (Cal. Code Regs., tit. 22, § 64449). Of the monitoring wells sampled by CalAm in February through June 2015, only five monitoring wells (MW-5M, MW-6S, MW-6M, MW-8D, and MW-9D) had concentrations of chloride below California's Secondary MCL of 250 mg/L. All other monitoring wells, 18 in total, within and proximate to the MPWSP capture zone exceeded the 250 mg/L chloride threshold. The data does not indicate areas of "fresh" groundwater as HGC asserts; rather, it shows, as discussed below, that certain wells are located within groundwater zones of varying stages of seawater intrusion.

As discussed above, seawater intrusion is a prolonged process and the concentrations of sodium, calcium, and chloride can be an indicator of incipient or established seawater intrusion. CalAm monitoring wells MW-1S, MW-1M, MW-3S, MW-3M, MW-4S, MW-4M, MW-8D, MW-8M, MW-9S and MW-9M have elevated sodium and chloride concentrations that suggest middle to late stages of seawater intrusion. CalAm monitoring wells MW-6M(L), MW-7S, and MW-7M exhibit calcium and chloride concentrations indicative of the early to mid-stages of

seawater intrusion. As discussed above, monitoring well MW-5S(P) is screened in a shallow perched aquifer, and is not correlative to conditions in the Dune Sands Aquifer. Sample results for monitoring well MW-5M showed relatively low concentrations of calcium and chloride. This is not, as implied by HGC, indicative of fresh water but more likely due to one or all of the following: 1) well screen length and placement; 2) differences in hydraulic heads resulting in ambient groundwater flow from the top of the screen to lower portions of the wells, and; 3) the shape of the seawater intrusion wedge and more saline conditions deeper in the aquifer zone.[11] Lower to moderate chloride concentrations reported in MW-6S and MW-6M are likely due to the location of the monitoring well ahead of the leading edge of the seawater intrusion wedge in the 180-Foot Aquifer. This is supported by the more elevated chloride concentration in the deeper well of the cluster [MW-6M(L)].

HGC also correlated TDS concentrations in the select monitoring wells to support the claim that "fresh" groundwater was present in the area between the MPWSP slant well site and the Salinas River. As was the case with chloride concentrations, the TDS concentrations were averages obtained from CalAm's 2015 sampling of groundwater monitoring wells (MW-5, MW-6, MW-7, and MW-8) and two MRWPCA wells. The TDS concentrations cited by HGC ranged from 350 mg/l TDS in one of the MRWPCA wells to 1,200 mg/L TDS in MW-4S. As discussed in EIR/EIS Section 4.4.1.4 and Master Response 8, Project Source Water and Seawater Intrusion, the California Secondary MCL for TDS is 500 mg/L (Cal. Code Regs., tit. 22, § 64449). Only the one groundwater sample from the MRWPCA well is under the 500 mg/L, all other TDS concentrations in the Dune Sand Aquifer and 180-FTE Aquifer in HGC's purported area of fresh groundwater, exceed the State Threshold. As discussed above for chloride, the concentrations of TDS detected in the CalAm monitoring wells do not indicate the presence of areas with "fresh" water, as HGC asserts, but indicate incipient seawater intrusion.

Furthermore, it is important to note that the proposed MPWSP slant wells would affect water quality within the capture zone but not in the larger cone of depression, as discussed in Master Response 8, Project Source Water and Seawater Intrusion. Consequently, even if the purported areas of "fresh" groundwater identified by HGC east of Highway were actually viable sources of potable water, they would not be impacted by slant well pumping because they are inland of the capture zone.

[11] Seawater intrusion typically advances inland in a "wedge" shape where the denser, more saline water is deeper in the aquifer zone and advances forward of the less dense saline water toward the top of the aquifer zone. For this reason, incipient seawater intrusion is commonly first detected in the deeper wells of an aquifer, before the shallower wells are impacted.

MCWD-HGC-10

Test Slant Well Salinity and CEMEX Wash Water

Pertains to HGC comments 15, 19, 33, and 36. HGC asserts that test slant well salinity is artificially increased due to CEMEX wash water recharging in nearby ponds. However, the opposite effect on the test slant well is occurring. Recharge water causes the salinity in the test slant well to decrease because dredge sand is processed with well water, which has a significantly lower salinity than the seawater, although it is still highly brackish. Consequently, the average TDS of the water recharging the groundwater near the test slant well is much lower in TDS than the seawater. In addition to sand washing operations, infiltration of precipitation also causes the salinity in the test slant well to decrease, as discussed in EIR/EIS Appendix E3, Section 2.1.7.4.

MCWD-HGC-11

Groundwater Cumulative Analysis

Pertains to HGC comments 31, 34, 35, and 39. See responses to comments MCWD-106, and LWMC-14 through LWMC-19 in Section 8.6.13 regarding the cumulative analysis of groundwater resource impacts of the MPWSP.

MCWD-HGC-12

HGC Comments on Mitigation Measures Prescribed in EIR/EIS Section 4.4

Pertains to HGC comments 7, 8, 10, 34, 35, 37, 38, and 40. See responses to comments MCWD-103 and MCWD-104, as well as CEMEX-11 and CEMEX-12 in Section 8.6.6.

MCWD-HGC-13

Application of the NMGWM^{2016}

Pertains to HGC comments 1, 4-6, 15, 25, 26, 28, 30-32, 34, 35, 38, 39, 41, and 42. HGC had several comments on the application and use of the NMGWM^{2016} as an analytical tool to evaluate impacts of the MPWSP. The groundwater model is described in EIR/EIS Section 4.4.4.2 and Appendix E2; additional information and clarification on the application of this model is in Master Response 12, The North Marina Groundwater Model (v. 2016).

The NMGWM^{2016} and the Use of Superposition

The calibrated NMGWM^{2016} was not "abandoned and replaced with the inferior superposition model" because of "technical problems," nor was it poorly calibrated. HGC claims that the purported "technical problems" stemmed from a lack of data on the hydrogeology and aquifer recharge mechanisms used by the U.S. Geological Survey in the Salinas Valley Integrated Ground and Surface Water Model (SVIGSM); the U.S. Geological Survey did not develop the SVIGSM. The "superposition model," as referred to by HGC and utilized for the MPWSP analysis, is an application of the NMGWM^{2016}. Superposition is a scientifically

valid, well-documented and routinely employed tool for solving complex problems, and enabled the efficient simulation of slant well pumping drawdown without having to correct the problems associated with pumping and recharge inputs derived from SVIGSM. The method of superposition was implemented to remove model bias due to deficient input data inherited from the SVIGSM, to calculate slant well pumping drawdown directly, and to provide for more transparent model results. The superposition approach is widely used (see Draft EIR/EIS Appendix E2, Section 5.2, Footnote 82, for examples of the use of superposition for solving groundwater problems), and the outputs it provided are the model-calculated water level and flow changes due solely to slant-well pumping. Superposition is employed to isolate the expected change in groundwater levels and fluxes due solely to the slant wells. These changes are additive to future changes that would occur as the net result of all other recharge and discharge processes in the basin. In other words, the superposition model results are simply added to the net effects from all other recharge and discharge processes in the basin to calculate the cumulative effect.

HGC incorrectly asserts that the superposition model fails to evaluate potential future cumulative conditions and that it would not be possible to evaluate impacts on wells tied to the MPWSP. Additionally, HGC states that the NMGWM^{2016} cannot determine the impact of the project on future basin management efforts planned to improve the groundwater conditions in the SVGB. As noted above, superposition is employed to isolate the expected changes and these changes are additive to future changes that occur as the net result of all other recharge and discharge processes in the basin. Any model-calculated drawdown due to proposed slant well pumping can be overlain or integrated with future basin management scenarios. Monitoring can provide information about the impact on future basin management efforts. For example, Figure 4.6 in Appendix E2 is an example of where superposition model results are compared to measured water levels collected in real-world monitoring wells. Figures 3.3a, 3.3b, and 3.3c in Appendix E2 show that aquifer parameters in the Fort Ord vicinity fall within the reported range of values from other sources. See Master Response 12, The North Marina Groundwater Model (v. 2016).

Applicability and Reliability of the NMGWM^{2016}

There are several instances where HGC claims that the NMGWM^{2016} is not an adequate groundwater model because it does not predict changes in water quality. The NMGWM^{2016} was not constructed or employed to calculate changes in water quality and water density due to the mixing of ocean water and groundwater. The use of equivalent freshwater head to represent seawater, and the constant groundwater density assumption to calculate the drawdown extent is a reasonable and appropriate approach and the error these approximations introduce is small relative to the uncertainty in other more influential factors like the specified pumping rates, return water volumes, projected sea levels, aquifer parameter values, and the relative

contributions of multiple aquifers to total slant well production (see EIR/EIS Appendix E-2, Section 6.0 Uncertainty, and Master Response 12, The North Marina Groundwater Model (v. 2016), for more information.

HGC claims that the NMGWM^{2016} is unreliable, which appears to be based on a misunderstanding of the NMGWM^{2016} and the use of superposition. As described below, HGC incorrectly assumes that modelers attempted to incorporate a "semi-perched layer of fresh water" in the Dune Sand Aquifer but were unsuccessful. Furthermore, HGC is incorrect in its assessment that the comparison between simulated results with observed groundwater level elevations produced model error in the Dune Sand Aquifer (Model Layer 2) on the order of 30 percent. The A-Aquifer (Model Layer 2 above the FO-SVA) was incorporated into the NMGWM^{2016} and improved model performance at MW-5S. Figure 4.2 in Appendix E2 shows the water level at MW-5S calculated by the NMGWM^{2015} (approximately 0 feet above mean sea level), is greatly improved following the update to the NMGWM^{2016} (approximately 29 feet, which is much closer to the measured value of 35 feet). The available data suggest that perched groundwater conditions and the corresponding poor model performance is limited to the southernmost portions of the Fort Ord area, whereas model performance is acceptable in the other portions of the Fort Ord area and where vertical gradients are less steep. Appendix E2 reported a Root Mean Square Error (RMSE) of 30.2 feet in Model Layer 2, and that included two perched wells (MW-BW-01-A and MW-OU2-29-A). As explained in Draft EIR/EIS Appendix E2 (pages 20-21), vertical gradients greater than 1.0 between Model Layer 2 and Model Layer 4 likely indicate an unsaturated zone between two saturated units. When these wells are excluded from the error statistics, the RMSE for Model Layer 2 decreases from 30.2 feet to 10.1 feet (the relative error decreases from almost 63 percent to about 16 percent).

HGC asserts that the EIR/EIS fails to evaluate the project's impacts on the semi-perched groundwater conditions within the Dune Sand Aquifer and the semi-confined conditions in the -2-Foot Dune Sand Aquifer and describes the failure as fatal to the ability of the EIR/EIS to adequately evaluate project impacts on groundwater. The area where perched groundwater conditions occurs appears to be of limited extent, and the model performs well in the remaining areas. The model's inability to simulate these conditions is therefore, not "fatal," and in fact the model performs well in the other areas. Furthermore, the primary purpose for the NMGWM^{2016} was to calculate drawdown in response to pumping, which depends primarily on the pumping rate, the water transmitting and storage properties of the aquifer, and any change in groundwater recharge or discharge that occurs solely as a result of that drawdown. The modeled and reported water transmitting and storage properties of sediments in the model domain compare favorably, and therefore, provide confidence in the drawdown calculated by the model. Indeed, the measured and model-calculated drawdown due to test slant well pumping plotted in Figure 4.6 of Appendix E2 agree well, and provide confidence in model performance. Lastly, the hydraulic conductivity values in the NMGWM^{2016} are

successful, as shown by the relatively low RMSE for the non-perched wells in Model Layer 2. These hydraulic conductivity values were developed from extensive review of the available hydrologic and geologic data.

HGC states that the recalibrated NMGWM^{2016} was not successful at providing shallow groundwater responses and is less representative of real world conditions than the NMGWM^{2015}. The NMGWM^{2016} successfully simulated the measured, real-world shallow groundwater response to test slant well pumping (see EIR/EIS Appendix E2, Figure 4.6). Moreover, in every test that compared model-calculations and "real-world" measurements, the NMGWM^{2016} was shown to be superior to the NMGWM^{2015}. The improvement is attributed to its better representation of "real world" conditions because of the substantial new borehole, water level, and aquifer test data considered and incorporated into the updated, NMGWM^{2016}. For example, Model Layer 2 represents the "Dune Sand Aquifer," "A-Aquifer," "Perched Aquifer," "Perched 'A' Aquifer," "35-Foot Aquifer," and "-2 Foot Aquifer." Similarly, Model Layer 3 incorporated the FO-SVA, and Model Layer 4 represents the "180-FT Aquifer," "180-FTE Aquifer," "Upper and Lower 180-Foot Aquifer," and "Pressure 180-Foot Aquifer." The geographic and hydrogeologic characteristics of these water bearing units are represented in the NMGWM^{2016} by almost 20 different zones assigned unique values for the water transmitting and storage property values derived from an extensive review and analysis of the existing data.

EIR/EIS Appendix E2, Section 4.0, explains model limitations which particularly influenced the discrepancies between measured and model-calculated water levels in the historical 1979-2011 run. The historical 1979-2011 run is another application of the NMGWM^{2016}. The history matching run (1979-2011) utilized all available wells within the model domain having historical water level measurements; south of the Salinas River, there are potential wells with data located in the Fort Ord Area, and monitoring well cluster sites having the longest water level data records were also utilized in the history matching run (cluster sites are where multiple wells monitor conditions in different aquifers). Additional well boring and aquifer test data were also incorporated into the conceptual hydrogeologic understanding of conditions south of the river and represented by the NMGWM^{2016}.

HGC claims that the NMGWM^{2016} was constructed with a landward gradient in the 180-Foot Aquifer and does not simulate the -2-Foot-Aquifer underlying the perched portion of the Dune Sand Aquifer. The NMGWM^{2016} does not contain a specific layer for the -2-Foot-Aquifer. Appendix E2, Table 2.1, shows that Model Layer 2 represents the shallow water-bearing sediments referred to as "Dune Sand Aquifer," "A-Aquifer," "Perched Aquifer," "Perched 'A' Aquifer," "35-Foot Aquifer," and "-2 Foot Aquifer." Model Layer 3 is utilized to represent the confining layer that separates these units from the underlying "180-FT Aquifer" or the equivalent units represented by Model Layer 4. Appendix E2 shows particle-tracking results calculated with the superposition NMGWM^{2016} and three imposed

gradients based on measured water levels (see Appendix E2, Figure 5.6, which delineates the area where particles placed beneath the coast line pass as they move to the slant wells).

HGC asserts that the EIR/EIS and modeling grossly understates the project's impacts using the superposition model and that a well-calibrated model is required to evaluate the impacts. Specifically, HGC asserts that it would be preferable to use a dual density model that uses components of the older Salinas Valley Integrated Groundwater Surface Water Model (SVIGSM) that can represent the "Marina Subarea". As discussed in Appendix E2, Section 4.1, the NMGWM^{2016} is comprised of 8 model layers and represents an approximately 149 square mile area that includes the City of Marina. The NMGWM^{2016} reasonably reproduces historical measured water levels throughout the model area, and utilizes all the recharge and discharge components from the older SVIGSM. The NMGWM^{2016} also included details to better represent hydrogeologic conditions south of the Salinas River and data collected for the test slant well project. None of this detailed information is lost when calculating the changes in water levels and groundwater flow using the NMGWM^{2016} and superposition approach. This is explained in further detail in Master Response 12, The North Marina Groundwater Model (v. 2016).

CEMEX Groundwater Model

HGC states that the modeling completed for the EIR/EIS relies on the CEMEX Model Update completed by Geosciences in 2016, and that its assumptions are unsupported and are based on the lack of available data. However, HGC does not specify the "unsupported assumptions" in the 2016 CEMEX Model Update. The NMGWM^{2016} update modified some parameter zones based on mapped geologic units associated with the dune sand, the older dune sand, and the clay zones associated with the FO-SVA. The parameter values for the modified zones are based on the 2016 CEMEX Model Update. Appendix E-2, Figure 4.6, shows a reasonable comparison between measured and model-calculated drawdown from the slant test well, and provides confidence in the updated zones and parameter values.

HGC states that the CEMEX model is too small to be used to project aquifer parameters across the NMGWM domain. The updated 2016 CEMEX model was not used to simulate regional effects. However, parameter values updated based on slant test well results were considered as part of the NMGWM^{2016} update. This is explained in EIR/EIS Appendix E2.

HGC claims that SVIGSM is inappropriately constructed in the project area and did not include boundary recharge into the Dune Sand Aquifer or the existence of the FO-SVA and cannot be used to feed realistic input into the NMGWM^{2016}. EIR/EIS Appendix E2 identifies the deficiencies of the SVIGSM, and explains how the NMGWM^{2016} was updated and superposition approach was employed to remove

these deficiencies. See Master Response 12, The North Marina Groundwater Model (v. 2016), for additional discussion.

HGC incorrectly states that there is limited regional data for model construction south of the Salinas River in the vicinity of the CEMEX site and that the initial field work and aquifer testing conducted for the Test Slant Well project has provided hydrogeological data indicating conditions that were not anticipated during construction of the model such as the semi-confinement of the 180-FTE Aquifer, mounded water in the Dune Sand Aquifer, confinement of the Dune Sand Aquifer along the river, and freshwater present in the 180-FTE Aquifer at MW-5. The updated NMGWM^{2016} utilized a substantial amount of available data south of the Salinas River near the CEMEX site, and the initial field work and aquifer testing conducted for the test slant well data. See Master Response 12, The North Marina Groundwater Model (v. 2016), for additional clarification.

Surface Water Features

HGC asserts that the impact assessment of surface water losses from the Salinas River and the Tembladero Slough/Reclamation Ditch are general and compared to annual conditions, and do not consider seasonal or climatic dry periods. HGC also states that EIR/EIS conclusions regarding the potential impacts on the Salinas River and the Tembladero Slough are inconsistent with its treatment of Elkhorn Slough in EIR/EIS Chapter 5, Alternatives. As described in the EIR/EIS Appendix E2, groundwater interaction with the Salinas River and the Tembladero Slough/Reclamation Ditch is simulated using the MODFLOW River Package. The River Package was used to simulate changes in river gains and losses in response to slant well pumping. The results from the superposition calculations are essentially independent of flow conditions – unless those flow conditions are such that the Salinas River and Tembladero Slough are dry. These effects are minor relative to the large stress of slant well pumping and likely have a minimal effect on the drawdown calculations. In contrast, Elkhorn Slough was appropriately simulated using general-head boundaries based on the understanding of the subsurface lithology. The general-head boundary in the NMGWM^{2016} has a modest effect on the model-calculated cone of depression, but that effect is insignificant for making drawdown comparisons between the CEMEX and Potrero Road Sites. See Attachment 2 of Appendix E2, and Master Response 12, The North Marina Groundwater Model (v. 2016), for additional explanation.

Miscellaneous Concerns Regarding Modeling

HGC claims that the NMGWM^{2016} cannot quantify the amount of seawater or fresh groundwater that will be produced and that hydraulic conductivity values assigned in the NMGWM^{2016} are not reliable. The hydraulic conductivity values assigned in the NMGWM^{2016} are based on extensive review and analysis of available data and therefore, considered reliable. The NMGWM^{2016}, therefore, provides a reasonable

representation of "real world" conditions because it is based on substantial borehole, water level, and aquifer test data.

HGC claims that based on work informed by analysis performed by GeoHydros, the proposed MPWSP would draw a substantial portion of groundwater during the first year and would significantly reduce groundwater storage within the "Marina Subarea." HGC states that the EIR/EIS must disclose the amount of groundwater that the MPWSP would deplete from the "Marina Subarea." The water extracted from any well would initially come from aquifer storage. The resulting decline in water levels (drawdown) is determined by the water transmitting and storage properties of the aquifer and changes in groundwater recharge or discharge that occurs solely as a result of that drawdown. In the situation where slant wells are employed near the ocean, that drawdown changes recharge and discharge conditions associated with the ocean, which represents a substantial source of recharge to the well. Hence, as time increases, the proportion of water extracted by the well that comes from aquifer storage diminishes substantially. See Master Response 8, Project Source water and Seawater Intrusion, for additional clarity on the MPWSP capture zone and source water. Furthermore, conclusions based on GeoHydros depletion analysis are based on a flawed application of superposition and an incorrect application of its results. See response to comments MCWD-GeoHydros, for additional information regarding the GeoHydros review of the HydroFocus modeling. Also, refer to Master Response 12, The North Marina Groundwater Model (v. 2016), and Master Response 4, The Agency Act and Return Water, and EIR/EIS Appendix E3 for information on the calculation of OWP in the MPWSP feedwater.

HGC questions the validity of the vertical hydraulic conductivity used in the $NMGWM^{2016}$ at the Potrero Road site and states that it is untested and not substantiated by production test data and is "2 orders of magnitude less than the CEMEX site estimate." HGC also states that while the horizontal hydraulic conductivity value was estimated at 2 times greater than the modeled value at the CEMEX site, the reduced vertical hydraulic conductivity indicates a confined/semi-confined condition. HGC claims that simulated aquifer parameter estimations by the $NMGWM^{2016}$ result in a reduced vertical flow from the ocean and reduced seawater infiltration, and therefore, the higher horizontal hydraulic conductivity, combined with reduced vertical flow, results in more groundwater production. Sediment texture graphs (see Figures 46 and 47 in EIR/EIS Appendix C3) suggest that the vertical hydraulic conductivity of the Dune Sand/Perched "A" Aquifer near Potrero Rd and Moss Landing range from 0.04 to 1.52 ft/d. The vertical hydraulic conductivity (K) value specified for the Model Layer 2 parameter zone that contains the Potrero Rd site (0.1602 ft/d) falls within this range. More detailed data at the Potrero Road site was not available. Additionally, the sensitivity tests reported in Appendix E2 both increased and decreased the anisotropy of this parameter zone by dividing and multiplying the vertical hydraulic conductivity value by 5. Hence, the anisotropy range included vertical hydraulic conductivity

values that ranged from 0.03 to 0.8 ft/d. The "groundwater production" simulated by the model was fixed by the proposed pumping rates defined by the operating scenarios and was not determined by the modeled hydraulic conductivity values. The results of those sensitivity runs are included in Appendix E2, Figure 6.4a and 6.4b, and show that the model-calculated cone-of-depression consistently extends a smaller distance offshore relative to the portion that extends inland, thereby indicating substantially more recharge occurs from seawater infiltration than from inland groundwater. The offshore extension beneath the ocean is consistently greater than the range for results mapped for the sensitivity tests conducted on the CEMEX site.

8.5.2.3 Responses to Comments from MWCD – GeoHydros

MCWD-GH-1

EIR/EIS Appendix E2, Table 3.1 summarizes modifications that were made to the $NMGWM^{2015}$ to improve overall model functionality and its correspondence with the conceptual model described in Appendix E2, Section 2.1; that model is herein referred to as $NMGWM^{2016}$ and was used in the EIR/EIS analysis. As explained in EIR/EIS Appendix E2, Section 3.0, updates to the $NMGWM^{2015}$ included adding the Fort Ord Salinas Valley Aquitard (FO-SVA), modifying aquifer parameter zones based on new boring and test slant well pumping data, and borehole and water level data available from Fort Ord documents. These changes did not "favor" the conceptualized flow, but were based on cross sections and monitoring well data points.

The $NMGWM^{2016}$ was used to calculate changes in groundwater levels (drawdown), and to delineate the area where drawdown (cone of depression) would be 1-foot or greater in response to proposed slant well pumping. Scenarios were developed to calculate drawdown and to assess its sensitivity (uncertainty) to model input and model assumptions. Groundwater "capture zone" boundaries were delineated using $NMGWM^{2016}$ steady-state flow condition results and particle tracking using the MODFLOW computer code post-processer MODPATH.

MCWD-GH-2

The commenter states that the "model boundaries are arbitrary and do not represent natural hydrologic divides therefore the model simulates flow across the external boundaries that cannot be verified from data." However, the $NMGWM^{2016}$ is based on the telescopic mesh refinement approach, where the model boundaries correspond with internal portions of the regional model; the regional model boundaries are defined by the physical limits of the aquifer. Hydraulic continuity is maintained between the two models using fixed heads. Specifically, the water levels simulated by the regional model along the internal boundaries corresponding to the outer edge of the $NMGWM^{2016}$ are extrapolated and assigned to the head-dependent flux boundaries at the outer edge of the $NMGWM^{2016}$. See Master Response 12, The North Marina Groundwater Model (v. 2016), for more information.

The model simulates flow across external boundaries which can be verified from data. The NMGWM[2016] is bounded on the west by the Pacific Ocean, and inland the model is bounded by adjacent portions of the Salinas Valley Groundwater Basin (Appendix E2, Figure 2.3). As described in EIR/EIS Section 4.4.4.2 (see EIR/EIS Figure 4.4-12), the model includes Elkhorn Slough to Prunedale on the north side, Prunedale to south of Salinas on the east side, south of Salinas to just north of the Fort Ord Dunes State Park on the south side, and extending approximately 5 miles into Monterey Bay to coincide with the western boundary of the SVIGSM (see EIR/EIS Appendix E2 Figure 2.2) since the Dune Sands Aquifer, the 180-Foot/FTE Aquifer and the 400-Foot Aquifer daylight a few miles offshore (see EIR/EIS Appendix C2, Figure 7a). The ocean boundary is represented using specified water levels equal to sea level which is easily verifiable. The specified water levels are referred to as "constant head boundaries" because they allow the model to simulate unlimited water flow in or out of these cells to maintain constant water levels throughout the simulation.

The movement of groundwater across the inland NMGWM[2016] boundaries is represented by "head-dependent flow boundaries" (denoted as general-head boundaries in Appendix E2, Figure 2.3). Head-dependent flow boundaries allow for water flow in or out of the model in proportion to the model-calculated water level at the boundary, a specified monthly water level external to the model boundary, and the specified subsurface water-transmitting properties. The specified external water levels at the NMGWM[2016] head-dependent flow boundaries were extrapolated from the distribution of monthly model-calculated water levels from the SVIGSM. These boundaries can also be verified with data.

MCWD-GH-3

The NMGWM[2015] and NMGWM[2016] both utilized equivalent freshwater heads, which are non-zero constant head values specified in the model. See Master Response 12, The North Marina Groundwater Model (v. 2016).

MCWD-GH-4

EIR/EIS Appendix E2 Section 4.3 explains the NMGWM[2016] was developed using the MODFLOW computer code, which does not consider variable density effects. The NMGWM[2016] employed equivalent freshwater heads to simulate the density contrast between seawater and the underlying groundwater. Using equivalent freshwater head is a common approach to mimic the water density contrast near ocean boundaries. Equivalent freshwater heads increase the water level in constant density models to account for the greater density of seawater. Comparisons between MODFLOW calculated water level changes and calculations using a variable density flow model (SEAWAT) indicated slight differences in calculated water levels (approximately one foot). These differences exist nearest the coast, where there is a measured difference in groundwater salinity ranging from seawater to freshwater. Near the coast, and where density effects are greatest, slant well pumping will have a much greater influence on water level changes and flow than

the spatial differences in salinity and water density. However, as the salinity concentration decreases with increasing distance from the coast, the differences in model calculated water levels diminish and become insignificant. The effects of variable density flow on NMGWM^{2016} model results were therefore, considered negligible, and a dual density model is not necessary. See also response to comment MCWD-87 and Master Response 12, The North Marina Groundwater Model (v. 2016).

EIR/EIS Appendix E2 Section 5.3 explains that slant well pumping effects on the inland movement of saltwater was assessed using the NMGWM2016 and MODPATH. Particles were placed along the edge of the inferred 2013 seawater intrusion front in the 180-FT Aquifer (Model Layer 4) and 400-FT Aquifer (Model Layer 6), as reported by MCWRA. Forward particle-tracking was then employed to show the change in front location after 63 years of slant well pumping. Without slant well pumping, the particles representing saltwater would continue to migrate inland. With slant well pumping, the movement of saltwater is in response to the regional background gradient and drawdown created by slant well pumping. We therefore utilized the superposition NMGWM2016 without the regional gradient to isolate changes in saltwater movement due solely to slant well pumping. The change in particle locations initially placed at the seawater interface represent the change in saltwater location relative to its inland location due to continued background recharge, pumping and regional gradients (e.g., the acceleration or retardation of existing saltwater intrusion).

MCWD-GH-5

The NMGWM^{2016} is based on the telescopic mesh refinement approach, where a relatively coarse model grid is utilized to represent the regional groundwater system defined by the physical limits of the aquifer, and a second model having a relatively fine grid is utilized to represent a sub-region of the aquifer. Continuity between the two models is maintained using either specified heads, or fluxes. The NMGWM^{2016} is a more accurate representation of the hydrostratigraphic framework in the Fort Ord area than the NMGWM^{2015} and SVIGSM, since it includes the A-Aquifer and Fort Ord Salinas Valley Aquitard (FO-SVA). As noted in Appendix E2 Section 4.1, the discrepancies in model-calculated water levels in Model Layer 2 are attributed primarily to deficiencies in SVIGSM initial water levels specified at the NMGWM^{2016} boundaries rather than the hydrostratigraphy represented by the model. The discrepancy in initial water levels that was introduced by SVIGSM and other problems inherited from the SVIGSM were removed by the use of superposition, and have no effect on superposition model results and simulation of the drawdown effects of slant well pumping. Errors in the vertical gradients between model-calculated water levels are attributed to limitations in MODFLOW's ability to simulate perched conditions. For more information, see Master Response 12, The North Marina Groundwater Model (v. 2016).

MCWD-GH-6

EIR/EIS Appendix E2, Section 4.0, documents that the NMGWM^{2016} utilized calibration wells in all four aquifers, and the NMGWM^{2016} reasonably represents the magnitudes, seasonal trends, and longer term trends in the measured water levels (see Appendix E2, Figures 4.1a and 4.1b). The NMGWM^{2016} recharge and pumping input files from the History Matching Assessment (see EIR/EIS Appendix E2, Section 4.1) include the historical river losses and gains due to the hydraulic interactions between groundwater, the Salinas River, and Tembladero Slough. In order to account for the changes in river gains and losses, the NMGWM^{2016} was modified as explained in EIR/EIS Appendix E2 Section 5.3. But the GeoHydros approach failed to account for these changes in groundwater-surface water interactions, and therefore, failed to account for the surface water losses that occur in response to the new pumping stress introduced by the slant wells. Therefore, the drawdown calculated by the GeoHydros approach is greater than reported in Appendix E2 and Figures 6-9 provided by the comment are not correct. Hence, the NMGWM^{2016} yields plausible hydraulic conditions in all four aquifers and the GeoHydros results are flawed and therefore, not credible for assessing the adequacy of the NMGWM^{2016} and the superposition approach. See Master Response 12, The North Marina Groundwater Model (v. 2016) and EIR/EIS Appendix E3.

MCWD-GH-7

Model Layer 2 (Dune Sand Aquifer) is not dry at the start of the simulation; therefore, it is "present." As identified in EIR/EIS Appendix E2, the initial heads inherited from the SVIGSM are too low in Model Layer 2. However, Model Layer 2 water levels increase to appropriate levels by the end of the calibration run, confirming the water storage and transmitting properties are reasonable. The superposition modeling approach utilizes the same water transmitting properties as the calibrated NMGWM^{2016}. For more information, see Master Response 12, The North Marina Groundwater Model (v. 2016).

MCWD-GH-8

See response to comment MCWD-GH-1. The NMGWM^{2015} did not include the FO-SVA, where in the real world, localized perching in the A-Aquifer (Model Layer 2 in the Fort Ord vicinity) can exist. Therefore, it is not unexpected for the simulated groundwater surfaces in Model Layer 2 to be different between NMGWM^{2015} and NMGWM^{2016}, otherwise there would be no reason to refine the modeled stratigraphy in this portion of the model. By the end of the historical model run, there is a mound beneath the Fort Ord area that slowly flattens into the CEMEX area. Groundwater-level contours generated from the A-Aquifer Fort Ord monitoring wells show similar mounding and gradients. The water levels inherited from the SVIGSM and specified for the southern-most general head boundary conditions are too low, and were removed for the slant well analysis using the method of superposition. For more information, see Master Response 12, The North Marina Groundwater Model (v. 2016).

MCWD-GH-9

The 400-Foot and 900-Foot/Deep Aquifers are hundreds of feet below the bottom of the ocean, and therefore, eastward (inland) groundwater movement in offshore portions of these aquifers is not derived in part from groundwater in storage and not directly from ocean water recharge. Groundwater also flows into the model from north and south inland areas, and an eastward gradient does not indicate that all inland freshwater has been replaced by saltwater. Appendix E2, Figure 4.1b, shows that the NMGWM^{2016}-calculated water levels generally agree with measured water levels in Model Layer 6 (400-Foot Aquifer) and Model Layer 8 (900-Foot/Deep Aquifer). Since these wells measure real world conditions, and model-calculated water levels generally agree with the real world, the model provides an adequate representation of measured water levels, gradient and direction. Using the model-calculated gradients and an estimated porosity of 0.1 for the 400-Foot and 900-Foot/Deep Aquifers, the calculated representative flow velocities are low and indicate a slow inland advancement of the submarine groundwater. For example, after 32 years the model-calculated submarine groundwater would advance a maximum of only 3,500 feet. Moreover, saltwater intrusion is a dynamic process, and although it has been occurring for decades in the basin, the intrusion process has not likely occurred uniformly in all aquifers. There are several examples from the scientific literature that describe the non-homogeneous nature of sea-water intrusion (e.g., Werner et al., 2013; Nishikawa et al., 2009; and Venhuizen, K.D., 1991).

MCWD-GH-10

The evaluation of model error described in Appendix E2 Section 4.1, utilized six (6) tests, and the tests are widely used and accepted within the groundwater modeling community. The decision to accept or reject a model depends in part on its performance under these multiple tests and also the intended application for which the model was created. A valid error comparison between two models must utilize the same wells and water level data. When the same wells and water level data are utilized, the summary of error statistics shows that the NMGWM^{2016} performance is superior to the NMGWM^{2015}. See Master Response 12, The North Marina Groundwater Model (v. 2016), for more information.

MCWD-GH-11

The Root Mean Square Error, or RMSE, of 30.2 feet in Model Layer 2 (see Appendix E2, Figure 4.3b) included the results from two Fort Ord wells that appear to be affected by perched conditions. As stated in Appendix E2, Section 4.1, "Errors at this model location are attributed to limitations in MODFLOW and its inability to simulate steep vertical gradients and perched conditions. This limitation appears to be localized, and model performance is acceptable in other portions of the Fort Ord Area where the vertical gradients are less steep." When these wells are excluded, the RMSE for Model Layer 2 becomes 10.1 feet.

A valid error comparison between two models must utilize the same wells and water level data. When properly conducted, RMSE comparisons indicate that the

NMGWM^{2016} is an improvement relative to the NMGWM^{2015}. Model performance improves in part because the NMGWM^{2016} is a more accurate representation of the hydrostratigraphic framework in the Fort Ord area than the NMGWM^{2015} and SVIGSM. The NMGWM^{2016} includes the A-Aquifer and the FO-SVA.

Problematic boundary and initial conditions were identified in Appendix E2 and their influence was removed by using the method of superposition. See Master Response 12, The North Marina Groundwater Model (v. 2016), for more details.

MCWD-GH-12 The errors at a specific location in the Fort Ord area are localized and model performance is acceptable in other parts of the Fort Ord area. Figure 4.1a in Appendix E2 confirms that the NMGWM^{2016} reasonably simulates water level changes in the Layer 2. The hydraulic conductivity values in the Fort Ord area fall within the range of reported values from multiple sources, including reported values from Fort Ord Area studies (see Appendix E2, Figure 3.3). This includes over 25 horizontal hydraulic conductivity estimates for the A-Aquifer (Model Layer 2) and six (6) vertical hydraulic conductivity values for the FO-SVA (Model Layer 3).

MCWD-GH-13 When employing a model to predict future conditions, the parameter sensitivity analysis identifies the hydraulic conductivity and storativity values that have the most influence on the predicted water level changes (parameter prediction sensitivity). Because the proposed project pumping would be an entirely new stress, the most sensitive prediction parameters are not necessarily going to be the same as the most sensitive calibration parameters (most often they are not). Hence, the prediction parameter sensitivity results provide little to no information about the reliability of the model calibration. The range of values employed for the sensitivity analysis provided conservative estimates of the possible range in model-calculated drawdown by slant well pumping, and the results provide little to no information about model calibration reliability. See Master Response 12, The North Marina Groundwater Model (v. 2016), for more details.

MCWD-GH-14 The historical model-calculated water budget (Appendix E2, Figure 4.5) shows that there is inflow into the model across the south boundary. The superposition approach sets the specified water levels at the boundaries to zero and calculates the change in inflow as a result of slant well pumping. Therefore, the relative differences in inflow from the northern, eastern, and southern boundaries are due entirely to the modeled water transmitting and storage properties of the aquifer materials and the new stress (slant well pumping). Model-calculated inflow in Model Layer 2 along the southern boundary is most influenced by the conductivity values for the A-Aquifer, which was specified based on reported values from other studies in the Fort Ord area (see Appendix E2, Figure 3.3). See Master Response 12, The North Marina Groundwater Model (v. 2016), for more details.

MCWD-GH-15 The NMGWM^{2016} was employed to calculate the water level decline (drawdown) in response to proposed project pumping, and was not constructed or employed to calculate changes in water quality and water density due to the mixing of ocean water and groundwater. The error introduced by the constant groundwater density assumption is relatively small because pumping has a much greater influence on water level changes (drawdown) than spatial differences in water density. See Master Response 12, The North Marina Groundwater Model (v. 2016), for more details.

MCWD-GH-16 The superposition method increases confidence in the predictions relative to previous modeling efforts. A key advantage of the superposition approach is the simulation of effects of one stress when other stresses are not well quantified. In this case, pumping and recharge are not well quantified for the Salinas Valley Groundwater Basin, and future climate, pumping, and recharge are predicted with even less accuracy. Thus, superposition is a superior approach compared to attempts at calibrating a regional model because the simulation of these unquantified stresses is unnecessary and the superposition approach can provide reliable information about the effects solely due to pumping. See response to comment MCWD-GH-17, and Master Response 12, The North Marina Groundwater Model (v. 2016), for more details.

MCWD-GH-17

(1) Superposition modeling does not preclude evaluation of changes to the water budget associated with the proposed pumping. As explained in EIR/EIS Appendix E2, Section 4.1, the computer code ZONEBUDGET was used to extract model simulated volumetric fluxes; monthly fluxes are summarized and reported as average annual water budget components for 1979-2011 in Figure 4.5. The water budget components from superposition modeling represent the net change in inflow and outflow of water within the boundaries and at the edges of the NMGWM^{2016}.

(2) Model-calculated drawdown due to slant-well pumping can be compared to measured drawdown to validate model predictions. EIR/EIS Appendix E2, Figure 4.6, shows measured vs. model calibrated drawdown in CEMEX monitoring wells during slant well pumping.

(3) The calibrated NMGWM^{2016} contains deficiencies in initial water levels, specified recharge and pumping, and boundary conditions that limit it from effectively performing and providing the information necessary for evaluation of this project. See response to comment MCWD-GH-5

(4) Appendix E2 Section 3.0 describes necessary revisions to the Geoscience model (NMGWM^{2015}) to improve agreement with existing information. Those improvements include modified aquifer parameter values, layering, and an update to the conceptual model in the Fort Ord area. Therefore, the

Geosciences model was not the best option for this analysis since it does not represent the most up-to-date conceptual model.

(5) The drawdown from proposed slant well pumping can be isolated by subtracting two model runs, one run with the new stress and a second run without the stress, or directly using superposition. For example, in their report to Marina Coast Water District, GeoHydros employed the superposition method to isolate the model-calculated drawdown due to slant well pumping using the NMGWM^{2016}. If correctly implemented, the results from the two approaches must be identical, as was shown by the example problem in Attachment 1 to Appendix E2. However, GeoHydros employed the theory of superposition, but chose to use the approach of subtracting two model runs to isolate the drawdown due solely to the proposed slant well pumping rather than calculate it directly using a superposition model as reported in Appendix E2. If correctly implemented, the results from the two approaches would be identical. But the flawed results are different from the results reported in EIR/EIS Appendix E2; see response to comment MCWD-GH-6.

MCWD-GH-18 The NMGWM^{2016} results are reliable because the superposition method resolves discrepancies with the boundary conditions, and the drawdown due to proposed pumping is determined primarily by the water transmitting and storage properties of the aquifer sediments. However, the GeoHydros analysis referenced in the comment was not conducted correctly; see response to comment MCWD-GH-6.

MCWD-GH-19 These results are generally consistent with the superposition model showing drawdown in Model Layers 2, 4, and 6 but none in Model Layer 8. See EIR/EIS Appendix E2, Figures 5.3 and 5.4.

MCWD-GH-20 Figures 18-21 provided in the comment are results from the method of superposition. However, the mapped changes are calculated by subtracting two model runs rather than calculating them directly as was done in EIR/EIS Appendix E2. If correctly implemented, the results from the two approaches must be identical, as was shown by the example problem in Attachment 1 to Appendix E2. However, the analysis reflected in Figure 18-21 was not conducted correctly; see response to comment MCWD-GH-6. Therefore, the flawed results are different from the results reported in Appendix E2. EIR/EIS Appendix E2, Figures 5.3 and 5.4, shows that Model Layer 8 (the 900-FT aquifer) has less than one foot of drawdown. See Master Response 12, The North Marina Groundwater Model (v. 2016).

MCWD-GH-21 The water budget results are from the method of superposition. However, the changes are calculated by subtracting two model runs rather than calculating them directly; if correctly implemented, the results from the two approaches must be

identical, as was shown by the example problem in Attachment 1 to Appendix E2. However, the analysis employed by the commenter to develop the water budget numbers was not conducted correctly; see response to comment MCWD-GH-6. Furthermore, the method provides the change in water budget components and those changes must be applied to the real-world groundwater conditions. When appropriately interpreted relative to field measured conditions, the budget changes indicate slant well pumping is expected to reduce outflow from the 180-Foot Aquifer to the 400-Foot Aquifer, likely providing a water quality benefit to the deep aquifers. See Master Response 12, The North Marina Groundwater Model (v. 2016), for more details.

MCWD-GH-22 When properly conducted using the same well dataset, RMSE comparisons indicate that the NMGWM^{2016} is an improvement relative to the NMGWM^{2015}. Additionally, the use of equivalent freshwater heads had negligible effect on the history matching results and model calibration. See Master Response 12, The North Marina Groundwater Model (v. 2016), for more details.

MCWD-GH-23 A valid error comparison between two models must utilize the same wells and water level data. When the same wells and water level data are utilized, the summary of error statistics shows that the NMGWM^{2016} performance is superior to the NMGWM^{2015}. See Master Response 12, The North Marina Groundwater Model (v. 2016), for more details.

MCWD-GH-24 Hydraulic conductivity values used in the NMGWM^{2016} are within the referenced range of measured values for each stratigraphic unit (see Appendix E2, Figures 3.3a and 3.3b). Additionally, Appendix E2, Figure 4.6, indicates good agreement between measured and model calibrated drawdown in Dune Sand during test slant well pumping. See Master Response 12, The North Marina Groundwater Model (v. 2016), for more details.

MCWD-GH-25 See response to comment MCWD-GH-9.

MCWD-GH-26 The NMGWM^{2016} was employed to calculate the water level decline (drawdown) in response to proposed project pumping. The NMGWM^{2016} was not constructed or employed to calculate changes in water quality and water density due to the mixing of ocean water and groundwater. The model was also utilized to provide insight into the change in groundwater-flow directions in response to pumping, from which changes in the extent of saltwater intrusion are inferred (see EIR/EIS Appendix E2, Section 5.3, Saltwater Intrusion).

MCWD-GH-27 The NMGWM^{2016} employed equivalent freshwater heads to simulate the density contrast between seawater and the underlying groundwater. The use of equivalent freshwater heads had negligible effect on the model calibration. See Master Response 12, The North Marina Groundwater Model (v. 2016), for more information.

MCWD-GH-28 See response to comment MCWD-GH-15.

MCWD-GH-29 See response to comment MCWD-GH-5.

MCWD-GH-30 Superposition modeling is appropriate for this evaluation because:

(1) The NMGWM^{2016} was employed to calculate the water level decline (drawdown) in response to proposed project pumping, and was not constructed or employed to calculate changes in water quality and water density due to the mixing of ocean water and groundwater. Furthermore, identification of source water contributions to the proposed extractions is not essential for estimating effects on groundwater levels. Appendix E2, Figures 5.6 and 5.12 show the oceanic capture zones from slant well pumping, which identifies the areas of groundwater captured from proposed slant well pumping using the NMGWM^{2016}. See also Master Response 8, Project Source Water and Seawater Intrusion, including Figures 8.2.8-1, 8.2.8-2 and 8.2.8-3.

(2) Model-calculated drawdown due to slant-well pumping can be compared to measured drawdown to validate model predictions. EIR/EIS Appendix E2, Figure 4.6, shows measured vs. model calibrated drawdown in CEMEX monitoring wells during slant well pumping.

(3) The NMGWM^{2016} results are reliable because superposition method resolves discrepancies with the boundary conditions, and the drawdown due to proposed pumping is determined primarily by the water transmitting and storage properties of the aquifer sediments.

(4) The drawdown from proposed slant well pumping can be isolated by subtracting two model runs, one run with the new stress and a second run without the stress, or directly using superposition. For example, in their report to Marina Coast Water District, GeoHydros employed the superposition method to isolate the model-calculated drawdown due to slant well pumping using the NMGWM^{2016}. If correctly implemented, the results from the two approaches must be identical, as was shown by the example problem in Attachment 1 to Appendix E2. However, the GeoHydros analysis was not conducted correctly; see response to comment MCWD-GH-6.

MCWD-GH-31 See response to comment MCWD-GH-21.

MCWD-GH-32 These predicted drawdowns provided in the comment are generally similar to those calculated by superposition and shown in Appendix E2, Figures 5.2, 5.3, 5.4, and 5.8. The results are not identical because the analysis conducted by the commenter and described above is flawed; see response to comment MCWD-GH-6.

MCWD-GH-33 See response to comment MCWD-GH-15. Extreme values do not indicate that the values used in the calibrated model are wrong nor does this sensitivity testing provide any support for the importance of achieving better calibration. See Master Response 12, The North Marina Groundwater Model (v. 2016), for more details.

MCWD-GH-34 The $NMGWM^{2016}$ was not constructed or employed to calculate changes in water quality and water density due to the mixing of ocean water and groundwater, and the pumping stress and aquifer properties have a much larger effect on the model-calculated drawdown than variations in water quality and density. For more information, see Master Response 12, The North Marina Groundwater Model (v. 2016).

MCWD-GH-35 Scientific support for the simulation of the MPWSP's groundwater impacts has been documented thoroughly in EIR/EIS Appendix E2. Specifically:

- Appendix E2 summarizes and provides extensive technical detail about the $NMGWM^{2016}$ in relation to the hydrogeology, model construction, assessment of model inputs and output, revisions to the $NMGWM^{2015}$ and its application to calculate drawdown using superposition.
- Model inputs are based on thorough scientific review of available data.
- The applicability of the equivalent fresh-water heads is well documented in Appendix E2, Master Response 12, and the scientific literature.
- Comparisons between MODFLOW (constant density model) calculated water level changes and calculations using SEAWAT (variable density model) indicated slight differences in calculated water levels.
- The model adequately simulates measured water levels and seasonal trends, which demonstrates scientific validity.
- The model adequately simulates measured drawdown in response to test slant well pumping, which demonstrates its scientific validity.
- RMSE comparisons and evaluation of other model performance criteria demonstrate that the $NMGWM^{2016}$ is an improvement relative to the $NMGWM^{2015}$ and model errors and uncertainty minimally influence model output.

- The use of sensitivity analysis to provide a range of water-level drawdown is well documented and based on extensive data for hydraulic conductivity.
- The use of superposition is well documented in the scientific literature and, as explained in EIR/EIS Appendix E2, is a logical and technically valid approach for determining the effects of slant-well pumping. It also overcomes the influence of deficiencies in quantifying initial conditions, pumping and recharge inherent in the SVGSM. The superposition approach provides substantial benefit in terms of reliability over the calibrated version of the model.

In contrast, GeoHydros' comments were based on their flawed application of superposition and therefore, a lack of scientific validity. Specifically, GeoHydros employed the theory of superposition, and chose to use the approach of subtracting two model runs to isolate the drawdown due solely to the proposed slant well pumping rather than calculate it directly using a superposition model as reported in Appendix E2. If correctly implemented, the results from the two approaches would be identical. But the GeoHydros analysis was not conducted correctly since it did not account for changes in groundwater-surface water interactions; see response to comment MCWD-GH-6.

8.5.2.4 Responses to Comments from MWCD – EKI

MCWD-EKI-1

EIR/EIS Section 2.6 examines whether, based upon the evidence currently available, the CPUC could conclude that there is a sufficient degree of likelihood that CalAm will possess rights to the water that would supply the desalination plant such that the proposed project can be deemed to be feasible. By letter dated September 26, 2012, the CPUC asked the SWRCB to assist the CPUC, and issue an opinion as to whether CalAm has a credible legal claim to the supply water for the MPWSP. The SWRCB carefully considered the then-available facts and evidence concerning the MPWSP, prepared a draft report on water rights, circulated that draft for public comments and ultimately issued its July 31, 2013, Final Review of CalAm's MPWSP (Report). The Report is attached to this EIR/EIS as Appendix B2. EIR/EIS Section 2.6 addresses the issue of *harm and injury* and CalAm's water rights, as they apply to the proposed MPWSP. See also Master Response 3, Water Rights.

As discussed in EIR/EIS Section 4.4.4.3, the SWRCB evaluation of the proposed project was considered as guidance for the analysis of groundwater impacts because it elucidates and provides context for the nexus between the thresholds of significance used in this section and recommendations and considerations of the SWRCB relative to water rights. Section 4.4.5.2 explains the feedwater for the proposed MPWSP slant wells would be drawn from a capture zone adjacent to the coast where the groundwater has been documented to far exceed the 3,000 mg/L Total Dissolved Solids (TDS) threshold that the SWRCB identifies in its Resolution No. 88-63, discussed below. The MPWSP slant wells would not draw

groundwater from inland sources into the capture zone, and thus would not encroach on beneficial groundwater sources or on supplies of other users.

MCWD-EKI-2

See response to MCWD-EKI-1 regarding water rights and SWRCB compliance. EIR/EIS Section 4.4.5.2 concluded that the proposed MPWSP would not violate or degrade groundwater quality in the Dune Sand Aquifer or the 180-FTE Aquifer. The conclusion was based on the understanding that the existing groundwater quality near the proposed MPWSP slant well pumping is highly brackish to saline. See also Master Response 8, Project Source Water and Seawater Intrusion. SWRCB Resolution No. 88-63 (Appendix A-9 of the Water Quality Control Plan for the Central Coastal Basin [Basin Plan]) resolves that "[a]ll surface and groundwater of the state are considered to be suitable, or potentially suitable, for municipal or domestic water supply and should be so designated by the Regional Boards with the exception of: *Surface and groundwater where the total dissolved solids exceed 3,000 mg/l and it is not reasonably expected by Regional Boards to supply a public water system*" *(*emphasis added). The groundwater underlying the capture zone of the proposed MPWSP slant wells is: 1) an order of magnitude more brackish (23,400 mg/L to 30,900 mg/L) than the Basin Plan threshold; 2) does not currently support a public water system or individual users, and; 3) other than its potential use for desalination, would not be reasonably expected to supply a public water system. As discussed in EIR/EIS Section 4.4.5.2, while the groundwater in the projected MPWSP capture zone may become more saline because of MPWSP pumping (seawater would eventually replace the ambient highly brackish water), it would not degrade a groundwater source considered by the SWRCB to be a suitable municipal or domestic water supply under the Basin Plan. The proposed MPWSP slant well pumping water quality effects would be confined to a localized capture zone that would not extend inland from the coast or draw less brackish groundwater from inland regions of the Dune Sand and 180-FTE Aquifer, as explained further below and in Master Response 8, Project Source Water and Seawater Intrusion.

MCWD-EKI-3

CalAm constructed eight monitoring well clusters and operated and monitored a test slant well to evaluate and characterize the groundwater response and the water quality changes from the test slant well and the proposed MPWSP slant well pumping. These wells adequately represent the MPWSP area of groundwater influence as they include the capture zone and projected cone of depression. The groundwater investigative work and findings are described in the EIR/EIS, Section 4.4.4 and Appendix E3, Hydrogeologic Investigation Technical Report. The 300 plus Fort Ord wells mentioned in the comment are located inland of the MPWSP area of influence and capture zone, and are completed in a perched/mounded aquifer that is not hydraulically connection to the Dune Sand Aquifer. Therefore, analysis of water quality data from these wells was not necessary for the environmental setting in the EIR/EIS and it does not represent a data gap in the analysis. However, the Fort

Ord area monitoring well data were incorporated into the analysis presented in the EIR/EIS analysis through refinements to the North Marina Groundwater Model, version 2016 ($NMGWM^{2016}$), a key tool used to analyze the environmental impacts of the MPWSP on groundwater resources. The refinements to the $NMGWM^{2016}$ included additional water level calibration points from the CEMEX and Fort Ord areas; see EIR/EIS Appendix E2, Section 3, including Table 3.1. Additionally, aquifer parameter zones were added and refined to include the former Fort Ord area wells. The $NMGWM^{2016}$ was improved by making adjustments to the water transmitting and storage properties in the coastal parameter zones and by modifying the conceptual geologic framework in the Fort Ord Area (see Master Response 12, The North Marina Groundwater Model, (v.2016)). Groundwater contour maps using Dune Sand and 180-FTE Aquifer groundwater elevations from the eight CalAm monitoring well clusters and the Fort Ord area wells were developed and presented to assess the regional groundwater conditions. These contour maps are presented in EIR/EIS Appendix E3.

Baseline groundwater elevations and water quality data have been gathered continuously from the monitoring wells and test slant well since early 2015; see Master Response 11, CalAm Test Slant Well, Section 8.2.11.4. The baseline data collected was adequate to inform the $NMGWM^{2016}$ and the EIR/EIS analysis of potential groundwater resource impacts. Please refer to response to comment MCWD-97 regarding establishing water level and water quality baseline data.

The comment asserts that the $NMGWM^{2016}$ does not accurately characterize baseline water level conditions in the Dune Sand and 180-FTE aquifer zones due to limited information included in the EIR/EIS for this area and extremely poor model calibration results that are reported for the Dune Sand Aquifer. It should be noted that Model Layer 2 of the $NMGWM^{2016}$ represents the shallow water-bearing sediments referred to as "Dune Sand Aquifer," "A-Aquifer," "Perched Aquifer," "Perched 'A' Aquifer," "35-Foot Aquifer," and "-2-foot Aquifer." Similarly, Model Layer 4 represents the "180-foot Aquifer," "180-foot Equivalent Aquifer," "Upper and Lower 180-foot Aquifer," and "Pressure 180-foot Aquifer." The geographic and hydrogeologic characteristics of these water bearing units are not equivalent. It is therefore, erroneous to use model results for an entire model layer to make global conclusions regarding one of these units, such as the Dune Sand Aquifer.

In response to the assertion of poor $NMGWM^{2016}$ calibration, it is important to note that the Root Mean Square Error (RMSE) of 30.2 feet in Model Layer 2 included the results from two Fort Ord wells that appear to be affected by perched conditions; see EIR/EIS Appendix E2, Figure 4.3b. As stated in EIR/EIS Appendix E2, "Errors at this model location are attributed to limitations in MODFLOW and its inability to simulate steep vertical gradients and perched conditions. This limitation appears to be localized, and model performance is acceptable in other portions of the Fort Ord Area where the vertical gradients are less steep." When these wells are excluded, the

RMSE for Model Layer 2 becomes an acceptable 10.1 feet. Furthermore, Dune Sand Aquifer monitoring well data collected during test slant well pumping was available and utilized to adjust aquifer parameter zones and parameter values in Model Layer 2 and Model Layer 4 (see EIR/EIS Appendix E2, Section 3.2, Aquifer Parameter Zones). Appendix E2, Figure 4.6 shows generally good agreement between the model-calculated and measured timing of water level drawdown and recovery in Dune Sand Aquifer monitoring wells, and demonstrates that the model can be employed to reliably project water level drawdown in the CEMEX area in response to proposed slant well pumping. See Master Response 12, The North Marina Groundwater Model (v. 2016), for additional information.

MCWD-EKI-3.1

Contrary to the assertion in the comment, the hydrogeologic conditions in the Dune Sand Aquifer and the 180-FTE/180-Foot Aquifer are supported by a comprehensive hydrogeologic conceptual model that is verified by nearly two years of test slant well pumping and baseline groundwater level and quality monitoring. Groundwater conditions presented in the EIR/EIS were based on the eight MPWSP monitoring well clusters and other private production wells located east of CEMEX (i.e., wells owned by the MRWPCA, Monterey Landfill and Bill Bailee, see EIR/EIS Table 4.4-10). However, prior to the completion of the MPWSP monitoring wells, there were only a few existing wells near CEMEX due to seawater intrusion along the coast, and therefore, scant historical groundwater level and hydraulic gradient data were available for this area. The MPWSP monitoring well network supplements the available groundwater data and provides a basis for groundwater flow and gradient mapping. The 300 plus Fort Ord wells mentioned in this comment and comment MCWD-EKI-3, above, are located south and outside of the MPWSP area of influence (shown in EIR/EIS Figures 4.4-14 through 16). While these wells provided data for the refinement of the $NMGWM^{2016}$, they are beyond the area of MPWSP influence and would not be affected by the MPWSP slant well pumping. This is especially the case for the Fort Ord wells completed in the upper perched/mounded aquifer, which is not hydraulically connected to the Dune Sand Aquifer. Groundwater contouring, based on fall and spring 2015 data, for the Fort Ord perched/mounded aquifer, the Dune Sand Aquifer, and the 180 FTE/180-foot Aquifer, and the 400-Foot Aquifer are shown in EIR/EIS Appendix E3 [Technical Memorandum (TM-2)].

Contrary to the comment, the groundwater contouring provided in TM-2 (see EIR/EIS Appendix E3) does not “further complicate or obscure the continuity of groundwater flow;” rather, it correctly distinguishes the aquifer zones that are in hydraulic connection and describes the groundwater flow and hydraulic gradients based on available data. As discussed in the EIR/EIS Appendix E3, the Dune Sand Aquifer is in hydraulic connection with the -2-Foot Aquifer at the Monterey Peninsula Landfill and Perched “A” Aquifer in the Salinas Valley. These are separate and disconnected from the shallow perched/mounded aquifers that exist at the location of CalAm monitoring well MW-5S(P), the 35-Foot Aquifer in the

Monterey Peninsula Landfill area, and the A-Aquifer in the Fort Ord Area, which flows over the Fort Ord-Salinas Valley Aquitard (FO-SVA). Therefore, the contouring map provided as Figure 5 in the EKI comment letter is in error because it included the groundwater elevation in MW-5S(P), which is now understood to represent the water level in the perched/mounded aquifer (35-Foot Aquifer in the landfill area and the A-Aquifer near Fort Ord) and not the Dune Sand Aquifer represented by the shallow completions of the MPWSP monitoring wells. Using well MW-5S(P) results in an erroneous seaward (west) gradient. Furthermore, the groundwater contour maps developed by EKI shows groundwater elevation contours where there is no groundwater data to support them.

Understanding the hydrogeologic characteristics of the Dune Sand Aquifer, there are two important considerations. First, wells from the Dune Sand Aquifer (and equivalents) cannot be contoured with wells from the shallow perched/mounded aquifers to develop contour maps because these are two distinct and hydraulically disconnected aquifers. Second, the primary "connection" between the two, distinct water-bearing zones is that the areal extent of the shallow perched/mounded aquifers, including the A-Aquifer underlying Fort Ord, is limited, which results in perched/mounded water flowing over the edge of the perching clay layer (similar to a waterfall) into the underlying Dune Sand Aquifer (and equivalents) or 180-FTE Aquifer. The edge of the perched clay layer occurs about 1.5 miles inland of the ocean shoreline. Please see response to the comment letter MCWD-HGC and EIR/EIS Appendix E3, Section 2.4.5.2, for additional clarification regarding the hydrogeologic connection of the Dune Sand Aquifer, the 180-FTE Aquifer, and the shallow perched/mounded aquifer.

The comment appears to support the theory that the fresh groundwater that waterfalls (also described as "U-turns") and enters the Dune Sand Aquifer and/or 180-Foot Aquifer protects these water bearing units from seawater intrusion. However, the flows from the shallow perched/mounded aquifers are limited in quantity and it is unlikely that these flows have created the barrier to seawater intrusion because monitoring well data have shown that seawater intrusion has continued to migrate inland for the last several decades regardless of these perched flows. However, whether or not this natural process is an actual barrier to seawater intrusion is no consequence to the proposed MPWSP because the slant well capture zone would be located 1.5 miles to the west at the coast, and would not encroach on this natural process, thereby allowing it to continue into the future unimpeded after onset of MPWSP pumping.

MCWD-EKI-3.2 A detailed discussion of the local groundwater chemistry and purported fresh water zones in the Dune Sand and 180-FTE aquifer is provided in response to comment MCWD-HGC. There is adequate evidence to verify that the groundwater underlying the CEMEX site and further inland has been impacted by seawater intrusion for decades. EIR/EIS Section 4.4.1.4 references the MCWRA monitoring

data that have been collected through an ongoing program for decades and was considered a reasonable benchmark to assess regional groundwater quality for the impact analysis in the EIR/EIS. See EIR/EIS Figures 4.4-10 and 4.4-11.

The monitoring wells installed by CalAm to support the MPWSP, and the Monterey Peninsula Landfill supply wells sampled as part of CalAm's program, also confirm the presence of seawater intrusion inland of the coast. Monitoring wells at the CEMEX site where the MPWSP slant wells would be drawing source water is considered highly brackish to saline while samples from monitoring wells inland of the capture zone indicate brackish water (considered for the purposes of this analysis to range between 500 mg/L to 33,500 mg/L TDS).

The comment attempts to draw a connection between length of monitoring well screens and depth of lower and higher salinity in the monitoring wells. The comment states that TDS concentrations detected in wells with long screen intervals, such as those constructed by CalAm for the MPWSP, likely reflect a mix of lower salinity (fresh) water from the upper portions of the 180-FTE Aquifer and more saline water from the deeper portion of the aquifer. The comment concludes that data from these wells is difficult to interpret and inadequate for characterizing salinity within the upper portions of the 180-FTE Aquifer.

It is first worth noting that the CalAm monitoring wells were constructed as clustered wells where each of the three wells in the cluster represents and monitors a distinct groundwater zone: the Dune Sand Aquifer (S), the 180-FTE Aquifer (M), and the 400-Foot Aquifer (D). Because of this, these wells were not constructed with particularly long screens; well screens in most of the CalAm monitoring wells range from 30 to 90 feet. The exception is MW-5M with a well screen of 210 feet (this is the only CalAm well cited by EKI in the comment).

As discussed in response to comment MCWD-HGC, the relatively low to moderate salinity measured at MW-5M is likely due to: 1) the relatively long screen interval that extends up to shallower elevations; 2) ambient groundwater inflow (with lower TDS) through the shallower screened section to lower portions of the monitoring well screen; and 3) typical seawater intrusion wedge, which results in denser seawater concentrations in the lower portion of the aquifer zone. Alternatively, the lower salinity observed at MW-5M could reflect the combined effects of inland groundwater pumping and aquifer heterogeneity.

Contrary to the comment's interpretation of TDS concentrations in the MPWSP monitoring wells, the salinity differences in the water column are more likely due to the various stages of seawater intrusion throughout the area. As evaluated and discussed in response to comment MCWD-HGC, elevated calcium and chloride levels in three of the MPWSP monitoring wells indicate early to middle stage seawater intrusion (MW-6M(L), MW-7S, and MW-7M). In other MPWSP monitoring wells screened in the Dune Sand and 180-FTE Aquifer (MW-1S,

MW-1M, MW-3S, MW-3M, MW-4S, MW-4M, MW-8S, MW-8M, MW-9S, and MW-9M), elevated sodium and chloride indicate later stage seawater intrusion. The relatively low to moderate salinity reported at well MW-6M is likely due to its proximity to the leading edge of seawater intrusion in the 180-FTE Aquifer, and the shape of the seawater intrusion wedge relative to the screened interval of MW-6M. The much higher chloride concentration (814 mg/L) in MW-6M(L), compared to the chloride concentration in MW-6M (167 mg/L), demonstrates the presence of the seawater intrusion wedge at this location. See EIR/EIS Appendix E3 for additional details.

The comments assert that not considering groundwater data from the monitoring wells in the Fort Ord Area leads to an incomplete understanding of the hydrogeologic conditions and the importance of the Dune Sand Aquifer. The wells in the Fort Ord Area monitor groundwater in the shallow perched/mounded aquifer (also referred to as the Fort Ord A-Aquifer) and not the Dune Sand Aquifer, and the connection of these two zones is described in the response to comment MCWD-EKI-3.1. To reiterate from the discussion above, the connection between the Fort Ord shallow perched/mounded aquifer zone and the Dune Sand/180-FTE Aquifers is considered to be located 1.5 miles inland from the MPWSP capture zone and thus, the MPWSP would not impact the purported barrier to seawater.

Furthermore, contrary to the assertion in the comment, the EIR/EIS does not dismiss the beneficial use and condition of the local groundwater system but does conclude that the ambient groundwater and eventual mix of seawater created in the MPWSP slant well capture zone would not harm other users, would not impact production wells, or would not degrade water quality because this groundwater currently far exceeds the 3,000 mg/L threshold set forth for suitable municipal or domestic supply by the RWQCB Basin Plan and SWRCB Resolution 88-63. See discussion in response to comment MCWD-EKI-2.

MCWD-EKI-4

The comment claims that construction and operation of the proposed project would limit recharge of fresh water from the Dune Sand Aquifer into the upper 180-FTE Aquifer, influence this natural hydraulic barrier and decrease the existing freshwater zone within a portion of MCWD's service area. These assertions are inaccurate. The comment is somewhat unclear as to where the "recharge" of fresh water from the Dune Sand Aquifer to the 180-FTE Aquifer is thought to occur but based on the previous comments, it is assumed that the comment is referring to the inland groundwater zone where groundwater from the shallow perched/mounded aquifer "waterfalls" into the Dune Sand Aquifer and/or 180-FTE Aquifer about 1.5 miles inland from the projected MPWSP capture zone; see response to comment MCWD-EKI-3.1. Since recharge from the shallow perched/mounded aquifer is occurring 1.5 miles inland from the capture zone of the MPWSP slant wells, the proposed MPWSP wells would not impact this process.

The comment asserts that the proposed MPWSP project pumping would cause brackish groundwater in the capture zone to become more saline and states that no current water quality data exists in the southern portion of these capture zones, an area close to MCWD's Service Area where non-saline water may currently exist. The projected capture zones of the proposed MPWSP slant wells are shown in Master Response 8, Project Source Water and Seawater Intrusion, Figures 8.2.8-1 and 8.2.8-2, EIR/EIS Appendix E2 Figure 5.6, and the EIR/EIS, Figure 4.4-13b.

EIR/EIS Appendix E2 presents three capture zones that were projected by the NMGWM^{2016} using estimated inland gradients of 0.0004, 0.0007, and 0.0011. Measurements of local gradients reveal that the highest gradient used in this analysis (0.0011) is more representative of the average local gradient and the 0.0007 gradient is more representative of the minimum local gradient. Therefore, the smallest capture zone shown on EIR/EIS Appendix E2 Figure 5.6 would be more typical of the capture zone created by the proposed MPWSP slant well pumping and the capture zone shown on Figures 8.2.8-1 and 8.2.8-2 can be considered worst case (or largest of the projected capture zones) because they are based on a gradient of 0.0007.

These capture zones would occupy an area that monitoring wells have identified as containing brackish water in the early to later stages of seawater intrusion, to highly brackish/saline groundwater, most with TDS concentrations exceeding 3,000 mg/L. While there may not be monitoring well data to confirm water quality in the northern and southern extremities of the projected slant well capture zones, it is reasonable to assume that similar groundwater quality exists throughout the capture zone due to its proximity to the coast. This is verified by data gathered during the Airborne Electromagnetics (AEM) survey conducted in May 2017 by Stanford University and MCWD that show a significant band of highly brackish groundwater extending inland from the coast up to 2,000 feet to include the area where the projected slant well capture zone would form. Evaluation of the data and findings from the AEM survey is provided in Master Response 9, Electrical Resistivity Tomography (ERT) and Airborne Electromagnetics (AEM), and EIR/EIS Appendix E3, Section 3.1.8. Considering that the capture zone under a regional gradient between 0.0007 and 0.0011 would only extend a few thousand feet into the Monterey Subbasin, additional characterization of groundwater quality to confirm the presence of seawater-intruded groundwater this close to the coast would likely not be warranted.

One central concept that appears to be misinterpreted in the comment is the relationship between the projected area of influence from the proposed MPWSP slant well pumping (also referred to as the cone of depression) and the projected slant well capture zone. The cone of depression that forms from groundwater pumping and the capture zone that provides feedwater to the slant wells are not the same. As discussed in EIR/EIS Section 4.4.4, Master Response 8, Project Source Water and Seawater Intrusion (Section 8.2.8.1) and EIR/EIS Appendix E3

(Section 3.26), the fundamental difference between the capture zone, which is supplying the water to the slant wells, and the cone of depression, which forms in response to pumping, is that the groundwater entering the slant wells would originate only from within the capture zone, while the regional gradient controls the groundwater flow beyond the capture zone. Because of this, while the area of influence (shown by the 1-foot drawdown line in EIR/EIS Figures 4.4-14 through 16) may extend inland up to 4-miles, the groundwater drawn into the slant well would only be occurring in the capture zone, which is a confined area adjacent to the coast around the slant wells, as shown in Master Response 8, Figures 8.2.8-1 and 8.2.8-2. Therefore, the assertion in the comment that the proposed project would hinder MCWD's ability to implement groundwater recharge augmentation at Armstrong Ranch is unfounded because the proposed MPWSP slant wells would not draw water from the inland sources, especially as far inland as the groundwater recharge augmentation site proposed by MCWD at Armstrong Ranch.

MCWD-EKI-5

EIR/EIS Appendix E2, North Marina Groundwater Model Review, Revision, and Implementation for Future Slant Well Pumping Scenarios, provides documentation of the groundwater modeling inputs and outputs. Appendix E2, Figure 4.1 shows measured and model-calculated water levels by model layer with corresponding well locations – gradients are readily calculated with this data. The drawdown due to proposed pumping is determined primarily by the water transmitting and storage properties of the aquifer sediments. There is ample documentation in Appendix E2, Section 3 of hydraulic conductivity values, storativity (Figure 3.3 provides values and sources of parameter values), and boundary conditions. Appendix E2 Section 5.0 shows by way of particle tracking, the projected groundwater flow paths after project implementation. See also Master Response 12, The North Marina Groundwater Model (v. 2016), for further clarification on $NMGWM^{2016}$ construction, calibration and output.

Superposition modeling provides estimates of changes in flow direction and groundwater levels due to slant well pumping. The superposition method is routinely employed for solving complex problems and is useful in saving time and effort and eliminating uncertainty. Its usefulness is well documented in the peer-reviewed literature (see Master Response 12, Section 8.2.12.4 "Superposition"). Because superposition isolates the drawdown directly, it does not "obscure model deficiencies." In fact, rather than provide results obscured by other factors that cannot be predicted, such as future climatic conditions and water use practices, superposition provides the results directly.

The changes calculated with superposition are additive to future changes that occur as the net result of all other factors like climate, background pumping, background recharge, and land use changes that cannot be predicted with certainty. Accordingly, validating the future drawdown calculated by the superposition modeling approach, which corresponds to validating the change in future water

levels due solely to proposed project pumping, is in practical terms less difficult than validating model projections that include the additional complexity of assumed climate, water use, and land use changes which are not known with certainty. See Appendix E2, Section 4.2, Test Slant Well Pumping, for an example where real-world monitoring data is utilized to compare measured drawdown with the drawdown calculated with the superposition model.

The $NMGWM^{2016}$ was employed to calculate the water level decline (drawdown) in response to proposed project pumping, and was not constructed or employed to calculate changes in water quality and water density due to the mixing of ocean water and groundwater. The error introduced by the constant groundwater density assumption is relatively small because pumping has a much greater influence on water level changes (drawdown) than spatial differences in water density. See Master Response 12 for more details.

MCWD-EKI-6

Contrary to the statement in the comment, the EIR/EIS does not conclude that the proposed MPWSP slant wells would draw water from the Dune Sand Aquifer and 180-FTE Aquifer 1.5 to 4.5 miles inland. The maximum (worst case) projected influence from slant well pumping would result in a 1-foot drawdown in the 180-FTE Aquifer up to 4 miles inland under the 0 percent return water scenario and current sea level rise. As stated in the response to comment MCWD-EKI-4, groundwater and seawater would only be drawn into the MPWSP slant wells from within the capture zone adjacent to the coast, which would eventually be recharged by seawater. The slant wells would not have an influence on inland groundwater sources beyond the eastern extent of the capture zone.

The EIR/EIS does not dismiss the beneficial uses of the groundwater in the Dune Sand and 180-FTE Aquifer but it does conclude that the groundwater that would be drawn from the capture zone of the slant wells would be a highly brackish to saline mix of groundwater and seawater that far exceeds the SWRCB threshold (3000 mg/L TDS) for groundwater that is considered suitable or potentially suitable for municipal or domestic water supply.

The EIR/EIS concluded that there would be no significant environmental impacts on groundwater resources from the proposed MPWSP slant well pumping, and therefore, no mitigation was necessary. Contrary to the comment, there is no evidence that the MPWSP would harm MCWD's water rights (see EIR/EIS Section 2.6, and Master Response 3, Water Rights, Section 8.2.3.7) or preclude MCWD from utilizing the Dune Sand Aquifer for storage and augmentation at Armstrong Ranch. However, as an Applicant-Proposed Measure (see EIR/EIS, Section 4.4.4.5, Applicant-Proposed Measure 4.4-3), CalAm would work with MCWRA to expand the existing regional groundwater monitoring program to include new and existing private wells through a voluntary monitoring program in the area where groundwater elevations are anticipated to decrease by 1 foot or

more. CalAm has proposed returning water to the basin not as a mitigation measure needed to reduce groundwater impacts; rather, the return water would ensure that the proposed project remains in compliance with the Agency Act. This is discussed in detail in Master Response 4, The Agency Act and Return Water, Sections 8.2.4.1 and 8.2.4.2.

MCWD-EKI-7

Contrary to the comment, the EIR/EIS demonstrates that the proposed MPWSP would not harm or cause injury to other basin users. However, as discussed in EIR/EIS Applicant Proposed Measure 4.4-3, CalAm would work with MCWRA to fund and develop a groundwater monitoring and reporting program that expands the current regional groundwater monitoring network to include the area near the proposed slant wells. As noted in response to comment MCWD-EKI-4, data gathered during the AEM survey conducted in May 2017 verifies that the baseline water quality conditions in the Dune Sand and 180-FTE aquifers include a significant band of highly brackish groundwater extending inland from the coast up to 2,000 feet to include the area of the projected slant well capture zone. Installation of new monitoring wells at appropriate locations near the boundary of the MPWSP area of influence would complement the existing monitoring well network, which would monitor drawdown due to the MPWSP pumping throughout the life of the project.

See response to comment MCWD-EKI-7; groundwater and seawater would only be drawn into the MPWSP slant wells from within the capture zone adjacent to the coast, which would eventually be recharged by seawater. The slant wells would not have an influence on inland groundwater sources beyond the eastern extent of the capture zone. The groundwater modeling does not, therefore, need to be expanded to demonstrate the proposed project would not degrade groundwater quality in the MCWD Service Area. See Master Response 3, Water Rights, Sections 8.2.3.8 and 8.2.3.9.

Applicant-Proposed Measure 4.4-3 requires that CalAm, working with MCWRA, shall fund and develop a groundwater monitoring and reporting program that expands the current regional groundwater monitoring network to include the area near the proposed slant wells. Once expanded, the program will monitor groundwater levels and water quality within the area where groundwater elevations are anticipated to decrease in the Dune Sand Aquifer and the 180-FTE Aquifer and within at least 1 mile outside of the predicted radius of influence. The Applicant-Proposed Measure describes additional elements proposed under this measure.

8.5.2.5 Responses to Comments from MWCD – IntakeWorks

MCWD-IW-1

References cited in the EIR/EIS continue to be publicly available at https://tinyurl.com/MPWSPRefs. The EIR/EIS did not conclude that slant wells were the only potentially feasible subsurface intake system for the MPWSP. As

explained in EIR/EIS Section 5.3.6.1, "Ranney wells (Intake Option 13) were shown to result in similar environmental effects compared to the proposed slant wells, resulting in neither increased or decreased impacts. Ranney wells do offer an opportunity to replace slant well technology at either the CEMEX or the Potrero Road site if necessary."

MCWD-IW-2 EIR/EIS Chapter 5 provides a robust and comprehensive alternatives analysis; see response to comment MCWD-168 and MCWD-170. CEQA Guidelines Section 15126.6(a) acknowledges an EIR "need not consider every conceivable alternative to a project. Rather it must consider a reasonable range of potentially feasible alternatives that will foster informed decision making and public participation."

EIR/EIS Section 5.3 describes the process employed to develop, screen and evaluate potential alternative components, and develop whole alternatives for analysis. Section 5.3.1 describes the regulatory considerations applicable to the successful implementation of a desalination project and Section 5.3.2 describes the screening and evaluation process for components of whole alternatives. Components that are not carried forward are described, with the reason for their dismissal, in Appendix I1, which is the stated focus of this comment letter.

The components that are carried forward from the first screening (EIR/EIS Section 5.3.2) are evaluated against each other in Section 5.3.6. Components that are considered to be the least environmentally damaging are then combined into "whole" alternatives in Section 5.4, which are evaluated in Section 5.5.

MCWD-IW-3 The comment is correct; open water intakes should be cleaned more often than every 3-5 years. As noted in EIR/EIS Section 5.4.5.3, the screened open water intake associated with Alternative 3 would be cleaned annually by divers and pipelines would be pigged. Appendix I1 has been revised accordingly; the revision does not change any conclusion in the EIR/EIS.

MCWD-IW-4 This comment addresses statements in the EIR/EIS that were cited from WateReuse, 2011, and is not a comment on the EIR/EIS. The potential for impingement of marine organisms or organic material on the seafloor as a result of the proposed project subsurface intakes is evaluated in EIR/EIS Section 4.5.5.2.

MCWD-IW-5 This comment acknowledges there are significant advantages of using subsurface intakes for obtaining desalination source water, which are discussed in EIR/EIS Appendix I1. See responses to the following specific comments regarding subsurface intakes.

MCWD-IW-6 Vertical wells were not considered in the EIR/EIS Section 5.3 component screening and evaluation; see response to comment MCWD-172.

The analysis in EIR/EIS Appendix I1 concluded that other alternative subsurface intake technologies would have a smaller construction footprint and permanent footprint because other subsurface intakes would require fewer wells to generate the same volume of source water. The number of vertical wells that would be needed to provide a reliable source water flow to the desalination plant is considered infeasible, both from a construction and operational perspective and in terms of economic, legal (permitting) and environmental factors. Therefore, vertical wells are not considered further.

MCWD-IW-7 EIR/EIS Section 5.2.3 discusses the implementation of Assembly Bill 1182 (Keeley) and the development of the CPUC Plan B. As noted in Footnote 1 in that section, the Plan B report determined that a desalination plant at Sand City would be less appropriate for the desired scale of production than a desalination plant at Moss Landing. A desalination plant at Moss Landing was proposed by CalAm; the Coastal Water Project is described in EIR/EIS Section 5.2.4. See response to comment MCWD-IW-2 and MCWD-172. See also response to comment Surfrider-6; the EIR/EIS has not identified a significant unavoidable impact for any resource that would require an alternative to avoid or lessen a potentially significant impact.

MCWD-IW-8 The Huntington Beach ISTAP Phase 1 Feasibility Report (HB ISTAP, 2014) concluded that an infiltration gallery was a feasible subsurface option at Huntington Beach, but the Phase II Feasibility Report (HB ISTAP, 2015) concluded that the beach infiltration gallery is infeasible at the Huntington Beach location. Furthermore, on October 4, 2017, the CA State Lands Commission issued a Notice of Availability and Intent to Consider Certification of the Final Supplemental EIR for the Seawater Desalination Project at Huntington Beach; the Final EIR considers a lease modification that would allow Poseidon to install wedgewire screens on an existing open water intake that would provide almost 107 mgd of desalination feedwater. EIR/EIS Appendix I1 explains that an infiltration gallery within MBNMS would have a greater impact on marine biological resources than slant wells. Based on the extent of temporary and permanent disturbance that an infiltration gallery would have on the sand dunes and marine habitat in MBNMS, this technology is considered infeasible at this location. See response to comment MCWD-173.

MCWD-IW-9 The Lead Agencies appreciate the background provided by the comment on horizontal wells using Neodren or other horizontal well technology for subsurface intake systems. EIR/EIS Appendix I1 has been revised to provide the following additional information about the Neodren™ intake technology:

The Neodren™ HDD intake technology is patented by the Spanish company Catalana de Perforacions. This technology has been used for over ten years in several small and medium-size seawater desalination plants in Spain, but does not have any applications in the United States. One of the largest seawater desalination plants using HDD wells in operation is the New Cartagena Canal (San Pedro de Pinatar) plant. It is located in Almeria, Spain and has a capacity of 17 mgd. The individual intake wells are between 1,650 and 1,980 feet long and are 14-inches in diameter. Each well produces between 2.3 and 3.1 mgd and the desalination plant operates at 45 percent recovery. The water is collected in a large wet well (located under a parking lot to reduce visual impacts) located underground and pumped to the plant using submersible pumps.

Experience with the use of HDD wells at this plant, indicates that the plant intake has encountered significant "technical issues and limitations" causing the plant's owner to switch to an open water intake system for the plant's Phase-2 expansion (Shea, 2007). Four of the wells lost over 40 percent of their production capacity within the first nine months of plant operation; furthermore, the capacity of the other wells has continued to diminish over time. Such productivity reduction triggered the need to install additional intake wells and ultimately to build open intake for the second phase of the plant expansion.

When HDD wells were introduced on the market in late 1998, they initially received acceptance in Spain and have been considered a viable intake alternative for a number of other countries. However, after five years of operational experience, many of the plant intakes have faced production reliability challenges (loss of productivity due to blockage of the perforated piping). As a result, HDD wells have not been used for full-scale desalination projects worldwide since 2010. An HDD intake system that would be capable of collecting source water needed for the MPWSP desalination plant would consist the same number of wells proposed by the MPWSP, and would collect water into a common wet well located inland from the beach.

Based on experience with other forms of infiltration galleries, HDD intake maintenance maybe challenging due to their historical tendency to clog. Furthermore, experience shows that once the intake collectors become plugged and the productivity of the individual collectors' decreases, it is impossible to recover the original full capacity (Rachman, 2014).

The construction of HDD intake systems would involve the use a drill rig launched from an onshore location to drill a pilot bore. The drill rig would be positioned over the bore hole centerline a sufficient distance behind the entry point to allow the drill bit to enter the ground at the correct location and angle. Depending on the rig size and entry angle, this distance may be 3 feet to 20 feet behind the entry point. The entry angle usually is between eight degrees and 16 degrees, although entry angles of up to 20 degrees have been used on some large diameter projects. A small pit is usually excavated over the entry point, using a backhoe or shovel. When

performing HDD in an unconsolidated media like sand, it will be necessary to pressurize the bore hole and stabilize the walls by coating them with drilling mud (e.g., bentonite) or another similar drilling fluid. Because of the pressure involved to coat the hole walls with mud, frac-out of the drilling mud has occurred in other HDD operations. Such a prospect would result in the potential release of drilling fluid into the ocean environment.

The pilot bore would be enlarged by one or more back reamers to the size required for the intake pipe; the pipes would be assembled on barges, lowered to the seafloor and pulled back through the borehole (float-and-sink method) during the final reaming process. Daylighting the drill offshore could result in the release of drilling fluid to the ocean. Neodren™ claims that they have a new technique that avoids daylighting the drill offshore ("push" method) and this was the technique assumed for the MPWSP. However, as of late 2015, the push method of construction has yet to be demonstrated successfully for an intake well. The area required for construction and the associated impacts will likely be similar to slant wells, but for the off-shore support services, e.g. barges, that would be associated with assembling and pulling the HDD pipe through the borehole.

MCWD-IW-10

EIR/EIS Appendix I explains that horizontal wells installed with HDD technology were not evaluated further for the reasons correctly cited by the comment, and nothing in this comment letter or the associated responses has caused the Lead Agencies to revise that conclusion. However, based on information provided by this comment, EIR/EIS Appendix I1 has been revised as follows:

> Horizontal wells are not evaluated further for the following reasons: (1) the amount of pipeline that would be pushed under the seafloor (upwards of 2,500 feet) would be challenging in terms of ~~construction time,~~ physical limitations ~~and the disposal of drilling sludge (and consequently much more expensive than other options)~~; and (2) ~~installing artificial filter packs to stabilize unconsolidated formations like those found in the project area has yet to be demonstrated successfully and on a consistent basis, and; (3)~~ HDD would not avoid or minimize any of the impacts associated with the proposed action.

The Lead Agencies acknowledge that HDD construction techniques are feasible for installing pipe over distances greater than 2,500 feet (float-and-sink), but it would be challenging to "push" that length of pipe as concluded in Appendix I1 for installing HDD intake system. As noted in EIR/EIS Section 5.4.5.1, seawater would be conveyed through approximately 3,600 feet of 42-inch diameter pipeline from the DeepWater Desal intake structure to an onshore pump station, and the discharge pipeline would extend approximately 3,400 feet offshore into Monterey Bay. Both the intake and discharge pipelines proposed by Deepwater Desal, and evaluated in EIR/EIS Section 5.5, would be installed using HDD techniques, and would use the float and sink method to pull pipes through the seafloor; see EIR/EIS Section 5.4.5.2.

The off-shore support services associated with the float and sink method would result in greater impacts to the marine environment in MBNMS than the proposed slant wells, and this technique was not considered for the MPWSP in EIR/EIS Appendix I1. As noted in response to comment MCWD-IW-9, while pipes can be pulled through the borehole from offshore, the push method of construction, the assumed HDD technique for installing HDD wells, has yet to be demonstrated successfully for an intake well. Some of the projects listed by the comment in Table 2 exceed 2,500 feet, but they were each installed using the float and sink method. No HDD intake wells (or, drain) shown in the examples provided by/attached to the Intake Works comment letter however, exceed 600 meters (1,968 feet) in length, which supports the conclusion in the EIR/EIS that the amount of pipeline required to be pushed for HDD wells for the MPWSP would be challenging.

The San Diego County Water Authority (SDCWA) is indeed proceeding with a pilot project that would compare the pre-treatment requirements (and associated costs) for an open water intake and for a subsurface intake. The SDCWA has selected a Neodren system to test the subsurface intake requirements. The 20 gallon per minute pilot project, including an 800 to 1,000-foot long, 8-inch diameter HDPE subsurface intake pipe, is still in the permitting phase, with construction expected to begin in early 2019; the installation will utilize the float-and-sink technique (Jeremy Crutchfield, SDCWA personal communication, November 27, 2017).

As noted earlier in this response, the disposal of drilling sludge and the cost of HDD have been removed from the EIR/EIS Appendix I1 text, but does not change the conclusion. HDD wells would not eliminate the need for the Castroville Pipeline; see also response to comment MCWD-IW-11 regarding the Salinas Valley Return Water.

Also as noted above in this response, the text regarding artificial filter packs has been removed from EIR/EIS Appendix I1, but does not change the conclusion.

No revisions were made to the conclusion in EIR/EIS Appendix I1 regarding HDD wells. See also response to comment MCWD-IW-2 and MCWD-IW-11.

MCWD-IW-11

The slant well heads as proposed, would be located approximately 900 feet (275 meters) inland of the Mean High Water (MHW) line; see EIR/EIS Figure 3-3b. If an HDD system “could be located well further inland” as the comment suggests, “outside any endangered species habitat and avoiding endangered species along the coast,” that would locate the HDD wells somewhere inland of the CEMEX property. The CEMEX entrance/parking lot is located approximately 2,200 feet (670 meters) inland of MHW. As noted in response to comment MCWD-IW-10, no one single HDD intake well (or, drain) shown in the examples provided by/attached to the comment, exceed 600 meters, and the subsea geology of the largest project, San Pedro del Pinatar, was permeable fractured rock material, not sand and gravel like at

CEMEX. Therefore, HDD wells at CEMEX would be drilled into the Dune Sands Aquifer -- or the 180-FTE depending on the depth, see EIR/EIS Figure 4.2-3 -- for their entire length, and would not reach any further under the ocean than the proposed slant wells. HDD wells at CEMEX, like the slant wells, would draw source water that originated in the SVGB, and a Salinas Valley return water obligation would still be required, as would the return water (Castroville) pipeline.

As shown on EIR/EIS Appendix C3, Figure 8, HDD wells at the Potrero Road site would also penetrate the Dune Sands Aquifer. Therefore, HDD wells at Potrero Road, like the proposed slant wells, would also draw source water that originated in the SVGB, and the return water obligation (and Castroville Pipeline) would still be required.

HDD wells could potentially be located closer to the CalAm Service Area, but the source water would still need to be piped to the desalination plant, making the alternative impractical and excessively expensive.

MCWD-IW-12

EIR/EIS Section 5.3.3 explains that open water intakes and subsurface intakes have different site requirements, design features, and construction techniques, and the two intake technologies are described in Appendix I1. Thirteen intake options were identified and screened for fatal flaws (see response to comment MCWD-IW-2) and are shown on EIR/EIS Figures 5.3-1 and 5.3-2, and in Table 5.3-1. Three of the 13 intake options evaluated include Ranney Wells: at Moss Landing (Intake Option-5), at Seaside/Sand City (Intake Option-11) and at CEMEX (Intake Option-13); see EIR/EIS Sections 5.3.3.5, 5.3.3.11, and 5.3.3.13. As described in EIR/EIS Section 5.3.3.13, each caisson (referred to as a shaft in the comment) at CEMEX would be 12 feet in diameter, and would be buried approximately 50 feet into the sand, not 90 to 260 feet deep as stated by the comment.

Six of the 13 intake options were not carried forward for further analysis, and they are described in EIR/EIS Appendix I2, along with an explanation for their elimination (Intake Option-5 and -11 were eliminated). Options that were retained are evaluated against the proposed project's slant wells at CEMEX in EIR/EIS Section 5.3.6. Table 5.3-1 presents the intake options, and summarizes the results of the screening process.

Intake Option-13, Ranney Wells at CEMEX, was carried forward; see EIR/EIS Table 5.3-4, and response to comment MCWD-IW-1.

MCWD-IW-13

The Monterey Peninsula Water Management District 95-10 Project Constraints Analysis (referred to herein as the 2008 Constraints Analysis) (ICF et al., 2008) identified 25 individual well locations for using HDD (e.g., slant wells), radial

wells (e.g., Ranney collector wells), or conventional wells; see response to comment MCWD-178.

The 2008 Constraints Analysis did not look at any alternatives south of Seaside/ Sand City. The EIR/EIS also did not consider alternative intake locations south of Seaside/Sand City (Intake Option-11, Ranney Wells at Seaside/Sand City. The Carmel River State Beach is located about 10 miles south of Sand City and would require a 20-mile source water pipeline, making this alternative impractical, if not excessively expensive; see response to comment MCWD-IW-2. CalAm would utilize a diverse portfolio of water supplies (see EIR/EIS Section 2.4) to manage supply uncertainties.

MCWD-IW-14 See response to comment MCWD-174 regarding slant well technology, and response to comment MCWD-82 regarding slant well replacement.

MCWD-IW-15 Chemical parameters reported from the test slant well are presented in EIR/EIS Table 4.4-4, and a more extensive summary of test slant well laboratory water quality results are presented monthly by CalAm; results continue to be made publicly available at https://www.watersupplyproject.org/test-well. EIR/EIS Section 4.4 referenced Geoscience, 2016b, which is Monthly Monitoring Report No.7; see Table 3 therein for the full suite of water quality constituents.

MCWD-IW-16 EIR/EIS Section 3.2.2.2 describes the configuration of the proposed MPWSP desalination plant RO system, Section 5.4.5.1 describes the similar RO system for Alternative 3 (DeepWater Desal) and Section 5.4.6.1 describes the similar RO system for Alternative 4 (People's Project).

MCWD-IW-17 EIR/EIS Section 3.4.1 describes that during maintenance of the slant wells, workers would access the well from the wellhead, and would lower mechanical brushes into the wells to clean the screens. If chemical cleaning products are needed for maintenance, only environmentally inert products would be used. The periodic well maintenance procedures are also described in the 2013 Hydrogeologic Investigation Work Plan (see Appendix B to EIR/EIS Appendix E3), and include simultaneously swabbing and airlifting the screened interval to dislodge and remove materials collected on the well screen, and aggressively pumping and surging the well until fluids removed are effectively free of sand, sediment, and other material. Contrary to the comment, the casing would not be withdrawn.

MCWD-IW-18 EIR/EIS Section 4.18.4.2 explains that the proposed RO system would incorporate an energy recovery system that utilizes pressure exchange technologies to recover

energy from the high-pressure waste stream and reduce overall pumping power requirements (and energy consumption) for the RO modules.

MCWD-IW-19 See responses to comments MCWD-IW-2 through MCWD-IW-14.

8.5.2.6 Responses to Comments from MCWD – Hopkins Groundwater Consultants2

These responses address September 29, 2017 comments submitted by Hopkins Groundwater Consultants, Inc. (HGC) to the Marina Coast Water District (MCWD) regarding estimates of return water volumes associated with Monterey Peninsula Water Supply Project (MPWSP).[12] HGC considers the September 29, 2017 memorandum an update of its January 22, 2016 report to the MCWD regarding the MPWSP return water proposal that was submitted to the California Public Utilities Commission (CPUC) with the direct testimony of Curtis Hopkins dated January 22, 2017. In the September 29, 2017 memorandum, HGC supplements the analysis presented in its January 22, 2016 report and provides its professional opinion on the MPWSP Return Water Settlement Agreement. HGC asserts that providing return water to the Castroville area, as proposed, would not address or mitigate the adverse groundwater impacts caused by the proposed MPWSP in the North Marina Area of the 180-400 Foot Aquifer Subbasin within the Salinas Valley Groundwater Basin (SVGB). Additionally, the HGC September 29, 2017 memorandum claims to address new evidence, including the recent Airborne Electromagnetics (AEM) survey data collected by Dr. Rosemary Knight and her team from Stanford University, that supports HGC's original hypothesis that extensive groundwater resources in the shallow aquifers along the coastline around CEMEX would be adversely impacted by the MPWSP.

Many of the comments in HGC's September 29, 2017 memorandum repeat or are similar to those received from HGC in its March 27, 2017 letter to MCWD regarding the MPWSP Draft EIR/EIS, which have been responded to in response to comment MCWD-HGC in Section 8.5.2.2. While some of the comments in HGC's September 29, 2017 memorandum address the Draft EIR/EIS, many address the MPWSP Return Water Settlement Agreement and HGC's assessment of the regional hydrogeology. This response generally focuses on the HGC comments that address the adequacy of the Draft EIR/EIS and is subdivided based on general topics. The September 29, 2017 HGC memorandum presents no new data, information, or findings that change the conclusions of the impact analyses presented in the Draft EIR/EIS.

MCWD-HGC2-1

Return Water

The assertions in the September 29, 2017 HGC memorandum suggest a general misunderstanding of the purpose and need of the return water proposed under the MPWSP. The return water is not intended to mitigate adverse impacts on groundwater resources in the SVGB that would be caused by the MPWSP. As

[12] Section 8.5.2.2 provides responses to technical comments dated March 27, 2017, that HGC provided on the MPWSP Draft EIR/EIS, on behalf of MCWD.

analyzed and discussed in EIR/EIS Chapter 4.4, impacts on groundwater resources in the SVGB were determined to be less than significant and, therefore, mitigation to restore aquifer groundwater levels or groundwater supplies for other users is not required. The EIR/EIS concludes that the proposed MPWSP pumping from the intake wells on the CEMEX property would not cause harm or cause injury to groundwater users in the SVGB. The return water is the amount of desalinated groundwater that CalAm has agreed, as part of the MPWSP Return Water Settlement Agreement (see response to comment MCWD-84), to return to the SVGB to comply with the Monterey County Water Resources Agency (MCWRA) Act (see Master Response 4, The Agency Act and Return Water), which prohibits groundwater from being exported out of the SVGB. The volume of groundwater that CalAm must return under the agreement would be determined annually by an agreed upon calculation of the Ocean Water Percentage (OWP) in the MPWSP feedwater. The return water would then be conveyed to the Castroville Community Services District (CCSD) and the Castroville Seawater Intrusion Project (CSIP) to be used in lieu of pumping an equal amount of groundwater. HGC opines that by delivering the required return water to the CCSD and CSIP, it would not be benefiting the groundwater aquifers affected by the MPWSP slant well pumping located south of the Salinas River in an area it refers to as the "Northern Marina Subarea" (discussed below). Not only is delivery of water south of the Salinas River not necessary as mitigation due the projected less-than-significant effects on the SVGB by MPWSP proposed pumping, but the Agency Act concerns itself with the SVGB as a whole and does not regulate use of SVGB water based upon any geographic locale or administrative jurisdiction within the overall SVGB. For more information about the Agency Act and the proposed return water, see Master Response 4, The Agency Act and Return Water.

HGC asserts that the Draft EIR/EIS did not provide discussion to explain or support the range of return water, which was estimated for the purposes of the EIR/EIS as between 0 percent and 12 percent. When the Draft EIR/EIS was prepared, the estimate of the OWP in the source water was not finalized but based on monitoring work at the test slant well at CEMEX, it appeared that the actual Ocean Water Percentage (OWP) necessary to gauge return water amounts would range between 0 and 12 percent. This range was supported by the observation that the test slant well at the time (November 2015) was extracting water reported to be in the range of 29,800 mg/L (see Table 3 in Geoscience, 2016a), or 12 percent of ocean water salinity (33,500 mg/L), suggesting 12 percent was a reasonable upper limit.

Projecting return water volumes based on OWP projection has since been refined by the HWG by employing a dual methodology consisting of an analytical equation (analytical mixing model), a numerical modeling using the existing CEMEX Model (variable solute transport model), and actual field data. Results of the analytical/ numerical methods indicate that the OWP would range from 88 to 92 percent the first year, increase to 93-97 percent after two years, and exceed 94 percent over the long term. This is consistent with two years of field data from the test slant well

that indicated OWP ranging from 92 to 95 percent in the first year and 90 to 92 percent in year 2.[13] These methodologies and results are discussed in Master Response 4, Agency Act and Return Water, and are described in detail in EIR/EIS Appendix E3, the Hydrogeologic Working Group (HWG) Hydrogeologic Investigation Technical Report. The combined analytical and numerical methodology plus the actual field data adequately support the estimated OWP range of 0 to 12 percent used in the Draft EIR/EIS. Given the data acquired to date, it is unlikely that a greater volume of return water would be required in the years following the start-up of MPWSP pumping.

In the September 29, 2017 letter, HGC focuses on the stated value of 7 percent return water that Mr. Ian Crooks of CalAm provided during his direct testimony on September 15, 2017. In reviewing the direct testimony, it appears that Mr. Crooks used 7 percent return water value merely as an estimate in a system supply/demand comparison. Nonetheless, 7 percent return water is not an unreasonable estimate based on the OWP estimates developed through analytical/numerical modeling and field data.

MCWD-HGC2-2

Current Seawater Intrusion

EIR/EIS Section 4.4.1.4 references the MCWRA seawater intrusion monitoring data (see EIR/EIS Figures 4.4-10 and 4.4-11) that have been collected for decades through an ongoing program that was considered a reasonable benchmark to assess regional groundwater quality for the impact analysis in the EIR/EIS. It is important to reiterate that Draft EIR/EIS Section 4.4 states that based on estimates from the MCWRA, seawater has intruded within the 180-Foot and 400-Foot Aquifers by approximately 8 miles and 3.5 miles inland, respectively, based on chloride concentrations greater than 500 mg/L. There is adequate evidence to verify that the groundwater underlying the CEMEX site and further inland has been impacted by seawater intrusion for decades. The Draft EIR/EIS or the modeling completed to analyze the impacts of the MPWSP, did not assume that "groundwater comparable to that of seawater occurs up to 8 miles inland." It is also important to note that 2 percent ocean water (98 percent groundwater) equates to groundwater quality with 250 to 500 mg/L chloride and between 1,000 and 1,500 mg/L TDS, which as described below, are California's secondary drinking water Maximum Contaminant Levels for chloride and TDS. Figure 13, presented by HGC on page 18 of the September 29, 2017 memorandum, therefore, is not an effective way to interpret or demonstrate the extent of seawater intrusion. A detailed discussion of the local groundwater chemistry and purported fresh water zones in the Dune Sand and 180-FTE aquifer is provided in response to comment MCWD-HGC-9.

[13] The decrease in salinity in Year 2 can be explained by the infiltration of fresh rainwater during an above normal rainfall year and percolation of fresh water during sand washing operations at CEMEX.

MCWD-HGC2-3

NMGWM^{2016} Modeling

HGC reasserts that the modeling performed for the Draft EIR/EIS is inadequate to evaluate the direct and cumulative impacts from the MPWSP on groundwater resources in the SVGB. These comments reflect those same comments that HGC provided in its March 27, 2017 letter to MCWD on the Draft EIR/EIS. Responses to comments on the development and calibration of the NMGWM^{2016} model, its applied use to project groundwater response in the SVGB from the MPWSP, and its effectiveness to evaluate environmental impacts of that groundwater response have been addressed in detail and are presented in response to comment MCWD-HGC-13, and Master Response 12, The North Marina Groundwater Model (v. 2016).

MCWD-HGC2-4

Northern Marina Subarea and Protective Groundwater Levels

HGC contends that the return water component of the MPWSP be sufficient to maintain "protective groundwater levels" in the Northern Marina Subarea to prevent seawater intrusion. The "Northern Marina Subarea"[14] and purported "protective groundwater levels" are summarized here and discussed in further detail in response to comments MCWD-HGC-3, -5, and -9. The term "Northern Marina Subarea" as defined by HGC is not based on or consistent with the accepted definitions of basins in the SVGB and the term appears to have been created by HGC to describe an area which it appears to believe possesses unique hydrogeology. The area considered by HGC as the Northern Marina Subarea is simply part of a continuous, hydraulically connected portion of the 180/400-Foot Aquifer subbasin of the SVGB.

"Protective groundwater levels," discussed in the September 29, 2017 HGC letter and in other comments provided previously by HGC, apparently refer to purported areas of "freshwater" in the perched/mounded Fort Ord Salinas Valley Aquifer. HGC theorizes that groundwater in these perched/mounded aquifers flow westward and "waterfalls" into the Dune Sands and 180-Foot Aquifer creating a barrier to seawater intrusion. If these flows are present, they are hydraulically disconnected and located 1.5 miles inland of CEMEX, beyond the influence of the capture zone that would be created by MPWSP pumping. Furthermore, the ability of these flows to reduce seawater intrusion appears to be unsupported considering seawater intrusion has been documented along and inland of the coast for decades. For this reason, assertions such as (Page 29) "unique groundwater recharge condition creating shallow mounding in the Northern Marina Area will be removed by the project . . ." are a mischaracterization of the conceptual model of the SVGB that

14 The March 29, 2017 HGC technical memorandum, which provided its technical comments to the MCWD on the MPWSP Draft EIR/EIS, referred to the "Northern Marina Subarea" as the "Marina Subarea". It is assumed that the two names refer to the same areas.

has been put forth by the HWG and by this EIR/EIS and misrepresents the dynamics of groundwater gradients and flow in this area.

MCWD-HGC2-5

Reliance on Recent AEM Survey Data

HGC references the preliminary findings from the May 2017 Airborne Electromagnetic (AEM) Survey conducted by Dr. Rosemary Knight and her team from Stanford University to support its theory that there is a substantial freshwater resource in the "Northern Marina Subarea." Dr. Knight and her team released a preliminary report of the May 2017 AEM survey on June 16, 2017, the final report is under way and is expected in spring 2018. The 2017 AEM survey and its value in interpreting the groundwater conditions in the coastal area of the SVGB is discussed in detail in EIR/EIS Section 4.4, Groundwater Resources, in Master Response 9, Electrical Resistivity Tomography (ERT) and Airborne Electromagnetics (AEM) and in Final EIR/EIS Appendix E-3.

It appears that HGC interprets the preliminary AEM data presented in the June 2017 report to assert that groundwater with 3,000 milligrams per Liter (mg/L) TDS is fresh water. However, groundwater quality data from the MPWSP monitoring wells indicate that the groundwater with 3,000 mg/L TDS contains over 1,000 mg/L of chloride. As stated in the Final EIR/EIS Section 4.4, the State of California secondary maximum contaminate level in drinking water for TDS is 500 mg/L (recommended with 1,000 mg/L maximum) and 250 mg/L for chloride as per the California Code of regulations.[15] Therefore, HGC's assertion that groundwater with 3,000 mg/L TDS is freshwater is not an accurate way to translate this state threshold to represent the presence of a fresh groundwater resource.

HGC further misinterprets the AEM resistivity data because it presents the data as groundwater quality (fresh water to brackish water) when, in actuality, the preliminary AEM resistivity profiles represent the combined (bulk) resistivity of the water bearing sediments and the pore water in those sediments, rather than just the groundwater alone. This interpretation can lead to confusion because until the data are presented in such a way that distinguishes between the bulk resistivity and the resistivity/conductivity in the groundwater itself, the use of the preliminary AEM findings and the cross sections developed from the data to describe the current groundwater conditions is a misrepresentation of the data. Furthermore, the preliminary data is just that, and should not be used to draw conclusions or support previous assertions on whether or not significant freshwater pockets exists inland from the coast. For these reasons, many of HGC's assertions in the September 29, 2017 memorandum regarding groundwater flow, occurrence, and quality, which are based on the preliminary AEM data, are inaccurate and not discussed further.

15 California Code of Regulation Title 22. Division 4. Environmental Health Chapter 15. Domestic Water Quality and Monitoring Regulations Article 16. Secondary Water Standards, May, 2006.

MCWD-HGC2-6

Purported Presence of Fresh Groundwater in Dune Sand and 180-FTE Aquifers

HGC asserts in the September 29, 2017 letter, as it did in its March 27, 2017 memorandum, that there are areas in the Dune Sand Aquifer and 180-FTE Aquifer that contain significant quantities of fresh groundwater. HGC asserts that this contradicts the findings in the Draft EIR/EIS that indicate this area has been historically intruded by seawater. This issue is discussed in detail in response to comment MCWD-HGC-9. On Page 11 of the September 29, 2017 letter, HGC states that, "[g]iven the potential magnitude of the increased groundwater production in the Dune Sand Aquifer and the 180-foot aquifer, the impacts to the SVGB, in particular the North Marina Subarea are grossly understated by the MPWSP modeling to date." There is not now nor has there historically been water supply pumping from the Dune Sand Aquifer, due to low quantity and quality. The Dune Sand Aquifer and the 180-FTE Aquifer in the vicinity of CEMEX, in the area projected to be impacted by the project, is documented as containing highly brackish to saline water due to historic seawater intrusion. If there are localized areas of less brackish groundwater in the Dune Sand Aquifer, they are likely discontinuous and would become more brackish or saline once proposed project pumping began. Figures 9 and 10 presented in the September 29, 2017 letter are the same figures presented in its March 29 letter. These figures misrepresent the extent of the so-called fresh water because HGC fails to adequately consider the mechanics of seawater intrusion, bases the extent of the fresh water on only a select number of data points, and relies on an unrealistic threshold of freshwater (1,000 to 3,000 mg/L). Please refer to response to comment MCWD-HGC-9 for a complete discussion.

MCWD-HGC2-7

Salinity Effects of CEMEX Operations

HGC claims that CEMEX operations influence the salinity of the feedwater, and that CalAm's return water estimates fail to address how CEMEX operations impact the test slant well discharge and whether similar effects would occur for the proposed MPWSP production wells. HGC also states that there are local sources of saline water (namely, the dredge pond and percolation ponds) at CEMEX that are not located elsewhere, particularly where the MPWSP production wells are proposed, and implies that without these sources, the actual OWP in the MPWSP feedwater would be lower.

The dredge pond and percolation ponds do not create a unique source of saline water that influences salinity in the shallow groundwater. The dredge pond is excavated to a depth that exposes the groundwater surface so the water in the dredge pond is representative of the quality of groundwater beneath the CEMEX site. CEMEX uses dredge pond water and well water in its sand rinsing and sorting operations and conveys it through a flume to a percolation pond for disposal. The

percolation pond is adjacent to the dredge pond. When the dredge is operating (approximately 8 to 10 hours per day), the water in the flume is a mixture of brackish well water [approximate conductivity of 19,000 microseimens per centimeter (µs/cm)] and dredge pond water (conductivity of about 48,000 µs/cm). During the remainder of the time, only lower salinity well water is conveyed to the percolation pond. In essence, all that CEMEX is doing in its operation is transferring saline water from the dredge pond, mixing it with lower salinity well water during sand rinsing, and conveying that brackish-saline mixture back to the percolation pond where it infiltrates back into the shallow aquifer.

Conductivity in the test slant well and monitoring wells decreased in the winter-spring of 2017 due to the percolation of rainwater into the Dune Sands Aquifer. The winter of 2016-2017 was a record year for rainfall in Monterey County. Conductivity also decreased due to the disposal of rinse water to the percolation pond, as described above. Consequently, the average TDS of the water recharging the groundwater near the test slant well was much lower in TDS than the seawater. Precipitation and introduction of wash water can reduce conductivity in the test slant well but this condition is unique to the area overlying the dredge pond and CEMEX sand washing operations. The proposed MPWSP wells would be located south of the CEMEX operations and beyond the influence of the percolation pond infiltration. Rainfall infiltration would still contribute to the MPWSP feedwater and that is considered in the OWP calculation as it accounts for annual average precipitation occurring over the projected capture zone of the MPWSP production wells. Refer to Appendix E-3, Sections 3.1.7.3 and 3.2.3 for a detailed analysis of freshwater contributions to the test slant well discharge and OWP calculations.

MCWD-HGC2-8

Responses to Figures in the September 29, 2017 HGC Letter

Page 8, **Figure 5** (Water Level Elevation and Shoreline Proximity), is a confusing and somewhat misleading representation of groundwater data and is not considered by experts in hydrogeology as a standard method of representing groundwater flow. Groundwater flow in this region is shown accurately on groundwater contour maps presented in Appendix E-3 (*Appendix E, MPWSP Well Completion Report and CEMEX Update, TM2*).

Page 9, **Figure 6** (Resistivity Profile B-B' groundwater Flow direction) shows an inferred groundwater flow direction but there is no correlation with known lithology or basis for the flow paths. Also, because the colors represent bulk resistivity, the actual groundwater TDS concentrations are not represented. Therefore, this figure does not support HGC's assertions of freshwater inland from the coast.

8.5.2.7 Responses to Comments from MWCD – EKI2

These responses address comments that EKI provided to Marina Coast Water District (MCWD) in a memo report dated June 22, 2017. In that memo report, EKI outlines the groundwater remedial actions and establishment of remedial goals in the Dune Sand Aquifer (identified as the A-Aquifer) and the 180-Foot Aquifer at Fort Ord. EKI acknowledges in its memo report that MCWD and its counsel intend to meet with the Central Coast Regional Water Quality Control Board (CCRWQCB) to discuss the potential environmental impacts of the proposed Monterey Peninsula Water Supply Project (MPWSP).

EKI states that the MPWSP has the potential to degrade groundwater water quality and impact the beneficial uses of groundwater within the Dune Sand Aquifer and the 180-Foot Aquifer underlying MCWD's service area. EKI asserts the MPWSP Draft EIR/EIS characterized the Dune Sand Aquifer and the 180-Foot Aquifer as having "poor water quality" and that these aquifers are impacted by salt water intrusion. EKI also states the Draft EIR/EIS did not acknowledge that further degradation of the groundwater quality in these aquifers would violate the Water Quality Control Plan for the Central Coast Basin (Basin Plan), which designates all groundwater within the Salinas Valley Groundwater Basin (SVGB) as a potential drinking water source. Furthermore, EKI states that the Draft EIR/EIS findings contradict the restoration efforts that have been completed and continue to be completed to clean-up groundwater to drinking water standards in the aquifers underlying the former Fort Ord and that CalAm should be held to the same groundwater restoration standards as those required at Fort Ord.

The responses to EKI's comments are provided below and focus on the comments that address the adequacy of the Draft EIR/EIS. The responses are organized based on general topic areas. Many of the comments are similar to, or reflect those previously provided by HGC and EKI (see Sections 8.5.2.2 and 8.5.2.4, respectively).

The June 22, 2017 EKI memo report presents no new data, information, or findings that would cause a change in the conclusions of the impact analyses presented in the Draft EIR/EIS.

MCWD-EKI2-1

Characterization of Seawater Intrusion in the MPWSP EIR/EIS

The MPWSP Draft EIR/EIS, Section 4.4 did not use the term "poor water quality" to describe the groundwater in the Dune Sand Aquifer and 180-Foot Aquifer but it does acknowledge that these aquifers have been subject to years of seawater intrusion. The EIR/EIS references the Monterey County Water Resources Agency (MCWRA) seawater intrusion monitoring data (see EIR/EIS Figures 4.4-10 and 4.4-11) that have been collected from the 180-Foot Aquifer and the 400-Foot Aquifer for decades through its ongoing seawater intrusion monitoring program, and thus, was considered a reasonable benchmark to assess existing regional groundwater quality for the analysis in the EIR/EIS. EIR/EIS Section 4.4 states that, based on estimates from the MCWRA, seawater has intruded within the 180-Foot Aquifer and 400-Foot Aquifer by approximately 8 miles and 3.5 miles inland, respectively, based on chloride concentrations greater than 500 mg/L. There

is adequate evidence to verify that the groundwater underlying the CEMEX site and further inland has been impacted by seawater intrusion for decades. There is not now, nor has there historically been water supply pumping from the Dune Sand Aquifer, due to low quantity and quality. It is documented through groundwater monitoring that the Dune Sand Aquifer at CEMEX contains highly brackish to saline water due to historic seawater intrusion. If there are localized areas of less brackish groundwater in the Dune Sand Aquifer, they are likely discontinuous and would become brackish or saline once proposed project pumping began.

MCWD-EKI2-2

Impacts on Groundwater Quality from the MPWSP

The proposed MPWSP slant well pumping would be confined to a localized capture zone at the coast that would not extend inland from the coast or draw less brackish groundwater from inland regions of the Dune Sand and 180-FTE Aquifer. EIR/EIS Section 4.4 concluded that the proposed MPWSP would not violate or degrade groundwater quality in the Dune Sand Aquifer or the 180-FTE Aquifer. The conclusion was largely based on the understanding that the groundwater quality near the proposed MPWSP intake wells was highly brackish to saline. SWRCB Resolution No. 88-63 [Appendix A-9 of the Water Quality Control Plan for the Central Coastal Basin (Basin Plan)] resolves that "[a]ll surface and groundwater of the state are considered to be suitable, or potentially suitable, for municipal or domestic water supply and should be so designated by the Regional Boards with the exception of: *Surface and groundwater where the total dissolved solids exceed 3,000 mg/l and it is not reasonably expected by Regional Boards to supply a public water system" (*emphasis added). The groundwater underlying the capture zone of the proposed MPWSP slant wells is: 1) an order of magnitude more brackish (23,400 mg/L to 30,900 mg/L) than the Basin Plan threshold; 2) does not currently support a public water system or individual users, and; 3) other than its potential use for desalination, would not be reasonably expected to supply a public water system. As discussed in EIR/EIS Section 4.4, while the groundwater in the projected capture zone may become more saline because of MPWSP pumping (seawater would eventually replace the ambient highly brackish water), it would not degrade a groundwater source considered by the SWRCB as a suitable municipal or domestic water supply under the Basin Plan.

MCWD-EKI2-3

Relationship between the A-Aquifer at Fort Ord and the Dune Sand Aquifer at CEMEX

The Dune Sand Aquifer includes the -2 Foot Aquifer at the Monterey Peninsula Landfill and Perched "A" Aquifer in the Salinas Valley. These are separate from the shallow perched/mounded aquifers that include the 35-Foot Aquifer in the Monterey Peninsula Landfill area, and the A-Aquifer in the Fort Ord Area, which flows over the Fort Ord-Salinas Valley Aquitard (FO-SVA).

With this understanding, there are several important distinctions. First, the Dune Sand Aquifer (and equivalents) and the shallow perched/mounded aquifers are two distinct and hydraulically disconnected aquifers. Second, the primary "connection" between the two distinct water-bearing zones , is that the areal extent of the shallow perched/mounded aquifers, including the A-Aquifer underlying Fort Ord, is limited, which results in perched/mounded water flowing over the edge of the perching clay layer (similar to a waterfall) into the underlying Dune Sand Aquifer (and equivalents) or 180-FTE Aquifer. The edge of the perching clay layer occurs about 1.5 miles inland of the CEMEX site and the proposed MPWSP pumping. HGC and EKI have described the condition where freshwater "U-turns" from the perched/mounded A-Aquifer at Fort Ord and enters the Dune Sand Aquifer and/or 180-Foot aquifer and claim that these freshwater flows somehow develop a natural protection against seawater intrusion. However, the flows from the shallow perched/mounded aquifers are limited in quantity and it is unlikely that these flows have created the barrier to seawater intrusion because MCWRA monitoring data have shown that seawater intrusion has continued to migrate inland for the last several decades. However, whether or not this natural process is an actual barrier to seawater intrusion is of no consequence to the proposed MPWSP because the slant well capture zone would be located at the coast, 1.5 miles west, and would not encroach on this natural process, thereby allowing it to continue on into the future unimpeded after onset of MPWSP pumping. EKI states that the purported natural barrier to seawater intrusion ". . . appears to have been undermined north of Fort Ord through groundwater extraction and/or salt water discharges into the Dune Sand Aquifer at the CEMEX sand mining site and would likely be further disturbed by the Cal Am project." It is unclear what EKI is intending to convey by its claim that groundwater pumping north of Fort Ord and salt water discharges at CEMEX have undermined this natural barrier to seawater intrusion. While the groundwater beneath CEMEX is highly brackish to saline, CEMEX does not discharge saltwater. CEMEX discharges a mixture of brackish well water and dredge pond water to percolation ponds as part of its sand rinsing operation. Therefore, the water released to the percolation ponds has salinity less than that of seawater. In response to EKI's assertion that the proposed MPWSP would further disturb the "natural barrier" it is reiterated that if the flows from the perched/mounded A-aquifer near Fort Ord indeed create a freshwater barrier to seawater intrusion, it is occurring at least a mile and a half inland beyond the projected influence of the MPWSP capture zone.

MCWD-EKI2-4

MPWSP EIR/EIS Consideration of Ongoing Fort Ord Remediation

EIR/EIS Section 4.7.1.1 describes the three groundwater plumes at the Fort Ord Army Base that contain the contaminate carbon tetrachloride, which are identified as OUCTP A-Aquifer Plume, OUCTP Upper 180-Foot Aquifer Plume, and the OUCTP Lower 180-Foot Aquifer Plume (Figure 4.7-1). EIR/EIS Section 4.4

(Impact 4.4-4) considers whether the cone of depression, as projected by groundwater modeling ($NMGWM^{2016}$), would interfere with these plumes.

As discussed in EIR/EIS Impact 4.4-4, the OUCTP A-Aquifer Plume is located about 2 miles southeast of the proposed slant wells that is currently being treated using enhanced in situ bioremediation in the A-Aquifer, pump and treat in the Upper 180-Foot Aquifer, and natural attenuation in the Lower 180-Foot Aquifer. The EIR/EIS considers the consequence of the expanding MPWSP cone of depression reaching the western portion of the OUCTP A-Aquifer Plume and concludes that if it did, the projected decline in groundwater elevations could possibly spread contamination to areas currently not impacted by the plume. At 2 miles, the accuracy of the $NMGWM^{2016}$ decreases and thus, the projected 1 to 2-foot groundwater elevation is less certain to extend that far. The EIR/EIS considers the potential for the cone of depression of the MPWSP pumping to intersect the OUCTP A-Aquifer Plume a significant impact. Mitigation was proposed (Mitigation Measure 4.4-4) that would monitor changes in the groundwater surface elevation caused by MPWSP pumping near the OUCTP plumes. If it is determined that MPWSP pumping could interfere with the Fort Ord plumes, the mitigation measure requires CalAm to take necessary actions so the plumes do not expand and contaminate other areas, such as reimbursing the US Army for work necessary to change the plume flow direction, arrest migration of the plumes, and/or to remediate areas of new contamination created by MPWSP pumping. The EIR/EIS considers the impacts from the MPWSP on the OUCTP Upper and Lower 180-Foot Aquifer plumes less than significant. However, the mitigation measure referenced above would monitor the three plumes, as noted.

MCWD-EKI2-5

Remedial Actions and CCRWQCB Oversight

EKI suggests that CalAm should be held to the same groundwater remediation standard as those at Fort Ord because they claim the MPWSP would impact beneficial uses of groundwater in the Monterey Subbasin. Further, EKI opines that the modeling conducted to analyze the impacts of the proposed MPWSP does not adequately assess salinity impacts on the groundwater near the MPWSP.

There was no evidence, developed either through groundwater modeling or from available groundwater data, to conclude that the proposed MPWSP would impact the beneficial uses of groundwater in the SVGB. This is detailed in EIR/EIS Section 4.4. Salinity underlying the CEMEX property, where the proposed MPWSP slant wells would extract a mixture of brackish groundwater and seawater, is well documented through over two years of groundwater monitoring and operation of the test slant well. This work has verified the availability of brackish to saline groundwater for the MPWSP and confirmed it is feasible to extract it; see EIR/EIS Appendix E3. The feedwater for the proposed MPWSP would be extracted from a capture zone located adjacent to the coast, which contains

groundwater that exceeds, by an order of magnitude, the State of California's upper threshold for beneficial use of groundwater (3,000 mg/L TDS). The MPWSP groundwater wells would draw highly brackish groundwater from the capture zone, which over time would draw in a greater quantity of seawater. The inland flow to the proposed MPWSP slant wells would occur only within the localized capture zone and the slant wells would not initiate inland groundwater flow beyond the influence of the capture zone. Groundwater level response in the Dune Sand and 180-Foot Aquifers from the slant well pumping has been conservatively modeled; the modeling determined that the pumping would not impact other groundwater users in the SVGB.

The groundwater monitoring network developed for the test slant well adequately monitored groundwater levels and quality at and near the test slant well extraction. Additional monitoring wells in the Dune Sand Aquifer, 180-Foot Aquifer, the 400-Foot Aquifer and the Deeper Aquifer (see Applicant Proposed Measure 4.4-3, Groundwater Monitoring and Avoidance of Well Damage) would supplement the existing monitoring well network, which would monitor water levels prior to and at the onset of full-scale pumping. Additional monitoring wells would be placed based on the area of influence as it migrates away from the capture zone. Additional discussion of the conclusions derived from monitoring and test slant well operations and recommendations for continued monitoring is provided in EIR/EIS, Appendix E3.

There has been considerable effort to respond to comments on the adequacy of the groundwater modeling conducted for the EIR/EIS analysis, so it is not repeated here. Refer to EIR/EIS Section 4.4, response to comments MCWD – HGC, response to comments MCWD – EKI, and Master Response 12, North Marina Groundwater Model (v. 2016), for a detailed description of the development, calibration, assumptions, and results of the NMGWM^{2016}.

8.5.3 Responses to Comments from Monterey Bay Air Resources District

MBARD-1 To further reduce exhaust emissions that would be associated with project construction, Mitigation Measure 4.10-1a identified in EIR/EIS Section 4.10 has been revised as follows to include requirements for construction equipment powered by electricity or natural gas. For the context of the other revisions to the mitigation measure, refer to responses to comments MBARD-3 and MBARD-4, below.

> **Mitigation Measure 4.10-1a: Equipment with High-Tiered Engine Standards.**
>
> For diesel-fueled off-road construction equipment of more than 50 horsepower, CalAm and/or its construction contractor shall make a good faith effort to use available construction equipment that meets the highest USEPA-certified tiered emission standards or is alternatively powered (e.g., with electricity, natural gas, propane, methanol and ethanol blends, or gasoline) construction equipment. For all pieces of equipment that would ~~not~~ neither meet ~~at least~~ Tier ~~3~~ 4 emission standards nor be alternatively powered, CalAm or its construction contractor shall provide to the CPUC documentation from two local heavy construction equipment rental companies that indicate~~s~~ that the companies do not have access to higher-tiered equipment or alternatively powered equipment for the given class of equipment. Such documentation shall be provided to the CPUC at least two weeks prior to the anticipated use of those pieces of equipment.

MBARD-2 The following paragraph has been added to the end of EIR/EIS Section 4.10.2.2, Regional Agencies and Regulations, to acknowledge that if asbestos-containing pipes or materials are encountered during open trenching for pipeline installations, the requirements of air district Rule 424 and National Emissions Standards for Hazardous Air Pollutants could be triggered.

> ***Asbestos Program***
>
> The purpose of the Asbestos Program is to protect the public from uncontrolled emissions of asbestos through enforcement of the federal Asbestos Standard and Air District Rule 424. The program covers most renovations and demolition projects and may be triggered if asbestos-containing pipes or materials are encountered during open trenching for pipeline installations. Elements of the program include survey and notification requirements prior to beginning a project, as well as work practice standards and disposal requirements. The program operates on a "cradle to grave" basis through the regulation of all aspects related to the handling of asbestos materials from discovery and removal, through transportation and disposal (MBUAPCD, 2017).

MBARD-3 To further reduce exhaust emissions of NO_x that would be associated with project construction, Mitigation Measure 4.10-1a has been revised to identify construction equipment that meets Tier 4 standards as opposed to Tier 3 standards. For the revised mitigation measure, see response to comment MBARD-1.

MBARD-4 Mitigation Measure 4.10-1a has been revised to include the use of non-diesel powered equipment where feasible. For this revision, see response to comment MBARD-1.

MBARD-5 State Water Resources Control Board (SWRCB) Order 2016-0016 requires CalAm to terminate its water diversions from the Carmel River in excess of its legal entitlement by December 2021. To ensure a continuous water supply, the project must be completely constructed, tested, and operational by December 2021. The proposed project facilities are expected to be completely constructed by June 2020 (see Final EIR/EIS Section 3.3.9, Construction Schedule). Using measures to limit simultaneous construction activities would affect project schedule. Extending the construction schedule by too many months to avoid multiple simultaneous construction activities during the May-October ozone season may cause CalAm to violate the terms of SWRCB Order 2016-0016 (indeed, there is no feasible construction phasing schedule that could reduce construction NO_x impacts to a less-than-significant level). However, some construction scheduling to reduce overlapping high-emitting construction activities may be feasible. For example, Mitigation Measure 4.6-1d (Protective Measures for Western Snowy Plover), Subpart 2, restricts construction work at the slant well heads and along the segment of the Source Water Pipeline located west of the CEMEX processing plant to between October 1 through February 28 unless otherwise approved by the USFWS. Thus, construction activities accounting for approximately 13 percent of the estimated maximum daily construction emissions in Table 4.10-5 would likely occur mostly outside of the May-October ozone season. Similarly, Mitigation Measure 4.6-1h (Avoidance and Minimization Measures for Western Burrowing Owl), Subpart 5, may restrict some construction of the Source Water Pipeline, new Desalinated Water Pipeline, and new Transmission Main to between October 15 and April 1; together, the Source Water Pipeline and new Transmission Main account for approximately 17 percent of the estimated maximum daily construction emissions in Table 4.10-5. Therefore, to the extent feasible and anticipated to be required by wildlife permitting agencies, construction scheduling limitations would coincide with the May-October ozone season to reduce overlap among project components.

As noted above, further adjusting the construction schedule to reduce construction NO_x emissions would pose practical and economic constraints that do not meet the CEQA Guidelines feasibility criteria. Construction scheduling flexibility would be reduced as would CalAm's ability to manage unforeseen changes in field conditions. Because unexpected delays in contractor and materials availability would be more likely to occur when using a prolonged and phased construction

schedule, the total construction period could be extended beyond 42 months, in which case CalAm would be unable to meet its obligations under SWRCB Order 2016-0016. Therefore, mitigation to impose phased construction schedule requirements in order to reduce NOx emissions to a greater extent than described above is considered infeasible for this project.

MBARD-6 The representative of the Lead Agencies contacted the MBARD to determine the feasibility of funding an off-site mitigation program to mitigate the impact of construction-related NO_x off-site mitigation to offset construction-related impacts associated with emissions of NO_x.

The MBARD confirmed that it has worked with other project applicants to fund off-site mitigation programs for significant impacts under CEQA. In these cases, the emissions to be offset were typically long-term operational emissions, as opposed to short-term construction emissions. One exception is a housing development project that is being constructed over a number of years. For that project, the MBARD developed a mitigation fee per housing unit based on an annual fee per ton-year paid by the developer to be spent on various emissions offset ventures, including converting diesel-powered farm engines to run on electricity or an alternative fuel, development of electric vehicle infrastructure, and/or diesel school bus retrofits (MBARD, 2017a).

The MBARD indicated that one challenge for off-site mitigation programs to offset short-term construction emissions is that their implementation can be delayed due to uncertainties, such as securing third-party agreements. In addition, there is considerable front-end research required by MBARD staff that has posed some staffing challenges to administer the programs. For these reasons, the MBARD prefers mitigation to be on-site, but if impacts are not reduced to less than significant with incorporation of on-site mitigation, the MBARD indicated its planners would work with CalAm on an off-site mitigation program for the proposed project (MBARD, 2017a).

In order for a similar off-site mitigation program to effectively reduce construction-related impacts associated with the proposed MPWSP, the off-site mitigation program offsets would have to occur contemporaneously with project construction. This may or may not be feasible depending on the timing of the initiation of the offsets. In addition, the CEQA and NEPA Lead Agencies would have no ability to ensure that any third-party agreements that may be needed to initiate an off-site mitigation program would be successfully negotiated. Nonetheless, because air quality impacts associated with construction activities would not be reduced to a less-than-significant level with implementation of on-site mitigation, such as Mitigation Measure 4.10-1a, Mitigation Measure 4.10-1e, Off-site Mitigation Program, and related discussion has been added to the Final EIR/EIS (see below). It should be noted that since we cannot substantiate at this time that off-site

mitigation in the form of emissions offsets are feasible, the impact continues to be significant and unavoidable.

The following sentences have been revised in the EIR/EIS Gaseous Criteria Pollutant Emissions discussion of Impact 4.10-1 (see Air Quality Section 4.10.5.1, Construction Impacts).

> Implementation of **Mitigation Measures 4.10-1a (Equipment with High-Tiered Engine Standards),** ~~and~~ **4.10-1b (Idling Restrictions)**, and **4.10-1e (Off-site Mitigation Program)** would reduce NO_x emissions by requiring CalAm and/or its construction contractor(s) to make a good faith effort to use construction equipment that meets the highest USEPA-certified tiered emission standards~~, as well as~~ to ensure on-road and off-road equipment idling is minimized, and to fund an off-site mitigation program.

The following sentence has been added to the EIR/EIS Gaseous Criteria Pollutant Emissions discussion of Impact 4.10-1 (see Air Quality Section 4.10.5.1, Construction Impacts).

> In addition, it cannot be substantiated at this time that off-site mitigation in the form of emissions offsets is feasible given the schedule of proposed construction activities and schedule uncertainties associated with implementing such a program; therefore, off-site emission reductions that would be associated with this Mitigation Measure 4.10-1e cannot be quantified.

The following mitigation measure has been added to the EIR/EIS discussion of Impact 4.10-1 (see Air Quality Section 4.10.5.1, Construction Impacts).

> *Mitigation Measure 4.10-1e applies to all of the proposed project components.*
>
> **Mitigation Measure 4.10-1e: Off-site Mitigation Program.**
>
> CalAm shall work with the Monterey Bay Air Resources District (MBARD) and put forth a good faith effort to fund an off-site mitigation program that would be contemporaneous with project construction to offset construction-related NO_x. CalAm shall provide to the Lead Agencies documentation showing that it has reached an agreement with MBARD to fund an off-site emissions mitigation program that shall include offsets to be executed during construction of the project. If such a program is determined by CalAm and MBARD to be infeasible given the construction schedule of the project, CalAm shall provide documentation to the Lead Agencies that substantiates such a determination. All documentation shall be provided to the Lead Agencies at least two weeks prior to the commencement of construction.

MBARD-7 Operational NOx emissions would not exceed the applicable significance threshold (see Table 4.10-7); therefore, as described in Impact 4.10-4, no mitigation for NOx during operation is required. There would be no vehicle fleet associated with project operations.

MBARD-8 The first bullet item of Mitigation Measure 4.10-1c, Construction Fugitive Dust Control Plan, has been revised to include more frequent (three times daily) watering (see Air Quality Section 4.10.5.1, Construction Impacts).

As described below, modulating dust producing activities along populated corridors would not provide a meaningful reduction in the overall construction PM_{10} emissions.

The majority of the construction activities that would occur along populated corridors would be associated with installation of the proposed pipelines, which would occur at rates of 150 to 250 feet per day. The fugitive dust emission estimates assume that all six pipelines that would be constructed at various locations throughout Monterey County would be constructed concurrently. Concurrent construction of all pipelines combined with implementation of Mitigation Measure 4.10-1c, Construction Fugitive Dust Control Plan, is estimated to result in a maximum of 2 pounds per day of fugitive dust in the form of PM_{10} (see Final EIR/EIS Appendix G1.7). This equates to an average of about 0.3 pound per day per pipeline, and thus the emissions near specific sensitive receptors would be less than the total estimated daily emissions. There would also be earth moving associated with the ASR wells and Carmel Valley Pump Station in the vicinity of sensitive receptors; however, these activities would be limited to areas of 0.25 acre and 0.08 acre respectively, which would result in mitigated emissions of 1.8 pounds and 0.6 pound per day respectively. Therefore, even if fugitive dust emissions could be reduced by an additional 50 percent by modulating dust-producing activities in the vicinity of sensitive receptors, the resulting reductions would equate to less than 1 pound per day at any given location, which would not equate to a meaningful reduction, and would not be necessary to achieve a less-than-significant impact.

8.5.4 Responses to Comments from Monterey County Resource Management Agency

MCRMA-1 EIR/EIS Section 4.14 evaluated impacts of the proposed project on aesthetic (visual) resources. The visual setting at the desalination plant site is described in EIR/EIS Section 4.14.2.3; conformance with applicable Monterey County General Plan policies is described in Table 4.14-2. Construction impacts at the desalination plant site are addressed in Section 4.14.6.1. Operational and facility siting impacts at the desalination plant location, including consideration of effects on public views and visual compatibility with surrounding land uses, are addressed in Section 4.14.6.2 (see also Figure 4.14-4).

MCRMA-2 The text in EIR/EIS Section 4.8.2.3 has been revised to read: "~~*2010*~~*1982 Monterey County General Plan*." Additionally, a footnote has been added to clarify that for purposes of implementation of the LCP, the relevant 1982 General Plan policies currently remain applicable, although a comprehensive update was adopted in 2010.

MCRMA-3 The text in EIR/EIS Table 4.8-2 has been revised as follows:

> Lands with a General Plan land use designation of Permanent Grazing may need to be redesignated to accommodate the proposed MPWSP Desalination Plant unless the County issues a Use Permit, which~~. As necessary, such conversion~~ would occur through the requisite local planning and permit review processes. The proposed MPWSP Desalination Plant would be compatible with the adjacent Monterey County Landfill and the MRWPCA Regional Wastewater Treatment Facility.

MCRMA-4 The text in Draft EIR/EIS Table 4.8-2 has been revised as follows:

> Potentially Inconsistent: Impacts related to cultural, agricultural, and biological resources and water quality, are discussed in EIR/EIS Sections 4.15, 4.16, 4.6, and 4.3, respectively. Specifically, please refer to Tables 4.15-6, 4.16-2, 4.6-2, and 4.3-5 for additional discussion of the project's conformity with applicable North County Land Use Plan policies related to cultural, agricultural, terrestrial biological resources, and water quality ~~these resource areas~~, respectively. In all but one instance related to compatibility with established land use policies regarding biological resources (i.e., Impact 4.6-4), potential land use policy and regulation conflicts are resolvable with the implementation of recommended mitigation. Because this policy pertains to topics other than land use and recreation and is addressed elsewhere in the EIR/EIS, it is not discussed further in Section 4.8.

MCRMA-5 As noted in Draft EIR/EIS Section 4.16.2.1, the Farmland Protection Policy Act (FPPA) seeks to protect Prime Farmland, Unique Farmland, Farmland of Statewide Importance, and Farmland of Local Importance from conversion to non-agricultural

uses (7 USC §4201(c)(1)). As described in Section 4.16.5, Direct and Indirect Effects of the Proposed Project, the proposed project would not irreversibly convert any of these farmland designations to non-agricultural use. The conversion of land designated or zoned as grazing land, such as would occur due to construction of the MPWSP Desalination Plant on the 25-acre parcel designated Grazing Land and zoned for Permanent Grazing, would not conflict with the FPPA. The text in the last paragraph of Section 4.16.2.1 has been clarified as follows:

> The proposed project would not be subject to FPPA requirements because the project would not irreversibly convert Prime Farmland, Unique Farmland, Farmland of Statewide Importance, or Farmland of Local Importance ~~farmland~~ to non-agricultural use.

As described in Section 4.16.3, there are two impact significance criteria related to the conversion of farmland (or other agricultural land) to non-agricultural use: 1) involves changes in the existing environment that, due to their location or nature, could result in the conversion of farmland to non-agricultural use; or 2) converts Prime Farmland, Unique Farmland, or Farmland of Statewide Importance, as shown on the maps prepared pursuant to the FMMP, to non-agricultural use. The land on which the MPWSP Desalination Plant would be located is not designated as Prime, Unique, or Farmland of Statewide Importance by the FMMP, and thus would not result in a significant impact under the second criterion.

With respect to the first criterion, Impact 4.16-1 concludes that construction of the MPWSP Desalination Plant would have a less-than-significant impact with respect to conversion of agricultural land to non-agricultural uses because no agricultural uses currently are present in this location. CEQA Guidelines Section 15126.2(a) states that "In assessing the impact of a proposed project on the environment, the lead agency should normally limit its examination to changes in the existing physical conditions in the affected area as they exist at the time the notice of preparation is published…" The physical conditions on the proposed MPWSP Desalination Plant site are described in Section 4.16.1; the land has not been used for grazing for at least several decades. Because the land does not and has not sustained agricultural use for many years, constructing the MPWSP Desalination Plant would not be responsible for converting this land to non-agricultural use; thus, it would not result in a significant impact. According to CEQA Guidelines Section 15126.4(a)(3), mitigation measures are not required for effects which are not found to be significant. See also response to comment Marina-125 in Section 8.5.1 for further explanation regarding the conclusion that the proposed MPWSP would have a less-than-significant impact on the conversion of farmland to non-agricultural use.

Notwithstanding this limitation on the CPUC's ability under CEQA to impose mitigation on CalAm for the use of land zoned for grazing, CEQA does not affect

any agency's authority to condition permit approval in any way consistent with that agency's statutory and constitutional powers. If Monterey County would like to consider requiring additional mitigation for this use of the 25-acre site in the context of its issuance of a conditional use permit for the proposed project, CEQA would not prohibit it from doing so. It would be the responsibility of CalAm to consult with the appropriate entities (which could include the Ag Land Trust) regarding such issues at that time.

MCRMA-6 Mitigation Measure 4.16-1, Minimize Disturbance to Farmland (on Draft EIR/EIS page 4.16-14) lists several measures that CalAm and its construction contractors shall incorporate into construction plans and specifications for all construction activities located in farmland areas to minimize adverse impacts on farmland. Such measures apply to the proposed alignments of the Source Water Pipeline, new Desalinated Water Pipeline, and Castroville Pipeline north of Charles Benson Road. Included in Mitigation Measure 4.16-1 is the requirement that CalAm shall notify affected property owners at least 90 days prior to initiating construction activities that have the potential to interfere with agricultural operations. The mitigation also includes several other measures to minimize disturbance to farmland.

In response to this comment, the second bullet point under Mitigation Measure 4.16-1 has been revised to require CalAm and its construction contractors to consult with affected property owners to determine the best construction schedule for their operations:

- Construction contractor(s) shall minimize the extent of the construction disturbance, including construction access, in agricultural areas to the maximum extent feasible. <u>Minimization efforts shall include, but not be limited to, consulting with affected property owners to schedule construction activities to minimize impacts during planting, growing, and/or harvest seasons.</u>

See response to comment MCRMA-5 regarding the County's authority to further condition permit approval, including by requiring that the project be reviewed by the County Agricultural Commissioner's Ag Advisory Committee.

8.5.5 Responses to Comments from Monterey County Water Resources Agency

MCWRA-1 MCWRA's review of the EIR/EIS, and general comments on Chapter 2 (Water Demand, Supplies and Water Rights), Section 4.3 (Surface Water Hydrology and Water Quality), Section 4.4 (Groundwater Resources) and Appendix E2 (updated Groundwater Modeling) are acknowledged. See responses to the more specific comments MCWRA-2 through MCWRA-8.

MCWRA-2 The text corrections have been made in EIR/EIS Section 4.2.1.3.

MCWRA-3 The Department of Water Resources' (DWR) 2016 Bulletin 118 Interim Update responds to the Sustainable Groundwater Management Act (SGMA), which is discussed in Master Response 6, The Sustainable Groundwater Management Act. Section 8.2.6.2 of Master Response 6 provides a discussion of basin name designations including the current basin and subbasin boundaries, and notes that the designation of basin names and boundaries may change. Regardless of where the boundaries will eventually be established and named, the EIR/EIS hydrogeologic and groundwater investigations used the names described in this EIR/EIS, although the groundwater models further subdivided the areas into cells that used input parameters specific to that individual cell, as explained in Section 4.4.4.2, Groundwater Modeling. Therefore, to maintain consistency throughout the EIR/EIS, and the hydrogeologic and groundwater modeling (Appendices B2, C3, E1, and E2), the names of the basins have not been changed in Final EIR/EIS Figure 4.4-1.

MCWRA-4 In response to this comment, the discussion of the Seaside Groundwater Basin and Aquifers in Section 4.4.1.2 (Draft EIR/EIS page 4.4-12) has been clarified as follows:

> The Seaside Groundwater Basin (SGB)<u>, as defined by the California Department of Water Resources, the Seaside Watermaster, and the Monterey Peninsula Water Management District,</u> encompasses approximately 24 square miles at the southwest corner of the Salinas Valley adjacent to the Pacific Ocean (Yates et al., 2005). The <u>Seaside Watermaster</u> ~~SGB is~~ further subdivided <u>the SGB</u> into the Northern and Southern Subbasins by the Laguna Seca Anticline and a segment of the Ord Terrace Fault, which restrict groundwater flow between the subbasins (HydroMetrics, 2009a). The two subbasins are further subdivided into coastal and inland subareas with the division boundary just west of General Jim Moore Boulevard.

All references in the EIR/EIS to the Seaside Groundwater Basin (SGB) refer to the basin defined in the above-cited paragraph and not to the "Seaside Area Subbasin" referenced in the comment.

MCWRA-5 In the process of further evaluating basin names and boundaries in response to the SGMA, the California DWR has recently renamed the area in between the southern boundary of the Pressure Area and the adjudicated Seaside Groundwater Basin shown on Figure 4.4-1. In response to this comment, the following new language has been inserted into EIR/EIS Section 4.4.1.2, at the end of the subsection titled Salinas Valley Groundwater Basin (Draft EIR/EIS page 4.4-5):

> The boundaries and names of the basins have been updated to reflect the currently available information, as shown on **Figure 4.4-1**. This figure illustrates the updated basin boundaries in the western part of the SVGB, which were used in the modeling for the proposed project (HydroFocus, 2016). Subsequent to the publication of the Draft EIR/EIS, the California Department of Water Resources made further changes by designating the area in between the Pressure Area (now called Salinas Valley Basin, Subbasin 180/400 Foot Aquifer) and the adjudicated Seaside Groundwater Basin as the Monterey Subbasin of the SVGB. In this EIR/EIS, the primary area of study within the SVGB is within the Pressure Area.

MCWRA-6 Draft EIR/EIS page 4.4-19 incorrectly states that the 2015 Brown and Caldwell report was prepared for the MCWRA, when it was actually prepared for the Monterey County Resource Management Agency (MCRMA). The text in has been revised accordingly in the Final EIR/EIS.

MCWRA-7 The referenced text in the section on Groundwater Enhancement Programs in the SVGB in Section 4.4.1.3, Groundwater Flow and Occurrence has been revised to clarify that the CSIP is operated in tandem with the SVRP.

MCWRA-8 The text on Draft EIR/EIS page 4.4-28 discusses the extent of seawater intrusion as measured by the concentration of Total Dissolved Solids (TDS), which can also be measured using chloride concentrations. Both measurement methods would result in delineating the same extent of seawater intrusion, shown on Figures 4.4-10 and 4.4-11. However, in the section on Seawater Intrusion in Section 4.4.1.4, Groundwater Quality, the text has been revised to clarify that the MCWRA uses chloride measurements.

8.5.6 Responses to Comments from Monterey Peninsula Regional Water Authority

MPRWA-1 The Lead Agencies acknowledge the Monterey Peninsula Regional Water Authority's commendation of the Draft EIR/EIS.

MPRWA-2 As described in detail in EIR/EIS Section 4.3.5.2, the assessment of impacts and regulatory compliance related to the discharge of brine via the existing MRWPCA outfall diffuser is based on model analyses that incorporate conservative (i.e., worst-case) assumptions regarding effluent and receiving water density, dilution and mixing dynamics, and concentrations of water quality constituents. Consistent with such an approach, the model analyses utilized a combination of water quality characteristics for the desalination brine and receiving water, such as temperature and salinity, that resulted in the maximum density, and thus the most conservative (lowest) dilution results specific to each assessed discharge scenario.

As discussed in Master Response 8, Project Source Water and Seawater Intrusion, Section 8.2.8.1, the groundwater entering the slant wells would originate only from within the capture zone and after the ambient groundwater is extracted from the capture zone, the capture zone would continue to be recharged by ocean water. As explained in Master Response 4, The Agency Act and Return Water, Section 8.2.4.3, the steady-state water inflows to the capture volume would be seawater inflow from Monterey Bay and recharge from precipitation on the land surface overlying the capture zone.

Increasing the temperature of the brine, as suggested, based on monitoring data from the test well and/or from the desalination process (which would not add heat)[1] would result in slightly decreased assumed brine density and a subsequent slight increase in the assessed dilution; increased dilution would further reduce potential water quality impacts associated with operational discharges reported and discussed in the EIR/EIS. Therefore, using ocean water temperature without heat gain from the treatment process remains a reasonable and conservative assumption.

MPRWA-3 Whereas the April 2015 Draft EIR did not directly address hypoxia or the Coanda effect (sometimes referred to as the Coanda attachment, see also Appendix Section 4.3), this EIR/EIS addresses both in EIR/EIS Section 4.3.5.2. The dilution modeling conducted for this EIR/EIS considered the near-field to be limited to the edge of the Zone of Initial Dilution (ZID), which is the point at which the plume would no longer driven by the dynamics of the discharge port, and dilution would become influenced by the ocean waves and currents; this distance would range between 10 and 39 feet from the diffuser ports (see Table 4.3-13). The far-field is

[1] See EIR/EIS Section 4.3.3: "There would be no heating mechanism or any process that would increase the temperature of the source water as it passes through the treatment units."

considered to be the area between the edge of the ZID and the edge of the regulatory BMZ at 100 meters (328 feet). EIR/EIS Table 4.3-13 shows that for the most-dense operational scenario modeled (brine-only, Scenario 2), salinity at the edge of the BMZ would be 1.34 ppt above ambient. Since the salinity increment above ambient would be low, and the Coanda attachment would not occur, hypoxia would not occur, consistent with the conclusion found by Geosyntec using the mass balance analysis. In response to the comment, the second paragraph on p. 4.3-84 of the Draft EIR/EIS has been revised as follows:

> Comments specifically expressed concern that, due to sediment oxygen demand and potential limited mixing due to dense discharges forming Coanda attachments, limited dilution and mixing could restrict oxygen supply. As described above, Coanda attachments would not occur, and modeled salinity levels are less than 2 ppt above ambient salinity at the edge of the ZID. Further, to evaluate the potential for hypoxia, Geosyntec (2015) performed a mass-balance analysis (a mass-balance analysis accounts for a given material entering and leaving a system) based on dilution and dispersion analyses for operational discharges completed by ESA (ESA, 2015). The analysis applied a mass-balance approach to a conservative areal extent of a brine-only plume (i.e., the most-dense of the proposed operational discharges) to derive estimates of oxygen demand in local sediments (70 to 180 kilograms/day) and estimates of oxygen supplied (less than 5,600 kilograms/day) by the operational discharges (including entrained seawater). Based on the results of the mass-balance analysis, the amount of oxygen supplied to the discharged plume by ambient seawater entrained during turbulent mixing and dilution is more than 30 times greater than that consumed by the sediments. As such the concentration of dissolved oxygen in receiving ocean waters would not become depressed by more than 10 percent from that which occurs naturally, hypoxia is unlikely to occur as a result of proposed operational discharges and impacts would be less than significant.

MPRWA-4 The total annual net project energy demand used to estimate project greenhouse gas (GHG) emissions includes consideration of a net reduction of 8,100 acre-feet per year (afy) of product water pumping in the existing Monterey Main System, which includes facilities in Carmel, Seaside, Ryan Ranch, Bishop, and Hidden Hills. However, for a conservative analysis, it was assumed that no CO_2 degassing currently occurs due to groundwater pumping for the Monterey Main System due to the relatively shallow depths of the existing Carmel Valley wells.

In addition, the project GHG emissions estimates identified in the EIR/EIS do not include consideration of the 800 afy of reduced groundwater pumping by the Castroville Community Services District (CCSD) from the Salinas Valley Groundwater Basin. However, assuming the same energy use factor that was used for estimating the existing Monterey Main System (i.e., 913 kWh per acre-foot of

water produced), and the same groundwater degassing rate as estimated for the project (i.e., 735 metric tons CO_2 per 23,219 acre-feet water pumped), the reduced groundwater pumping by the CCSD would result in a net reduction of project-related GHG emissions of about 120 metric tons CO_2e per year. Compared to the amortized emissions of the project presented in the Final EIR/EIS (i.e., 8,365 metric tons CO_2e per year), the reduction would represent approximately 1.5 percent of the GHG emissions estimated for the project and this potential reduction in GHG emissions is considered negligible.

MPRWA-5 Subsequent to the release of the Draft EIR/EIS, Mitigation Measure 4.11-1 has been revised to include a net zero indirect operational GHG emissions requirement for the project (see Impact 4.11-1 discussion in Final EIS/EIR Section 4.5.11). One of the items identified in the revised measure's emission reduction loading order is to procure renewable energy from off-site sources within California via purchases from one or more of a variety of specified sources, including Monterey Bay Community Power.

MPRWA-6 Text has been revised to clarify that the offshore portion of the outfall consists of 60-inch and 48-inch diameter pipe (E2 Consulting Engineers, 2014).

MPRWA-7 Figure 10 in Appendix D1 is a reproduction of a figure presented in the study referenced in the figure title and is accurately labeled.

MPRWA-8 In response to the comment, the last bullet on page 4.3-73 of the Draft EIR/EIS has been revised as follows:

> Estimate regions within the BMZ where salinity would exceed 2 ppt <u>above background salinity</u>.

References

E2 Consulting Engineers, 2014. Basis of Design Report for Proposed Brine Mixing Facility – Section 4. January. Prepared for MRWPCA.

8.5.7 Responses to Comments from Monterey Peninsula Water Management District

MPWMD-1 EIR/EIS Table 3-8, Anticipated Permits and Approvals, includes the Monterey Peninsula Water Management District (MPWMD) Water System Expansion permit under Ordinance 96 of the MPWMD Board of Directors. Ordinance 96 includes Rule 20-A, which describes permits to create/establish a water distribution system.

MPWMD-2 The referenced sections, including EIR/EIS Section 3.2.3.5, have been revised; Terminal Reservoir has been removed from the description of the proposed project, from Figure 3.3-9b and from all sections of the EIR/EIS that evaluated the component. The treated water storage tanks were properly described in Draft EIR/EIS Section 3.2.3.1.

MPWMD-3 In response to this comment, the first paragraph of EIR/EIS Section 2.2.1 has been revised to include the Monterey Peninsula Airport District. This does not change the analysis or conclusions presented in the EIR/EIS, which recognized that the airport district is within the area served by the project.

MPWMD-4 In response to this comment, the 2016 Cease and Desist Order (CDO) has been added to the referenced sentence in EIR/EIS Section 2.1.

MPWMD-5 In response to this comment, the referenced text in EIR/EIS Section 2.2.1.1 has been revised as shown:

> The majority of the Monterey District water supply comes from 21 extraction wells screened in the upper alluvial deposits of the Carmel River in Carmel Valley known as the Carmel Valley Alluvial Aquifer. CalAm's supply also includes ~~Carmel River supplies are supplemented, especially during the summer high-demand season, by~~ groundwater production wells in the Seaside Groundwater Basin.

Furthermore, as a result of the September 2016 Phase 2 decision that authorized the construction of the Monterey Pipeline, text at the end of EIR/EIS Section 2.2.1.1 that references the hydraulic trough has been deleted.

MPWMD-6 The existing interconnections are emergency interconnections according to the Monterey Peninsula, Carmel Bay, and South Monterey Bay Integrated Regional Water Management Plan (MPWMD and Denise Duffy & Associates, 2014). In response to this comment, the EIR/EIS text has been revised, but these revisions do not change the analysis or conclusions presented in the Draft EIR/EIS. The revisions include the addition of a footnote in Section 2.2.1:

> Because the Toro and Ambler areas would not be served by the proposed project, these areas are not included in the proposed project's demand and supply assumptions.[4]
>
> [4] There is an existing emergency interconnection between the Toro and Hidden Hills systems; the project would not change the use of this emergency interconnection.

In addition, the second and third paragraphs of EIR/EIS Section 2.2.2.2 have been revised for clarity.

MPWMD-7 In response to this comment, the footnote on Draft EIR/EIS page 2-4 (now footnote 7 in the Final EIR/EIS due to other revisions) has been revised to include the sentence,

> "In January 2017, the MPWMD approved a contract for preparation of an alternatives study for Los Padres Dam and sediment management in the reservoir (MPWMD, 2017)."

MPWMD-8 The description of the Monterey Peninsula Water Resources System presented on page 2-5 of the Draft EIR/EIS is based on information in the MPWMD comment letter that was submitted on the 2015 MPWSP Draft EIR, which stated in relevant part, regarding the corresponding section of Chapter 2 in the 2015 Draft EIR, "The District's jurisdiction extends throughout its entire boundary; however, *MPWMD has defined the sources of supply to the CalAm system as the MPWRS.* Amendments to the MPWRS are made through ordinances such as Ordinance No. 135, which changed the definition of the MPWRS to include all of the Seaside Groundwater Basin, including the Laguna Seca Subarea…." (MPWMD 2015, page 2, emphasis added.)

Neither MPWMD's 2015 comment on the Draft EIR cited above, nor the current Draft EIR/EIS text cited in the current comment, state or imply that CalAm's sources of supply are for CalAm's exclusive use. To clarify the text in response to this comment, the paragraph under Section 2.2.2.3, Allocation Program has been revised as follows:

> The MPWMD augments, manages, and regulates surface and groundwater resources in the Carmel Valley and the greater Monterey Peninsula. MPWMD's jurisdiction includes the area served by CalAm's Monterey District (shown in **Figure 3-1** in Chapter 3, Description of the Proposed Project) and CalAm's sources of supply (the Seaside Groundwater Basin and Carmel Valley Alluvial Aquifer), which MPWMD defines as the Monterey Peninsula Water Resource System (MPWMD, 2015b). The Monterey Peninsula Water Resource System includes supplies for non-CalAm pumpers in the Seaside Groundwater Basin and Carmel Valley Alluvial Aquifer, as well. The MPWMD was established…

MPWMD-9 In response to this comment, the text in the first paragraph of EIR/EIS Section 2.2.2.4 has been revised to include Order 2016-0016.

MPWMD-10 In response to this comment and consistent with Section 3(b)(viii) of Cease and Desist Order 2016-0016, the text in the last paragraph on page 2-7 of the Draft EIR/EIS is revised as follows:

> …. If CalAm fails to meet a milestone, the Revised CDO specifies that the annual diversion limit will be reduced by 1,000 afy. The revised CDO also provides that "[i]f the State Water Board determines that the cause [for failing to achieve a milestone] is beyond Applicants' control, it may suspend any corresponding reductions under [the specified CDO condition] until such time as the Applicants can reasonably control progress towards the Milestone."[13] Section 5.4.2, No Project / No Federal Action, provides further discussion on the CDO and the milestones.
>
> [13] Order WR 2016-0016 Schedule and Condition 3(b)(viii).

MPWMD-11 EIR/EIS Table 2-3, Other Demand Assumptions, accurately presents the demand assumptions identified by CalAm in its Application A.12-04-019 to the CPUC for approval of the MPWSP, and does not explicitly identify a timeline associated with Pebble Beach water entitlements or legal lots of record. In response to this and other comments, as well as the SWRCB's recognition of the Pebble Beach water entitlements in the CDOs, the discussion of Pebble Beach Water Entitlements throughout the EIR/EIS has been revised to show that the Pebble Beach entitlements are considered existing service area demand that CalAm is obligated to serve, with or without the proposed project. See EIR/EIS Section 1.6.2. Therefore, given that "Service Area Demand" now includes the demands of existing service area customers as well as the existing Pebble Beach entitlements, EIR/EIS Table 2-3 and the corresponding Table 6.3-1 in EIR/EIS Section 6.3 have been revised to qualify the term as follows:

> "Existing Annual Service Area Demand."

Please also see responses to comments MPWMD-21, MPWMD-57, and MPWMD-59.

MPWMD-12 Draft EIR/EIS Section 2.3.3.3 (Final EIR/EIS Section 2.3.2.2) discusses the two preliminary MPWMD estimates and describes MPWMD's opinion that CalAm's estimate of supply needed to serve lots of record is not a valid number. The comment augments information presented in Draft EIR/EIS Section 2.3.3.3 on the lots of record estimates, noting that additional development has occurred in the service area since the preliminary estimates MPWMD prepared in the early 2000s, and implying that there are likely now fewer vacant legal lots of record than when MPWMD's estimates were prepared. As described in Draft EIR/EIS Section 2.3.3.3, the more recent of MPWMD's two estimates (1,211 afy), from 2002, was greater

than CalAm's estimate even though the 2002 estimate did not include vacant lots on improved parcels in unincorporated Monterey County. MPWMD testified in 2013 (Stoldt, 2013) that CalAm's estimate may therefore, underestimate demand associated with lots of record. This comment observes that some vacant lots on unimproved parcels may never be split from those parcels and developed.

The EIR/EIS discloses the uncertainty of the estimates of water demand associated with lots of record, noting that MPWMD adopted neither of the estimates it had commissioned due to their shortcomings. The analysis of potential growth inducing impacts in EIR/EIS Section 6.3 compares the water supply that would be provided by the proposed project to serve additional development (such as lots of record) with the updated estimate of demand associated with general plan buildout that MPWMD prepared in 2006 in consultation with service area jurisdictions (see Draft EIR/EIS Section 2.5.3.4, pages 6-35 through 6-37).

To explicitly recognize that development has occurred in the service area since the estimates were prepared and update the EIR/EIS discussion pursuant to this comment, the third and fourth paragraphs in Final EIR/EIS Section 2.3.2.2 (which had been Draft EIR/EIS Section 2.3.3.3) has been revised as follows:

> The summary identifies two reports on the topic of lots-of-record water demand that were prepared for the MPWMD in 2000 and 2002, and notes that the 2001 estimate cited in CalAm's 2006 Management Plan was from an interim period between these two reports. The 2000 report, which had identified demand of 1,166.3 afy for vacant lots and remodels, was not adopted by the MPWMD Board because it did not include estimates for the city of Monterey or the unincorporated county; the revised 2002 report, which identified demand of 1,211 afy, included estimates for the city of Monterey but not for the unincorporated county (MPWMD, 2013c). The MPWMD's direct testimony to the CPUC in February 2013 reiterated these observations, stating that the MPWMD does not consider the 1,181 afy estimate a valid value and that the higher 2002 estimate did not account for vacant lots on improved parcels in the unincorporated areas (Stoldt, 2013). While MPWMD testified that ~~Thus,~~ CalAm's estimate may therefore underestimate the actual demand for lots of record (Stoldt, 2013)~~.~~, MPWMD observed in 2017 that development of lots of record has occurred since the estimates were prepared in the early 2000s and that some vacant lots on improved parcels that were included in MPWMD's vacant lot study may never be split from the main property and developed (MPWMD, 2017). Whether development of lots of record since the early 2000s has offset, or more than offset, the number of uncounted lots that should have been included in the 2002 study, and by how much, cannot be determined from available data.

~~On the other hand,~~ Another factor affecting the estimate of demand associated with lots of record is water use rates. ~~c~~Comment on the 2015 MPWSP Draft EIR suggested that water demand per lot has likely decreased in years since those reports were prepared. It may be the case that per-lot water demand is somewhat lower than 15 years ago, considering the general trend in lower per capita demand in the service area and throughout the state; however, the extent of such reductions may not be quantifiable based on available data ~~and, more important, water demand for lots in the unincorporated part of the service area had not been estimated at all in the 2000 study and were only partly taken into account in the 2002 study, as stated in the MPWMD testimony~~. (Refer to Section 6.3, Growth Inducement, for additional discussion of this demand component.)

The first paragraph under "Vacant Lots of Record" in Section 6.3.5.1, Proposed MPWSP Water Service Capacity, has been revised as follows:

…The District never adopted this estimate because it did not include demand associated with vacant lots on improved parcels in the unincorporated County areas (Stoldt, 2013). While MPWMD testified in ~~In~~ 2013~~, the MPWMD testified~~ that CalAm's estimate of 1,181 afy may therefore underestimate demand associated with lots of record (Stoldt, 2013), in 2017 MPWMD observed that development has occurred since those estimates were prepared in the early 2000s and that some vacant lots on improved parcels that were included in MPWMD's vacant lot study may never be split from the main property and developed (MPWMD, 2017). MPWMD's most recent estimate of future service area demand, prepared…

The new reference added in Section 6.3.5.1 (MPWMD, 2017) is shown in response to comment MPWMD-7. Nothing in this comment or response would result in a revision to the EIR/EIS analysis or conclusions.

MPWMD-13 Draft EIR/EIS Section 2.3.4.2 (changed to Section 2.3.3.2 in the Final EIR/EIS), to which this comment refers, accurately summarizes information presented in CalAm's 2010 Urban Water Management Plan (UWMP), including its non-revenue demand estimates and projections, and no changes to that section are warranted in response to this comment.

Draft EIR/EIS Section 2.5.3.3, Non-revenue Water Reduction, provides more current information on CalAm's non-revenue water than is included in the 2010 UWMP. EIR/EIS Section 2.5.3.3, which includes information from quarterly reports CalAm submits to the SWRCB in compliance with the 2009 CDO, shows that since 2009 CalAm has substantially reduced non-revenue water (referred to as unaccounted-for water in the reports), consistent with this comment. The quarterly reports show 12-month running averages of unaccounted-for water (e.g., for the periods January 2015-December 2015, February 2015-January 2016, etc.).

Quarterly reports in 2016 show that non-revenue water for the period January-December 2015 (i.e., the calendar year) was 247 af, consistent with the information cited in this comment. (The quarterly reports do not provide total production data with which the percentage of non-revenue water might be calculated.) The 12-month running averages show that the amount of system losses fluctuates from period to period, and occasionally show anomalous results, which is why the Draft EIR/EIS showed the average trends over several years. In general, non-revenue water has continued to decrease, as indicated in the EIR/EIS and this comment. For example, in most of the 12-month running averages reported since January-December 2015, non-revenue water has totaled less than 200 af, although for the period April 2016 to March 2017 non-revenue water was slightly higher than for January-December 2015 (271 af compared to 247 af) (CalAm 2016; 2017). In response to this comment, the text in EIR/EIS Section 2.5.3.3 has been revised to update the information on non-revenue water, as follows:

> CalAm submits quarterly compliance reports to the State Water Board under the CDO (CalAm, 2011, 2012b, 2013, 2014, 2015~~.~~). ~~In t~~Those reports show~~, CalAm states~~ that between the 2011 and 2015 water years, CalAm ~~the company has~~ reduced system losses by an average of 506 afy~~,~~ compared to the base year system losses in water year 2009, and that by the end of this period the reductions in water losses exceeded the reduction target of 549 afy that had been established in the 2009 CDO:~~. Further, for the last three years,~~ the reduction in system losses ranged from 752 af in water year 2013 to 919 af in water year 2015~~, which exceeds the 549 afy target established in the CDO~~. System losses (i.e., the amount of non-revenue or unaccounted-for water), as opposed to the *reduction* in losses, for the period October 2014 through September 2015 (water year 2015) totaled 357 af and system losses for the period January through December 2015 (calendar year 2015) totaled 247 af (CalAm, 2016d). Since then, through March 2017, system losses were less than 200 afy in all 12-month periods except one (April 2016-March 2017), when non-revenue water totaled 271 af. CalAm notes that the actual components of unaccounted-for water are difficult to identify because unaccounted-for water represents a combination of system leaks and unmetered water use. Savings from system repairs and line replacements and the like through 2015 ~~would be~~are reflected in CalAm's system demands data ~~for those years, as part of the 10 years of demand data~~ discussed in Section 2.3.1.

California American Water (CalAm), 2017. Letter report to Barbara Evoy, Division Chief, Division of Water Rights, SWRCB, Re: SWRCB Order WR 2009-0060, 2nd Quarterly Report for the 2016-2017 Water Year Addressing Operations for the Period of January 1, 2017 to March 31, 2017. Dated May 1, 2017. Available: https://amwater.com/caaw/customer-service-billing/billing-payment-info/water-rates/monterey-district.

MPWMD-14 The Monterey Pipeline referenced in this comment was evaluated and approved as part of the CPUC's September 2016 Phase 2 GWR decision. Attachment 1 referenced in this comment is a table entitled "Effects of the Monterey Pipeline on ASR Yields by Water Year Type" and shows Carmel Valley well field capacity and permitted diversions for both ASR Phase 1 and ASR Phase 2 projects (Permits 20808A and 20808C, respectively). MPWMD's estimate of the long term annual yield for ASR Phases 1 and 2 and additional CalAm improvements noted in this comment is similar to the estimate of 1,920 afy for ASR Phases 1 and 2 that was presented in an Addendum prepared for the ASR project (Denise Duffy & Associates, 2012), as cited on page 2-19 of the Draft EIR/EIS. However, based on the information presented in Attachment 1, the yield of the two phases appears to be about 1,600 afy with the Monterey Pipeline in place in normal rainfall years. In addition, since the time that Attachment 1 was provided with this comment, MPWMD has added three new columns to the table (Stoldt, 2017) that show the weighted average yields based on the relative frequency of different water year types. As shown in the table below, the weighted average increased yield from adding the Monterey Pipeline is 714 afy and the weighted average total yield of the Phase 1 and 2 ASR projects is 1,641 afy or about 1,600 afy.

	Operational Days		Project Yield (AF)			Percent of Time	Weighted Increased Yield	Weighted Total Yield
	20808A	20808 C	Without Pipeline	With Pipeline	Increased Yield			
Critically Dry	4	3	53	86	33	12.5%	4.1	10.8
Dry	18	14	239	393	154	12.5%	19.3	49.2
Below Normal	41	33	545	908	363	12.5%	45.4	113.5
Normal	69	62	918	1,600	682	25.0%	170.5	399.9
Above Normal	94	102	1,357	2.372	1,016	12.5%	127.0	296.5
Wet	115	114	1,530	2,784	1,254	12.5%	156.8	347.9
Extremely Wet	139	140	1,862	3,389	1,527	12.5%	190.8	423.6
						Weighted Average:	713.8	1,641.46

SOURCE: Stoldt, 2017

As discussed in EIR/EIS Section 2.4.3, because of the variability of precipitation and instream flow levels and because diversions allowed under the ASR permits are contingent on maintaining instream flows, CalAm assumes a more conservative yield – 1,300 afy – from the ASR Phase I and II projects and the proposed MPWSP ASR-5 and ASR-6 wells. Given the low yields during dry years and critically dry years (53 to 239 af per year without the Monterey Pipeline and 86 to 393 afy with the pipeline, respectively), the recent severe five-year drought, and that more frequent and severe droughts will occur in the state in coming years due to climate change,[1] CalAm's lower estimate of long term reliable yield from the ASR is not unreasonable. Estimates in this EIR/EIS of supply provided by the MPWSP in conjunction with other sources assume operation of the proposed desalination plant at or close to 100 percent capacity. Should the MPWMD's current estimate prove more accurate than CalAm's, and the ASR system thereby provides more supply than CalAm currently expects, CalAm could operate the desalination plant at a less intensive level, as discussed in Master Response 13, Demand (Project Need) and Growth. The difference between MPWMD's and CalAm's ASR's yield estimates, 700 afy, is equivalent to about 0.6 mgd. Assuming ASR provides 700 afy more than was assumed for the MPWSP, a 9.6 mgd desalination plant could operate at 93 to 94 percent capacity, rather than 100 percent, to produce about 9 mgd of product water.

The discussion under "Water Available for Growth" in Master Response 13, Section 8.2.13.3, considers other possible supply and demand scenarios. If supply from the Carmel River ASR system provided either 1,300 or 1,600 afy, in combination with the other assumed supplies, the desalination plant could be reduced by one or two 1.6-mgd reverse osmosis units, depending on the particular demand scenario. See Master Response 13 for more information.

MPWMD-15 The typographical errors in the numbers of the two water rights permits in the paragraph at the bottom of page 2-20 and top of page 2-21 of the Draft EIR/EIS have been corrected.

MPWMD-16 The text in EIR/EIS Section 2.4.6.2, Malpaso Water Company LLC, is primarily based on information presented in the Findings in MPWMD Ordinance 165, as indicated in the cited references, which uses the term "Malpaso Water Company Water Use Permit subscribers" several times (e.g., in Findings No. 3, No. 6, and No. 8). Text in Section 2.4.6.2 has been revised to adhere to the term used in the Findings of Ordinance 165 and to clarify the use of "subscribers."

MPWMD-17 In response to this comment, the discussion under "Los Padres Reservoir" in EIR/EIS Section 2.5.2.1 has been updated as follows:

[1] For example, at the same time the California governor directed the State Water Resources Control Board to lift specific provisions of the drought emergency in April 2017, he also proposed legislation to establish long-term water conservation measures and "improved planning for more frequent and severe droughts" (SWRCB, 2017).

> …Based on the 2008 study, MPWMD estimated~~s~~ that the long-term sedimentation rate of the reservoir was~~is~~ 21 afy and that more than 510 af of replacement supply would likely be needed to offset the lost capacity (MPWMD, 2015b). A 2016 resurvey conducted for MPWMD determined that although the reservoir can hold up to 1,810 af at the spillway level, the safe usable storage was less than 1,400 af due to concerns about releasing anoxic water or water with hydrogen sulfide in the lowest portion of the reservoir (MPWMD, 2017). MPWMD currently estimates that sedimentations rates could range from 11 to 19 afy. Based on the 2016 resurvey and changes in reservoir operation, MPWMD currently believes that the previous estimate of needed replacement supply may be low. However, because the need for this replacement supply is long-term, MPWMD believes that water supply available from the Seaside Groundwater Basin at the end of CalAm's in-lieu replenishment period (discussed in Section 2.2.4) may be adequate to offset losses in supply from the Los Padres Dam and Reservoir (MPWMD, 2017).[30] As noted in Section 2.2.2, MPWMD and CalAm are currently studying the long term options for the Los Padres Dam and Reservoir.
>
> [30] The estimate of safe useable reservoir capacity based on the 2016 resurvey is 779 af less than the capacity identified in Order 95-10 (2,179 af), and an additional 700 afy will be available to CalAm at the end of the Seaside Groundwater Basin in-lieu replenishment period.

The new reference added in Section 2.5.2.1 (MPWMD, 2017) is shown in response to comment MPWMD-7.

MPWMD-18 The completion date shown in the Draft EIR/EIS is based on the cited reference, MPWMD Ordinance 168 (specifically, Item 5 on page 2 of the ordinance). In response to this comment, however, the second paragraph in EIR/EIS Section 2.5.3.1 has been revised and this comment letter is cited as a reference. See response to comment MPWMD-7 for the new reference.

MPWMD-19 Please see the response to comment MPWMD-13, which addresses the discussion of non-revenue water presented in Section 2.5.3.3.

MPWMD-20 EIR/EIS Table 2-5 presents the estimates of future water supply need (demand) prepared by MPWMD in consultation with service area jurisdictions in 2006 and revisions to some of those estimates based on more recent information. The revisions included an updated estimate for Monterey County based on the 2030 water demand estimate presented in Monterey County General Plan Final EIR Table 4.3-9e, Carmel River/Seaside Aquifer Existing and 2030 Estimated Water Demand. Table note "h" at the updated county estimate in EIR/EIS Table 2-5 explains that the updated estimate is "for the unincorporated county areas served by the Carmel River and Seaside Basin aquifer;" therefore this demand estimate would not include demand for the city of Marina. In addition, a review of the

Monterey County General Plan land use plans for the Greater Monterey Peninsula and Carmel Valley Master Plan planning areas shows that the areas south and east of CalAm's service area largely consist of lands designated as "rural grazing" and "resource conservation," which are unlikely to generate much water demand. The same Table 2-5 without further revisions is included in EIR/EIS Chapter 2.

The only reference to the "Greater Monterey Peninsula" on the page cited in this comment is Footnote 31, which is part of a discussion of several updates to the projection of future water supply needs associated with general plan buildout that had been prepared by MPWMD in 2006. Footnote 31 explains that because the Monterey County General Plan Final EIR used a higher per capita demand rate than currently assumed, and because the population estimate assumed in the General Plan EIR was higher than what AMBAG more recently projects, the EIR/EIS used the General Plan Final EIR estimate of 2030 demand (1,005 afy) rather than the estimate of buildout demand (4,439 afy).

The commenter's opinion of the County General Plan estimates of future demand and population are acknowledged The revised estimate of future supply needs in EIR/EIS Table 2-5 represents the most current data available on demand anticipated by the adopted general plan for the area that most closely conforms to the area served by CalAm, and table note "h" discloses the breakdown of demand for subareas within that portion of the unincorporated county that are included in the estimate. The future demand estimates presented in this table were not the basis for sizing the MPWSP but are presented to provide a general comparison of demand associated with anticipated development under adopted general plans with the proposed project water supply that would be available to serve additional development. Please note that the revised county estimate in EIR/EIS Table 2-5 *reduces* MPWMD's own estimate, which was prepared in consultation with the county for the area served by CalAm.

Finally, in comment MPWMD-62, the commenter endorses the revised estimate of 3,526 afy shown in EIR/EIS Table 2-5 (and Table 6.3-8), of which the county estimate is part, suggesting at least general agreement with the revised estimate. See also EIR/EIS Appendix L, which considers several other possible supply and demand scenarios. The results of these scenarios are summarized in Master Response 13, Section 8.2.13.5.

MPWMD-21 This comment confirming that the MPWMD has not determined how water provided by the MPWSP may be allocated and suggesting how it may be allocated or reserved is noted. Absent definitive information about the allocation, it was necessary to make assumptions for purposes of the growth inducement analysis presented in EIR/EIS Section 6.3. The discussion in EIR/EIS Section 2.5.4 discloses the EIR/EIS *assumptions*, as opposed to presenting more definitive information, as indicated in the section heading, "Assumptions about the Allocation of MPWSP Water," and section text. The assumption that water

provided by the project that is not needed for existing demands or Salinas Valley return water would be used to meet demand associated with future development is an appropriately conservative assumption for the impact analysis, in the absence of verifiable commitments that project water would not be so used. The assumption that water not needed for existing demand or return water obligations would be distributed in general proportion to projected planned growth in the CalAm service area is also appropriate, in the absence of definitive information on any MPWMD plans to the contrary.

Regarding the statement that MPWMD "may" maintain a reserve to offset Pebble Beach water entitlements, note that based on comments by the Pebble Beach Company, other comments by MPWMD, and the SWRCB's recognition of the Pebble Beach water entitlements, the EIR/EIS has been revised to characterize the Pebble Beach entitlements as an "existing" demand. Thus the EIR/EIS assumes that water supply provided by the MPWSP or other sources water would be retained – by whatever means the MPWMD determines – to offset the Pebble Beach entitlements (see, e.g., responses to comments MPWMD-11 and MPWMD-57).

In response to this comment, the text of the second paragraph of Draft EIR/EIS Section 2.5.4 on page 2-30 has been revised to expand the discussion of MPWSP water allocation, as follows:

> One of the MPWMD's key functions is to allocate water supply within its boundaries. The water supply that the proposed project would provide, along with other existing and planned supplies, would continue to be subject to MPWMD's allocation program. Although MPWMD has not yet begun to address allocation of the proposed MPWSP supply, this analysis assumes that the same considerations that informed the past and current allocations will be relevant to the allocation of the MPWSP supply. This EIR/EIS assumes for purposes of the impact analyses presented in Chapters 4 through 6 that water provided by the proposed project will be used to ~~allocated to~~ meet existing demand and that any water left over would be allocated in general proportion to projected planned growth in the CalAm service area jurisdictions. MPWMD recently confirmed that the future allocation process has not been defined and that MPWMD will update its 1990 Allocation Program EIR only when it is clear that CalAm will complete construction of a project to provide replacement supplies [for the reductions that resulted from SWRCB Order 95-10 and related CDOs and the Seaside Basin adjudication] (MPWMD, 2017). MPWMD indicates that it may not allocate all the water, choosing instead to retain some for future allocation to jurisdictions, "as general plans change over time," or to "retain a reserve for public benefit projects, maintain a reserve to offset Pebble Beach entitlements, maintain a buffer for fluctuating demand due to economic or climate issues, or retain allocable water to allow a lower plant capacity factor for operations" (MPWMD, 2017). In the absence of

> definitive commitments as to how water provided by the project would be allocated (or not), the assumption that water provided by the project and not needed for existing demands or Salinas Valley return water would be used to meet demand associated with additional development, distributed in general proportion to projected planned growth in the CalAm service area, is a reasonable and appropriately conservative assumption for the EIR/EIS impact analysis.

The new reference added in Section 2.5.4 (MPWMD, 2017) is shown in response to comment MPWMD-7.

MPWMD-22 The referenced footnote in EIR/EIS Chapter 2, Water Demand, Supplies, and Water Rights) has been revised as requested in this comment.

MPWMD-23 EIR/EIS Figure 3-1 has been revised to include the Toro portion of CalAm's Service Area.

MPWMD-24 See response to comment USARMY-7 in Section 8.3.2.

MPWMD-25 EIR/EIS Table 4.1-2 has been revised to reflect the addition of two new extraction wells by CalAm at the Sand City Desalination Plant.

MPWMD-26 Project No. 17 has been removed from the cumulative analysis.

MPWMD-27 In response to this comment as well as comment MPWMD-40, the first paragraph on page 4.3-63 of the Draft EIR/EIS has been revised to remove the reference to the prior use of the depression during the development of ASR-3 and ASR-4 wells.

MPWMD-28 This comment is addressed in Master Response 6, Sustainable Management Act, which includes a discussion of basin boundaries.

MPWMD-29 The referenced text has been corrected in Section 4.3, Surface Water Hydrology and Water Quality, to state that the capacity of Los Padres Reservoir has been reduced by about 60 percent capacity, as opposed to 2 percent capacity.

MPWMD-30 This comment is addressed in Master Response 6, Sustainable Management Act, which includes a discussion of basin boundaries.

MPWMD-31 As noted on Draft EIR/EIS page 4.4-25, Pueblo Water Resources 2016 was the reference, and the cited text has been revised to reflect Water Year 2015, as follows:

> For the 2015~~2013~~ water year, groundwater in Well PCA-E was estimated to contain about~~22 to~~ 30 percent injected potable water.

MPWMD-32 The reference to the Seaside Ozone Treatment Plant in Section 4.4.1.4 has been revised to "Santa Margarita Chemical Building."

MPWMD-33 The referenced text in Section 4.8.2.4, Special Districts, has been clarified to reference "an amendment to [CalAm's] Water Distribution System Permit" rather than "a Water System Expansion Permit."

MPWMD-34 A footnote has been added to Section 4.4.2.2 to clarify that "The RWQCB regulates ASR operations throughout California under SWRCB Order 2012-0010 General Waste Discharge Requirements for Aquifer Storage and Recovery Projects that Inject Water into Groundwater. However, the MPWMD operates the Seaside Basin ASR wells under Permit 20808C, which predates the statewide order."

MPWMD-35 The discussion of Division of Water Rights Permit 20808C – Amended Permit for Diversion and Use of Water in Section 4.4.2.2 has been updated as follows:

> ***Division of Water Rights Permit 20808~~C~~ – Amended Permit for Diversion and Use of Water***
>
> In 1995, the State Water Resources Control Board (SWRCB) issued Permit 20808 to the Monterey Peninsula Water Management District (MPWMD) for the proposed Los Padres Reservoir project. The permit was later split and modified several times, and now addresses additional requirements for the diversion of surface and under stream flow from the Carmel River, protection of the Carmel Lagoon and fish habitat, and the injection and storage of Carmel River water in the Seaside Basin using the ASR injection/extraction wells. The MPWMD and CalAm now jointly own Permits 20808A and 20808C, which total 5,326 acre feet per year. The ASR project that diverts excess water off of the Carmel River operates under Permits 20808A and 20808C.
>
> The requirement to limit recovered water to 1,500 acre feet in any given year is associated with a side agreement between MPWMD, CalAm, and the California Department of Fish and Wildlife (CDFW) concerning recovery of water injected into the Seaside Basin under Permit 20808A. The Quarterly Water Budget Group which was set up to determine how the CalAm system should be operated can decide to extract less. This agreement does not include water recovered under Permit 20808C. However, Condition 7 in the Cease and Desist Order (CDO) (see Section 2.2.3 State Water Board Order 95-10 and Cease and Desist Order 2009-0060 for discussion) requires that all water injected under either Permit 20808A or 20808C be recovered in the same year, unless the CDFW and the National Marine Fisheries Service (NMFS) agree to an alternate recovery plan. Under the CDO, the first 600 acre feet per year of water diverted to ASR in

any water year must go toward offsetting Carmel River diversions in the water year it is diverted.

These requirements and others placed by the SWRCB on ASR recovery will be lifted once the CDO is met; thus, these limits will not be an operational or budgetary limit after replacement supplies are operational and CalAm has reduced its Carmel River diversions to authorized amounts.

MPWMD owns Permit 20808B for 18,674 acre feet per year, which is referred to as the "remainder" permit and is associated with a project to build a new main stem reservoir on the Carmel River downstream of the existing Los Padres Dam. That permit has a different set of instream flow requirements that were fixed to the permit by the SWRCB in 1995 prior to NMFS listing steelhead as a threatened species. No water has been diverted under Permit 20808B to date.

~~Permit 20808C set requirements for the ASR system and established a maximum annual Carmel River diversion of 2,900 afy for injection and storage in the Seaside Basin, timing and monitoring requirements for diversion, fish protection measures, and rules for the recovery of the stored water. The current annual volume of stored water that can be recovered is 1,500 afy, plus unrecovered carryover water from previous years, if available. In addition, the volume of recovered water may not exceed 1,500 af for a given year if the volume of water injected that year, plus carryover from previous years, does not equal 1,500 af. In that case, only the volume of water injected that year, plus whatever carryover water is available may be recovered.~~ Implementation of the proposed project would allow CalAm to more effectively utilize its Carmel River water rights by increasing its capacity to inject water for storage when river flows are sufficiently high to allow for diversion. CalAm is presently operating within the terms of the permit and nothing about the proposed project would change its ability to operate consistent with the permit.

MPWMD-36 See Master Response 4, Agency Act and Return Water, Sections 8.2.4.1 through 8.2.4.3 for additional information on the return water calculations and input from the Hydrogeologic Working Group (HWG).

MPWMD-37 The Proposed Return Water Settlement mentions there may be limitations in the capacity of the CSIP to accommodate **all of the return water** under some conditions [emphasis added]. EIR/EIS Section 3.2.3.7 articulates that "the first 800 afy would go to CCSD and the remaining water would go to the CSIP." There are no indications or reasons to believe that the CSIP could not feasibly accept the balance of the return water.

MPWMD-38 The referenced text has been revised to clarify the relationship between the SEAWAT model and the Seaside Groundwater Basin Modeling.

MPWMD-39 See EIR/EIS Section 3.4.2, Operation of the ASR System, which explains that the Seaside Groundwater Basin annual monitoring reports prepared by the Seaside Groundwater Basin Watermaster would be reviewed yearly to identify the current location of the groundwater depression in the Santa Margarita Formation, the aquifer unit where the ASR system water would be banked.

MPWMD-40 See response to comment MPWMD-27.

MPWMD-41 The requested clarification has been made.

MPWMD-42 The requested clarification regarding the ASR source aquifer (i.e., the Santa Margarita Sandstone) has been made in EIR/EIS Section 4.4.5.2.

MPWMD-43 EIR/EIS Section 3.2.4 explains that CalAm proposes to expand the existing Seaside Groundwater Basin ASR system to provide additional injection/extraction capacity for both desalinated product water and Carmel River supplies, and to increase system reliability. EIR/EIS Table 3-8 has been revised to reflect the need for CalAm to file a Petition for Change with the SWRCB in order to use ASR-5 and ASR-6 wells for the injection and extraction of Carmel River water.

MPWMD-44 The EIR/EIS Section 4.4.5.2 text referred to in this comment has been revised to make the clear distinction between in lieu recharge and delivered water. See also response to comment Thomas-10 in Section 8.7.24.

MPWMD-45 The reference to Figure 4.7-2 in the subsection "Interference with Existing Groundwater Remediation Systems" has been revised to include reference to Figure 4.7-1 as well. Together, these two figures show the entire project area; therefore, while the ASR wells are visible on Figure 4.7-2 only, there are several nearby sites that are shown on Figure 4.7-1 that are located north of the ASR well area.

MPWMD-46 Carbon dioxide (CO_2) would have the opportunity to be released once the seawater concentrate reaches the brine equalization basin where it would first be exposed to the atmosphere; however, this does not change the amount of CO_2 estimated to be released.

The following revisions to the Brine Degassing Emissions discussion in EIR/EIS Section 4.11.4.2 have been incorporated as shown below:

> The remaining 57 percent would be discharged to the brine storage basin where it would temporarily be stored ~~prior to being discharged back into the ocean where it would~~ and have the opportunity to come to equilibrium with the atmosphere ~~and~~ thereby releasing CO_2 ~~would be released~~.

MPWMD-47 Although EIR/EIS Table 4.19-1 accurately reflects the DOF's estimates of the increase in housing units for the individual service area cities and unincorporated county, the total number of housing units shown for the Monterey District Service Area in 2015 contains a transcription error. The correct total is 43,053 units (not 43,858), an increase of 195 units since 2010. Table 4.19-1 has been revised accordingly. The Department of Finance is an established, standard source of demographic estimates and projections in California. (Another potential source of 2015 estimates, the U.S. Census Bureau's American Community Survey, shows a greater increase in the number of units in most service area cities compared to the DOF estimates.)

MPWMD-48 The referenced text in Section 5.2.5 has been changed to read as follows,

> "… and the Monterey County Agency Act prohibition on out- of-basin transfers <u>of groundwater</u>…"

MPWMD-49 The EIR/EIS has been revised to include Pebble Beach entitlements as a component of existing demand, as stated in the response to comment MPWMD-11 and related responses. Accordingly, the first and last paragraphs under "Supply Shortages" and first paragraph under "Monterey Peninsula Water Conservation and Rationing Plan Actions" in EIR/EIS Section 5.4.2.3 have been revised to show that baseline demand under the No Project Alternative is 12,595 afy, rather than 12,270 afy, and that available supplies under the No Project Alternative represent 51 percent, rather than 52 percent, of baseline demand.

While some economic rebound at existing properties theoretically could occur under the No Project Alternative, it is not reasonably foreseeable. Considering the adverse socio-economic impacts of the No Project Alternative identified in EIR/EIS Section 5.5.20, Socioeconomics and Environmental Justice, and the shortfall that would exist for serving existing demands, an assumption that economic rebound would not occur and could not be served under this alternative is reasonable. MPWMD itself stated in comments to the State Water Board on the 2016 extension of the CDO, regarding reduced diversions from the Carmel River then under consideration, that the reduced diversion amount "will likely undermine the local economy" (MPWMD, 2016); the reduced Carmel River diversion amount then being considered was greater than combined total supplies that would be available under the No Project Alternative. MPWMD also anticipates adverse socioeconomic impacts under this alternative according to comment MPWMD-52.

A footnote has been added to the first paragraph under "Supply Shortages" in EIR/EIS Section 5.4.2.3 to clarify the reason demand associated with economic recovery at existing businesses is not assumed as part of baseline demand under the No Project Alternative:

> …Because the MPWSP or an alternative new water supply would not be implemented, this scenario assumes that potential demands associated with hospitality industry rebound[2] and legal lots of record….
>
> [2] Increased demand that resulted from economic recovery at existing businesses would not require new water connections or permits to be served. However, given the constrained supply that would result under the No Project Alternative, economic rebound resulting in increased demand at existing water customers is not considered reasonably foreseeable under this alternative. Therefore, additional demand at existing businesses resulting from economic recovery is not considered part of the baseline service area demand for this analysis. (See also Section 5.5.20 regarding anticipated socioeconomic impacts of the No Project Alternative, and the discussion of this demand component in Section 6.3, which assumes that a degree of economic rebound identified by CalAm in its application as future demand has already occurred and is therefore reflected in existing annual demand.)

In addition, the footnote in the first paragraph under "Monterey Peninsula Water Conservation and Rationing Plan Actions" has been revised to clarify that the comparisons of supply and demand under the No Project Alternative do not include demand associated with vacant legal lots of record or economic recovery.

MPWMD-50 The assumption in EIR/EIS Section 5.4.2.3 that reductions in Carmel River diversions would occur under the No Project Alternative due to failure to meet milestones required in the CDO does not presume that CalAm is "at fault" or "chooses" not to execute the project. However, neither does it presume to know how the SWRCB would interpret its CDO and the failure to meet CDO milestones.

According to the language in the CDO, suspension of reductions is not automatic but at the Water Board's discretion, it "may" suspend any corresponding reduction. The key result of the No Project Alternative is that the service area would experience a serious reduction in water supply. Whether the supply reduction would begin somewhat gradually in 2018 due to a missed milestone, as assumed in the description of the No Project Alternative, or occur at once at the end of the CDO extension in 2022 (illustrated as a supply gap "cliff" in some MPWMD presentations) may be debatable, but it is not unreasonable to assume that reductions would occur if milestones established in the CDO to ensure progress were missed.

The CDO also includes schedule and condition number 15, which states that "[t]he conditions of this Order, State Water Board Order WR 2009-0060 and State Water Board Order 95-10 shall remain in effect until (a) CalAm certifies, with supporting documentation, that it has obtained a permanent supply of water that has been substituted for the water illegally diverted from the Carmel River and (b) the Deputy Director for Water Rights concurs, in writing, with the certification." By the reasoning in this comment, this could be interpreted to mean that if CalAm fails to obtain a new permanent supply, but CalAm is not responsible for that failure, that the SWRCB would allow the level of illegal river diversions established for 2016 in the CDO to continue indefinitely. The 2009 and 2016 CDOs are intended to ensure progress toward obtaining a replacement supply and stop illegal diversions as required in Order 95-10, and it does not seem

reasonable that the SWRCB would allow (such as under a No Project Alternative scenario) illegal diversions to continue indefinitely.

MPWMD-51 As noted above in responses to comments MPWMD-11, MPWMD-49, and others, the EIR/EIS has been revised to recognize that CalAm is obligated to serve Pebble Beach entitlements with or without the project and that these entitlements are appropriately considered a category of existing demand. Text in EIR/EIS Section 5.5.21.2 and Table 5.5-18 have been revised accordingly, showing that demand associated with existing annual service area demand, existing water entitlements, and existing land uses under an improved economy totals 12,845 afy, rather than 12,520, and that demand associated with new development totals 1,430 afy, rather than 1,755 afy. EIR/EIS Section 5.5.21.2 text and Table 5.5-19 have been revised to show that the quantity of supply available after meeting the aforementioned existing demands and a 6 percent or 12 percent SVGB return water obligation would total 1,845 afy or 209 afy, respectively.

Provision of water to develop vacant lots of record meets the definition of a growth inducing effect described in CEQA Guidelines Section 15126.2(d), which is presented in Section 6.3.3, Regulatory Framework, of the EIR/EIS growth inducement analysis. Vacant lots of record cannot currently be served water; with the project, water supply would be available that would allow their development. Therefore, the project would remove water supply constraints as an obstacle to growth, consistent with the CEQA Guidelines definition of a growth inducing effect. The analysis in Section 6.3 concludes that the growth that would be supported by the MPWSP would be consistent with growth planned by cities and the county in the CalAm service area. The analysis also recognizes, in Section 6.3.6, Secondary Effects of Growth, that even planned growth would have environmental impacts, and discloses the impacts of growth that would be supported, in part,[2] by the project. The identified impacts are based primarily on the EIRs prepared for the General Plans and General Plan elements of jurisdictions in CalAm's service area. Some of those impacts are significant and mitigable and some are significant and unavoidable. Growth supported by the project – e.g., development of currently vacant lots – is therefore expected to result in at least some of the impacts expected from development under adopted land use plans of service area jurisdictions.

The degree to which a vacant legal lot of record that would be served by the project has undergone environmental review is uncertain. Arguably, some lots are likely to have been created before environmental review was required for a division of land. More to the point, however, is that CEQA specifically requires consideration of a project's potential to remove an obstacle to growth in its growth inducement analysis, as noted above. In the CalAm service area, water supply constraints have been such an obstacle. The effect a vacant parcel has on the

[2] While water service is only one of many factors affecting the growth potential of a community, it is one of the chief public services needed to support urban development.

environment is different from the effect of a developed parcel. Consistent with the CEQA Guidelines, the analysis did not assume that growth in the CalAm service area was necessarily beneficial, detrimental, or of little significance to the environment; as noted above, the analysis identified growth-related impacts based on the environmental documents prepared for city and county General Plans.

MPWMD-52 Consistent with CEQA and NEPA requirements presented in Section 6.3.3, the growth inducement analysis in Section 5.5.20 focuses on the ways and extent to which the proposed project or alternatives (including the No Project Alternative) would foster economic or population development, including by removing an obstacle to such development. The "negative growth" factor associated with the No Project Alternative, which is noted in the comment, is addressed in the socioeconomic and environmental justice effects in Section 5.5.20.3. The analysis concludes that the socioeconomic and environmental justice impact of the No Project Alternative would be significant and unavoidable.

MPWMD-53 The commenter's opinion about the significance of the impact of the proposed project and the No Project Alternative is acknowledged. See responses to comments MPWMD-51 and MPWMD-52.

MPWMD-54 The bullet referenced in this comment is part of EIR/EIS Section 6.1, Significant and Unavoidable Environmental Effects. The analysis conclusion summarized in this bullet is consistent with NEPA and CEQA requirements for the analysis of growth inducing impacts and the analysis of the project's growth inducing impact presented in Section 6.3. See also response to comment MPWMD-51.

MPWMD-55 In response to this comment, the seventh sentence in the first paragraph of EIR/EIS Section 6.3.1 has been revised to include the Monterey Peninsula Airport District.

MPWMD-56 The referenced description of MPWMD was based on information at its former (now replaced) website. In response to this comment the text and bullets in EIR/EIS Section 6.3.2.3 have been revised as requested.

MPWMD-57 As noted in response to comment MPWMD-11, the discussion of the Pebble Beach entitlements has been revised to show that they represent existing service area demand that CalAm is obligated to serve with or without the project. The text under "Pebble Beach Entitlements" in EIR/EIS Section 6.3.5.1 has been revised as follows:

> … Because the recently issued permits may not immediately translate to water connections or water use that is reflected in existing demand data, 325 afy is a reasonable estimate of ~~future~~ demand associated with these entitlements.

> The remaining entitlements represent an existing commitment by MPWMD to issue water permits to entitlement-holders and, as stated by the SWRCB in the CDO (SWRCB, 2016), the total entitlements represent less water than historically had been diverted from the Carmel River to serve areas now served by the wastewater project. Given that the Pebble Beach entitlements represent an existing commitment by MPWMD and duty to serve by CalAm whether or not the MPWSP is implemented, water supply limitations are not considered an obstacle to the development of the Del Monte Forest properties associated with these entitlements. Therefore, the Pebble Beach water entitlements are considered part of CalAm's existing demand and project water supply used to serve these entitlements would not be growth-inducing under CEQA or NEPA. ~~but the entitlements do not represent existing demand or development. Supply provided by the MPWSP would enable remaining entitlement holders to convert the entitlements to actual water permits – and water – to serve the development of properties in the Del Monte Forest. MPWSP supply used to serve the Pebble Beach entitlement-holders would remove water supply limitations as a constraint on that development, and would therefore, induce growth.~~

Regarding economic rebound, the comment that increased demand associated with economic rebound would occur at existing properties and would not be growth inducing is acknowledged and consistent with the EIR/EIS analysis. The EIR/EIS growth inducement analysis considers project water supply used to serve increased demand at existing businesses under improved economic conditions to be a component of existing demand, and not growth-inducing. The Draft EIR/EIS states (page 6-17): "This rebound in demand is assumed to occur due to increased occupancy rates without any expansion in physical capacity. Because no development or expansion of physical capacity would cause those demand increases, water supply provided to meet such increases would not be considered growth-inducing under CEQA or NEPA." The analysis does, however, conclude that CalAm's estimate of the amount of supply needed to serve economic recovery within the existing hospitality sector may be overstated. The proposed MPWSP would be capable of producing a given quantity of product water, and as stated in Draft EIR/EIS Section 2.5 (page 2-29), future demands cannot be predicted with absolute certainty. If less water supply than CalAm estimated was needed to meet demand at existing land uses due to economic rebound, more water (i.e., the difference between the estimated 500 afy and the amount actually needed, if it turns out to be less) would be available for other purposes. Absent a known, enforceable allocation or other mechanism to limit the proposed water supply to the uses specified in CalAm's application, it is appropriate for the EIR/EIS growth inducement analysis to consider that if some of the water supply identified for economic rebound is not used for that purpose it could be used to support development in the service area.

The EIR/EIS evaluates the project proposed by CalAm. To assess the potential increased water demand that could result from economic rebound of the hospitality industry (a major industry in the service area), the EIR/EIS reviews changes in commercial sector water consumption before and since the recession started; this approach is also consistent with MPWMD's approach as described in the document "MPWMD Analysis of Hospitality Bounce-Back" (cited as MPWMD, 2013b in EIR/EIS Chapter 2). In response to this comment, water consumption data for the industrial and public authority sectors were also reviewed to consider how the recession may have affected water consumption in those sectors. This additional review is described under "Economic Recovery" in Section 8.2.13.1 of Master Response 13, Demand (Project Need) and Growth.

The first three paragraphs under "Hospitality Industry Rebound" in EIR/EIS Section 6.3.5.1 have been revised to clarify the comparisons of commercial sector water use before and after the recession started and the basis for the EIR/EIS conclusion that demand associated with hospitality industry economic rebound may be less than CalAm's estimate, as shown below. The purpose of evaluating CalAm's estimate is to ensure that water supply provided by the project that may not be needed to serve these existing customers was appropriately considered in the growth inducement analysis.

> …MPWMD performed several comparisons of recent commercial sector water demand with earlier levels of demand, considering the years 1998 through 2011, and determined that recent demand ~~ranged from~~was 194, 236, ~~to~~or 440 afy lower than in previous years, depending on the years compared and the methodology used….
>
> … For example, consumption in 2003 was 980 af higher than in 2015.~~,~~ ~~whereas the~~ Average annual consumption for the four years before the recession (water years 2004 through 2007) was 233 af higher than average annual consumption for the four years after the recession started (2008 through 2011) and average annual consumption for the five years before the recession (water years 2003 through 2007) was 289 af higher than for the average of the five years after it started (2008 through 2012). Considering all 13 years shown, average annual consumption for the five ~~first seven~~ years prior to the recession ~~(water years 2003 through 2009)~~ was 434~~467~~ af higher than average annual consumption for the eight ~~in the last six~~ years since (water years 200819 through 2015), which included four drought years. Consumption in the last year before the recession (water year 2007) was higher than the year before and any year since. Since the region was experiencing a serious drought during the last four years of the~~is~~ 13-year record shown in Table 6.3-2, at least some of the reductions in demand shown in these years may reflect short term behavioral water conservation practices that may not be sustained during normal rainfall years.

… ~~In addition,~~ MPWMD's analysis of occupancy levels and commercial sector water consumption indicated that, based on four hospitality-industry businesses in Monterey and one in downtown Carmel, occupancy levels in 2011 were about 7 percent lower than the average occupancy levels for the years 1998 to 2001. Based on this difference, and on commercial sector water consumption data, MPWMD calculated that a 7 percent increase in the average annual commercial water demand for years 2009 to 2011 would increase annual demand by about 194 af. The greatest difference MPWMD found in its analysis, which compared average commercial water use for water years 2009 through 2011 with water use in the year 2000, was 440 afy; commercial water use was 3,207 af in the year 2000, which is higher than most years shown in Table 6.3-2. Of the comparisons presented above, the greatest differences are in the comparisons that include more distant pre-recession years or include post-recession years influenced by the recent drought.

Given the permanent reductions in water consumption achieved by ongoing conservation programs and the fact that the recent severe drought was not a factor constraining water use in the year CalAm used to represent existing annual water demand, the less extreme pre-and post-recession differences found in the above comparisons seem more likely indicators of the increased commercial sector water use that could occur in a fully recovered post-drought economy than do the more extreme differences. Therefore, based on the~~is~~ above considerations ~~comparison~~, increases in demand at area restaurants, lodging, and other commercial businesses from a rebounding economy ~~and hospitality industry~~ may more likely be on the order of 200 or 300 afy, rather than CalAm's estimate of 500 afy.

The commenter's opinion that economic rebound could occur with or without the project is acknowledged. Without the project or another water supply project to replace Carmel River and Seaside Basin supplies that are being reduced, it is reasonable to assume the resulting water supply shortage would constrain the local economy compared to existing conditions and make additional economic rebound less likely; refer to response to comment MPWMD-49. Regarding the evaluation of water supply for legal lots of record in the growth inducement analysis, see the last two paragraphs of response to comment MPWMD-51.

MPWMD-58 See response to comment MPWMD-57.

MPWMD-59 Draft EIR/EIS Section 2.3.3.2 (Final EIR/EIS Section 2.3.2.1) describes the analysis MPWMD prepared of commercial sector water consumption before and since the onset of the recession in 2008, in reference to CalAm's estimate of the additional water that would be needed (above existing service area demand) to serve the existing hospitality industry in a recovered economy. The MPWMD memo cited in Draft EIR/EIS Section 2.3.3.2 summarizes three comparisons of

demand before and since the recession started. The comparisons found that recent demand was 194, 236, or 440 afy lower than in years prior to the recession, depending on the years compared and the methodology used; Draft EIR/EIS Section 2.3.3.2 provides additional details about these comparisons.

Selectively focusing on any of these three results could be misleading by suggesting that one particular result was definitive. The MPWMD memo does not indicate that any one comparison was definitive or more compelling than the others. EIR/EIS Section 6.3.5.1 describes additional analysis of commercial sector consumption data prepared as part of the EIR/EIS evaluation; see response to comment MPWMD-57, above, for revisions clarifying that Draft EIR/EIS analysis. In addition, see Master Response 13, Section 8.2.13.1 regarding a review of water consumption data before and since the recession that also includes the industrial and public authority sectors. (Note also that while this comment refers to 440 afy for "CII demand" – indicating that the 440 afy referred to a change in commercial, industrial, and institutional sector demand – the MPWMD memo cited in Chapter 2 focuses on the rebound of the hospitality industry and refers to commercial sector demand.)

As stated in the first paragraph of Chapter 2, the chapter is descriptive: it describes water demand and supply information and assumptions included in CalAm's application and provides supplemental information about water supply and demand and factors affecting them in the CalAm service area. The growth inducement impact analysis presented in Section 6.3 takes a closer look at CalAm's assumptions to ensure the potential growth inducement potential of the project is adequately disclosed and analyzed.

MPWMD-60 The discussion of the Pebble Beach entitlements has been revised to show that they are considered existing service area demand that CalAm is obligated to serve with or without the project, and EIR/EIS text and tables have been revised accordingly.

The EIR/EIS does not assume that water in excess of the amount needed to meet demand associated with economic rebound, if less than the proposed 500 afy, would "automatically" go to the jurisdiction or that it would not be subject to the MPWMD allocation program. However, the EIR/EIS does assume that MPWMD *could* allocate such water supply to the jurisdictions. The information provided in this comment and comment MPWMD-21 on how MPWMD may retain or allocate project water, and some of the considerations MPWMD will weigh, is of interest; however, as these two comments indicate, MPWMD has not yet determined how project water available to its allocation program would be allocated. In addition, regarding the statement that "to assume the 500 afy is in excess is an unprovable assumption," the EIR/EIS does not assume that none of the 500 afy CalAm proposed to provide to meet economic recovery would be needed for that purpose. There is a degree of uncertainty associated with this estimate, and arguably the contrary is also "unprovable." See the discussion of economic rebound and

associated text revisions in response to comment MPWMD-57 for additional discussion of the EIR/EIS assessment of the estimate of water supply needed for this demand component.

In response to this comment, the first paragraph under "Assumptions Regarding Allocation and Use of MPWSP Water Service Capacity" in EIR/EIS Section 6.3.5.1 has been revised to state the assumption that supply provided by the proposed project would be "used" rather than "allocated" to meet existing demand within the CalAm service area, and the remainder of this section has been revised as follows:

> ~~This analysis also recognizes that the MPWMD could choose not to allocate to the County the approximately 325 afy proposed to serve Pebble Beach water entitlement-holders, to ensure that adequate water supply would be available when development associated with those entitlements was proposed. If, on the other hand, the MPWMD did allocate this water to the County, the County could then elect to allocate at least a portion of the 325 afy to other development – if, for example, other development was proposed first or the County determined that the entitlement-holders were unlikely to use the full amount. In either case, this portion of the proposed MPWSP supply would be used to serve new development.~~
>
> Similarly, because <u>at present</u> there is no guarantee that the 500 afy proposed to meet demand associated with hospitality industry rebound <u>would be reserved for</u> ~~will actually go to~~ that use, this analysis assumes that either the MPWMD or the local jurisdictions could elect not to set aside 500 afy exclusively for use by existing businesses. Therefore, some portion of this 500 afy could actually serve new development within the service area.
>
> <u>As discussed in Section 2.5.4, MPWMD recently confirmed that the future allocation process has not yet been defined; refer to Section 2.5.4 regarding options MPWMD would consider regarding the allocation or reservation of MPWSP water, once the MPWSP was approved and it is clear that the project would be constructed. These considerations do not change the allocation assumptions described above for this analysis.</u>

Tables 6.3.3 and 6.3.4 have been revised to show that demand associated with existing land uses and water entitlements totals 12,845 afy (rather than 12,520 afy) and that demand associated with anticipated development totals 1,430 afy (rather than 1,755 afy) along with associated changes to the "Surplus (or Deficit)" shown in Table 6.3-4. Similarly, the discussion in EIR/EIS Section 6.3.5.1 under "Conclusion: MPWSP Water Service Capacity" has been revised to clarify that demand associated with the Pebble Beach water entitlements is considered a component of existing demand.

MPWMD-61 The commenter's opinion on the AMBAG projections is noted. AMBAG prepared the projections with substantial feedback from jurisdictions in the AMBAG region, and the projections were adopted in 2014. The projections supplement information from the jurisdictions' general plans and CalAm's anticipation of development of lots record and indicate that a degree of growth is anticipated in the region, including the CalAm service area. Obviously most of the growth in CalAm's service area would be limited to the period after the moratorium on new connections was lifted. As the commenter points out in comment MPWMD-12, some development associated with water rights not affected by the 2009 CDO has occurred since the CDO was issued.

MPWMD-62 The commenter's opinion that Water Code requirements that would reduce estimated future demands by an additional 20 percent would not apply to the CalAm service area is noted. The future demand estimates presented in EIR/EIS Table 6.3-8 were not the basis for sizing the MPWSP (which is described in EIR/EIS Sections 2.3.1 through 2.3.3), but are presented to provide a general comparison of demand associated with anticipated development under adopted general plans with the future demand that CalAm proposes for the project to meet.

The Draft EIR/EIS does not assume that the Water Code Section 10608 requirements necessarily would apply; indeed, the text and Table 6.3-8 note "b" point out that CalAm's 2010 UWMP showed that CalAm's Monterey District was already in compliance with the 20 percent reduction requirements. Ultimately, however, that determination is not for the Lead Agencies to make. In addition, as the comments in this letter and responses indicate, there is some uncertainty associated with projections of various components of future supplies and demands. For example, comment MPWMD-20 suggests that estimated demand for unincorporated Monterey County, which is part of the service area estimate of 3,526 afy that this comment endorses, is high. Including the revised estimate (3,526 afy) further reduced by 20 percent shows that the water supply the MPWSP proposes to provide for additional development (e.g., to serve legal lots of record) would be consistent with (that is, would not exceed) even this constrained estimate of future supply needs associated with development under adopted general plans. Showing the estimate of 2,080 afy in Table 6.3-8 does not imply, nor is it intended to imply, that it necessarily supersedes the revised 3,526 afy estimate, which is also shown. Regarding the uncertainty associated with the supply and demand projections, see also the discussion under "Water Available for Growth" in Master Response 13, Section 8.2.13.3, which considers several other possible supply and demand scenarios.

MPWMD-63 The first sentence of the fourth paragraph under "Local Programs" in EIR/EIS Appendix K has been revised to say,

> "… properties that have not already been retrofitted be retrofitted upon change of ownership, remodel, or change of use."

Table K-1 and related text in Appendix K have been revised to include MPWMD's mandatory water retrofit requirements and to show the revised total of quantifiable estimated savings.

8.5.8 Responses to Comments from Monterey Regional Waste Management District

MRWMD-1 The Lead Agencies acknowledge MRWMD's support for the proposed alignments of the Source Water Pipeline, new Desalinated Water Pipeline, and Castroville Pipeline.

MRWMD-2 The 0.8-mile-long segment of the optional alignments of the Source Water Pipeline, new Desalinated Water Pipeline, and Castroville Pipeline along Charles Benson Road would be installed within the paved Charles Benson Road right-of-way.

Impact 4.9-2 in EIR/EIS Section 4.9.5.1 addresses impacts related to temporary lane closures. The analysis conservatively assumes that all pipelines could require construction within or adjacent to vehicle travel lanes and could require temporary lane closures and/or detours. Due to the width of Charles Benson Road (approximately 28 feet), temporary lane closures with one-way traffic control could be required during installation of these pipelines if the optional alignment is implemented. At a rate of 150 to 250 feet of pipeline installation per day, the lane closure along the portion of Charles Benson Road under construction could last approximately 16 to 27 days. With implementation of Mitigation Measure 4.9-1 (Traffic Control and Safety Assurance Plan), which includes measures to minimize the adverse effects of roadway construction and detours, these impacts would be reduced to a level that is considered less than significant.

However, the Lead Agencies acknowledge MRWMD's concern that one-way traffic controls for a period of up to one month would not be compatible with the volume and type of traffic on Charles Benson Road, and could disrupt daily operations. As a result of this comment, EIR/EIS Section 3.2.1.2 (Source Water Pipeline – optional alignment), Section 3.2.3.3 (New Desalinated Water Pipeline – optional alignment) and Section 3.2.3.6 (Castroville Pipeline – optional alignment 2) have been revised to acknowledge that construction of these optional alignments would be limited to after hours/nighttime construction-only, since the Waste Management District shuts down operations and closes the gate on Charles Benson Road daily at 4 p.m.

8.5.9 Responses to Comments from Monterey Regional Water Pollution Control Agency (MRWPCA, now named Monterey 1 Water)

MRWPCA-1 The EIR/EIS, beginning in Chapter 1 on page 1-2, describes the two options put forth by CalAm in its application to the CPUC to meet estimated service area demand of 15,296 afy: the proposed 9.6 mgd desalination plant, or a reduced-size (6.4 mgd) desalination plant in combination with a water purchase agreement for 3.2 mgd (3,500 afy) from the Groundwater Replenishment (GWR) Project. (The commenter refers to the "Pure Water Monterey (PWM) Project," which is the same and merely an updated name for the GWR project analyzed in the EIR/EIS.) EIR/EIS Table 4.1-1 presents an overview of alternatives evaluated in detail, and shows that, because the GWR project has been approved, a Water Purchase Agreement for GWR project water would be a component of the No Action Alternative, as well as Alternative 5a and 5b. EIR/EIS Section 1.1. explains that presenting and evaluating both desalination capacity options allows the fullest consideration of the scope of the potential project and alternatives that may be feasible to meet project objectives under various scenarios, and furthers public transparency of the analysis of the options proposed in CalAm's applications to the CPUC and MBNMS. Footnote 2 on Table 4.1-1 explains, "The GWR project is not considered for cumulative impacts in conjunction with the proposed project or Alternatives 1, 2, or 4 because if a desalination option is selected that is of a size sufficient to fully satisfy the project objectives in terms of water supply, such choice would presumably mean that the GWR project was not successful in securing funding, completing construction and undertaking operations. The GWR project is conservatively considered for cumulative impacts with Alternative 3 because under that option, CalAm could meet its full project water supply objectives via the DeepWater Desal project, or could obtain water from a combination of the DeepWater Desal project and the GWR Project." The approach to evaluating cumulative scenarios is explained in Section 4.1.7 and the approach to evaluating alternatives is described in Section 5.5.1.

With respect to the need for MRWPCA to rely on an analysis that includes impacts of the combined MPWSP and GWR Projects, the analysis of Alternatives 5a and 5b throughout Sections 5.5 and 5.6 does include impacts of both the reduced-size MPWSP desalination plant and the GWR Project, in part by referencing the stand-alone certified EIR for the GWR Project. See also responses to comments MRWPCA-7 and MRWPCA-9.

MRWPCA-2 EIR/EIS Section 4.13.5.2 identified the potential for the proposed project to increase corrosion of the MRWPCA outfall and diffuser as a result of brine discharge. Based on studies provided by the MRWPCA (E2 Consulting Engineers, 2015), Impact 4.13-5 determined the proposed project could accelerate corrosion of a nearshore portion of the offshore segment, as well as the

land segment, of the outfall. The Draft EIR/EIS concluded the impact could be significant and included Mitigation Measures 4.13-5a and 4.13-5b, which would apply to the offshore segment and the land segment, respectively.

The Lead Agencies acknowledge receipt of the Enclosure 3 (Brown and Caldwell Technical Memorandum: Land Outfall Pipeline Evaluation and Protection Measures, January 9, 2017) with its March 2017 comment letter on the Draft EIR/EIS that describes revised options to protect the land segment of the outfall from corrosion. Impact 4.13-5 and Mitigation Measure 4.13-5b has been revised in Final EIR/EIS Section 4.13.5.2 to incorporate this refinement. The changes do not implicate any new or more severe significant environmental impacts than were identified in the Draft EIR/EIS.

MRWPCA-3 A description of the proposed Brine Mixing Box and appurtenances has been included in Final EIR/EIS Section 3.2.2.5. The description is similar to the Brine Mixing Facility that is described and evaluated in the January 2016 GWR Consolidated Final EIR. The environmental impacts of the proposed Brine Mixing Box and appurtenances have been discussed and are analyzed throughout the resource sections of Final EIR/EIS Chapter 4. The inclusion of the Brine Mixing Box does not alter the environmental impact analysis, and none of the significance conclusions of the Draft EIR/EIS have been altered as a result of this new component.

MRWPCA-4 The MRWPCA is required to replace the exposed Beach Junction Structure and outfall components under an order from the California Coastal Commission, independent from and as a project separate from the MPWSP. Therefore, the replacement of the Beach Junction Structure is a cumulative project considered in the cumulative scenarios relevant to the MPWSP; see Table 4.1-2. The Final EIR/EIS analysis has assumed that this separate project would be completed prior to the start of operation of the MPWSP Desalination Plant. See also responses to comments MRWPCA-5 and MRWPCA-10, below.

MRWPCA-5 As explained on page 2 of Enclosure 3 that was provided with this comment, the MRWPCA engaged a diving contractor in 1990/1991 to install over 20 seals and stainless steel clamps at joints inside the outfall that had started to leak following the 1989 Loma Prieta earthquake. Brown and Caldwell (January 9, 2017) determined that since the clamps are over 20 years old and are susceptible to chloride corrosion, they should be replaced prior to using the outfall to discharge brine from the proposed project. Impact 4.13-5 and Mitigation Measure 4.13-5a have been revised in Final EIR/EIS Section 4.13, Public Services and Utilities, to include a description of the WEKO band seal replacement process and to consider potential secondary impacts. This revised analysis does not identify any new significant effects or substantially more severe significant effects than were addressed in the Draft EIR/EIS.

MRWPCA-6 Impact 4.3-5 in EIR/EIS Section 4.3.5 has been revised to reflect the concern that the existing outfall diffuser end gate may need to be modified in order for operational discharges from the proposed project to comply with Ocean Plan and NPDES permitting requirements. The model analyses assessing dilution, regulatory compliance, and water quality at the discharge diffuser were revised and expanded to include a description of the end gate modification design, an assessment of outfall hydraulics with a modified end gate, and calculation of the discharge dilutions associated with implementation of a modified end gate to assess, in part, whether overall dilution from the outfall diffuser ports would be reduced following modification of the end gate. The supporting model-based analyses are presented in Appendix D1 (see Roberts, 2017, Supplemental Report). The findings of the revised analyses have been incorporated into the assessment of impacts for the proposed project and alternatives presented in Sections 4.3 and 5.5.3 of the EIR/EIS respectively; the impacts remain less than significant with the implementation of Mitigation Measures 4.3-4 and 4.3-5. Further, an analysis of potential secondary impacts associated with constructing and operating a modified end gate has been added to EIR/EIS Section 4.3.5.4. This additional analysis does not identify any new significant effects or substantially more severe significant effects than were addressed in the Draft EIR/EIS. See Section 4.3 for further discussion regarding updated modeling, updated Ocean Plan constituent compliance analysis, and updated impacts considerations.

The end gate, described in detail under Impact 4.3-4 and in Appendix D1, is an opening about two inches high at the end of the diffuser pipe from which approximately 5 percent of total operational discharge flows exit for flushing purposes. Mitigation Measure 4.3-5 has been revised to include a specific design, developed in collaboration with MRWPCA staff, for modifying the end gate, if needed, to increase dilution and ensure compliance with Ocean Plan requirements and NPDES provisions relating to operational discharges and water quality. The feasibility for such a modification to meet Ocean Plan salinity requirements was assessed in detail in a supplemental dilution model analysis (see Appendix D1).

In summary, the minimum dilution of discharges exiting the end gate would be substantially increased by modifying the existing 2-inch opening with a Tideflex check valve installed at an upward angle to maximize dilution of dense discharges. As modeled by Roberts (Appendix D1), modifying the end gate with an inclined check valve would slightly reduce flow volume and increase exit velocity, resulting in substantially increased dilution at the end gate, as compared to existing conditions. As described in detail in Appendix D1 Section 3.1, any upward angle greater than 20 degrees would result in dilutions that meet the Brine Mixing Zone (BMZ) salinity requirements, with 60 degrees calculated as being an optimum angle to maximize dilution (see Figures 2 and 3, in Appendix D1).

As described in EIR/EIS Section 4.3.5.4, modification of the end gate would have minimal effect on the flow distribution between the 129 horizontally-oriented diffuser ports and minimal effect on head loss, and would not reduce dilution from the outfall diffuser ports for the assessed discharge scenarios (for details see Section 3.2 of Appendix D1). The end gate check valve would decrease the flow from the end gate and increase the flow from the 2-inch ports, altering overall dilution by less than 1 percent (i.e., no effect on dilution when rounded to a whole number).

MRWPCA-7 Implementation of the proposed project (as discussed in EIR/EIS Section 4.3.5.2), as well as Alternatives 1 and 2, and Alternative 5 (reduced size desalination facility implemented in combination with the Pure Water Monterey GWR Project, discussed in Section 5.5.3) could result in exceedances of Ocean Plan water quality objectives, resulting in potentially significant impacts related to water quality standards, waste discharge requirements and water quality of receiving waters in Monterey Bay. As described in detail in EIR/EIS Sections 4.3.5.2 and 5.5.3, potentially significant impacts related to water quality would be reduced to a less-than-significant level by implementing Mitigation Measure 4.3-5 (Implement Protocols to Avoid Exceeding Water Quality Objectives).

Mitigation Measure 4.3-5 requires that, prior to implementing operational discharges via the existing outfall, CalAm must perform an extensive water quality assessment using protocols defined in Appendix II "Minimum Levels" of the 2015 California Ocean Plan to demonstrate compliance with Ocean Plan water quality objectives and minimum initial dilution requirements. If the water quality assessment shows that releases via the existing outfall would exceed Ocean Plan water quality objectives, then additional design features, engineering solutions, and/or operational measures, would be implemented to reduce the concentration of water quality constituents in the operational discharges such that they conform with regulatory standards and objectives. Possible additional engineering measures and operational protocols needed to achieve compliance with regulatory standards, should any or all of them be required, are described in detail as part of Mitigation Measure 4.3-5. The feasibility for each of the engineering and/or operational protocols to achieve Ocean Plan and NPDES requirements is fully assessed and discussed in detail in Section 4.3.5.2 under the section titled "Determination of Efficacy of Mitigation Measures." Furthermore, the potential for secondary environmental impacts to result from implementation of the engineering and operational protocols detailed under Mitigation Measure 4.3-5 is comprehensively assessed in Section 4.3.5.4 of the EIR/EIS under the section titled "Secondary Impacts of Mitigation Measure 4.3-5."

Subsequent to the publication of the Draft EIR/EIS, in response to concerns raised by the MRWPCA with regards to the NPDES permitting of the Pure Water Monterey GWR Project, the EIR/EIS analyses assessing dilution, regulatory compliance, water quality at the discharge diffuser, feasibility of mitigation to

achieve regulatory requirements, and secondary impacts resulting from implementation of Mitigation Measure 4.3-5 were revised and expanded in Impacts 4.3-4 and 4.3-5; for additional details, see responses to comments MRWPCA-9 and MRWPCA-20, as well EIR/EIS Appendix D1. The revised and expanded analyses support the impact assessments and impact conclusions presented in the Draft EIR/EIS and were conducted in collaboration with MRWPCA staff specifically to ensure that the EIR/EIS contains adequate detail to enable MRWPCA and other responsible agencies to rely on the document for subsequent permit approvals. Although the revised analyses resulted in a revised Ocean Plan compliance analysis, the modeling indicated that potential constituent exceedances could be fully mitigated by implementing a diffuser retrofit with inclined jets, or other mechanisms as explained in Mitigation Measure 4.3-5. The additional analyses do not identify any new significant effects or substantially more severe significant effects than were addressed in the Draft EIR/EIS and the conclusions of the Draft EIR/EIS are unchanged.

Regarding the concerns related to other specific mitigation approaches that are described in Mitigation Measure 4.3-5, the addition of up to 5 mgd of freshwater has been demonstrated by Dr. Phil Roberts in EIR/EIS Appendix D1, Section 7.1 to be a technically feasible method for increasing dilution of dense and moderately dense brine discharges. Such an operational protocol is presented as one of a number of potential mitigation strategies that may be employed independently or in combination with other engineering or operational strategies to reduce potential impacts. It is not required to be implemented, but is included as an optional measure to ensure flexibility for implementing mitigation strategies over the lifetime of the project. While having up to 5 mgd of freshwater for dilution may not be feasible currently due to the lack of reliable availability of wastewater or another fresh water source, it is possible that additional flows may become available in the future. For this reason, the option for flow augmentation remains a part of Mitigation Measure 4.3-5. However, should flow augmentation remain impossible to implement due to a lack of availability of fresher water for blending, a variety of other mitigation solutions remain available to successfully increase dilution and/or reduce pollutant concentrations.

The option involving installation of a 20-inch pipe through the side of the MRWPCA outfall to convey brine to a dedicated brine diffuser is described in EIR/EIS Section 5.3.4.1. As explained in Section 5.3.6.1, all of the optional outfalls evaluated would have greater impacts than the proposed use of the MRWPCA outfall (Draft EIR/EIS page 5.3-55) and this alternative outfall configuration was not carried forward as part of the proposed project or any of the alternatives that are described and evaluated in Sections 5.4 and 5.5. Accordingly, no changes were made to the EIR/EIS in response to this comment.

MRWPCA-8 Text has been added to EIR/EIS Section 3.3.2.1, Subsurface Slant Wells, to indicate CalAm would need to obtain permission from the MRWPCA to accept well development water into the outfall.

MRWPCA-9 As described in EIR/EIS Sections 4.3 and 5.5.3, under certain operating scenarios, operational discharges associated with the proposed project, Alternatives 1, 2, and 5, could result in exceedances of Ocean Plan water quality objectives when various effluents are co-mingled (i.e., with MRWPCA secondary treated wastewater, brine, and/or GWR effluent), resulting in a potentially significant impact related to water quality that can be reduced to less-than-significant impact with the implementation of Mitigation Measures 4.3-4 (and 4.3-5, if necessary).

In response to concerns that were raised in this comment and comment MRWPCA-17, the dilution analyses presented in Appendix D1 of the EIR/EIS assessing minimum dilution at the outfall were revised and expanded. Discharge scenarios involving higher volumes of desalination brine and higher GWR effluent flows (only associated with Alternative 5) were modeled for the proposed project and alternatives to determine minimum dilution values and to assess impacts on water quality and regulatory compliance. Furthermore, discharge scenarios involving a wider variety of MRWPCA secondary effluent flows were modeled to support the assessment of potential water quality impacts at a higher degree of resolution. For example, water quality impacts were assessed for operational discharges involving MRWPCA secondary effluent flows, increased at 1 mgd increments.

As described in EIR/EIS Section 3.4.1, following a shutdown of the desalination facility for repair or routine maintenance, CalAm may temporarily (up to 11 days) operate the desalination facility with one additional reverse osmosis module in service to catch up on production; however, the total annual production would not be increased. Such an increase in production would result in temporary brine discharges of 16.31 mgd (as compared to 13.98 mgd under typical operations) for the proposed project (and Alternatives 1 and 2). For Alternatives 5a and 5b (reduced scale desalination facility), 11.24 mgd of brine would temporarily be produced following a shutdown (as compared to 8.99 mgd under typical operations). To reflect this operational scenario, the dilution modeling was revised to include higher brine flows following a shutdown of the desalination facility for the proposed project and relevant Alternatives (see Appendix D1). The analysis was also revised to include 0.1 mgd of trucked brine (see response to comment MRWPCA-14 for details).

Impact discussions for Impact 4.3-4 in EIR/EIS Sections 4.3.5.2 and 5.5.3 were revised to incorporate the results of the additional dilution analyses into the assessment of water quality impacts related to salinity concentrations and other water quality constituents; the revised analyses support and reinforce the

conclusions in the Draft EIR/EIS and impacts would continue to be less than significant with mitigation.

Summarizing key findings, when considering the increased brine flows following a shutdown, salinity levels associated with the proposed project and Alternatives 1, 2, and 5 are projected to continue to meet Ocean Plan salinity and dissolved oxygen standards. As was concluded for Impact 4.3-4 in the EIR/EIS, although impacts related to water quality from increased salinity have been determined to be less than significant, Mitigation Measure 4.3-4 (Operational Discharge Monitoring, Analysis, Reporting, and Compliance) continues to be required to ensure compliance with the Ocean Plan monitoring requirements and consistency with MBNMS guidelines.

The analysis to determine Ocean Plan Compliance for the proposed project and Alternatives for higher brine discharges following a shutdown, including for cumulative scenarios involving GWR effluent flows, has also been revised and expanded (see revised Appendix D3 of the EIR/EIS). The revised analysis was incorporated into the assessment of potential impacts in EIR/EIS Sections 4.3.5.2 and 5.5.3 related to water quality standards, waste discharge requirements, and numeric water quality objectives defined in the Ocean Plan. The analyses were also revised and expanded to assess potential water quality impacts related to a greater number of operational scenarios for typical operations to provide higher resolution water quality analysis, similar to that described for salinity, above.

None of the revisions made in response to this comment identified any new significant impact, or any substantially more severe significant impact, than previously evaluated and described in the Draft EIR/EIS.

MRWPCA-10 Table 4.1-1 in EIR/EIS Section 4.1 has been revised to include the Brine Mixing Structure and the Ocean Outfall End Gate Modification. However, the land outfall corrosion protection, and the WEKO Seal Band replacement have not been included in the table as components of the proposed project because they are mitigation measures in response to potential impacts resulting from the operation of the proposed project; although these mitigation measures are not part of the proposed project as submitted by Cal Am, these mitigation measures will be included in the Mitigation Monitoring and Reporting Plan (MMRP) and will therefore, become conditions of project approvals. The Outfall Protection Project (re-location of the Beach Junction Box), as explained in response to comment MRWPCA-4, is a cumulative project that has been added to EIR/EIS Table 4.1-2, and has been considered in the cumulative analyses. Response to comment MRWPCA-1 explains why the Pure Water Monterey GWR Project Water Purchase Agreement would not be in effect and why GWR would not be operating under all scenarios; SWRCB Order 2016-0016 will expire in 2021; no such change has been made to Table 4.1-2.

MRWPCA-11 The Ocean Outfall Manhole Protection project, also known as the Beach Junction Structure, has been added to Table 4.1-2 since it is a project separate from the proposed project that will be undertaken with approval of separate environmental review, while the other listed projects do not qualify as cumulative projects because they are either project components or mitigation measures designed in response to potential impacts resulting from operation of the proposed project. See responses to comments MRWPCA-1 (regarding the GWR Project), MRWPCA-2 (regarding the land segment outfall protection project), MRWPCA-3 (regarding the brine mixing structure), MRWPCA-4 (regarding the Ocean Outfall Manhole Protection project), MRWPCA-5 (regarding the WEKO band seal protection), and MRWPCA-6 (regarding the ocean outfall end gate correction/modification).

MRWPCA-12 In response to this comment, changes have been made to EIR/EIS Table 4.1-2.

MRWPCA-13 Table 4.3-9 in EIR/EIS Section 4.3.5.2 summarizes the average monthly MRWPCA wastewater flows for the years 1998-2012. As shown in Table 4.3-9, and discussed as part of the water quality impact assessments, the treated MRWPCA wastewater flow varies throughout the year. The highest flows are observed during the non-irrigation season (November through March) and the lowest flows are observed during the irrigation season (April through October), when the treated wastewater is processed through the Salinas Valley Reclamation Plant for tertiary treatment and distributed to irrigators through the Castroville Seawater Intrusion Project (CSIP).

To ensure the most recent data are accurately disclosed, Table 4.3-9 has been revised to include the recent data related to baseline wastewater flows provided by MRWPCA in its comment letter on the Draft EIR/EIS. Regarding the range of discharge scenarios modeled as part of dilution analyses to support impact assessments under CEQA and NEPA and additional model work conducted subsequent to the publication of the Draft EIR/EIS to support NPDES permitting of the Pure Water Monterey GWR Project, see response to comment MRWPCA-9. Regarding Table 4.3-10, see response to comment MRWPCA-14.

MRWPCA-14 See response to comment MRWPCA-1 regarding the GWR Project. The Pure Water Monterey GWR Project is assumed to be operational and is assessed in combination with desalination operations (Alternatives 5a and 5b) in detail for water quality impacts and regulatory compliance in EIR/EIS Section 5.5.3.8 and for marine biological resources in Section 5.5.5.8. Section 5.5.3.8 has been revised to consider a wide range of operational scenarios that include varying volumes (high/low) of GWR concentrate and varying volumes of MRWPCA wastewater being discharged via the existing ocean outfall along with desalination brine. In response to the comment, the dilution model analysis supporting water quality and regulatory compliance impact assessments for the proposed project and relevant Alternatives has been revised to include trucked brine. Detailed discussion and updated results are available in Appendix D1 and

the impact analyses presented in Sections 4.3 and 5.5.3 of the EIR/EIS have been revised accordingly.

EIR/EIS Section 5.5.5.8 uses the water quality impact assessment presented in Section 5.5.3.8 to assess impacts on marine biological resources from operational discharges from implementation of Alternative 5, which includes detailed assessment of water quality in the vicinity of the outfall diffuser from discharges that include effluent from the GWR project.

See also responses to comments MRWPCA-9 (regarding operation of GWR and revisions to the model analyses) and MRWPCA-13 (baseline MRWPCA wastewater flows to the existing ocean outfall diffuser).

MRWPCA-15 See response to comment MRWPCA-6 for concerns related to the outfall diffuser end gate.

MRWPCA-16 See responses to comments MRWPCA-1, MRWPCA-6, and MRWPCA-9.

MRWPCA-17 See response to comment MRWPCA-9. EIR/EIS Tables 4.3-15 and -16 have been revised to reflect the results of the additional and revised modeling of operational discharge scenarios associated with varying the volumes of co-mingled flows.

MRWPCA-18 The EIR/EIS includes comprehensive quantitative model analyses, presented in Appendix D3, that assess operational discharges associated with the proposed project and Alternatives for compliance with Ocean Plan water quality standards and numeric water quality objectives (WQO). The results of the model analyses presented in Appendix D3 are incorporated into the assessment of water quality impacts for operational discharges associated with the proposed project, Alternatives 1 and 2, and Alternative 5 (reduced size desalination facility implemented in combination with PWM/GWR Project) in EIR/EIS Section 4.3.5.2 and Section 5.5.3. See response to comment MRWPCA-7 for a detailed discussion of these impacts and associated mitigation measures.

Regarding additional assessment of the mitigation component involving retrofitting the outfall diffuser with inclined jets to increase dilution, see response to comment MRWPCA-20, which also provides details related to the assessment of potential secondary impacts on MRWPCA compliance with NPDES and Ocean Plan requirements from inclined jets when brine is absent (such as when the desalination facility is offline during repairs or routine maintenance).

MRWPCA-19 Advanced oxidation, additional filtration, and Granular Activated Carbon treatment methodologies have been demonstrated to be technically feasible methods for reducing the concentrations of certain constituents when used as part of a water quality treatment process. While none of these treatment methods would independently reduce the concentrations of all constituents regulated

under the California Ocean Plan, such treatment options are included as part of Mitigation Measure 4.3-5, Implement Protocols to Avoid Exceeding Water Quality Objectives, as components of a suite of potential mitigation strategies, both operational and engineering related measures, that may be employed independently or in combination with other mitigation component strategies to reduce identified constituent concentrations in operational discharges to ensure conformance with regulatory requirements. The various methodologies are included to ensure flexibility for implementing successful mitigation strategies over the lifetime of the project. In response to the comment, the inclusion of Biologically Active Filtration has been removed from Mitigation Measure 4.3-5.

MRWPCA-20 EIR/EIS Appendix D1 and Appendix D3 have been revised/supplemented to include a comprehensive analysis of inclined jets, such as included in Mitigation Measure 4.3-5, for operational discharges associated with the proposed project, Alternative 5, and the Alternative 5 cumulative scenario (i.e., with GWR effluent included). The analyses assessed changes to dilution, salinity, and Ocean Plan compliance associated with inclined jets for all ocean conditions and for a range of inclined angles to identify the optimum angle for meeting Ocean Plan water quality standards. Additionally, the assessment of Ocean Plan compliance (EIR/EIS Appendix D3) was revised to assess the potential for inclined jets to cause secondary impacts by preventing MRWPCA from meeting NPDES discharge requirements (for a buoyant discharge) when the desalination facility is offline. The results of the additional analyses have been incorporated into EIR/EIS Sections 4.3 and 5.5.3. As demonstrated by the revised analyses presented in Appendix D3 and incorporated into the assessment of impacts in EIR/EIS Sections 4.3 and 5.5.3, inclining the outfall diffuser jets increases dilution sufficiently to ensure that operational discharges would meet Ocean Plan standards and other regulatory requirements without causing secondary impacts to MRWPCA or cumulative scenarios (i.e., with GWR assumed to be operational). The revised and expanded analyses support the impact assessments and impact conclusions presented in the Draft EIR/EIS and were conducted in collaboration with MRWPCA staff specifically to ensure that the EIR/EIS contains adequate detail to enable MRWPCA and other responsible agencies to rely on the document for subsequent permit approvals. The additional analyses do not identify any new significant effects or substantially more severe significant effects than were addressed in the Draft EIR/EIS and the conclusions of the Draft EIR/EIS are unchanged.

MRWPCA suggests alternate mitigation, such as reducing the number of open ports on the outfall diffuser, reducing the diffuser size, and/or the removal or modification of the Tideflex duckbill diffuser nozzles to increase dilution. Altering the number of open ports was assessed by Roberts (2016) in EIR/EIS Appendix D1 and the approach was found to have only a negligible effect on dilution. Additionally, reducing the size of the ports could result in reduced head pressure, which would require discharges to be pumped under pressure rather

than flow by gravity as it currently operates, which would require the construction of a new pump station, potentially resulting in additional environmental impacts, and increased operating costs. For these reasons, the suggested mitigation strategies have not been added to Mitigation Measure 4.3-5.

MRWPCA-21 See response to comment MRWPCA-7.

MRWPCA-22 As discussed in EIR/EIS Section 4.4.1.2, Local and Regional Hydrogeology, the aquifers in the area near the subsurface intake system consist of the Dune Sand, 180-FTE, 400-Foot, and Deeper Aquifers. These aquifer names are based on the general depth at which the aquifers are encountered (see Master Response 7 regarding the clarification that what the Draft EIR/EIS referred to as the "900-Foot Aquifer" is more properly termed the "Deeper Aquifers" of the SVGB). However, the actual depth of each aquifer can vary depending on the location. The MRWPCA has three wells located at the Regional Wastewater Treatment Plant, but the well screen depth intervals do not precisely fit into the 180-FTE, 400-Foot, and Deeper Aquifer depth intervals as listed below.

Well	Screen Depth Interval below Ground Surface (feet)
14S/02E-20B01	260 to 340
14S/02E-20B02	260 to 290 and 300 to 340
14S/02E-20B03	670 to 730 and 785 to 805

Well 14S/02E-20B03 has depth intervals that are in between the 400- and 900-foot depth intervals. This well was assigned to the 900-Foot Aquifer (now Deeper Aquifers) since the well screen is in the Paso Robles Formation, which is the geologic unit below the Aromas Sand to which Deeper Aquifer wells are typically assigned.

Further examination of the geologic cross section on Draft EIR/EIS Figure 4.4-3 indicates that Wells 14S/02E-20B01 and 14S/02E-20B02 should be assigned to the 180-FTE Aquifer. These two wells have been deleted from Figure 4.4-16 (the proposed action response in the 400-Foot Aquifer) and added to Figure 4.4-15 (the proposed action response in the 180-Foot Aquifer). In addition, Table 4.4-10 has been revised.

MRWPCA-23 See responses to comments MRWPCA-1 and MRWPCA-14.

MRWPCA-24 See responses to comments MRWPCA-4, MRWPCA-5, and MRWPCA-6, which address revisions to the Draft EIR/EIS regarding descriptions and analyses of the construction and operation of the proposed protective measures for the Ocean Outfall, including the Beach Structure Evaluation and Protective Measures, the WEKO seal replacement and protection measures, and the End Gate protection measures.

In addition, see responses to comments MRWPCA-2, which addresses the land outfall protection mitigation, and MRWPCA-3, which addresses construction and operation of the Brine Mixing Facility.

MRWPCA-25 See response to comment MRWPCA-7.

MRWPCA-26 Text revisions have been made throughout the EIR/EIS regarding the correct phrasing of the Groundwater Replenishment Project and spelling of Trussell. With regards to use of the term "CSIP Pond" versus "Salinas Valley Reclamation Project" (SVRP), the following text revision has been made in EIR/EIS Section 1.4.4:

> 5. The preferred method of returning water to the Salinas Valley now includes a new 5-mile-long pipeline to the city of Castroville, with connections to the Castroville Community Services District (CCSD) and Salinas Valley Reclamation Project Storage Pond (hereafter referred to as Castroville Seawater Intrusion Project [CSIP] pond) distribution systems.

First Letter of Objection to Monterey Peninsula Water Supply Project (MPWSP) CalAm's defective and incomplete draft EIR/EIS

Dear Ms. Borak and Ms. Grimmer:

This correspondence and letter of objection (and our subsequent additional letters of objection) to the massively incomplete and defective draft EIR/EIS prepared for the California American (CalAm) De-Salination Project/slant wells are hereby submitted by and on behalf of **the Ag Land Trust of Monterey County (Monterey County Agricultural and Historic Lands Conservancy)** and its' Board of Directors (Ag Land Trust).

Organized in 1984, the Ag Land Trust is a 501(c)(3) non-profit corporation which holds/owns over 32,000 acres both of fee title and permanent conservation easements to prime and productive coastal agricultural lands that are protected California coastal resources pursuant to adopted and enforceable certified California Local Coastal Plans, state statutes, and federal regulations and legally recorded easements. These real property ownership interests fully include our percolated potable groundwater rights and resources that we have jealously protected, preserved, and conserved for potable use and agricultural irrigation purposes for over 30 years.

For over three decades, the **Ag Land Trust** is and has acted as a multiple grant recipient, agent, and de-facto trustee for both the United States Government (U.S. Department of Agriculture, the U.S. Department of Homeland Security, and the U.S. Department of Defense/National Guard Bureau) and for the State of California (California Coastal Conservancy and California Department of Conservation). The Ag Land Trust acts in this capacity to implement and enforce both legally adopted federal and state mandatory policies and regulations for permanent agricultural land and natural resources preservation, including preservation of potable irrigation groundwater resources for continuing agricultural production of those farmlands that have been federally designated for preservation due to their remarkable productivity. These responsibilities are ongoing contractual obligations between the Ag land Trust and the identified federal and state agencies, and may not be impaired by other private or federal or state agencies. Further, the reversionary property rights (water rights) held by the U.S. Government in the potable groundwater resources of our Armstrong Ranch farm, which CalAm and the CPUC are intentionally polluting with its' slant well, may not be "taken" by either CalAm or the State of California using any kind of "made-up", contrived theory of "salvage water rights" that result from the intentional pollution of the aquifers that is resulting from CalAm and the CPUC's combined actions. The EIR/EIS has failed to even mention, let alone mitigate, that the massive environmental degradation and adverse impacts to our potable aquifers which is being caused by CalAm's CPUC authorized pumping. Again, this demonstrates the bias of the CPUC against the property owners whose property rights are being taken by the combined CalAm/CPUC actions.

ALT1-1

The CalAm slant well and CalAm's excessive and wasteful pumping thereof is directly, knowingly, and intentionally contaminating and permanently polluting both our potable groundwater supplies/aquifers and our two agricultural irrigation wells (and the potable water supplies thereof) that underlie our Armstrong Ranch property. Our Armstrong Ranch, to which we own fee title and in which the U.S. federal

government holds a reversionary ownership interest (including its' potable groundwater supplies and rights) is immediately adjacent to the CEMEX site upon which CalAm has built its' slant well which is wrongfully exploiting our overlying potable groundwater resources.

CalAm has no groundwater rights in the Salinas Valley aquifers. None. It is undisputed law in California that in an overdrafted groundwater basin, a junior appropriator cannot acquire groundwater rights. Yet CalAm, by its' pumping of its' slant well is causing massive environmental damage, without any mitigation, tour potable groundwater aquifers. The EIR/EIS has systematically ignored the massive and adverse environmental impacts of CalAm's proposed project so as to avoid identifying the necessary and massively expensive mitigations that would be required of CalAm to actually mitigate CalAm's proposed wrongful exploitation of the protected Salinas Valley (coastal) groundwater aquifers and resources. Loss of prime coastal farmland and its attendant productivity of food crops (due to the unlawful and irreplaceable stealing of potable groundwater supplies and the resultant pollution of the potable aquifers by the excess pumping of the slant wells), along with the permanent and irreplaceable loss of farmworker jobs have not been addressed or mitigated in the draft EIR/EIS. The costs to purchase those prime and productive coastal farmlands and ranches that will have their potable groundwater supplies wrongfully taken by the ultra vires approval of the CPUC, without compensation to the innocent land owners, are not addressed in the EIR/EIS. Nor is the loss of employment and massive displacement of low-income, Latino farmworkers (and their families) who are employed on those farms and ranches even acknowledged, let alone mitigated in the draft EIR/EIS. Although the Ag Land Trust offered to discuss these issues with Mr. Zigas (as well as offered our water quality baseline test results going back to 2007 and our recorded title documents demonstrating the U.S. Governments reversionary interests in our farmland and groundwater rights) during his one visit to our Armstrong Ranch farm, **he never called us back**. This may be because, much to his and CalAm's consternation, we proved that our potable and operational irrigation wells actually existed (he had publicly denied their existence in the press) and that we use them to irrigate our farmland and our dune habitat restoration sites which are mandated by the terms of our federal grants. (SEE **http://www.montereybaypartisan.com/tag/marc-del-piero/** - **Monterey Bay Partisan (4 articles AND VIDEO included in** PUC experts finally track down the elusive Ag Land Trust wells by ROYAL CALKINS *on* DECEMBER 16, 2015). The impermissible continuing bias of the EIR/EIS consultants in favor of CalAm and its plans to wrongfully take groundwater to which it has no legal rights, to the massive economic and environmental detriment of landowners that actually own real potable groundwater resources and rights, continues to be demonstrated in the draft EIR/EIS by their ignoring of valid objections and their refusal to full investigate,characterize, and fully mitigate the massive and adverse environmental impacts that have been identified by the real parties in interest whose property rights are being taken, without compensation by the CPUC.

The first letter of objection the **Ag Land Trust** sent to the CPUC in opposition to CalAm's plans to wrongfully exploit our potable groundwater supplies was in 2006. A copy of the original letter along with significant documentation of the illegality and adverse environmental impacts of CalAm's proposed "taking" (children call it "theft") of our groundwater (which documentation has previously been provided to the CPUC and the California Coastal Commission) is herewith attached. In spite of our objections, with the exception of the single field trip (wherein Eric Zigas finally was forced to acknowledge the existence of our large irrigation wells, although he declined to inspect our federally mandated and protected coastal sand dunes habitat restoration project), the CPUC and its' consultants have never responded in writing to any of our correspondence. .

Moreover, in violation of CEQA notice mandates, the CPUC has never sent the required mailed notices of the CalAm project (and its' massive cone of depression and resulting induced seawater intrusion into the potable aquifers) to the potentially affected real property owners whose potable overlying groundwater supplies and rights will clearly be polluted and compromised by the excessive and uncontrolled pumping by CalAm.

Please accept this e-mail, and all the documents, statements, objections, references, and attachments thereto, as the first of three e-mails from the Ag Land Trust that are intended to demonstrate the massive illegalities of the CalAm project and the defects and failures of the draft

ALT1-1 cont.

ALT1-2

ALT1-3

ALT1-4

ALT1-5

ALT1-6

EIR/EIS, and the huge legal deficiencies of that draft (that have been "ignored" or "whitewashed") that will subject that document to successful challenge in court unless the EIR/EIS is re-drafted to cure the deficiencies and re-circulated.

Further, by this correspondence, the Ag Land Trust hereby incorporates by reference, (and adopts as our own comments and our own criticisms and our own objections), the criticisms, comments, statements, asserted facts, correspondence, and objections, and all documents and attachments thereto, of the following parties which have submitted comments on the defects, omissions, and inadequacy of the draft EIR/EIS:

1. **The Water Ratepayers Association of the Monterey Peninsula (WRAMP) – Comment letter dated March 17-18, 2017, and all other comment letters submitted by WRAMP commenting on the EIR/EIS.**

2. **Comment Letter by Mr. Larry Parrish dated February 23, 2017 and all of the unanswered questions therein regarding unmitigated environmental impacts that have not been addressed in the draft EIR/EIS.**

3. **All comment letters and objections from Mr. David Beech (including Beech-1, Beech-2, Beech-3, Beech-4, Beech-5, and Beech-(5a)), dated Feb. 20, 2017 et seq..**

4. **Comment letter by Mr. Michael Baer dated February 24, 2017, and all additional comments and objections filed by Mr. Michael Baer regarding the draft EIR/EIS.**

5. **All correspondence and objections submitted by Nancy Selfridge, including but not limited to her e-mailed correspondence and objections dated February 22-23, 2017 sent by Mr. Steven Collins.**

6. **All correspondence from Kathy Biala, resident of Marina, Citizens for Just Water ("Just Water") - including but not limited to her correspondence, objections, and attachments dated 02.23.17.**

7. **All correspondence and comment letters from "Water Plus", including all correspondence and objections signed by George Riley, and including his correspondence dated 20 February 2017.**

8. **All comments and objection letters from and filed by Ms. Myrleen Fisher.**

ALT1-6 cont.

The draft EIR/EIS is fatally flawed because of the bias of the consultants, the deficiencies in its' content, and their refusal to acknowledge, investigate, and document the identified significant adverse environmental impacts of the proposed project. The failure to acknowledge and fully characterize,and mitigate, these significant adverse environmental impacts will cause these documents to be over turned in court, unless they are fully and factually revised and recirculated in compliance with CEQA and NEPA.
I will forward additional comments under a separate cover.

Most Respectfully, For the Ag Land Trust of Monterey County,

Marc Del Piero, Director

Subject: Objection to Cal-Am appeal/application for test slant well

TO: The California Coastal Commission (Please Distribute/Forward This to All Members and Staff)

FROM: Monterey County Agricultural and Historic Lands Conservancy (THE AG LAND TRUST)

RE: Opposition to Proposed California American Water Company Appeal/Application to Acquire a Well Site to Violate Mandatory Policies of the Certified Local Coastal Plan and to Prescriptively "Take" Groundwater from the Overdrafted Salinas Valley Groundwater Basin and our Farm
Herewith enclosed, please accept this notice/letter of opposition to the appeal/application by the California American Water Company, along with the herewith attached EXHIBITS A, B, AND C.

Notice of Objection to proposed Cal-Am "test" slant well (11 pages)

Exhibit A - Board of Directors bios.

Exhibit B - Maps (showing induced seawater intrusion area and undisclosed A.L.T. wells)

Exhibit C - Prior objections correspondence (2006 - present)

The flawed Cal-Am appeal/application proposes to directly violate multiple mandatory Local Coastal Plan policies and state groundwater rights laws, and proposes an illegal "taking" of private property/groundwater rights, to economically benefit the privately held California American Water Company at the expense of the Ag Land Trust.

The application even fails to identify one of our agricultural groundwater wells on our farm property (the "Big Well"), which is the closest to the so-called Cal-Am "test well" and which will be the first to be permanently and irreparably contaminated by Cal-Am's illegal conduct. The proposed environmental review is incomplete and flawed.

No Coastal Commission staff review of these reasonably anticipated, immitigable adverse impacts on our protected coastal agricultural groundwater resources and farmland has been conducted or presented to the Commission in anticipation of this appeal hearing. The failure to even identify these unmitigated adverse impacts in the staff report, we assume, is because the Commission staff has relied exclusively on the flawed (by omission) Cal-Am appeal/application that has tried to "downplay" its intended "taking" of our groundwater supplies and its adverse environmental effects on our prime farmland. Coastal Commission staff has not contacted our Ag Land Trust in spite of our prior correspondence (see Exhibit C).

We anticipate presenting testimony pursuant to our attached Letter of Opposition and Exhibits at your Wednesday meeting in Half Moon Bay.

Please distribute our full comments and all attachments to each and all commissioners prior to the day of the meeting so that they may fully understand and consider the potential consequences of their actions.

Most Respectfully, Marc Del Piero, Director

Second Letter of Objection to Monterey Peninsula Water Supply Project (MPWSP) CalAm's defective and incomplete draft EIR/EIS

As was previously indicated in the prior e-mail sent on behalf of the Ag Land Trust of Monterey County, although the Ag Land Trust offered to provide additional information to the CPUC EIR consultant (Eric Zigas) for the draft EIR/EIS, no request was ever received. No phone call, no letter, no request for the environmental information that we offer was received in the past 20 months from the CPUC or Mr. Zigas. ALT2-1

Our information includes baseline laboratory water quality test data from 2009 forward, and recorded title documents showing the real property interests of the U.S. federal government in our farmland and its' groundwater supplies and aquifers. The recorded documents preclude any party (private, state, or federal) from taking the real property interests, including water supplies and rights, of the federal government for private, for-profit uses, as is CalAm's and the CPUC's intent with their "salvaged water theory". ALT2-2

Moreover, we object to the defective "groundwater model" used by the Hydrologic Working Group, which is controlled by interests which are contractually obligated to support CalAm's project and which hold no groundwater rights in the basin, because the model established no baseline hydrologic condition before CalAm began its' excessive and irresponsible slant well pumping, and because it intentionally excluded all adverse impacts to our groundwater resources and potable irrigation wells. This is a major and intentional defect by omission in the draft EIR/EIS expressly for the benefit of CalAm and its proposal. ALT2-3

Consequently, the draft EIR/EIS is defective by the intentional refusal and omission of available data by the CPUC EIR consultants and the CalAm consultants and engineers who have refused from the beginning of the CEQA process to acknowledge the significant and adverse environmental impacts that they are causing to the potable aquifers of the Salinas Valley and the injury to the landowners and farmworkers whose livelihoods and food production are dependent upon the protection and preservation of those freshwater potable aquifers that are beneath the prime coastal farmland that is subject to both federal and state statutory and regulatory protections. ALT2-4

Mr. Zigas, who was under contract to prepare a fair and impartial EIR, has never called or requested the offered environmental data, and his associates from CalAm and the CPUC hand-picked review panel, euphemistically referred to as the Hydrologic Working Group, has never contacted the Trust for that data either. Given their collective refusal to even acknowledge the existence of our wells for months, because they were inconvenient impediments to their pre-conceived plan to "take water from the Salinas Valley aquifers" that they are now polluting by inducing seawater intrusion from their slant well pumping, the Ag Land Trust has concluded that the draft EIR/EIS is massively defective.

In the earlier e-mail, the Ag Land Trust provided a "link" to the website of the Monterey Bay Partisan and the articles that it carried about our irrigation wells. It also has a link to a video where proof of the fully operational nature of our potable irrigation wells is proven. The bias of Mr. ALT2-5

Zigas and his associates that was also referred to in the earlier e-mail is demonstrated in the newspaper articles attached hereto, wherein Mr. Zigas and his friends continued to assert that our potable irrigation wells were either: 1. non-existent, 2. impossible to find (they are fully visible from CA Highway 1, or 3. were "capped" wells that were non-operational. Mr. Zigas, and the County of Monterey, and CalAm's engineers of the Hydrologic Working Group, and the Carmel Pine Cone newspaper were proven wrong when they visited our farm and personally witnessed our potable irrigation wells in operation pumping over 2000 gpm. It was also at that time that Mr. Zigas declined to look at our federally mandated coastal dune habitat restoration plot that we irrigate with potable water from our irrigation wells. This issue, and the threat and impacts of Cal-Am's wrongful actions to our federally required dune restoration efforts, are not addressed in the draft EIR/EIS.

Please see the attachments and view the video link at the Monterey Bay Partisan website, and the four (4) articles therein that proved the truthfulness of our assertions and the impermissible bias of the CPUC consultant who has omitted important information regarding the unmitigated significant and adverse environmental impacts of CalAm's proposed project. These acts of omission and impermissible bias of the drafters cause the draft EIR/EIS to require re-drafting and re-circulation.

Respectfully, the Board of Directors of the Ag Land Trust of Monterey County

Ag Land Trust
Letter 3 (ALT3)

From: mjdelpiero@aol.com
Subject: Supplimental documents re: federal rights and water quality
Date: March 29, 2017 at 4:51:11 PM PDT
To: Maryjo.Borak@cpuc.ca.gov, Karen.Grimmer@noaa.gov, MJDelPiero@aol.com, sdarington@redshift.com

Third Letter of Objection to Monterey Peninsula Water Supply Project (MPWSP) CalAm's defective and incomplete draft EIR/EIS

On behalf of the Ag Land Trust of Monterey County, and in order to offer proof of our previous assertions, herewith attached are excerpts from the recorded federal real property (including water rights) contract/deed documents that the federal government has with our Trust, and one sample of our original (2009) baseline water quality test data (that meets WHO drinking water standards) that the CPUC consultants, and CalAm's Hydrology working Group did not request, in spite of our offer to supply additional information to them for the draft EIR/EIS. ALT3-1

These documents demonstrate only a few of the intentional defects (by intentional omission of significant adverse impacts and lack of identified mitigations) in the draft EIR/EIS that necessitate re-drafting and re-circulation of the document. ALT3-2

Re: Comments on the Draft Environmental Impact Report/ Draft Environmental Impact Statement for the Proposed Monterey Peninsula Water Supply Project

Dear Ms. Borak and Ms. Grimmer:

We are writing on behalf of California Unions for Reliable Energy ("CURE") to provide comments on the Draft Environmental Impact Report and Draft Environmental Impact Statement ("DEIR/EIS") prepared by the California Public Utilities Commission ("CPUC") and by the Monterey Bay National Marine Sanctuary ("MBNMS"), pursuant to the California Environmental Quality Act, and its regulations ("CEQA"),[1] and the National Environmental Policy Act, and its regulations ("NEPA"),[2] respectively, for the Monterey Peninsula Water Supply

[1] California Public Resources Code, §§ 21000 et seq.
[2] National Environmental Policy Act, 42 U.S.C. 4321 et seq.

Project ("Project"). The Project is being proposed by the California American Water Company ("CalAm" or "Applicant") and will include the construction and operation of a seawater desalination plant and conveyance system with an initial capacity of 9.6 million gallons per day ("mgd") to provide a supplemental source of water to the Monterey Bay area.

The Project area extends approximately 18 miles, from the Project site located in the town of Castroville in the north to the City of Carmel in the south.[3] The Project would include:

- a seawater intake system (comprising of ten subsurface slant wells) extending offshore into submerged lands of MBNMS, and a Source Water Pipeline;[4]
- a 9.6 mgd desalination plant and related facilities (including pretreatment, reverse osmosis, and post-treatment systems), backwash supply and filtered water equalization tanks, chemical feed and storage facilities, brine storage and conveyance facilities, and other associated non-process facilities;[5]
- desalinated water conveyance facilities including pipelines and stand-alone pump station, and a Terminal Reservoir;[6]
- an expanded ASR system, including two additional injection/extraction wells, the ASR-5 and ASR-6 Wells, and three parallel pipelines, the ASR Conveyance Pipeline, ASR Pump-to-Waste Pipeline, and ASR injection/extraction wells and backwash effluent from the wells to an existing settling basin.[7]

The seawater intake system comprises of ten subsurface slant wells (eight active and two on standby), which would be constructed at the CEMEX sand mining site in the northern coastal area of the City of Marina.[8] An estimated 24.1 mgd of raw seawater — extracted through the seafloor in MBNMS — is needed to reliably generate 9.6 million gallons per day (mgd) of product water at the desalination

[3] DEIR/EIS, at p. ES-5.

[5] *Id.*
[6] *Id.*
[7] *Id.*
[8] *Id.*

printed on recycled paper

plant, which would be constructed in unincorporated Monterey County.[9] The plant would produce approximately 10,750 acre-feet per year ("afy").[10] The plant's related facilities include pretreatment, reverse osmosis ("RO"), and post-treatment systems; backwash supply and filtered water equalization tanks; chemical feed and storage facilities; brine storage and conveyance facilities; and other associated non-process facilities.[11]

The source water is conveyed through the slant well to the desalination plant and related facilities. There, it must first pass through a pretreatment system, which would remove suspended and dissolved contaminants and fine particulates. Backwash supply pumps would be used to clean the pretreatment system's filters. Next, the source water would pass through the RO system, which would remove salts and other minerals from the pretreated source water. Finally, the source water would pass through the post-treatment system, if necessary, to meet State Water Resources Control Board standards.[12]

Brine produced during the RO process and pretreatment backwash effluent (a total of approximately 13.98 mgd) would be stored at the desalination plant before being conveyed to the existing ocean outfall pipeline.[13] The brine may be blended with treated wastewater effluent to Monterey Bay.[14] During wet periods the brine would be blended with treated wastewater effluent from the MRWPCA Regional Wastewater Treatment Plant before discharge.[15] During dry months, the brine stream could be discharged without dilution.[16] The amount of treated wastewater effluent would vary throughout the year.[17] The salinity of the discharged brine would be roughly 71 to 74 percent higher than seawater.[18]

The desalinated water would be held in holding tanks from which water would be pumped to either the CalAm water system, the existing Castroville Seawater Intrusion Project ("CSIP") or the Castroville Pipeline.[19] The Project includes other desalinated water conveyance and storage facilities, including treated water storage tanks, desalinated water pumps, a new desalinated water pipeline, a new transmission main, a terminal reservoir tank to store desalinated water and ASR product water, the Carmel Valley Pump Station to provide additional pressure needed to pump water, improvements to interconnection pipelines, the Castroville Pipeline, which would convey desalinated water to the CSIP and the Castroville Community Services District ("CCSD") Well #3, and a pipeline to the CSIP pond for subsequent delivery to agricultural users in the Salinas Valley.[20] The ASR system, includes two new ASR injection/extraction wells (named ASR-5 and ASR-6), which would inject desalinated water into the Seaside Groundwater Basin for storage.[21] Three parallel pipelines would also be constructed to convey water.[22]

The Project would return approximately 700 afy to the Seaside Groundwater Basin over 25 years.[23] It would also include improvements to the Seaside Groundwater Basin aquifer storage and recovery ("ASR") system facilities to enable CalAm to inject desalinated product water into the groundwater basin for subsequent extraction and distribution to customers.[24] The improved ASR system would include two additional injection/extraction wells, the ASR-5 and ASR-6 Wells, and three parallel pipelines, the ASR Conveyance Pipeline, ASR Pump-to-Waste Pipeline, and ASR Recirculation Pipeline, and would improve the reliability of the existing ASR system.[25]

The Project also includes over 21 miles of water pipelines that convey source water between the subsurface intakes and the desalination plant, and desalinated water from the plant to the Terminal Reservoir.[26]

printed on recycled paper

CalAm's application for the Project also includes an option that would combine a reduced-capacity desalination plant (6.4 mgd) with a water purchase agreement for 3,500 afy of product water from another source, the Pure Water Monterey Groundwater Replenishment ("GWR") Project.[27] The Monterey Regional Water Pollution Control Agency ("MRWPCA") certified the Final EIR and approved the GWR project in October 2015.[28]

Finally, CalAm constructed and operated a test slant well at the CEMEX sand mining site. A separate environmental review document covered the test slant well construction and operation.[29] This DEIR/EIS does not evaluate the test slant well.[30] If the project with subsurface slant wells at CEMEX is not approved and implemented, the test slant well will be decommissioned.[31]

The Project requires a number of permits and approvals including incidental take permits, a Biological Opinion, and waste discharge permits, among others.[32]

Based upon our review of the DEIR/EIS and pertinent agency records, we conclude that the DEIR/EIS fails to comply with CEQA and NEPA and must be withdrawn. The DEIR/EIS fails to include a complete project description, provide an adequate description of the environmental setting, adequately analyze and mitigate the project's potentially significant impacts, provides deferred, unenforceable, or otherwise inadequate mitigation measures, evaluate certain alternatives, and consider growth-inducing impacts. The CPUC and MBNMS must revise the DEIR/EIS and recirculate the revised DEIR/EIS for public review.

We prepared these comments with the assistance of Phyllis Fox, Ph.D., Renée Owens, M.Sc., and Radoslaw Sobczynski, Ph.D. Their technical comments are attached hereto and submitted to the CPUC and MBNMS, in addition to the comments in this letter. [33] Accordingly, the CPUC and MBNMS must address and respond to the comments of Dr. Fox, Ms. Owens, and Dr. Sobczynski, separately.

I. STATEMENT OF INTEREST

CURE is a coalition of labor organizations whose members construct, operate, and maintain industrial facilities throughout California. CURE has an interest in enforcing environmental laws that encourage sustainable development and ensure a safe working environment for its members. Environmentally detrimental projects can jeopardize future jobs by making it more difficult and more expensive for industry to expand along the Monterey Bay, and by making it less desirable for businesses to locate and people to live in the area, including the Project vicinity. Continued degradation can, and has, caused construction moratoriums and other restrictions on growth that, in turn, reduce future employment opportunities.

CURE members live, work, recreate and raise their families in the Project vicinity along the Monterey Bay. Accordingly, CURE's members would be directly affected by the Project's adverse environmental impacts. The members of CURE's member organizations may also work on the Project itself. They will, therefore, be first in line to be exposed to any hazardous materials, air contaminants and other health and safety hazards that exist on the Project sites.

II. LEGAL BACKGROUND

A. National Environmental Policy Act ("NEPA")

NEPA is "our basic national charter for protection of the environment."[34] Its purpose is "to help public officials make decisions that are based on understanding of environmental consequences, and take actions that protect, restore, and enhance the environment."[35] NEPA therefore requires federal agencies to take a "hard look at [the] environmental consequences" of their proposed actions.[36] In so doing, NEPA makes certain "that environmental concerns will be integrated into the very process of agency decision-making."[37]

NEPA requires all agencies of the federal government to prepare a "detailed statement" that discusses the environmental effects of, and reasonable alternatives to, all "major Federal actions significantly affecting the quality of the human environment."[38] This statement is commonly known as an environmental impact statement ("EIS"). An EIS must describe: (1) the "environmental impact of the proposed action"; (2) any "adverse environmental effects which cannot be avoided should the proposal be implemented"; and (3) any "alternatives to the proposed action."[39] It further requires that "the policies, regulations, and public laws of the United States shall be interpreted and administered in accordance with the policies set forth" therein.[40] The environmental "effects" that must be considered in an EIS include both "direct effects which are caused by the action" and "indirect effects, which are caused by the action and are later in time or farther removed in distance, but are still reasonably foreseeable."[41]

B. California Environmental Quality Act

CEQA requires that an agency analyze the potential environmental impacts of its proposed actions in an environmental impact report ("EIR") (except in certain limited circumstances).[42] The EIR is the very heart of CEQA.[43] "The foremost principle in interpreting CEQA is that the Legislature intended the act to be read so as to afford the fullest possible protection to the environment within the reasonable scope of the statutory language."[44]

CEQA has two primary purposes. First, CEQA is designed to inform decision makers and the public about the potential, significant environmental effects of a project.[45] "Its purpose is to inform the public and its responsible officials of the environmental consequences of their decisions before they are made. Thus, the EIR 'protects not only the environment but also informed self-government.'"[46] The EIR has been described as "an environmental 'alarm bell' whose purpose it is to alert the public and its responsible officials to environmental changes before they have reached ecological points of no return."[47]

Second, CEQA requires public agencies to avoid or reduce environmental damage when "feasible" by requiring "environmentally superior" alternatives and all feasible mitigation measures.[48] The EIR serves to provide agencies and the public with information about the environmental impacts of a proposed project and to "identify ways that environmental damage can be avoided or significantly reduced."[49] If the project will have a significant effect on the environment, the agency may approve the project only if it finds that it has "eliminated or substantially lessened all significant effects on the environment where feasible" and

[49] 14 Cal. Code Regs. §15002(a)(2).

printed on recycled paper

that any unavoidable significant effects on the environment are "acceptable due to overriding concerns."[50]

While the courts review an EIR using an "abuse of discretion" standard, "the reviewing court is not to 'uncritically rely on every study or analysis presented by a project proponent in support of its position. *A clearly inadequate or unsupported study is entitled to no judicial deference.*"[51] As the courts have explained, "a prejudicial abuse of discretion occurs "if the failure to include relevant information precludes informed decision making and informed public participation, thereby thwarting the statutory goals of the EIR process."[52]

III. THE DEIR/EIS FAILS TO INCLUDE A COMPLETE PROJECT DESCRIPTION

The DEIR/EIS does not meet NEPA's or CEQA's requirements because it fails to include a complete project description, rendering the entire analysis inadequate. Without a complete project description, the environmental analysis under CEQA and NEPA will be impermissibly narrow, thus minimizing the project's impacts and undercutting public review.[53]

Under NEPA, a complete project description is necessary for the public and decision makers to understand the effects of the proposed action and its alternatives.[54] It follows that information in an EIS that is incomplete will skew the environmental consequences analysis and prevent informed public input. Courts have held that "[w]here the information in the initial EIS was so incomplete or misleading that the decision maker and the public could not make an informed comparison of the alternatives, revision of an EIS may be necessary to provide a

printed on recycled paper

reasonable, good faith, and objective presentation of the subjects required by NEPA."[55]

CEQA places the burden of environmental investigation on the government rather than the public. Accordingly, a lead agency may not hide behind its failure to obtain a complete and accurate project description.[56] CEQA requires that the project description contained in a CEQA document that is circulated for public review contain sufficiently detailed information to permit a meaningful evaluation and review of the potential environmental impacts of a proposed project.[57] California courts have repeatedly held that "an accurate, stable and finite project description is the sine qua non of an informative and legally sufficient [CEQA document]."[58] In contrast, an inaccurate or incomplete project description renders the analysis of environmental impacts inherently unreliable. Without a complete project description, the environmental analysis under CEQA will be impermissibly narrow, thus minimizing the project's impacts and undercutting public review.[59]

A. The DEIR/EIS Fails to Describe the Decommissioning Phase of the Project

NEPA and CEQA require a full description of the Project, including its decommissioning phase. Under NEPA, federal agencies must analyze and disclose the impacts of major Federal actions. They may not segment the project into separate components. The Council on Environmental Quality regulations state in relevant part that an EIS must consider the following types of actions:

> (1) Connected actions, which means that they are closely related and therefore should be discussed in the same impact statement. Actions are connected if they:

printed on recycled paper

> (i) Automatically trigger other actions which may require environmental impact statements.
>
> (ii) Cannot or will not proceed unless other actions are taken previously or simultaneously.
>
> (iii) Are interdependent parts of a larger action and depend on the larger action for their justification.
>
> (2) Cumulative actions, which when viewed with other proposed actions have cumulatively significant impacts and should therefore be discussed in the same impact statement.
>
> (3) Similar actions, which when viewed with other reasonably foreseeable or proposed agency actions, have similarities that provide a basis for evaluating their environmental consequences together, such as common timing or geography. An agency may wish to analyze these actions in the same impact statement. It should do so when the best way to assess adequately the combined impacts of similar actions or reasonable alternatives to such actions is to treat them in a single impact statement.[60]

In requiring agencies to analyze these types of actions in the same environmental review document, the agency is prevented from segmenting the project into multiple individual actions, each of which would have an insignificant impact, but collectively would have a significant one.[61]

CEQA is similar. It requires that a complete project description include the "later phases of the project, and any secondary, support, or off-site features necessary for its implementation."[62] The requirements of CEQA cannot be avoided

printed on recycled paper

by chopping a large project into many small parts or by excluding reasonably foreseeable future activities that may become part of the project.[63]

The DEIR/EIS must supply enough information so that the decision makers and the public can fully understand the scope of the Project.[64] The CPUC and MBNMS, as the lead agencies, must fully analyze the whole Project in a single environmental review document and may not piecemeal or split the Project into pieces for purposes of analysis.

Here, the DEIR/EIS fails to describe the full scope of the Project, and thus fails to disclose the full range and severity of the Project's environmental impacts. Throughout the document, the DEIR/EIS states that the Project will have an approximately "40-year operations phase."[65] The DEIR/EIS analyzes some of the impacts in this 40-year context. For example,

> The timeframe during which the MPWSP could contribute to cumulative surface water hydrology and water quality effects includes the 24-month construction period, as well as the estimated 40-year operations phase.[66]

Note, in the above example that the DEIR/EIS acknowledges that impacts will occur during the construction period and the 40-year operations phase, but not decommissioning. The DEIR/EIS must take into consideration impacts that occur during the decommissioning phase.

Where the DEIR/EIS does discuss decommissioning, the analysis is limited to coastal retreat — triggering decommissioning and abandoning the slant wells[67] —, and anticipated energy demand and energy efficiency of the proposed project as a whole, including decommissioning. This limited description and analysis of decommissioning is not enough to comply with CEQA's requirement to describe and analyze impacts from the whole project.

printed on recycled paper

1. Slant Wells' Decommissioning Is Not Adequately Described

For the slant wells, the DEIR/EIS admits that the presence of any slant well on the beach would result in a significant impact.[68] However, it states that "Mitigation Measure 4.2-9 (Slant Well Abandonment Plan) would reduce the impact to a less-than-significant level by requiring CalAm to monitor coastal retreat rates and initiate well decommissions before the beach migrates inland to the location of the subsurface slant wells."[69]

When it is anticipated that the slant well will become exposed in five years, "CalAm will implement the planning and permitting necessary to *abandon* the slant wells."[70] Then, the affected slant wells would be removed from service. Their casing would be pressure grouted such that the screened section would be sealed and the section well casing and pipelines at risk of exposure would be cut and removed to a depth of five feet below the 2060, 100 year lower profile envelope as determined by the 2014 Coastal Erosion Study or any permit condition.[71] Because "the rate of coastal retreat may vary due to unforeseen changes in climate change," this mitigation measure applies to all slant wells, even though the new slant wells would be located inland of the modeled anticipated inland extent of coastal retreat, unlike the test slant well, which might become exposed during the operational life of the project.[72]

CURE-2

This mitigation measure only appears to be triggered when there is a risk of exposure. The DEIR/EIS does not discuss what will be done with the slant wells at the decommissioning phase of the Project.[73] This is a significant, and unexplained, deviation from the test slant well's project description, discussing mitigation. In the 2014 Environmental Assessment for the test slant well, the lead agency, MBNMS, stated the well should be removed to an ultimate depth of no less than 40 feet below

[68] *Id.*

printed on recycled paper

existing ground surface at project decommissioning.[74] That document provided the following Mitigation Measure:

> At project decommissioning, the slant test well and all related infrastructure shall be removed to an ultimate depth of no less than 40 feet below existing ground surface to eliminate the possibility for future re-surfacing and exposure of submerged well casing or related project components as a result of coastal erosion and shoreline retreat. Removal of the well would take place upon completion of the test pumping and/or in segments over time as mutually agreed upon by MBNMS, MRWPCA, Cal Am, the California State Lands Commission, and other identified regulatory agencies. If removal to the total required depth of 40 feet below ground surface is not completed within 5 years following completion of the test pumping due to potential risk to the MRWPCA outfall, the applicant shall post a bond with the City to ensure future removal measures would be appropriately supported and timed to prevent any future resurfacing of the well casing or other project components and shall provide evidence of the bond to MBNMS.[75]

CURE-2 cont.

Unlike the description above for the test slant well, the DEIR/EIS does not provide an adequate project description by failing to provide an explanation of the decommissioning phase for this Project's test slant well (which will be converted to a permanent well) and the proposed wells. This is significant because, as a result of the inadequate project description, the DEIR/EIS fails to analyze significant impacts from decommissioning the wells and fails to require this or another mitigation measure for the test slant well and the proposed wells.

During Project decommissioning, well materials may have to be removed or destroyed in accordance with state well destruction standards. For example, California Well Standards Bulletin 74-81 and 74-90 requires removal or destruction

---

[74] Final Environmental Assessment for the California American Water Slant Test Well Project, September 2014, *available at* http://montereybay.noaa.gov/resourcepro/resmanissues/desal_projects/pdf/140912calam-slantwell_ea-final.pdf ("NOAA EA, 2014"), at Appendix A. [75] *Id.*

printed on recycled paper

of wells that are no longer useful or are abandoned.[76] The California Well Standards describe an intensive process for destroying wells, including cleaning, excavation, removing materials, filling, sealing and other activities.[77]

The DEIR/EIS fails to mention the common sense impact on the environment from decommissioning and abandoning slant wells in the event of coastal erosion. Given the real possibility decommissioning and abandonment may occur at least for the test slant well, this omission renders the project description inadequate. The DEIR/EIS must also evaluate if the decommissioned slant wells would need to be replaced with new slant wells in the event decommissioning and abandonment occurs during the 40-year operational lifetime of the Project.

CURE-2 cont.

Even though Mitigation Measure 4.2-9 (Slant Well Abandonment Plan) would bring the Project into conformance with a number of policies,[78] the DEIR/EIS cannot avoid providing a complete description of the Project and the Project's impacts from its construction, operation, and decommissioning and abandonment phases.[79] By recognizing that slant wells may need to be decommissioned and abandoned, but failing to describe the impact of these wells after their operating lifetime, the DEIR/EIS fails to adequately describe the project.

2. Other Desalination Facilities' Decommissioning Is Not Adequately Described

CURE-3

Although the DEIR/EIS discusses decommissioning of the slant wells and decommissioning in the context of energy demand and energy efficiency,[80] the DEIR/EIS must consider *all* potentially significant impacts from decommissioning

[76] California Well Standards, http://www.water.ca.gov/groundwater/well_info_and_other/california_well_standards/wws/wws_combined_sec20-22.html#22, **Attachment F-1**.
[77] California Well Standards, http://www.water.ca.gov/groundwater/well_info_and_other/california_well_standards/wws/wws_combined_sec23.html, **Attachment F-2**.
[78] DEIR/EIS, at p. 4.2-71.
[79] *Id.*, at p. 4.2-72.
[80] The DEIR/EIS states that the "amounts of direct energy consumption that would occur at the end of the useful life of the project (in approximately 40 years) related to decommissioning is unknown; however, it is anticipated that the amounts would be similar to those required for construction, discussed above." *Id.*, at p. 4.18-14.

printed on recycled paper

the *entire* Project. Decommissioning the desalination plant and related facilities (including, in part, abandoning the subsurface slant wells) would result in environmental impacts, including impacts to air quality, biological resources, water, and solid waste capacity.

In short, the DEIR/EIS's description and analysis of Project decommissioning do not come close to satisfying NEPA's and CEQA's requirements. Where the DEIR/EIS acknowledges that some Project components could be decommissioned, it completely fails to analyze the associated impacts. Further, the DEIR/EIS fails to even mention, let alone analyze, impacts from decommissioning the rest of the Project. As a result, the DEIR/EIS fails to identify the Project's potentially significant impacts from Project decommissioning and fails to incorporate mitigation measures to reduce those impacts to a less than significant level.

CURE-3 cont.

An accurate and complete project description is necessary to perform an adequate evaluation of the potential environmental effects of a proposed project. The CPUC and MBNMS must prepare a revised DEIR/EIS that fully describes decommissioning for all Project components, including the plant, the slant wells, pipelines, injection wells and other associated materials. Only by doing so will the agencies be able to properly analyze and mitigate impacts from decommissioning the whole Project.

B. The DEIR/EIS Fails to Describe the Operating Life of the Slant Wells

The DEIR/EIS fails to include a complete project description with respect to the operating life of the slant wells. The Project is designed to draw 24.1 mgd through ten slant wells (eight would be active, two would be on standby).[81] Each slant well is capable of drawing approximately 3 mgd.[82] The existing test slant well would be converted to a permanent one, and nine additional slant wells would be constructed.[83] Slant well construction would take approximately 15 months to complete, and could take place anytime throughout the overall 24-month

CURE-4

[81] DEIR/EIS, at p. 3-56.
[82] *Id.*
[83] *Id.*, at p. ES-10.

printed on recycled paper

construction duration for the proposed project.[84] Yet, the DEIR/EIS states that the proposed slant wells would have a productive span of only 20-25 years, far short of the Project's 40 year expected operating phase.

> [T]he proposed slant wells would now be located behind the predicted 2060, 100-year lower profile envelope. . . . The proposed slant wells would not be exposed during the operational life of the slant production wells (anticipated to be 20 to 25 years) and would not contribute to further coastal erosion or changes in the beach environment.[85]

Without providing further information, it is unclear how the Project will maintain consistent seawater intake over the 40-year operations phase if each well has a productive span of only 20-25 years. In order to maintain the Project's objective to draw 24.1 mgd over the span of 40 years, the Project would have to build another set of slant wells midway through the Project's operating phase.[86] The associated impacts with abandoning the no-longer-productive original slant wells, and building a new set of slant wells has not been evaluated, rendering the entire project analysis incomplete. What's more, the CPUC and MBNMS studied the location of the test slant well and proposed slant wells, but those studies never considered this possibility that more slant wells would need to be built to support the Project's objective to intake 24.1 mgd of water over the course of 40 years.[87]

CURE-4 cont.

The DEIR/EIS fails to describe and analyze the 20- to 25-year operational life of the slant production wells and the Project's need to build more than 10 slant wells over the 40-year operational life of the Project.

C. The DEIR/EIS Fails to Adequately Explain the Design of the Slant Wells

CURE-5

The DEIR/EIS fails to provide an adequate description of the slant wells to enable a meaningful evaluation and review of their associated environmental

[84] *Id.*, at p. 3-47.
[85] *Id.*, at p. 4.2-70.

printed on recycled paper

impacts.[88] The test slant well's purpose was to inform the design of the proposed slant wells. The test slant well was analyzed in an Environmental Assessment by The National Oceanic and Atmospheric Administration and the MBNMS in 2014 ("NOAA EA").[89]

> Cal Am proposes to construct a slant test well in the coastal foredunes and conduct a 24- month pumping and testing program to obtain information regarding the geologic, hydrogeologic and water quality characteristics of the underlying aquifers in the project area. The data obtained over the 24-month test period would be used to facilitate the planning and final design of a proposed subsurface intake system and desalination plant to serve as the primary future water supply source for the Monterey Peninsula.[90]

CURE-5 cont.

The test slant well was drilled at a 19º angle and was 724 feet long.[91] The test slant well facilities include a "a submersible well pump, a wellhead vault, electrical facilities and controls, temporary flow measurement and sampling equipment, monitoring wells, and a temporary pipeline connection to the adjacent MRWPCA ocean outfall pipeline for discharges of the test water."[92]

In contrast, according to the DEIR/EIS, the proposed slant wells will be at a 14º angle and will extend 900 to 1,000 feet.[93] They would not extend beyond a depth of 190 to 210 feet below the seafloor.[94] The proposed slant wells would be screened for approximately 400 to 800 linear feet at depths corresponding to both the Dune Sand Aquifer and the underlying 180-Foot-Equivalent Aquifer of the Salinas Valley Groundwater Basin.[95] The decision to adjust the angle of the proposed slant wells by 5º is not explained in the DEIR/EIS.[96]

printed on recycled paper

The DEIR/EIS also lacks any reference to the location of the submersible well pump within the slant wells.[97] At most, the DEIR/EIS states that "[a] submersible pump would be lowered several hundred feet into each well."[98] As Dr. Sobczynski points out in his comment letter, the location of the submersible pump is important for calculating the vertical infiltration rate,[99] which is necessary for evaluating impacts. However, the DEIR/EIS fails to disclose the location of the pump, rendering this DEIR/EIS inadequate as an information disclosure document.

The NOAA EA stated that, for the test slant well, the "water flow rate during the operational period would vary from 1,000 gallons per minute (gpm) to 2,500 gpm."[100] According to the DEIR/EIS each proposed slant well would be equipped with a 2,500 gpm, 300 hp submersible well pump for a total feedwater supply of 24.1 mgd from 8 active slant wells;[101] each active well would pump approximately 2,100 gpm.[102] This raises the question as to when, if ever, the slant wells would run at their maximum capacity of 2,500 gpm, rather than their average operating rate of 2,100 gpm. CURE-6

One possible time that the wells may run at maximum capacity may be after a shutdown, when the plant would need to "catch up on production" and produce 11.2 mgd of desalinated water, rather than its usual 9.6 mgd.[103] If, as the DEIR/EIS states, approximately 24.1 mgd of raw seawater is needed to produce 9.6 mgd of desalinated product water, then to produce 11.2 mgd of desalinated water after shutdown, approximately 28.11 mgd would be needed.[104] (Note, that the DEIR/EIS fails to provide a correct overall recovery rate. It states the recovery rate is 42 percent; however, 9.6 mgd out of 24.1 mgd is 39.8 percent.)[105] Under normal conditions, the eight active slant wells would draw approximately 3 mgd,[106] but in

[106] *Id.*

printed on recycled paper

this post-shutdown scenario, the eight wells would need to draw closer to 3.5 mgd. At a rate of 2,500 gpm, the eight slant wells could draw up to 3.6 mgd. Alternatively, all ten slant wells could be activated to draw approximately 2.8 mgd. Yet, none of this information regarding the water flow rate is adequately explained. In describing a shutdown situation, the DEIR/EIS only concerns itself with the RO modules stating:

> After a shutdown, CalAm might operate the plant with all RO modules in service (at the plant's maximum production capacity of 11.2 mgd) to catch up on production; however, the total annual production would not exceed 9.6 mgd.[107]

CURE-6 cont.

Dr. Sobczynski explains in his comment letter that the submersible pump will impact the vertical infiltration rate, which may result in an adverse impact to the environment.[108] In failing to disclose how the Project would "catch up on production,"[109] the DEIR/EIS leaves the public guessing as to how this would be achieved. As will be described in further detail below, the DEIR/EIS must consider these types of events in its impact analysis for the slant wells.

The NOAA EA also explained that the test well would feature a "packer device,"[110] which was used "to isolate one aquifer [either the Dune Sand or the 180-FTE] for testing and pumping."[111] As Dr. Sobczynski explains, this device alters the flow of water to the slant well intake, which can alter the vertical infiltration rate and thereby lead to environmental impacts.[112] Yet, the DEIR/EIS is silent as to whether this device would be utilized. The DEIR/EIS should inform the public and decision makers about whether this device would be installed, and if so, when it would be used.

printed on recycled paper

An adequate description of the design of the slant wells is important because, without it, the DEIR/EIS contains no discussion about slant wells' biofouling or corroding over time. Despite analysis pertaining to:

- corrosion at the MRWPCA outfall or diffusor[113];
- corrosion in other Project components[114]; and
- fouling at the RO membranes due to "[t]he accumulation of salts or scaling (from to [*sic*] microbial contamination, turbidity, and other contaminants such as iron and manganese),"[115]

the DEIR/EIS leaves out long term degradation concerns regarding the slant wells. Even Dr. Williams (the slant well patent holder)[116] points out in his article about slant well technology, that the slant wells will experience biofouling and corrosion.[117] Dr. Williams writes:

CURE-8

> The Monterey test slant well has an 18 in. pump house casing which can accommodate placement of large development pumps with capacities over 3,000 gpm. Properly developed wells constructed using corrosion resistant materials such as 2507 Super Duplex Stainless Steel minimize well deterioration due to corrosion and biofouling. As such, these design improvements result in less frequent well rehabilitation with intervals estimated at between 3–5 yrs.[118]

Though the DEIR/EIS does not provide the technical specifications of the slant well, the Request for Proposals call for the use of 2507 Super Duplex Stainless

printed on recycled paper

Steel,[119] assuming, for the same reason described above, that it minimizes deterioration due to corrosion and biofouling.[120] By not discussing the slant wells' degradation (even while admitting that certain materials would need to be used to minimize biofouling and corrosion), the DEIR/EIS fails as an information disclosure document because it leaves out information that is necessary for evaluating and reviewing an adverse environmental impact from the Project.

The courts may not look for "perfection" but would expect "adequacy, completeness, and a good faith effort at full disclosure,"[121] which has not occurred here. Incomplete information in an environmental review document will skew the environmental consequences analysis and prevent informed public input. The information described above about Project decommissioning, operating life, and design must be included in the DEIR/EIS because each component is necessary to inform the public and decision makers about the Project's potentially significant environmental impacts. By failing to provide an adequate and complete project description, the DEIR/EIS violates NEPA and CEQA.

CURE-8 cont.

IV. THE DEIR/EIS FAILS TO PROVIDE AN ADEQUATE DESCRIPTION OF THE ENVIRONMENTAL SETTING

The DEIR/EIS employs an incomplete baseline, thereby skewing the impact analysis. An accurate description of the environmental setting is important because it establishes the baseline physical conditions against which a lead agency can determine whether an impact is significant. The failure to adequately describe the existing setting contravenes the fundamental purpose of the environmental review process, which is to determine whether there is a potentially substantial, adverse change compared to the existing setting.

CURE-9

According to NEPA, an environmental review document must "succinctly describe the environment of the area(s) to be affected or created by the alternatives

[119] Monterey Peninsula Water Supply Project: Subsurface Source Water Slant Wells Design Documents, 2015, pdf. p. 7, *available at* https://www.dropbox.com/s/xs6tdmtg6qvk0fc/draft%20Source%20Water%20Slant%20Well%20supplemental%20conditions%20and%20tech%20specs%20and%20drawings.pdf?dl=0 (hereafter "MPWSP, Well Design, 2015"), **Attachment I-1**.

[120] Williams, Yield, 2015, *supra*, at p.4.

[121] CEQA Guidelines, § 15151.

printed on recycled paper

under consideration."[122] Without a description of the areas to be affected by a proposal, the potentially significant effects resulting from a proposal cannot be determined.[123] Indeed, "without establishing . . . baseline conditions . . . there is simply no way to determine what effect [an action] will have on the environment and, consequently, no way to comply with NEPA."[124] Moreover, adequate and accurate compilation of relevant data and information is critical in establishing whether the project would have a significant impact, while also allowing for public scrutiny and public participating in the decision-making process.[125]

CEQA requires the lead agency to include a description of the physical environmental conditions in the vicinity of the project, as they exist at the time environmental review commences.[126] The EIR must also describe the existing environmental setting in sufficient detail to enable a proper analysis of project impacts. "The adequacy of an EIR is determined in terms of what is reasonably feasible, in light of factors such as the magnitude of the project at issue, the severity of its likely environmental impacts, and the geographic scope of the project."[127] "A legally adequate EIR . . . must contain sufficient detail to help ensure the integrity of the process of decision-making by precluding stubborn problems or serious criticism from being swept under the rug."[128] Furthermore, special emphasis should be placed on environmental resources that are rare or unique to that region and would be affected by the project.[129]

The description of the environmental setting in the DEIR/EIS is inadequate because it omits highly relevant information regarding existing water quality and biological and marine resources that may be significantly impacted by the Project.

The CPUC and MBNMS are required to gather the relevant data and provide an adequate description of the existing environmental setting in a revised DEIR/EIS. CURE-9 cont.

A. The DEIR/EIS Fails to Set Forth an Adequate Environmental Setting for Ocean Water Quality

In order to adequately determine the impacts of discharging brine, the DEIR/EIS must provide the ionic composition of the ocean water. Ocean water salts include much more than sodium and chloride ions, ex. Ba, Ca, K, Sr, Mg.[130]

This Project must disclose the ionic composition of the ocean water due to the common ion effect.[131] The common ion effect occurs when, by increasing the concentration of one ion, *i.e.*, chloride, another ion becomes more soluble or more insoluble.[132] The interactions among the ions in ocean water are complex and failing to disclose the ionic composition deprives the public from knowing if certain compounds will precipitate out. For this reason, only taking aqueous samples without taking seafloor samples to determine compliance with the Ocean Plan may not suffice as some ions may precipitate out.[133] The Ocean Plan is not site-specific and the ionic composition in Monterey Bay must be disclosed to determine if there may be an impact due to the high increase of chloride ions being discharged.[134] CURE-10

B. The DEIR/EIS Fails to Set Forth an Adequate Environmental Setting for Marine Resources

The CPUC and MBNMS failed to conduct the requisite due diligence to investigate and disclose in the DEIR/EIS the physico-chemical character of ocean CURE-11

water and sediment in the Sanctuary. As Dr. Sobczynski explains in his comment letter, the DEIR/EIS does not provide critical information about the marine setting, which is important for an adequate impact analysis.[135] Without an adequate environmental setting, the lead agencies' finding that there would be less than significant impacts for marine resources is inaccurate.

1. DEIR/EIS Fails to Provide an Adequate Environmental Setting Due to Inconsistency Regarding Clay, and Lack of Data on Organic Matter

The DEIR/EIS provides inconsistent information about the existence of clay in the subsurface in the specific area of the slant wells.[136] On the one hand, the DEIR/EIS states that there is little to no silt, clay, and organic materials in the subsurface that would impede infiltration.[137] But, on the other hand, the DEIR/EIS states that, during slant well construction, clay and silt would be produced from the subsurface.[138] In examining the lithological bore logs from the test slant well, Dr. Sobczynski highlights that there are clay layers, which the slant well transects.[139] In failing to fully acknowledge the existence of clay in the subsurface, the DEIR/EIS failed to provide critical information about the existing subsurface environment.

CURE-11 cont.

As Dr. Sobczynski explains in his comments, even small amounts of clay will result in colloid buildup when microorganisms pass through the material.[140] The DEIR/EIS fails as an information disclosure document by providing inconsistent and unclear statements about the presence of clay in the subsurface, in the area where the slant wells are located, leading to potential colloidal buildup.[141] This potentially significant impact is discussed in further detail below.

printed on recycled paper

With respect to organic materials, the DEIR/EIS groups the existence of organic materials, or rather the lack thereof, with the existence of clay and silt.[142] Yet, as described above, Dr. Williams (the slant well patent holder) and Geosciences (Dr. Williams' company) anticipate biofouling to occur, which is why they call for the special construction materials (Super Duplex 2507) to minimize corrosion and biofouling for the slant well.[143]

The DEIR/EIS's unexplained silence on this issue of slant well biofouling is also evident in its minimal discussion about harmful algal blooms. The DEIR/EIS states that "Hazardous Algal Blooms would not be a reason for the [slant] wells to stop operating. Subsurface intakes are not affected by algal blooms."[144] Algae is organic matter and the location, quantity, intensity, and potential toxicity of algal blooms (including the extent of the dead algae's ultimate settling on the sea floor) should be adequately disclosed, particularly because the DEIR/EIS claims subsurface intakes would not be affected by algal blooms.[145] The DEIR/EIS must explain how this can be so. As is, the DEIR/EIS does not provide any evidence to reconcile the statement that organic matter would not impact slant well operations but that biofouling may occur at the slant well and its effects should be minimized through the use of Super Duplex 2507 stainless steel.[146]

printed on recycled paper

By failing to disclose the existing amount of dissolved organic matter, sedimentary organic matter, and microorganisms in the subsurface,[147] the DEIR/EIS fails to establish an adequate baseline. The DEIR/EIS's description that there is "little to no" organic material in the subsurface is not sufficiently detailed to enable an analysis of buildup, biofouling and algal blooms.[148] The DEIR/EIS's vague statements regarding existing subsurface material and organic matter conflict with the requirements of CEQA and NEPA because, without an adequate description of the existing setting, there is simply no way to determine what effect a project will have on the environment. This inhibits the decision makers and public from being able to determine if the Project will have significant impacts.

CURE-11 cont.

The DEIR/EIS must be revised and recirculated to adequately inform the public about the presence and extent of clay, and of organic matter, including the quantity and intensity of algal blooms.

C. The DEIR/EIS Fails to Set Forth an Adequate Environmental Setting for Biological Resources

CEQA requires agencies to place special emphasis on environmental resources that are rare or unique to a region.[149] According to independent expert biologist Renee Owens, the DEIR/EIS fails to acknowledge the high degree of importance of the Project area to conserving marine and terrestrial flora and fauna biodiversity.[150] As Ms. Owens explains, Monterey County has some of the most diverse flora in California.[151] It is a "hot spot" due in part to its high endemism of species, and it has been described as one of the most essential coastal regions in the world in terms of plant and wildlife biodiversity conservation.[152]

CURE-12

Both federal and state metrics indicate the biodiversity value of the Project area. The U.S. Fish and Wildlife Service reports that there are 35 listed threatened or endangered species within, or that may be affected by projects in, the Project

[147] DEIR/EIS, at p. 4.2-67.

printed on recycled paper

area.[153] The California Natural Diversity Database ("CNDDB") denotes within the Project area quads 17 Federal Endangered Species Act ("ESA") listed species, 10 California Endangered Species Act ("CESA") listed species, and 24 Species of Special Concern.[154] Due to the overall biological importance of the terrestrial habitats and species included in the Project footprint and buffer zone, the DEIR/EIS must emphasize the importance and resultant fragility of the ecosystems, habits, and sensitive species populations in describing the environmental setting.[155] The DEIR/EIS must analyze the Project's biological impacts, mitigation measures, and cumulative impacts with respect to an accurate environmental setting, which should emphasize the Project area's high degree of biological importance.

CURE-12 cont.

1. Sensitive species highlighted in the City of Marina's Local Coastal Land Use Plan are not analyzed in the DEIR/EIS

Not only does the DEIR/EIS fail to provide an adequate environmental setting by minimally discussing the biological importance of the area, but the DEIR/EIS also fails to provide an adequate and accurate list of species in the area. Specifically, the DEIR/EIS fails to consider sensitive species highlighted in the City of Marina's Local Coastal Land Use Plan ("LCLUP"), such as the globose dune beetle (*Coelus globosus*), Salinas Kangaroo Rat (*Dipodomys heermanni goldmani*), seaside painted cup (*Castilleja latifolia ssp. Latifolia*), and Eastwood's Ericameria (*Ericameria fasciculate*).[156] These species are present in the region and the DEIR/EIS fails to explain why it did not include an analysis of impacts to these species.[157] As Ms. Owens explains, the DEIR/EIS must include these species in the environmental setting and evaluate the potential impacts to these species and their habitat,[158] as required by NEPA and CEQA.[159]

CURE-13

Bd.* (9th Cir. 2011) 668 F.3d 1067, 1085-1086 (finding that the agency's inability to conduct on-the-ground surveys as part of the EIS process, and instead relying on outdated aerial surveys, violated NEPA's requirement that the agency takes a "hard look" at the potential environmental consequences.)

printed on recycled paper

2. The DEIR/EIS Fails to Adequately Survey Terrestrial Sensitive Species

For this Project's 2015 DEIR, Ms. Owens provided comments that protocol surveys should have been included.[160] Although the DEIR/EIS appears to acknowledge this need to provide project-level, protocol or focused surveys, the CPUC and MBNMS failed to obtain these adequate surveys.[161]

Instead, the DEIR/EIS relies largely on databases and outdated reports, rather than formal scientific observations made on the ground by permitted biologists who specialize in identifying species for which protocol surveys are required.[162] Furthermore, the DEIR/EIS's habitat assessment provides anecdotal observations or inferences from habitat onsite to make protected species status determinations.[163] As Ms. Owens explains, the CPUC and MBNMS must obtain results from protocol surveys to ensure specificity and accuracy in the DEIR/EIS for this Project, because many species may not actually be reported on the CNDDB or on the California Native Plant Society's Inventory of Rare and Endangered Species.[164] The CPUC and MBNMS must obtain site-specific, protocol level surveys in order to accurately describe species in the existing setting in order to analyze the Project's impacts on those species in a revised and recirculated DEIR/EIS.[165] CURE-14

Ms. Owens also explains that the DEIR/EIS still fails to provide a thorough, up-to-date, written biological report that describes in detail the results of project-wide, or facility-wide focused or protocol level surveys of special status plant or animal species.[166] Instead, the DEIR/EIS provides an impact analysis that is based on special-status species observations available to Environmental Science Associates ("ESA") as of June 20, 2016, and other documents from 2010 to 2014.[167] However, the 2016 ESA document only includes GIS shape files and does not

printed on recycled paper

include a written analysis about the biological setting.[168] This haphazard compilation of GIS files deprives the public of the opportunity to participate in the decision-making process.[169]

"Accurate scientific analysis, expert agency comments, and public scrutiny are essential to implementing NEPA."[170] The same is true for CEQA, which states that the purpose of the "EIR is to demonstrate to an apprehensive citizenry that the agency has, in fact, analyzed and considered the ecological implications of its action."[171] Here, as a result of the failure to provide data from surveys and an evaluation in a biological report, the information the DEIR/EIS provides is unverifiable and impossible to review for accuracy.[172] Ms. Owens summarizes this lack of data:

> Upon review of the entire discussion of terrestrial biological resources in the DEIR/S, it is apparent that every mention of focused, protocol, and most reconnaissance surveys for sensitive flora (not just habitat types) and fauna conducted for this Report hinge mostly upon data either not cited at all, vaguely alluded to by mentioning reports that covered only small sections of this Project footprint - some such report being 10 – 11 years old – and the citation of AECOM shape files, "AECOM 2016". In fact, "AECOM 2016" is cited at least 50 times throughout the document. Yet no report of data on individual species accounts are provided. For such a large, well-funded, and public Project that has had ample opportunity to contract biological specialists to conduct protocol level surveys for threatened, endangered, and Special Concern species, this is an overt oversight.[173]

To comply with NEPA and CEQA, the DEIR/EIS must adequately survey, and subsequently analyze the potential impact of the Project on, sensitive terrestrial species. As proposed, the DEIR/EIS fails to do so.

3. The DEIR/EIS Biological Resources Maps are Inadequate for Determining Existing Conditions Regarding Special Status Species

The DEIR/EIS provides unclear maps to indicate the occurrences of animals and plants species. As Ms. Owens explains, the DEIR/EIS should provide maps that clearly indicate which, and how many species, occur in a given location in order to enable review of existing site conditions.[174] The DEIR/EIS's failure to include clear maps is indicative of a larger problem — the DEIR/EIS lacks focused and protocol level surveys of species in the Project area that are necessary to adequately inform the public and decision makers about the existing environment.[175] CURE-15

4. The DEIR/EIS Fails to Consider the Western Snowy Plover Background and Relative Status for the Project Region

Ms. Owens provides extensive background about the western snowy plover, its status relative to the Project region, and threats and types of impacts to the species.[176] Given the severity of impacts that this Project may pose to the western snowy plover,[177] the DEIR/EIS must provide detailed information about the species' status in the Project area.[178] Currently, the DEIR/EIS does not provide enough information to accurately assess the impact of the Project's activities on the area's snowy plover population, and thereby to the regional population as a whole.[179] CURE-16

D. The DEIR/EIS Fails to Set Forth an Adequate Environmental Setting for the Socioeconomics and Environmental Justice Impacts in the Area CURE-17

The DEIR/EIS should incorporate the Office of Environmental Health Hazard Assessment's CalEnviroScreen 3.0 tool to inform decision makers and the public of

[178] CEQA Guidelines, § 15024 subd. (a) ("The adequacy of an EIR is determined in terms of what is reasonably feasible, in light of factors such as the magnitude of the project at issue, the severity of its likely environmental impacts, and the geographic scope of the project.")
[179] Owens Comments, at p. 19.

printed on recycled paper

the environmental burdens that the communities near the Project will face.[180] Since this information is available, and NEPA requires a socioeconomic and environmental justice analysis, the tool should be utilized to better describe the Project's setting.[181] By incorporating CalEnviroScreen 3.0, the DEIR/EIS can disclose relevant information needed to identify pollution burdens and vulnerabilities affecting communities near the Project. For example, the tool provides information such as potential burdens to communities posed by contaminants in drinking water, and potential social stressors relating to unemployment.[182] For a complete environmental setting, the DEIR/EIS should incorporate the CalEnviroScreen 3.0 information.

CURE-17 cont.

V. THE DEIR/EIS FAILS TO ADEQUATELY ANALYZE AND MITIGATE THE PROJECT'S POTENTIALLY SIGNIFICANT IMPACTS

NEPA requires a full and fair discussion of every significant impact, as well as disclosure to the decision makers and the public of reasonable alternatives, which would avoid or minimize adverse impacts.[183] The impacts analysis must include a discussion of the relationship between short-term uses of the environment and the maintenance and enhancement of long-term productivity, and any irreversible or irretrievable commitments of resources which would be involved in the proposal should it be implemented.[184] The discussion of impacts must include both "direct and indirect effects (secondary impacts) of a proposed project."[185] The agency need not speculate about all conceivable impacts, but it must evaluate the reasonably foreseeable significant effects of the proposed action.[186] In this context, reasonable foreseeability means that "the impact is sufficiently likely to occur that a person of ordinary prudence would take it into account in reaching a decision."[187]

printed on recycled paper

NEPA also requires a discussion regarding possible conflicts between the proposed action and the objectives of Federal, regional, State, and local land use plans, policies and controls for the area concerned.[188]

NEPA requires that agencies take a "hard look" at the environmental consequences of a proposed action.[189] A hard look is defined as a "reasoned analysis containing quantitative or detailed qualitative information."[190] The level of detail must be sufficient to support reasoned conclusions by comparing the amount and the degree of the impact caused by the proposed action and the alternatives.[191] An EIS must provide a "full and fair discussion of significant environmental impacts and shall inform the decision-makers and the public of the reasonable alternatives that would avoid or minimize adverse impacts or enhance the quality of the human environment."[192] "General statements about 'possible' effects and 'some risk' do not constitute a 'hard look' absent a justification regarding why more definitive information could not be provided."[193] "[L]ack of knowledge does not excuse the preparation of an EIS; rather it requires [the agency] to do the necessary work to obtain it."[194]

CURE-18 cont.

As described above in the legal background, CEQA has two basic purposes, neither of which the DEIR/EIS satisfies. First, CEQA is designed to inform decision-makers and the public about the potential, significant environmental effects of a project.[195] CEQA requires that an agency analyze potentially significant environmental impacts in an EIR.[196] The EIR should not rely on scientifically outdated information to assess the significance of impacts, and should result from

printed on recycled paper

"extensive research and information gathering," including consultation with state and federal agencies, local officials, and the interested public.[197] To be adequate, the EIR should evidence the lead agency's good faith effort at full disclosure.[198] Its purpose is to inform the public and responsible officials of the environmental consequences of their decisions *before* they are made. For this reason, the EIR has been described as "an environmental 'alarm bell' whose purpose it is to alert the public and its responsible officials to environmental changes before they have reached ecological points of no return."[199] Thus, the EIR "protects not only the environment but also informed self-government."[200]

Second, CEQA directs public agencies to avoid or reduce environmental damage when possible by requiring alternatives or mitigation measures.[201] The EIR serves to provide public agencies, and the public in general, with information about the effect that a proposed project is likely to have on the environment and to "identify ways that environmental damage can be avoided or significantly reduced."[202] If a project has a significant effect on the environment, the agency may approve the project only upon a finding that it has "eliminated or substantially lessened all significant effects on the environment where feasible," and that any unavoidable significant effects on the environment are "acceptable due to overriding concerns" specified in CEQA section 21081.[203]

CURE-18 cont.

The DEIR/EIS fails to satisfy the basic purposes of CEQA. Specifically, the DEIR/EIS fails to reflect a good faith effort at public disclosure by failing to adequately analyze and mitigate the Project's potentially significant impacts to ocean water quality, marine resources, biological resources, air quality, public health, and vibration issues, and others. The DEIR/EIS also fails to propose measures that could reduce these Project impacts to a less than significant level. In sum, the DEIR/EIS fails to inform decision-makers and the public of the Project's

potentially significant environmental effects and to reduce damage to the environment *before* they occur. CURE-18 cont.

A. The DEIR/EIS Fails to Adequately Analyze and Mitigate Potentially Significant Impacts to Ocean Water Quality

The Ocean Plan's Desalination Amendment provides regulations for desalination operations.[204] Scientists reviewed and commented on the Desalination Amendment.[205] The State Water Resourced Control Board provided responses to the external, scientific peer review.[206] The DEIR/EIS states that it will comply with the California Ocean Plan: Desalination Amendment.[207] With respect to discharges the DEIR/EIS states:

> Typically, constituent concentrations are permitted to exceed water quality objectives within the [Zone of Initial Dilution ("ZID")], which is limited in size. Thus, in the case of MPWSP, the Ocean Plan water quality objectives would apply to the edge of the ZID (Flow Science, Inc., 2014 in Appendix D2). Dilution occurring within the ZID from an operational discharge is conservatively calculated as the minimum probable initial dilution (Dm). The water quality objectives established in the Ocean Plan are considered in the context of the calculated Dm to derive the NPDES effluent limits for a wastewater discharge in-pipe (i.e., prior to ocean dilution).[208]

CURE-19

Although the Ocean Plan may permit constituents (defined as bacterial, physical, chemical, biological and chemical constituents) to exceed water quality objectives at the point of discharge, the Ocean Plan provides general regulations and does not provide site-specific impacts analyses for this Project.[209] For example, Dr. Lisa A. Levin, in the external peer review for the Desalination Amendment,

---

[204] State Water Resources Control Board (2015) Water Quality Control Plan: Ocean Waters of California, *available at* http://www.swrcb.ca.gov/water_issues/programs/ocean/docs/cop2015.pdf.

printed on recycled paper

stated that "subsurface intake options need to be evaluated in light of cumulative impacts and habitat status." In response, the Water Board stated that:

> Cumulative impacts will be evaluated on a project-specific basis taking into consideration site-specific considerations during the CEQA process for each desalination facility.[210]

Thus, the DEIR/EIS must comply with the CEQA and NEPA and cannot rely on compliance with the Ocean Plan as a substitute for a site-specific impact analysis.[211]

Despite providing various modeling, the DEIR/EIS lacks evidence to support the statement that excessive constituents *within* the ZID would not result in a potentially significant impact. In fact, the DEIR/EIS seems to suggest the opposite that there would be a significant impact at the point of discharge, but because the Ocean Plan allows for water quality objectives to be exceeded at the point of discharge, the Project's impact would be less than significant.[212] Thus, all the DEIR/EIS commits to is that, in the case of the MPWSP, the Ocean Plan water quality objectives would apply to the edge of the ZID.[213] The DEIR/EIS completely omits any impact analysis and any identification of potential mitigation for the potential significant impact at the point of discharge.

CURE-19 cont.

The DEIR/EIS cannot "completely ignore[]" a potential impact.[214] For the purposes of NEPA and CEQA, the DEIR/EIS fails to adequately analyze and mitigate potentially significant impacts to ocean water quality *within* the ZID. The CPUC and MBNMS cannot rely on compliance with the Ocean Plan to avoid analyzing and mitigating significant impacts within the ZID.

As the DEIR/EIS points out, "[o]perational discharges of the MPWSP under certain scenarios may exceed Ocean Plan water quality objective thresholds.

printed on recycled paper

Exceedances of these thresholds would be potentially inconsistent with Coastal Act policies."[215] However, the operational discharge scenarios all provide estimated concentrations at the *edge* of the ZID for Ocean Plan constituents.[216] The common-ion effect, described above, informs us that ions might become more or less soluble based on the influx of chloride ion at the point of discharge.[217] It does not appear from the DEIR/EIS that the various discharge scenarios considered an accumulation of constituents at the sea floor that had precipitated out at the point of discharge.[218] Certainly, accumulated constituents on the seafloor that are hazardous to marine (and human life) would pose a potentially significant effect. By failing to consider impacts at the point of discharge, and the complex chemical interactions due to the high level of chloride ions that would be discharged through the outfall, the DEIR/EIS fails to adequately analyze and mitigate potentially significant effects to ocean water quality.

CURE-19 cont.

Exacerbating matters regarding existing constituents, the DEIR/EIS proposes to add inert biodegradable additives for construction and cleaning, if needed.[219] CURE requested the Material Safety Data Sheets ("MSDS") for these chemicals and was informed that such documents were unavailable because "We [Environmental Science Associations] are not in possession of any MSDS(s). The exact products CalAm would use are unknown."[220] Even if those chemicals may be inert, that does not mean they may not have significant impacts. The DEIR/EIS lacks evidence to support its conclusions and must disclose this information in a revised and recirculated DEIR/EIS.

B. The DEIR/EIS Fails to Adequately Analyze and Mitigate Potentially Significant Impacts Related to Marine Resources

The DEIR/EIS fails to adequately analyze and mitigate potential significant impacts related to marine resources, particularly as those impacts are caused by the subsurface slant well technology.

1. Factors Influencing Vertical Infiltration Rates Are Not Adequately Analyzed

The DEIR/EIS does not include critical information, which will impact the vertical infiltration rate,[221] such as:

- the location of the submersible pump;[222]
- the sediment profile for the 19° test slant well and for 14° proposed slant wells;[223]
- the inflatable packers for the test slant well, and the possible packers in the proposed slant wells;[224] and
- the clogging in the seabed.[225]

CURE-20

According to independent expert physical chemist, Dr. Radoslaw Sobczynski, these factors will result in a higher vertical infiltration rate, which has not been adequately disclosed and may lead to a significant, undisclosed impact.[226] As Dr. Sobczynski provides in further detail in his letter, the vertical infiltration calculations were based on a calculation that Dr. Williams (the slant well patent holder) conducted based on site-specific information from the Doheny Desalination Plant's slant wells, and a calculation, which divided the amount of water (24.1 mgd) by the subsurface area above the slant wells (1,000,000 ft^2).[227] Because the CPUC and MBNMS considered these numbers to be sufficiently similar, it determined that

[227] *Id.*, at pp. 5-7.

printed on recycled paper

this vertical infiltration range was adequate for purposes of impact analysis.[228] Dr. Sobczynski identifies a number of factors, which could change this vertical infiltration rate, and which have not been adequately disclosed in the DEIR/EIS.[229] The implication of failing to provide an accurate infiltration rate is that there may be a significant, undisclosed impact.[230]

CURE-20 cont.

a) Submersible Pump

Critically, the DEIR/EIS fails to provide information about the location of the submersible pump.[231] As Dr. Sobczynski explains in his comments, the submersible pump's location is critical in evaluating the intake's environmental impact.[232] Based on information gleaned from the DEIR/EIS, the slant well patent, and Dr. Williams' article about the Monterey test slant well, Dr. Sobczynski assumed that the submersible pump is located at a depth of approximately 60-70 feet.[233] The test slant well uses a telescoping design, meaning that the part of the well closest to the surface is progressively wider than it is at its lowest point.[234]

CURE-21

As Dr. Sobczynski describes in further details in his letter, the submersible pump will create a pressure gradient, which will draw most of the water in the area of the pump.[235] By drawing most of the water in a limited area directly above the pump, the vertical infiltration rate will be higher, an important fact that the DEIR/EIS failed to consider.[236]

b) Sediment Profile

Next, the slant well is constructed through the Older Dune Sand and Terrace Deposits.[237] The Older Dune Sand is described as having high permeability.[238] The

CURE-22

[228] *Id.*, at p. 7; *see also* DEIR/EIS, at p. 4.5-52.
[229] *Id.*, at pp. 17-23.

[237] R. Sobczynski Comments, at pp. 10-14.
[238] DEIR/EIS, at p. 4.2-67.

printed on recycled paper

DEIR/EIS views this as a positive characteristic stating, "[t]he high permeability of the dune sand would be suitable for the infiltration of water."[239] Notably, the DEIR/EIS does not make any statement about the permeability of the Terrace Deposits, yet this will impact the vertical infiltration rate. If water will flow more easily through the Older Dune Sand, then that portion of the well (approximately the upper third) will be more productive.[240] This will once again result in a higher infiltration rate because most of the water will flow through the Older Dune Sand into the upper third of the slant well.[241]

CURE-22 cont.

c) Inflatable Packers

Third, the test slant well had an inflatable packer feature.[242] This packer feature is also disclosed in Dr. Williams' slant well patent.[243] However, the DEIR/EIS is silent on whether the proposed slant wells would have this feature.

The packers may be on either, or both sides of the submersible pump.[244] The slant well operator may inflate either or both of these packers.[245] By inflating the lower packer, for example, any suction power from the pump would be lost and the lower portion of the slant well (below the submersible pump) would become inactive.[246] Without providing further information, it is unclear from the DEIR/EIS if the proposed slant wells would include this feature. If they do include the packers, then the DEIR/EIS should disclose when either or both packers would be inflated (*i.e.*, to deal with a clog, or for regular maintenance).

By concentrating the water's flow to the area directly above the submersible pump, the vertical infiltration rate might be higher.[247] However, because the DEIR/EIS is silent about the presence of the inflatable packers, even though they could increase the vertical infiltration rate, Dr. Sobczynski did not include the

printed on recycled paper

packers' presence in his calculations to determine the vertical infiltration rate.[248] The CPUC and MBNMS must revise the DEIR/EIS to clarify whether and how the inflatable packers would be used and their effect on infiltration. CURE-23 cont.

d) Clogging of the Seabed

Fourth, according to Dr. Sobczynski, there is a high likelihood that the slant wells' intake screens and seabed will clog over time.[249] In fact, the intake screens are specially designed to minimize biofouling and corrosion and thereby to reduce the need for more frequent cleaning.[250] Though the intake screens can be cleaned by lowering mechanical brushes and possibly adding inert chemicals, the seabed through which the water will be filtered cannot be cleaned in this way.[251]

Clogging was an issue at the Doheny wells at Dana Point where the test slant wells lost their efficiency from an original value of 95% in 2006 to 52% in 2012.[252] Dr. Williams stated that the reason why the Doheny wells failed is because of technical limitations.[253] CURE-24

> "Due to the pump house casing limitation experienced at Dana Point and the inability to fully develop the well, the MPWSP test slant well included a larger diameter pump house casing. The Monterey test slant well has an 18 in. pump house casing which can accommodate placement of large development pumps with capacities over 3,000 gpm."[254]

The Monterey test slant well has allegedly not lost efficiency since beginning operations in 2015.[255] However, that is not to say clogging will not occur in the future for the test slant well and the proposed slant wells. The slant wells are

[248] *Id.*, at p. 15.

[255] DEIR/EIS, at Appendix G2, p.5 ("By the end of September 2016, the test slant well had been operating continuously for 5 months and intermittently since April 2015.")

printed on recycled paper

designed to draw brackish groundwater initially, but within 18 months[256] to 4 years[257] the slant wells should draw predominantly from ocean water that filters through the subsurface sediment (93% of source water).[258]

Assuming this is true, the buildup of sediment and organic matter traversing through the seabed will be at its highest when most of the source water will be coming from above the seafloor.[259] Additionally, an operational report for the Doheny wells stated that future wells must be carefully constructed so that the wells do not become immediately clogged.[260]

CURE-24 cont.

Yet, the DEIR/EIS does not disclose that there is a high likelihood that sediment and organic matter will build up in the subsurface, especially when after some time most of the source water will come from above the seafloor.[261] As Dr. Sobczynski points out, unless the mechanical cleaning process includes displacing the seabed above the intake, then the slant wells will likely become clogged over time.[262]

2. <u>The Recalculated Vertical Infiltration Rate is Higher than the Rate Provided</u>

CURE-25

Dr. Sobczynski recalculated the vertical infiltration rate.[263] He found that the infiltration rate was approximately ten times higher than what Dr. Williams calculated with respect to the Doheny wells and what the DEIR/EIS reported in its

[256] Final Summary Report for the Doheny Ocean Desalination Project Phase 3 Investigation: Extended Pumping and Pilot Plat Test Regional Watershed and Groundwater Modeling Full Scale Project Conceptual Assessment, January 2014. calculation dividing the area above the slant wells (one-million square feet) by the bulk flow of water (24.1 mgd).[264] Dr. Sobczynski found a vertical infiltration rate of 0.16 mm/sec.[265] Based on this new vertical infiltration rate, Dr. Sobczynski recalculated the ventilation parameter, which is important for determining whether microorganisms could be pulled into the seabed.[266] Dr. Sobczynski found that the infiltration rate will increase wave induced bottom stress by 10%, rather than the previously calculated 1%.[267] This increase was not adequately analyzed in the DEIR/EIS, because it was underestimated.[268] As a result, the DEIR/EIS failed to disclosed and evaluate significant impacts from the Project's higher infiltration rate. CURE-25 cont.

3. Accumulation of Biomatter Above the Slant Well is Not Adequately Analyzed and Mitigated

The DEIR/EIS fails to adequately analyze and mitigate potentially significant impacts related to marine resources as a result of the slant well.[269] Dr. Sobczynski describes the potential for the accumulation of biomatter above the slant wells.[270] The DEIR/EIS should account for how it will handle the sediment layer at the bottom of the seafloor. CURE-26

4. Impacts from Maintaining and Abandoning the Slant Well Have Not Been Adequately Analyzed and Mitigated

The DEIR/EIS fails to adequately analyze and mitigate potentially significant impacts related to maintaining[271] and abandoning the slant well materials in the ocean subsurface,[272] and to the wells' degradation over time. Whereas active slant wells would require maintenance every 5 years,[273] the DEIR/EIS does not mention CURE-27

printed on recycled paper

maintenance activities associated with the decommissioned, abandoned slant wells, which would likely foul and corrode for as long as they remain in the subsurface.[274] According to the abandonment plan, which does not consider removing abandoned slant wells, the wells would remain in the seabed in perpetuity, degrading over time.[275] By not analyzing this degradation over the time, particularly in the context of slant well abandonment, the DEIR/EIS fails to adequately analyze and mitigate potentially significant impacts from the whole Project.

CURE-27 cont.

Given Dr. Sobczynski's findings about accumulation of biomatter above the slant well,[276] the DEIR/EIS must also consider the impact of abandoning the slant wells and the resultant degradation arising from the wells' corrosion and biofouling, and the decomposing biomatter above the slant well.[277] The biomatter accumulation and subsequent decay can lead to a potentially significant impact (*i.e.*, toxic gases) that has not been adequately disclosed and mitigated.[278]

C. The DEIR/EIS Fails to Adequately Analyze and Mitigate Potentially Significant Cumulative Impacts Related to Marine Resources

CURE-28

In evaluating significance, NEPA requires consideration of whether the action is related to other actions with individually insignificant but cumulatively significant impacts.[279] The lead agency must make a finding of significance if it is "reasonable to anticipate a cumulatively significant impact on the environment."[280] The CEQ regulations further require that significance "cannot be avoided by terming an action temporary or by breaking it down into small component parts."[281]

An EIR is required to discuss the cumulative impacts of a project "when the project's incremental effect is cumulatively considerable."[282] An EIR is required to

discuss significant impacts that the proposed project will cause in the area that is affected by the project.[283] "This area cannot be so narrowly defined that it necessarily eliminates a portion of the affected environmental setting."[284]

The CEQA Guidelines specifically direct the lead agency to "define the geographic scope of the area affected by the cumulative effect and provide a reasonable explanation for the geographic limitation used."[285] The courts have held that it is vitally important that an EIR avoid minimizing the cumulative impacts. Rather, it must reflect a conscientious effort to provide public agencies and the general public with adequate and relevant detailed information about them.[286] An EIR's cumulative impacts discussion "should be guided by the standards of practicality and reasonableness," but several elements are deemed "necessary to an adequate discussion of significant cumulative impacts" including "[a] list of past, present, and probable future projects producing related or cumulative impacts, including, if necessary, those projects outside the control of the agency."[287]

CURE-28 cont.

Both the State Water Resources Control Board[288] and the MBNMS Desalination Guidelines establish subsurface intakes as the preferred technology for seawater intakes.[289] There are a number of desalination proposals for Monterey Bay and along the California Coast, which have considered or are evaluating the feasibility of subsurface intake systems.[290] Consequently, there may be a significant

cumulative impact from the subsurface slant wells due to bioaccumulation, as Dr. Sobczynski described.[291] Moreover, the Desalination Amendment uses the same Williams and Jenkins calculations, relied upon in this DEIR/EIS,[292] to demonstrate that there will be no impingement of organic matter on the seafloor.[293] Dr. Sobczynski demonstrates that these calculations may not be correct and that the vertical infiltration may be much higher.[294] Organic matter may become impinged and pulled through the sea floor.[295] During maintenance, or upon abandonment, the subsurface slant wells are deprived of dissolved oxygen that normally flows through the subsurface.[296] Multiple desalination plants with subsurface intakes — all of which draw organic matter through the subsurface — may lead to significant cumulative impacts, such as the ones Dr. Sobczynski described.

CURE-28 cont.

D. The DEIR/EIS Fails to Adequately Analyze and Mitigate Potentially Significant Impacts to Biological Resources

As described above, the DEIR/EIS fails to provide updated biological information in a meaningful way. Rather than provide an accurate analysis of the biological setting, the DEIR/EIS provides GIS shape files.[297] GIS shape files do not provide the level of detail necessary for thoroughly assessing what sensitive species are present throughout the project site, as a biological technical report (with focused and protocol surveys) would.[298] The DEIR/EIS's lack of focused and protocol surveys leads to an inability to accurately analyze the Project's impacts on biological

resources.[299] Consequently, the DEIR/EIS fails to mitigate potentially significant impacts to biological resources.[300]

As Ms. Owens explains, an updated Biological Technical Report would provide real data from protocol surveys required for listed species, and details on how the surveys were conducted, so that others may determine if the methodology was done correctly.[301] Focused and protocol survey data are essential for conservation and mitigation analysis.[302] Not only are they important for an adequate CEQA review but also for section 7 and section 10 consultation under the federal ESA.[303] Since this Project may significantly impact ESA listed species, take is likely to occur.[304] The DEIR/EIS must require that qualified biologists conduct surveys not just at a habitat level, but also on an individual species level.[305] As is, the DEIR/EIS violates NEPA and CEQA by failing to adequately analyze and mitigate potentially significant impacts to biological resources.

CURE-29 cont.

1. Snowy Plover Impacts are Not Adequately Analyzed and Mitigated

Ms. Owens explains that the DEIR/EIS fails to adequately analyze and mitigation impacts to snowy plover critical habitat.[306] The snowy plover's critical habitat must be minimally disturbed.[307] Yet, the Project will border approximately 9 miles of coastal snowy plover critical habitat.[308] Additionally, to properly protect the snowy plover, the Project must avoid impacts to non-breeding season snowy plover habitat.[309] In failing to adequately analyze the impacts to plovers during both breeding and non-breeding season, the DEIR/EIS has not proposed sufficient mitigation measures to adequately protect the species.[310]

Additionally, the DEIR/EIS should provide a more accurate cumulative impact analysis with respect to snowy plovers.[311] There are a number of project in the coastal zone in the vicinity of the Project that have not been adequately analyzed to determine their contribution to the cumulative impact of the species.[312] Additionally, compensatory mitigation details are necessary for complete snowy plover impact analysis. Ms. Owens suggests that the compensatory mitigation measure should incorporate collaboration with local snowy plover conservationists.[313]

CURE-30 cont.

2. Wildlife Corridors Impacts are Not Adequately Analyzed and Mitigated

The DEIR/EIS states that there would be no significant impacts to species due to the lack of wildlife corridors.[314] This, however, is inaccurate as Ms. Owens explains.[315] According to Ms. Owens, species use wildlife corridors and nurseries in agricultural and industrial areas.[316] The DEIR/EIS's conclusion, therefore, is not supported.[317] Ms. Owens concludes that this impact must be analyzed with greater detail and supporting documentation.[318]

CURE-31

3. Coastal Dunes Impacts are Not Adequately Analyzed and Mitigated

The DEIR/EIS does not adequately analyze coastal dune habitat. This critical habitat must be managed pursuant to Environmentally Sensitive Habitat Area requirements.[319]

E. The DEIR/EIS Fails to Adequately Analyze and Mitigate Potentially Significant Impacts to Air Quality

The DEIR/EIS fails to adequately analyze and mitigate potentially significant impacts to air quality, with respect to significant pollutants, criteria pollutants, and indirect emissions.

1. Construction Criteria Pollutant Emissions are Significant and Unmitigated

The DEIR/EIS estimated maximum daily emissions of ROG, NO_x, CO, PM10, and PM2.5 from Project construction and concluded that emissions of NO_x and PM10 are significant and require mitigation.[320] Dr. Fox explains that the impact analysis is unsupported and the mitigation is inadequate to reduce impacts to less than significant.[321] CURE-33

First, the construction emissions from off-road and on-road construction equipment are not supported by substantial evidence.[322] As Dr. Fox states, the DEIR/EIR fails to provide adequate documentation for some of its off-road emissions estimates.[323] In addition, the DEIR/EIS does not include input and output sheets or provide adequate explanation for its on-road construction emissions estimates.[324] The DEIR/EIS's assumptions used in emissions modeling should be subject to public review.[325] As such, the DEIR/EIS fails to disclose information pertaining to construction emission calculations and should be recirculated to include identification of all Project-specific assumptions and input parameters, a copy of the model run inputs and outputs, and any documentation used to make the final construction emission calculations.[326]

[324] *Id.*, at pp. 4-5.
[325] *Id.*
[326] *Id.*

printed on recycled paper

Second, Dr. Fox explains that construction mitigation is not adequate to reduce impacts to less than significant.[327] The DEIR/EIS concludes that the air quality impact with respect to ozone and NO2 standards would be significant and unavoidable even with implantation of Mitigation Measures 4.10-1a and 4.10-1b.[328] However, the CPUC and MBNMS cannot simply conclude that an impact is significant and unavoidable without requiring all feasible mitigation. Additional feasible mitigation is possible to mitigate for ozone and NO2.[329]

Mitigation Measure 4.10-1a proposes the use of equipment that meets asserted high-tiered engine standards.[330] Dr. Fox explains that Tier 3 engines are not the highest tier (lowest emission) off-road engines available; rather, this measure should require Tier 4 engines.[331] If Tier 4 engines cannot be obtained, then the mitigation measure should be expanded to require the consideration of leasing or renting from private vendors within 1,000 miles of the Project site.[332] The request to deviate from the use of Tier 4 engines should only be considered after all feasible actions have been taken to comply.[333]

Mitigation Measure 4.10-1b establishes limits on idling time for on-road and off-road engines.[334] Idling should be limited to no longer than five minutes, which is consistent with California Code of Regulations, title 13, § 2449, subd. (d)(3).[335] Therefore, this is not a valid mitigation measure because this is already what the law requires.[336] Dr. Fox states that this mitigation measure should be modified to limit idling to two minutes, which has been required for other similar projects.[337] This policy should be distributed to employees and enforced by the on-site construction manager.[338]

printed on recycled paper

Third, additional feasible mitigation for construction ozone and NO_2 emissions exists.[339] The Project's Draft Initial Study and Mitigated Negative Declaration provided feasible measures, which are not included in this DEIR/EIS.[340] Feasible mitigation measures for NO_x and ROG can also be found in the Monterey Bay Unified Air Pollution Control District's CEQA Guidelines, other projects (i.e., Chevron Modernization Program), and U.S. EPA programs.[341] In her letter, Dr. Fox includes these feasible mitigation measures for NO_x and ROG, which are not included in the DEIR/EIS.[342] The DEIR/EIS fails to include all feasible mitigation for an impact that is significant and unavoidable.

CURE-34 cont.

2. The DEIR/EIS Omits Indirect Operational Emissions

The DEIR/EIS estimates operational emissions from on-road vehicle exhaust, emergency generator testing, and slant well maintenance.[343] However, according to Dr. Fox, the major source of Project emissions is indirect emissions from the generation of electricity.[344] The DEIR/EIS does not include those emissions. The CPUC and MBNMS argue that "[i]t is generally not possible to determine the exact generator source(s) of electricity on the power grid that would supply the proposed project, or whether or not the electricity would even be generated within the Air Basin."[345] The lead agencies are wrong.

CURE-35

CEQA does not allow the CPUC and MBNMS to exclude this major source of emissions from the DEIR/EIS.[346] As noted by Dr. Fox, EIRs routinely include indirect emissions from electricity generation.[347] In fact, the GHG section of this DEIR includes indirect GHG emissions from power generation.[348] Furthermore, the Monterey Bay Unified Air Pollution Control District's ("MBUAPCD"). CEQA Guidelines state: "The following thresholds apply to all indirect and direct

[339] *Id.,* at pp. 8-9.

[347] *Id.*
[348] *Id.*

printed on recycled paper

emissions, whether or not they are subject to District permit authority, unless noted otherwise."[349] The MBUAPCD's guidelines indicate that the NO_x and ROG significance thresholds should be compared to "direct + indirect" emissions.[350] Thus, Dr. Fox concludes that "the DEIR/EIS must include the increase in emissions from the net increase in power production to support the Project."[351]

Furthermore, Dr. Fox explains that indirect emissions need not be limited to the Project's Air Basin.[352] Dr. Fox states that "[e]lectricity from any generator in California could be used at the Project site. As the significance criteria are based on the maximum day, finding the 'maximum' is all that is required."[353]

The DEIR/EIS indicates that PG&E would supply the power for the Project. According to Dr. Fox, the sources of PG&E's power are known and "emissions should be estimated for the plausible worst case daily maximum emissions. . . ."[354] However, the DEIR/EIS does not include any of the information required to estimate these emissions.[355] Thus, the DEIR/EIS fails as an informational document under CEQA, leaving the public to generate independent emissions estimates in order to evaluate the Project's impacts.[356]

CURE-35 cont.

Dr. Fox provides her own estimates.[357] Dr. Fox finds that "the Project would increase NO_x emissions by up to 363 lb/day, which exceeds the MBUAPCD's NO_x significance threshold of 137 lb/day."[358] The NO_x emissions from producing a net increase of 51,698 MWh per year of electricity "is large enough taken alone to exceed the MBUAPCD's NO_x significance threshold."[359] This is a significant impact not disclosed or mitigated in the DEIR/EIS.

---

[358] *Id.*, at p. 13.
[359] *Id.*

printed on recycled paper

In addition, Dr. Fox identified all PG&E owned power plants in California, determining the maximum daily emissions from each, using EPA's CAMD daily data for 2014.[360] She then concludes — assuming 1,152 lb of NO_x is emitted on the maximum day from the Gateway Generating Station — that operational NO_x emissions would increase to 1,179 lb/day,[361] which exceeds the MBUAPCD's NO_x threshold (137 lb/day) by a significant amount.[362] Thus, Dr. Fox concludes that operational NO_x emissions from power production are a significant impact not disclosed in the DEIR/EIS that must be mitigated.[363] This significant impact is not disclosed or mitigated in the DEIR/EIS.

CURE-35 cont.

Dr. Fox offers suggestions for mitigating this impact, including "purchasing local and contemporaneous emission reduction credits or by collaborating with a nearby NO_x source to reduce their NO_x emissions. Alternatively, the increase in electricity demand could be met by using 100% renewable sources of electricity."[364]

CEQA requires the lead agencies' to disclose, analyze, and require mitigation for the Project's indirect electricity generation emissions for all criteria pollutants and to require mitigation for the resulting significant NO_x impacts.

3. The DEIR/EIS Fails to Evaluate All Air Quality Impacts

Under CEQA, a lead agency has discretion to determine how to classify the significance of impacts.[365] However, an agency's judgment must be supported by scientific information and other factual data, and the agency does not have discretion to simply not evaluate the significance of impacts.[366] In her letter, Dr. Fox states that the DEIR/EIS fails to evaluate the significance of pollutants for which the Monterey Bay Unified Air Pollution Control District ("MBUAPCD") has not set official CEQA significance thresholds.[367] Specifically, the DEIR/EIS fails to evaluate the significance of impacts from two pollutants: NO_x emissions for impacts

printed on recycled paper

other than its contribution to ozone, and ROG for its impacts other than its contribution to ozone.[368]

a) NO_x

The MBUAPCD's significance criteria for NO_x (137 lb/day) is based only on ozone.[369] Thus, the DEIR/EIS only evaluates NO_x as an ozone precursor.[370] However, as Dr. Fox points out, NO_x "can also causes adverse health effects, acid rain, form particulate matter, and contribute to global warming, water quality deterioration, and visibility impairment."[371] NO_x can damage lung tissue and reduce lung function.[372] The DEIR acknowledges that there are primary and secondary state and federal ambient air quality standards for nitrogen oxides established using NO_2 as a surrogate for all nitrogen oxides.[373] The primary standards (1-hour) are set to protect public health, including the health of sensitive populations.[374] The secondary standards (annual) are set to protect public welfare, including protection against decreased visibility and damage to animals, crops, vegetation, and buildings.[375] The DEIR/EIS fails to evaluate these primary and secondary impacts of NO_x.[376]

CURE-36 cont.

The absence of a MBUAPCD "CEQA significance threshold" for non-ozone precursor NO_x impacts does not obviate the need to evaluate this impact as the ambient air quality standards themselves can be used as CEQA significance thresholds.[377] According to Dr. Fox, when a CEQA significance threshold is missing, a lead agency can model emissions to determine if they cause or contribute to an exceedance of the ambient standards or look to other sources, such as other air districts, for significance criteria expressed as emission rates.[378]

In *Bakersfield Citizens For Local Control v. City of Bakersfield*, the Fifth District appellate court held that an EIR was inadequate because it failed to correlate adverse air quality impacts to resulting adverse health impacts.[379] In that case, a local citizens group filed a CEQA petition challenging the EIRs for two retail shopping centers planned for the southwestern portion of Bakersfield, California.[380] Both EIRs concluded that the shopping center projects would have significant and unavoidable adverse impacts on air quality, yet the court found:

> neither EIR acknowledges the health consequences that necessarily result from the identified adverse air quality impacts. Buried in the description of some of the various substances that make up the soup known as 'air pollution' are brief references to respiratory illnesses. However, there is no acknowledgement or analysis of the well-known connection between reduction in air quality and increases in specific respiratory conditions and illnesses. After reading the EIR's, the public would have no idea of the health consequences that result when more pollutants are added to a nonattainment basin.[381]

CURE-36 cont.

The court concluded that the disclosures were inadequate and stated that the health impacts resulting from the adverse air quality impacts must be identified and analyzed in new EIRs.[382]

Here, although the DEIR/EIS acknowledges the impacts of NO_x as an ozone precursor, it fails to identify the respiratory impacts and other impacts resulting from NO_x emissions.[383] The CPUC and MBNMS must prepare a revised DEIR/EIS that adequately discloses, analyzes and mitigates all potentially significant impacts from the Project's NO_x emissions. Furthermore, and discussed in further detail below, the NO_x and Reactive Organic Gases emissions reported exceed the non-ozone significance thresholds established by four air districts pursuant to CEQA.[384]

b) Reactive Organic Gases (ROG)

Reactive Organic Gases ("ROG"), in addition to forming ozone, can cause "severe eye, nose, and throat [irritation] and increases susceptibility to respiratory infections."[385] As with NO_x, the DEIR/EIS only evaluates ROG as an ozone precursor.[386] The Volatile Organic Compounds ("VOCs") present in ROG before it is converted into ozone include compounds that are hazardous to human health.[387] The DEIR/EIS's health risk assessment ("HRA") only evaluated diesel particulate matter; it did not evaluate the health impacts from toxic air pollutants ("TAC") subsumed in ROG that are not converted to ozone when they reach sensitive receptors.[388] According to Dr. Fox, these TACs include "acutely and chronically toxic chemicals such as toluene, xylene, ethylbenzene, and 1,3 butadiene and carcinogens such as benzene, formaldehyde, acrolein, and acetaldehyde."[389] CURE-37

Like the NO_x discussion above, Dr. Fox states that other air districts have established CEQA significance thresholds for ROG.[390] The DEIR/EIS does not take this approach and the DEIR/EIS must include TAC impacts in a revised HRA.[391] The DEIR/EIS fails to meet CEQA standards because it does not evaluate the Project's non-ozone impacts from ROG emissions.[392]

F. The DEIR/EIS Fails to Adequately Evaluate Health Risks

The DEIR/EIS evaluated health risks of Project construction from Diesel Particulate Matter ("DPM") at two sites, the Carmel Valley Pump Station and ASR Injection/Extraction Wells.[393] As Dr. Fox notes, this analysis concluded that cancer and chronic health risks are less than significant.[394] However, the analysis is flawed and when corrected, Dr. Fox finds that there would be a significant health impact. CURE-38

printed on recycled paper

Further, she finds that the HRA analysis is unsupported, incomplete, and fails to include acute impacts.[395]

First, all sensitive receptors were not evaluated.[396] As Dr. Fox points out, there are other facilities that are near sensitive receptors that were excluded from the HRA, including Wells ASR-5 and ASR-6, which would be constructed within 50 feet of existing residences.[397] The ASR Conveyance Pipeline, ASR Recirculation Pipeline, and the ASR Pump-to-Waste Pipeline would be within 250 feet of Seaside Middle School, and within 50 to 100 feet of residences in the Fitch Park military housing area along Hatten Road and Ardennes Circle.[398]

Second, the DEIR/DEIS did not follow OEHHA Guidelines, which resulted in the DEIR/EIS substantially underestimating the Project's health risk.[399] The OEHHA guidelines, adopted in March 2015, provide recommendations for preparing health risk assessments.[400] Dr. Fox points out that the DEIR/EIS analysis only evaluated risk for exposures of 0.25 years, or 3 months after birth.[401] However, if exposure is increased to 6 months after birth, per OEHHA guidance, then the cancer risk increases from 5.2 in one million to 10 in one million, which is per se significant.[402] The 10 in one million number is the significance threshold for a lifetime exposure, which dilutes the short term risk.[403] Instead, the DEIR/EIS should have a lower significance threshold than the 10 in one million used for a 70 year exposure.[404] Dr. Fox provides differing scenarios in evaluating the cancer risk.[405] In either scenario, however, the cancer risk from diesel exhaust alone would be highly significant and unmitigated. This significant impact is not disclosed in the

DEIR/EIS.[406] At a minimum, all diesel fuel equipment should have diesel particulate traps to mitigate this significant impact.[407]

Third, all hazardous pollutants were not included in the HRA.[408] As already mentioned, the HRA only evaluated diesel exhaust, which is emitted from construction equipment and on-road vehicles.[409] But there are also VOCs, present in ROG before it is converted into ozone, which are hazardous to human health.[410] The HRA should have evaluated toxic air pollutants subsumed in ROG that are not converted to ozone when they reach sensitive receptors.[411] By failing to include unconverted VOCs, the HRA underestimates health impacts and further fails to evaluate acute health impacts.[412]

CURE-38 cont.

G. The DEIR/EIS Fails to Identify Significant Health Impacts Due to Valley Fever

Dr. Fox provided evidence in her 2015 comments that the DEIR/EIS fails to identify significant health impacts due to Valley Fever.[413] Yet the DEIR/EIS continues to dismiss the risk of Valley Fever to Project workers and nearby sensitive receptors.[414] In the attached comments, Dr. Fox provides evidence about the health risks associated with Valley Fever for this Project, which is located in an endemic zone.[415] Valley Fever is contracted by inhaling *Coccidioides ssp. (*"Cocci spores"*)*, a component of PM10, or PM2.5.[416]

CURE-39

First the DEIR/EIS misrepresents the status quo by stating that Valley Fever is declining.[417] However, the decline recorded in 2014 (to which the DEIR/EIS relies

printed on recycled paper

on for its support) was an anomaly.[418] In fact, there were 50% more cases in 2016 than in 2015.[419]

Second, the DEIR/EIS makes assertions that are inconsistent with CEQA and are unsupported and incorrect.[420] The DEIR/EIS concludes that much of the population of Monterey County has already been exposed to Cocci spores.[421] Valley Fever is contracted by inhaling Cocci spores, which become airborne during earth moving construction, which increases PM10 and PM2.5.[422] Project construction would disturb over 173 acres of endemic land, likely to contain spores.[423] Additional disturbance would occur during maintenance.[424] Therefore, the DEIR/EIS concludes that Valley Fever-related impacts would not be considered significant because residents are continually exposed to spores and construction would not represent an increased risk to public health.[425] Even if everyone in Monterey County has been exposed to Cocci spores, Dr. Fox states, this does not mean that an increase in the number of Cocci spores due to Project construction would not result in new cases, or that construction workers from non-endemic areas would not contract Valley Fever.[426]

CURE-39 cont.

Dr. Fox writes, "[w]hile some residents of Monterey County may have been exposed to Cocci spores as they live adjacent to agricultural fields or a construction site, this does not mean that an increase in the number spores due to Project construction would not result in an increase in Valley Fever cases."[427] Additionally, the record contains no evidence that all residents downwind of Project construction and all construction workers who would build the Project have in fact been exposed to Cocci spores in sufficient amounts to assure immunity.[428] Dr. Fox challenges this

[428] *Id.*

printed on recycled paper

immunity argument, stating that being exposed to Cocci spores does not imply nor can it guarantee immunity to Valley Fever from increased exposure.[429]

Moreover, the Requests for Proposal for the slant wells and conveyance facilities state that the Contractor must make a good faith effort to employ individuals, who have lived for at least one year out of the three years prior to the opening of proposals, from Monterey, San Benito, or Santa Cruz Counties.[430] Therefore, Dr. Fox states that it is a highly unlikely scenario that all potentially exposed parties have already been exposed in Monterey County.[431]

The DEIR/EIS must evaluate the significance of Cocci spore exposure relative to the baseline, just as it had evaluated the significance of PM10 and PM2.5 emissions relative to the baseline.[432] By stating that residents have already been exposed to Cocci spores (present in PM10, or PM2.5) is a statement of the baseline.[433] It does not adequately inform the public about the Project's Valley Fever health risk.

CURE-39 cont.

Construction workers who would be exposed to land disturbance activities would be at considerable risk of catching Valley Fever.[434] Construction workers, alongside agricultural workers, are the most at-risk populations.[435] This is because these labor groups are in intimate contact with soil in a Valley Fever endemic area and many may be from non-endemic zones or may have never worked in an endemic area.[436] The DEIR/EIS fails to adequately evaluate this significant construction impact, not only on construction workers, but also on the nearby sensitive receptors and the larger population (spores can travel as much as 500 miles).[437] Since the DEIR/EIS evaluated the increase of PM10 and PM2.5, of which Cocci spores are a component, the DEIR/EIS should also disclose that Cocci spores will increase.[438]

Third, the DEIR/EIS fails to mitigate the significant Valley Fever health risks.[439] Although the DEIR/EIS provides Mitigation Measure 4.10-1c (a conventional construction fugitive dust mitigation measure that would allegedly mitigate the risk to a less than significant level), this measure is ineffective at controlling Valley Fever.[440] Conventional dust control measures are effective at controlling visible dust or larger dust particles (PM10), but not the very fine particulate matter (PM2.5), where Valley Fever spores are found.[441] Dr. Fox states that the spores, which may be difficult to see and have low settling rates, are not controlled by conventional dust control measures.[442] Additionally, the Project's construction period coincides with a period when there might be a higher risk of catching Valley Fever.[443]

Dr. Fox provides a number of recommended mitigation measures to reduce the risk of Valley Fever.[444] These recommended measures go beyond the conventional dust control measures for controlling PM10 emissions.[445] These recommendations include continuously wetting the soil before and while digging, thoroughly cleaning equipment, vehicles and other items before they are moved off-site to other work locations, developing a protocol with medical professionals to medically evaluate employees who have symptoms of Valley Fever, and others.[446] Dr. Fox also identifies flaws in Mitigation Measure 4.10-1a, such as required daily sweeping, which generates fugitive dust that may contain spores.[447]

Not only do the PM10 mitigation measures not adequately control Valley Fever, but they also fail to mitigate PM10 impacts.[448] Projects that have implemented conventional PM10 dust control measures, like the ones for this Project, have experienced several incidences of severe dust storms and reported

cases of Valley Fever.[449] The DEIR/EIS must adopt an enhanced dust control plan, as suggested by Dr. Fox, to reduce the risk to construction workers, on-site employees and the public of contracting Valley Fever.[450] These measures are feasible as many of them have been adopted by the County of Monterey in other EIRs.[451] Still, even if all of the above feasible measures are adopted, a recirculated DEIR/EIS is required to analyze whether these measures are adequate to reduce the Valley Fever significant impact to a level below significance.[452]

CURE-39 cont.

H. The DEIR/EIS Fails to Adequately Explain Why the Project's GHG Impacts Are Significant and Unavoidable and Improperly Defers Mitigation

In *Keep Berkeley Jets Over the Bay Com. v. Board of Port Comrs.*, the First Appellate court concluded that "simply labeling the effect 'significant' without accompanying analysis" violates "the environmental assessment requirements of CEQA."[453] Before the lead agencies can make a "significant and unavoidable" finding, it must specifically identify the GHG mitigation measures and estimate the reduction in GHG achieved by each.[454]

CURE-40

An agency may defer mitigation only when three narrow, specific prerequisites are met: (1) an EIR contains criteria or performance standards to govern future actions implementing the mitigation; (2) practical considerations preclude development of the measures at the time of initial project approval; and (3) the agency has assurances that the future mitigation will be *both* "feasible and efficacious."[455] An agency may not satisfy its mitigation requirements by merely

printed on recycled paper

ordering a project proponent to "obtain a . . . report and then comply with any recommendations that may be made in the report."[456]

In *Communities for a Better Environment v. City of Richmond*,[457] an EIR for a Chevron refinery project was deemed legally inadequate in part because the mitigation measures for GHG emissions were impermissibly deferred. The EIR in that case was "legally required to describe, evaluate and ultimately adopt feasible mitigation measures which would 'mitigate or avoid' [GHG] impacts."[458]

The mitigation measure at issue in the Chevron project EIR stated that "[n]o later than one (1) year after approval of this Conditional Use Permit, Chevron shall submit to the City, for approval by the City Council, a plan for achieving complete reduction of GHG emissions. . ."[459] As the court explained, the mitigation measure "required Chevron, within one year of Project approval, to hire and fully fund 'a qualified independent expert' to complete an inventory of greenhouse gas emissions and to identify potential emissions reduction opportunities."[460] Furthermore, the measure stated that Chevron "shall consider implementation of measures that achieve GHG reductions including, but not limited to, the following measures . . ."[461] The measure then listed several potential mitigation measures. The respondents in the case argued that the EIR failed to adequately formulate a plan to mitigate GHG emissions, but instead offered "a menu of potential mitigation measures, with the specific measures to be selected by Chevron and approved by the City Council a year after Project approval."[462]

CURE-40 cont.

The court found that the measure was deferred mitigation, which is impermissible under CEQA. The court stated, in part, that the measure amounted to "a generalized goal of no net increase in greenhouse gas emissions and . . . a handful of cursorily described mitigation measures for future."[463] Furthermore, the court found that "[n]o effort [was] made to calculate what, if any, reductions in the

printed on recycled paper

Project's anticipated greenhouse gas emissions would result from each of these vaguely described future mitigation measures" and that the list of potential mitigation measures was "nonexclusive, undefined, untested and of unknown efficacy."[464]

As Dr. Fox explains, the DEIR/EIS fails to substantiate that its GHG emissions cannot be reduced to an insignificant level and fails to include all feasible mitigation measures.[465] It also improperly defers mitigation by stating it will implement a GHG Emissions Reduction Plan and Construction Equipment Efficiency Plan prior to the start of construction, but after Project approval.[466]

The DEIR/EIS concludes that GHG emissions from construction and operation of the Project are significant and unavoidable.[467] The DEIR/EIS then proposes Mitigation Measure 4.11-1 to reduce the Project's GHG emissions from construction and operation and Mitigation Measure 4.18-1 for construction GHG emissions.[468] The DEIR/EIS concludes that even after complying with these measures, "it is not possible to substantiate numerically that the GHG emissions would be reduced to a less-than-significant level."[469] Consequently, the GHG emissions remain significant and unavoidable.[470]

CURE-40 cont.

The DEIR/EIS must provide further explanation for its conclusion that the Project's GHG emissions impacts are significant and unavoidable.[471] Furthermore, it must explain the Project's consistency with the State's energy and climate objectives.[472]

The CPUC's inability to numerically substantiate the Project's mitigated emissions is a result of its improper deferral of the identification of mitigation

measures.[473] Indeed, as Dr. Fox points out, other applicants and lead agencies have successfully quantified GHG emission reductions.[474]

Mitigation Measure 4.11-1 requires that CalAm prepare a GHG Emissions Reduction Plan and submit it to the CPUC for approval prior to the start of construction.[475] CalAm shall also make a good faith effort to ensure that at least 20 percent of the approved project's operation energy use requirements are achieved with "clean" renewable energy.[476] Mitigation Measure 4.11-1 improperly defers mitigation and is inadequate for six reasons, which Dr. Fox explains in further detail in her letter.[477]

First, a "good faith effort" to use renewable energy for 20% of the Project's operational needs is not adequate CEQA mitigation because for a significant and unavoidable impact, all feasible mitigation under CEQA must be implemented.[478] One-hundred percent of the Project's operational electricity demand can be met through renewable energy.[479] The County of Monterey has also included a similar policy with respect to desalination plants.[480]

CURE-40 cont.

> The EIRs prepared for the desalination plants are expected to require that construction equipment use alternative fuels or other means to reduce their emissions of ozone precursors. Although, depending upon the intensity of construction, there is the potential for a significant impact on air quality from ozone precursors. . . Taking a conservative view, the indirect impacts of the water supply projects to be built would potentially make considerable contributions to air quality, biological, and electrical energy use.[481]

[481] Fox Comments, at pp. 40-41.

printed on recycled paper

Second, preparing the Emissions Reduction Plan is improperly deferred until after Project approval.[482] This plan must be part of the DEIR/EIS and circulated for public review, as explained by the Court in *CBE v. Richmond*.[483]

Third, "good faith effort" measures are not adequate because they are not enforceable, as required under CEQA.[484] Under CEQA, an EIR must not only discuss measures to avoid or minimize adverse impacts, it also must ensure that mitigation measures are fully enforceable through permit conditions, agreements, or other legally binding instruments.[485] Mitigation measures cannot be vague or have uncertain effectiveness or feasibility.[486]

Fourth, the DEIR/EIS should require that a registered professional (mechanical) engineer in California confirm that the Plan includes all feasible measures.[487]

CURE-40 cont.

Fifth, the Plan should have ongoing monitoring by a registered professional engineer to ensure successful mitigation under CEQA.[488]

Sixth, and last, the Plan should include construction GHG emissions, and opportunities throughout the CalAm system, not just Project operational facilities.[489]

Mitigation Measure 4.18-1 requires that CalAm contract a "qualified professional" to prepare a "Construction Equipment Efficiency Plan" that will increase the efficient use of construction equipment to the maximum extent feasible.[490] This mitigation measure has some of the same deficiencies as Mitigation 4.11-1.[491]

printed on recycled paper

First, the Efficiency Plan is deferred until after the Project is approved, pre-empting public review.[492] This Plan must be part of the DEIR/EIS and circulated for public review, as required by the Court in *CBE v. Richmond*.[493]

Second, the measure should be modified to require that a registered professional (civil) engineer confirm that the Plan includes all feasible construction equipment efficiency measures.[494]

Third, the Plan must include all feasible mitigation measures, such as NO_x and ROG mitigation measures identified above.[495] Dr. Fox provides a list of additional measures that were recently required as GHG construction mitigation in the Chevron Modernization Final EIR,[496] including maintenance of construction equipment, further idling restrictions and other measures.[497]

Fourth, the measure fails to identify any method to verify compliance.[498] Dr. Fox proposes "a comprehensive inventory of all off-road equipment that will be used to construct the Project . . . The inventory should include the horsepower rating, engine production year, hours of use, and amount and type of fuel used."[499] Furthermore, "[a]t least 48 hours prior to the use of heavy-duty off-road equipment at a new construction site, the project representative shall provide the inspector and MBUAPCD with the construction timeline, including start date and name and phone number of project manager and on-site foreman."[500]

printed on recycled paper

Finally, the Efficiency Plan fails to provide adequate monitoring, according to Dr. Fox, who suggests a similar monitoring program as stated above.[501] Dr. Fox concludes that the Efficiency Plan "fails to adequately mitigate the air quality impacts resulting from Project construction."[502]

The CPUC must ensure that all feasible mitigation is incorporated in the DEIR to address the significant and unavoidable GHG impacts. As stated in *CBE v. Richmond*, "the time . . . to formulate mitigation measures to minimize or avoid those impacts [is] during the EIR process, before the Project was brought to the [approving body] for final approval."[503] The DEIR/EIS must be revised in accordance with these comments and recirculated before the Project can be lawfully approved under CEQA.

CURE-40 cont.

I. Vibration Impacts Are Significant and Unmitigated

The DEIR/EIS fails as an information document with respect to construction activities that can produce significant ground born vibration that can damage nearby buildings and annoy sensitive receptors.[504] The Project fails to provide supporting calculations, citations to specific pages from the methodology it used, or disclose input values used in calculations, which would have allowed Dr. Fox to reproduce and verify the vibration analysis.[505] The DEIR/EIS concluded that vibration from pipeline installation using both compactors and pile drivers would result in significant building damage and annoyance from constructing the Castroville Pipeline and Source Water Pipeline, the new Desalinated Water Pipeline, and the new Transmission Main where trenchless construction methods are required.[506] The DEIR/EIS imposes Mitigation Measures 4.15-1a and Measure 4.12-3, which it asserts would allegedly make the vibration impact no longer significant.[507] These, however, are fundamentally flawed and are not adequate to reduce vibration impacts to a less than significant level.[508]

CURE-41

Mitigation Measure 4.15-1a is not described.[509] Although there is an Impact 4.15-1, there is no mitigation measure associated with that impact and therefore no way to determine what Mitigation Measure 4.15-1a entails.[510]

Mitigation Measure 4.12-3 proposes vibration reduction measures, which are not practically enforceable.[511] Additionally, there are more aggressive mitigation measures that this city should comply with in order to mitigate the potentially significant vibration impact.[512] However, without supporting analysis to demonstrate that the vibration impacts would be less than significant with the proposed mitigation, the DEIR/EIS fails as an information disclosure document.[513] The City of Monterey includes a "Vibration Control Plan for Monterey Pipeline Project," which includes more aggressive mitigation measures for vibration impacts than what is identified in the DEIR/EIS.[514] The City's Vibration Control Plan should replace the weak measures in the DEIR/EIS and should be included for public review in an appendix to the DEIR/EIS.[515]

CURE-41 cont.

However, without providing reproducible analysis to demonstrate that the vibration impacts would be less than significant with the proposed mitigation, the DEIR/EIS fails as an information disclosure document.[516]

J. The DEIR Fails to Adequately Analyze and Mitigate Potentially Significant Impacts to Historic Resources

CURE-42

The DEIR/EIS states that construction will not cause an adverse impact to historical resources.[517] However, as Dr. Fox explains, this impact was narrowly evaluated.[518] The DEIR/EIS only looked at historical resources listed in or eligible

---

for listing in the California Register or historic properties listed in or eligible for listing in the National Register that are within the Area of Potential Impact of all project components.[519] In so doing, the DEIR/EIS neglects evaluating the impact of construction equipment induced vibration on properties listed in the City of Monterey's Vibration Control Plan.[520] This list includes 24 historic structures that are close enough to be damaged — constituting a significant adverse impact to historical resources.[521] This new impact was not disclosed or mitigated in the DEIR/EIS.[522]

CURE-42 cont.

K. The DEIR/EIS Fails to Adequately Analyze and Mitigate Potentially Significant Impacts from Decommissioning Activities

At the end of the Project's 40-year life, the Project would be decommissioned. As explained above, the decommissioning phase of the Project is part of the whole Project.[523] CEQA requires the CPUC to analyze all phases of the Project. Similarly, NEPA requires that an environmental document analyze all stages of a project to the extent they are interdependent.[524] Despite this requirement, the DEIR/EIS provides no analysis of the Project's decommissioning activities and, therefore, violates CEQA and NEPA.

CURE-43

As explained above, the DEIR/EIS only briefly mentions decommissioning in the context of coastal erosion for the slant wells.[525] The CPUC and MBNMS must provide a complete description of the decommissioning activities necessary to assess all of the Project's impacts, including those that our independent experts identified (e.g., terrestrial sensitive species impacts, biomatter accumulation, Valley Fever.)[526]

printed on recycled paper

The public and decision makers cannot engage in a meaningful assessment of these potential impacts without a proper description and analysis of decommissioning-related impacts.

Furthermore, the CPUC and MBNMS have enough information, such as the type of equipment to be utilized and range of activities to be performed, as well as baseline knowledge of impacts resulting from the Project's construction and operation, to make a reasonable assessment of impacts from decommissioning.[527] For example, the DEIR/EIS fails to adequately investigate and mitigate air and water quality impacts related to decommissioning, which may be similar in nature to construction emissions and discharges.[528] For example, the construction phase already produces emissions beyond an acceptable threshold, and Dr. Fox identified problems with the Construction Equipment Efficiency Plan, which considers both construction and decommissioning activities.[529] The flawed equipment efficiency plan is inadequate as a mitigation measure.[530]

CURE-43 cont.

To properly disclose the Project's impacts from decommissioning, the CPUC and MBNMS must revise the DEIR/EIS to include the type (*i.e.*, direct, indirect, or cumulative), the duration (*i.e.*, temporary or permanent), the nature (*i.e.*, source) and extent (*i.e.*, scale) of the associated potential impacts.[531] The CPUC and MBNMS must then develop mitigation measures that are certain, enforceable and linked to measurable performance standards.[532] Absent additional information, the CPUC and MBNMS cannot conclude that the Project's impacts have been fully assessed and properly mitigated.

VI. MITIGATION MEASURES PROPOSED IN THE DEIR/EIS ARE DEFERRED, UNENFORCEABLE OR OTHERWISE INADEQUATE

An EIS must include a discussion of "appropriate mitigation measures not already included in the proposed action or alternatives."[533] An EIS is not complete unless it contains "a reasonably complete discussion of possible mitigation measures."[534] Mitigation includes "avoiding the impact altogether by not taking a certain action or parts of an action."[535] It also includes "minimizing impacts by limiting the degree or magnitude of the action and its implementation."[536] The mandate to thoroughly evaluate all feasible mitigation measures is critical to NEPA's purposes.[537] Hence, a "perfunctory description" or a "mere listing" of possible mitigation measures is not adequate to satisfy NEPA's requirements.[538] That individual harms are somewhat uncertain due to limited understanding of the Project characteristics and baseline conditions does not relieve an agency of the responsibility under NEPA to discuss mitigation of reasonably likely impacts at the outset.[539]

CURE-44

Courts have interpreted these provisions further. In *Northern Plains Resource Council, Inc. v. Surface Transp. Bd.*, the agency provided a mitigation measure, which stated that the agency would gather baseline data at a later point.[540] The court found the agency's mitigation measures to be inconsistent with NEPA's requirements.[541] Consequently, the court found that the agency acted arbitrarily and capriciously.[542] Without baseline data, the agency could not have

printed on recycled paper

carefully considered information about significant impacts.[543] Even if the mitigation measures guaranteed that data would be collected at some point in the future, the data was not available during the EIS process and was not available to the public for comment.[544] The EIS process, therefore, did not serve its larger informational role.[545] In essence, data must exist "*before approval* so that [an agency] can understand the adverse environmental affects *ab initio*."[546] Where baseline data exists through some scientific study or methodology that the agency's experts deem reliable, the court will not "act as a panel of scientists" instructing the agency how to make its scientific determinations.[547] However, where mitigation measures are deferred for gathering baseline data, or where the agency deprives the public of reviewing data, the EIS will not be sufficient for NEPA purposes.[548]

CURE-44 cont.

In enacting CEQA, the Legislature declared that it is "the policy of the state that public agencies should not approve projects as proposed if there are feasible alternatives or feasible mitigation measures available which would substantially lessen the significant environmental effects of such projects."[549] An EIR is inadequate unless it includes "a detailed statement setting forth . . . mitigation measures proposed to minimize [the project's] significant effects on the environment."[550] CEQA requires lead agencies to incorporate all feasible mitigation measures into a project to reduce the project's potentially significant impacts to a level of insignificance.[551] Finally, CEQA requires the lead agency to find, based on substantial evidence, "that the mitigation measures are required in or incorporated into the project; or that the measures are the responsibility of another agency and have been, or can and should be, adopted by the other agency."[552]

Courts have imposed several parameters for the adequacy of mitigation measures. We address some of the relevant criteria here. First, the lead agency may not defer the formulation of mitigation measures until a future time, unless the EIR also specifies the specific performance standards capable of mitigating the project's impacts to a less than significant level.[553] Deferral is impermissible where an agency "simply requires a project applicant to obtain a . . . report and then comply with any recommendations that may be made in the report."[554] Second, a public agency may not rely on mitigation measures of uncertain efficacy or feasibility.[555] Third, "[m]itigation measures must be fully enforceable through permit conditions, agreements, or other legally binding instruments."[556] Fourth, mitigation measures that are vague or so undefined that it is impossible to evaluate their effectiveness are legally inadequate.[557]

As explained in the following paragraphs, there are several mitigation measures in various sections of the DEIR/EIS that are deferred, unenforceable or otherwise inadequate. The DEIR/EIS must be revised to include effective and enforceable mitigation for all significant impacts.

CURE-44 cont.

A. Mitigation Measures Proposed for Terrestrial Biological Resources Are Inadequate to Reduce Impacts to Less-Than-Significant Levels

The DEIR/EIS provides a number of mitigation measures to address significant impacts to terrestrial species.[558] Ms. Owens addresses some of these measures and explains that the mitigation measures, which in some cases are improperly deferred, do not reduce the impacts to terrestrial species to a less-than-significant level.

printed on recycled paper

Mitigation Measure 4.6-1a, states a lead biologist should be retained to oversee implementation of protective measures.[559] Ms. Owens states that this measure should have some standard or assurance within the mitigation measure to ensure that the lead biologist, onsite, has the irrevocable authority to stop work when needed.[560] Ms. Owens also explains that this mitigation measure is vague as it does not explain what "at risk" means with respect to relocating special status species that are at risk.[561]

Mitigation Measure 4.6-1d, aimed at addressing impacts to the Western Snowy Plover is improperly deferred.[562] Additionally, visual barriers will not serve to significantly reduce the direct and indirect impacts of noise on breeding birds.[563] Ms. Owens also challenges the DEIR/EIS's assertion that displacement can be easily mitigated, which she states is contrary to the Snowy Plover Recovery Plan.[564] Mitigation Measure 4.6-1n is inadequate because the measure should require collaboration with local snowy plover conservationists.[565]

Mitigation Measure 4.6-1e, which states that CalAm or its contractor shall conduct focused botanical surveys for special-species plants.[566] Ms. Owens states that these types of surveys are insufficient for sensitive species and their habitat protection.[567] The measures must include appropriate site-specific considerations, such as timing (*i.e.*, dormant season).[568] The DEIR/EIS fails to provide appropriate mitigation measures, which are specific to species, and to each site, including parcels set aside for habitat loss compensation.[569] Without sufficient information,

the mitigation measure may not effectively reduce potential impacts for rare plants to below significant.[570]

Mitigation Measure 4.6-1f for the Smith's Blue Butterfly is premised on a lack of data, which skews the impact analysis and this mitigation measure.[571] Ms. Owens provides information about the species specific flight period, which is important for the species' success.[572] Yet, there is no information about this specific flight period and therefore the mitigation measure does not provide a way to avoid impacts.[573]

Mitigation Measure 4.6-1g for the Black Legless Lizard, Silvery Legless Lizard, and Coast Horned Lizard is inadequate for some of the same reasons mentioned above.[574] There is a lack of data on the reptiles, which deprives the public from being able to determine if the mitigation measures will be adequate.[575]

CURE-44 cont.

Mitigation Measure 4.6-1i for nesting birds should apply throughout the duration of construction to ensure that nesting birds are not impacted.[576] According to Ms. Owens continuous surveying will ensure the birds are not harassed by Project activities.[577]

Finally, Mitigation Measure 4.6-1n describes the Habitat Mitigation and Monitoring Plan, which Ms. Owens explains does not reduce impacts to below significant.[578] The compensatory mitigation lacks data, description, detail, and standard criteria to analyze its efficacy and success.[579]

B. Substantial Evidence Shows the Project Would Result in Potentially Significant Impacts, Despite Compliance with Laws

The DEIR/EIS concludes in several sections that the Project's compliance with laws and regulations are sufficient to mitigate potentially significant impacts to a level of insignificance. In many cases, the DEIR/EIS simply concludes that impacts are less than significant by assuming compliance with laws. However, compliance with a regulation or law is not an indication of the sufficiency of mitigation measures where there is substantial evidence that the project may result in significant impacts.[580] CEQA requires a lead agency to fully assess the significance of a Project's impacts in light of substantial evidence "notwithstanding compliance with the adopted regulations or requirements."[581] Furthermore, the DEIR/EIS may not simply assert "a bare conclusion . . . not supported by facts or analysis."[582]

CURE-45

In *Communities for a Better Env't v. California Res. Agency*, the court struck down a CEQA Guideline because it "impermissibly allow[ed] an agency to find a cumulative effect insignificant based on a project's compliance with some generalized plan rather than on the project's actual environmental impacts."[583] The court concluded that "[i]f there is substantial evidence that the possible effects of a particular project are still cumulatively considerable notwithstanding that the project complies with the specified plan or mitigation program addressing the cumulative problem, an EIR must be prepared for the project."[584] Thus, the ruling supports the notion that compliance with an applicable standard outside of the CEQA process does not automatically obviate a lead agency's obligation to consider substantial evidence and analyze and mitigate potentially significant impacts.

In *Keep our Mountains Quiet v. County of Santa Clara*, neighbors of a wedding venue sued over the County's failure to prepare an EIR due to significant noise impacts. The court concluded that "a fair argument [exists] that the Project

printed on recycled paper

may have a significant environmental noise impact" and reasoned that although the noise levels would likely comply with local noise standards, "compliance with the ordinance does not foreclose the possibility of significant noise impacts."[585] The court ordered the County to prepare an EIR.

CURE-45 cont.

C. The DEIR Fails to Require Compliance with Laws as Enforceable Mitigation

1. Project Fails to Require Compliance with NPDES and the Ocean Plan

The DEIR/EIS states that the Project will be consistent with the Ocean Plan and the NPDES permit process:

> The MPWSP would be consistent with the Monitoring and Reporting Plan requirements of the Ocean Plan because such requirements form a part of the NPDES permit process and, further, CalAm would submit and, once approved by the RWQCB and MBNMS, execute a facility specific Monitoring and Reporting Plan.[586]

CURE-46

The Ocean Plan requires more than a monitoring and reporting plan. CalAm must also meet certain reporting requirements, such as providing a Marine Life Mortality Report. Based on the results of this Marine Life Mortality Report, CalAm must either complete a mitigation project or implement a fee-based mitigation program to mitigate for the mortality of all forms of marine life.[587]

2. Project Fails to Require Compliance with City of Marina Local Coastal Land Use Plan (LCLUP)

CURE-47

The Project fails to comply with habitat management and conservation plans, policies, or regulations in local regional land use plans.[588] The following regions

---

[585] *Keep our Mountains Quiet*, *supra*, 236 Cal.App.4th, at p. 733.

[587] SWRCB, California Ocean Plan, *supra,* at pp. 43-44.
[588] Owens Comments, at pp. 4-8.

printed on recycled paper

have habitat management and conservation plans: the City of Marina General Plan, the City of Marina Local Coastal Land Use Plan, the Marina Municipal Code, the Fort Ord Dunes State Park General Plan and EIR, the Monterey City Code, the Seaside General Plan, the Seaside Municipal Code, Carmel Valley Master Plan, Greater Monterey Peninsula Area Plan, Monterey County Code, Monterey County General Plan, North County Land Use Plan, Fort Ord Reuse Plan.[589]

The DEIR/EIS concludes that where this Project may be inconsistent with the applicable plan, policy, or regulation, the impact will be separately identified.[590] Where the impact would be considered significant, then feasible mitigation would be identified to resolve or minimize that conflict.[591] Yet, the DEIR/EIS does not adequately address all of the potential conflicts with these plans and, as a result, fails to require mitigation measures to ensure consistency with those plans.

CURE-47 cont.

As Ms. Owens explains, the City of Marina Local Coastal Land Use Plan has very specific policies and mitigation measures regarding potential impacts to sensitive species and habitats.[592] These policies include establishing a list of biologists qualified to prepare habitat evaluation reports, determining the extent and landward boundary of a wetland, and identifying plant and animal species which are locally or generally rare, endangered, threatened, or are necessary for the survival of an endangered species.[593]

The City of Marina Local Coastal Land Use Plan has specific minimum habitat mitigation and restoration plan requirements to protect the biodiversity in the area.[594] All direct and potential impacts to primary and secondary habitats shall be fully mitigated.[595] Habitat restoration plans should be prepared by a qualified biologist, and where appropriate with a qualified hydrologist. Plans should be developed in consultation with the Department of Fish and Wildlife and the U.S. Fish and Wildlife Service in cases where these agencies have jurisdiction.[596] To

[594] *Id.,* at p. 6.
[595] *Id.*
[596] *Id.*

printed on recycled paper

enforce these plans, they should be authorized by a coastal development permit and must be approved prior to issuance of any grading or building permits.[597] The plan shall include at a minimum: (1) a detailed site plan; (2) a baseline ecological assessment; (3) goals, objectives, performance standards and success criteria for the site; (4) management methods to ensure the site achieves the goals, objectives, and performance standards; (5) provisions for the full restoration of any impacts that are identifies as temporarily necessary to install the restoration or enhancement elements; (6) submitting documentation at the completion of initial restoration work; (7) provision for a detailed monitoring program to include a provision for assessing the initial biological and ecological status of the site; and (8) provision for the prompt remediation of a site if the monitoring results indicate the site does not meet the goals, objectives and performance standards identified in the approved mitigation program.[598]

CURE-47 cont.

The DEIR/EIS admits that it is potentially inconsistent with the City of Marina LCLUP with respect to installing the subsurface slant wells, source water pipeline, new desalinated water pipeline, and new transmission main, and maintenance of the subsurface slant wells.[599] These installations and maintenance will occur within special status species habitats, including wetlands and primary and secondary habitat in the City of Marina.[600] Ms. Owens notes that although the DEIR/EIS proposes mitigation measures to reduce or avoid impacts on special-status species, the measures are insufficient because they may not include all direct, indirect, and cumulative impacts.[601] Further, and as provided above, the DEIR/EIS must comply with the City of Marina's minimum habitat mitigation/restoration plan requirements, which are more aggressive at ensuring protection of biological resources than the mitigation measures provided in the DEIR/EIS.[602]

[602] *Id.*

printed on recycled paper

3. Project Fails to Require Compliance with Other Laws

The DEIR/EIS abdicates its duty under CEQA in several resource areas. For example, under Impact 4.2-1 (increased soil erosion or loss of topsoil during construction), the DEIR/EIS finds that the Project could result in substantial soil erosion or loss of topsoil during construction."[603] However, the DEIR/EIS simply concludes that "the proposed project would be required to comply with the NPDES General Permit for Discharges of Storm Water Runoff Associated with Construction and Land Disturbance Activities (Order 2009-0009-DWQ, NPDES No. CAS000002; as amended by Orders 2010-0014-DWQ and 2012-006-DWQ) (Construction General Permit), the Monterey County Grading Ordinance, and Monterey County Erosion Control Ordinance, all of which are described in Section 4.2.2, Regulatory Framework"; therefore, "impacts associated with substantial increases in soil erosion during construction would be less than significant for all project components."[604] The DEIR/EIS fails to provide further substantive analysis and mitigation for soil erosion impacts aside from requirements under the applicable laws. In addition, compliance with these laws is not encapsulated as enforceable mitigation. Simply assuming the Applicant will comply with laws outside of CEQA does not satisfy CEQA's requirement for a full analysis and mitigation of potentially significant impacts. CURE-48

Additional impacts that are assumed to be less than significant based on compliance with other laws include:

> damage to structural elements from earthquake (Impact 4.2-3);[605] exposure of people or structures to substantial adverse effects related to liquefaction and lateral spreading (Impact 4.2-4);[606] water quality impact associated with construction activities (Impact 4.3-1);[607] discharges of treated water and disinfectant from existing and newly

[607] *Id.,* at p. 4.3-58 (compliance with NPDES).

printed on recycled paper

> installed pipelines during construction (Impact 4.3-3);[608] degradation of water quality due to discharges associated with maintenance of the subsurface intake wells and ASR injection/extraction wells (Impact 4.3-6);[609] alteration of drainage patterns such that there is a resultant increase in erosion, siltation, or the rate or amount of surface runoff (Impact 4.3-7);[610] and construction-related impact to water quality in jurisdictional waters related to increased soil erosion and/or inadvertent releases of toxic construction chemicals (Impact 4.6-3).[611]

In the analyses for all of these impacts, the DEIR/EIS acknowledges the impacts could be significant, but then concludes no significant impact based on compliance with laws without actually analyzing the impact and incorporating any enforceable mitigation. For example, under Impact 4.3-3, the DEIR/EIS states:

> The treated water generated from the draining of existing pipelines and the effluent generated from disinfection of newly installed pipelines would be discharged to the local storm drainage system. Without proper controls, these discharges could adversely affect water quality in downstream receiving water bodies by increasing turbidity (if discharged directly without appropriate treatment) or due to high chlorine (the primary disinfectant used for drinking water) concentrations.[612]

CURE-48 cont.

The DEIR/EIS further states that "General [Waste Discharge Requirements (Order No. R3-2011-0223, NPDES Permit No. CAG993001)] WDRs require that CalAm neutralize the residual chlorine remaining in disinfection effluent such that detectable chlorine levels are less than 0.02 mg/L, and require that the total dissolved solids be within surface water and groundwater quality objectives."[613] The DEIR then concludes that "[c]ompliance with the General WDRs and the conditions therein would protect water quality in receiving water bodies [and] the impact would be less than significant,"[614] without requiring any mitigation. Under

printed on recycled paper

CEQA, the DEIR/EIS must actually analyze the potential for the increased turbidity and high chlorine levels, and incorporate compliance with the WDR standards as enforceable mitigation.

The CPUC and MBNMS may not rely solely on compliance with regulations or laws as reducing impacts to less than significant levels without a full analysis of impacts or enforceable mitigation. As the DEIR/EIS is currently presented, the CPUC and MBNMS cannot conclude that the Project's impacts have been fully assessed and properly mitigated to less than significant.

CURE-48 cont.

VII. THE DEIR/EIS FAILS TO EVALUATE CERTAIN ALTERNATIVES

NEPA regulations identify the need to consider reasonable alternatives.[615] NEPA requires consideration of all aspects that may be relevant and important to decision-makers, including factors that are not related to environmental quality. NEPA requires substantial treatment of each alternative, including the proposed action, so that reviewers may evaluate their comparative merits.[616]

Under CEQA, the lead agency is required to consider project alternatives that might eliminate or reduce the Project's significant adverse environmental effects. CEQA requires that an EIR "[d]escribe a range of reasonable alternatives . . . which could feasibly attain the basic objectives of the project and evaluate the comparative merits of the alternatives."[617] An EIR must "produce information sufficient to permit a reasonable choice of alternatives so far as environmental aspects are concerned."[618] The key issue is whether the alternatives analysis fosters informed decision-making and informed public participation.[619]

CURE-49

The discussion must focus on alternatives capable of either eliminating any significant adverse environmental effects or reducing them to a level of

[615] 40 C.F.R. § 1502.14(c).
[616] *Id.*, at § 1502.14.

[619] CEQA Guidelines, § 15126.6.

printed on recycled paper

insignificance, even if such alternatives would be more costly or to some degree would impede the project's objectives. One of the most substantive aspects of CEQA is that section 21002 of the statute forbids agencies from approving projects with significant adverse impacts when feasible alternatives (or feasible mitigation measures) can substantially lessen such impacts.[620]

Aside from the proposed Project and the No Project alternative, the DEIR/EIS provides six different alternatives:

- Alternative 1 – Slant wells at Potrero Road[621]
- Alternative 2 – Open-Water Intake at Moss Landing[622]
- Alternative 3 – Monterey Bay Regional Water Project (MBRWP or DeepWater Desal Project)[623]
- Alternative 4 – People's Moss Landing Water Desalination Project (People's Project)[624]
- Alternative 5a – Reduced Project 6.4-mgd Desalination Plant (Intake Slant Wells at CEMEX[625]
- Alternative 5b – Reduced Project 6.4-mgd Desalination Plant (Intake Slant Wells at Potrero Road)[626]

CURE-49 cont.

All of these project alternatives rely on the same basic technology: reverse osmosis. Yet, there is no discussion of other desalination technologies that would allow for CalAm to meet its water production objective, such as:

- Electrodialysis
- Multi-stage flash distillation
- Multiple effect distillation
- Vapor compression desalination[627]

[626] *Id.*, at § 5.4.8.

printed on recycled paper

Among these processes are also those that embrace renewable energy, such as:

- Solar humidification
- Membrane distillation[628]

The DEIR/EIS proposes a reduced project alternative, which is the environmentally superior option.[629] But it fails to consider aggregated, small scale desalination projects.[630] This is particularly relevant given that other desalination proposals are being considered in Monterey Bay, which may provide sufficient water quantities to the County.[631]

CURE-49 cont.

VIII. OTHER CONSIDERATIONS

A. Growth Related Impacts Must Be Adequately Considered

CEQA requires a separate and distinct analysis of growth-inducing impacts. The requirement to assess "growth-inducing impacts" must include the following:

> [T]he ways in which the proposed project could foster economic or population growth, or the construction of additional housing, either directly or indirectly, in the surrounding environment. Included in this are projects which would remove obstacles to population growth (a major expansion of a waste water treatment plant might, for example, allow for more construction in service areas). Increases in the population may tax existing community service facilities, requiring construction of new facilities that could cause significant environmental effects. Also discuss the characteristic of some projects which may encourage and facilitate other activities that could significantly affect the environment, either individually or cumulatively. It must not be assumed that growth in any area is

printed on recycled paper

> necessarily beneficial, detrimental, or of little significance to the environment.[632]

In *City of Davis v. Coleman*, the court set aside a Negative Declaration and required preparation of an EIR where evidence supported the finding that the construction of a highway interchange would cause urban growth.[633] However, the court reached its holding in reliance on the common sense conclusion that a project that is intended to support future growth ***will*** also cause potentially significant urban growth impacts which must be analyzed in an EIR.[634] As articulated by the court:

> The growth-inducing effects of the Kidwell Interchange project are its raison d'etre, and with growth will come growth's problems: increased population, increased traffic, increased pollution, and increased demand for services such as utilities, education, police and fire protection, and recreational facilities.[635]

CURE-50 cont.

In Monterey, water scarcity has constrained development.[636] Removing this constraint would allow for development projects to move forward.[637] The impacts associated increased development, such as impacts on air quality and water quality, in particular, as compared to the current "constrained" environmental setting may be significant.[638] New building will lead to water quality impacts from urban runoff, which the DEIR/EIS has not considered.[639] With respect to ocean water quality, the levels of contaminants are already at the brink of exceeding Ocean Plan thresholds.[640] Allowing additional development to go forward, with the associated air and water impacts, will likely cause these thresholds to be exceeded.

[640] *See id.*, Table 4.3-16.

printed on recycled paper

Although the DEIR/EIS claims that additional growth would be consistent with adopted land use plans, consistency with adopted goals, polices and guidelines is not a valid basis for finding that impacts of a Project are not cumulatively considerable.[641]

While an EIR's cumulative impact analysis generally may rely on a summary of projections contained in an adopted general plan or related planning document instead of on a list of past, present, and probable future projects[642], it may not do so if the projections in the general plan or related planning document are inaccurate or outdated and thus do not adequately evaluate the potentially significant cumulative impacts of the project.[643] The fact that a particular project's incremental impact may not have been found significant under old, out-of-date growth projections, does not mean that the same project will not contribute to a cumulatively considerable impact when development projections change. Accordingly, consistency with existing zoning, community plan or general plan policies does not relieve a lead agency from the requirement to conduct environmental review of potentially significant cumulative impacts that were not analyzed, discussed or identified in the EIR prepared for the planning document.[644] An EIR's reliance on out-of-date growth projections that do not take into account identified probable future projects thus violates CEQA.

CURE-50 cont.

In *Bakersfield Citizens for Local Control v. City of Bakersfield*, the court found that an agency's reliance on projections contained in a general plan was improper where the general plan's projections did not take into account new projects that were not identified at the time the general plan was prepared, but were reasonably foreseeable at the time of the current EIR.[645] In reaching this decision, the court held that "use of a planning document does not preclude challenge to the accuracy or sufficiency of the cumulative impacts analysis."[646] The Court further held that the "summary-of-projections approach may present problems if the projections in the general plan or related planning document are inaccurate or

printed on recycled paper

outdated."[647] The Port's position is also inconsistent with the Court's decision in *Citizens to Preserve the Ojai v. County of Ventura*.[648] In that case, the Court held that an EIR's cumulative analysis of air quality impacts was inadequate where it relied upon a prior Air Quality Management Plan that did not take into account new evidence of the cumulative contribution to air pollution from offshore emissions.[649]

Consistency with adopted goals, polices and guidelines is not a valid basis for finding that impacts of a Project are not cumulatively considerable.[650] Impacts do not become automatically less than significant merely because the actions are consistent with adopted goals, polices and guidelines.

The same is true here. Lifting the water constraint will open the Monterey Peninsula to foreseeable growth that must be adequately accounted for, as required by NEPA and CEQA.

CURE-50 cont.

IX. CONCLUSION

The DEIR/EIS does not satisfy CEQA's procedural and evidentiary standards for preparing an EIR, or NEPA's standards for preparing an EIS. The DEIR/EIS fails to include an adequate description of the Project and fails to adequately describe the environmental setting. The DEIR/EIS also fails to address the Project's potentially significant impacts to biological resources, marine resources, air quality, public health, vibration issues, and others. Furthermore, the DEIR/EIS proposes mitigation measures that are deferred, unenforceable, or otherwise inadequate to mitigate impacts to below a level of significance. In the case of significant and unavoidable impacts, the DEIR/EIS fails to propose all feasible mitigation. It also fails to propose legally sufficient alternatives. For these reasons, the CPUC and MBNMS must withdraw the DEIR/EIS and prepare and recirculate

Draft Environmental Impact Report/ Environmental Impact Statement (DEIR/DEIS)

for the

CalAm Monterey Peninsula Water Supply Project

Prepared

for

Adams Broadwell Joseph & Cardozo

Prepared by

Phyllis Fox, Ph.D., PE
Consulting Engineer
745 White Pine Ave.
Rockledge, FL 32955

February 27, 2017

The California American Water Company (CalAm) is proposing to construct and operate the Monterey Peninsula Water Supply Project (MPWSP or Project) in the Monterey Bay Area. The California Public Utilities Commission (CPUC) as lead agency for the State and the National Oceanic and Atmospheric Administration for the United States (NOAA) have prepared a Draft Environmental Impact Report and Environmental Impact Statement (DEIR/EIS) for the Project.[1]

The purpose of the Project is to replace existing water supplies that were limited by the adjudication of the Carmel River and Seaside Groundwater Basin. The Project would replace the lost water with desalinated sea water and increase the CalAm storage capacity in the Seaside Groundwater Basin. CalAm proposes to build either a desalination plant with the capacity to produce up to 9.6 million gallons per day (mgd) of desalinated product water, or to build a smaller project that would include the purchase of product water from the proposed Pure Water Monterey Groundwater Replenishment (GWR) project and construction of a 6.4 mgd desalination plant.

The Project includes construction of up to ten subsurface slant wells, a 9.6-mgd desalination plant to produce about 10,267 ac-ft/yr of desalinated water, improvements to the existing Seaside Groundwater Basin Aquifer Storage and Recovery (ASR) system facilities, 30 miles of pipeline, two pump stations, a Terminal Reservoir, and water storage tanks.[2]

CURE-Fox-1

I reviewed the air quality, greenhouse gas, historic resources, and vibration sections of the DEIR/EIS for the Project as well as the 2015 DEIR.[3] My comments on the 2015 DEIR are incorporated here by reference.[4] My review of the DEIR/EIS indicates:

- The DEIR/EIS fails to evaluate all air quality impacts.
- Construction emissions are not supported by substantial evidence.

CURE-Fox-2

[4] Phyllis Fox, Comments on Draft Environmental Impact Report for the CalAm Monterey Peninsula Water Supply Project, July 1, 2015, Attachment A to comments submitted by Adams Broadwell Joseph and Cardozo ("Fox 2015 DEIR Comments"); Available at: http://www.cpuc.ca.gov/Environment/info/esa/mpwsp/deir_comments/G_CURE4_p1.pdf.

- The DEIR/EIS fails to require all feasible mitigation for significant and unavoidable construction ROG and NOx impacts.
- The DEIR/EIS fails to include indirect operational impacts from electricity generation, which are significant for NOx.
- The DEIR/EIS fails to identify and mitigate significant cancer health risks from diesel particulate matter emissions during Project construction.
- The DEIR/EIS fails to identify a significant risk of Valley Fever for construction and well maintenance workers as well as local residents.
- The DEIR/EIS relies on conventional dust control measure to mitigate Valley Fever impacts, which are well known to be ineffective due to the small size of the Cocci spores.
- The DEIR/EIS fails to adequately explain why the Project's GHG impacts are significant and unavoidable.
- The DEIR/EIS fails to require all feasible mitigation for significant GHG emissions.
- The DEIR/EIS fails to identify and mitigate significant vibration impacts.
- The DEIR/EIS fails to identify and mitigate significant adverse impacts to historical resources.

CURE-Fox-2 cont.

My resume is included in Exhibit 1 to these Comments. I have over 40 years of experience in the field of environmental engineering, including air emissions and air pollution control; greenhouse gas (GHG) emission inventory and control; water quality and water supply investigations; hazardous waste investigations; hazard investigations; risk of upset modeling; environmental permitting; nuisance investigations (odor, noise); environmental impact reports (EIRs), including CEQA/NEPA documentation; health risk assessments; and litigation support. I have M.S. and Ph.D. degrees in environmental engineering from the University of California at Berkeley with minors in Hydrology and Mathematics. I am a licensed professional chemical engineer in California.

CURE-Fox-3

I have prepared comments, responses to comments and sections of environmental impact reports (EIRs) for both proponents and opponents of projects on air quality, water supply, water quality, hazardous waste, public health, risk assessment, worker health and safety, odor, risk of upset, noise, land use and other areas for well over 500 CEQA documents. This work includes EIRs, Negative Declarations (NDs), and Mitigated Negative Declarations (MNDs). My work has been cited in two published CEQA opinions: (1) *Berkeley Keep Jets Over the Bay Committee, City of San Leandro, and City of Alameda et al. v. Board of Port Commissioners* (2001) 111 Cal.Rptr.2d 598 and *Communities for a Better*

Environment v. South Coast Air Quality Management Dist. (2010) 48 Cal.4th 310 and has supported the record in many other CEQA cases. CURE-Fox-3 cont.

I. AIR QUALITY IMPACTS

The Project would emit pollutants limited by state and federal ambient air quality standards during construction and operation. These include: carbon monoxide (CO), reactive organic gases (ROG), nitrogen oxides (NOx), sulfur oxides (SOx), particulate matter equal to or smaller than 10 microns (PM10), and particulate matter equal to or smaller than 2.5 microns (PM2.5). CURE-Fox-4

A. Construction Criteria Pollutant Emissions Are Significant And Unmitigated

The DEIR/EIS estimated maximum daily emissions of ROG, NOx, CO, PM10, and PM2.5 from Project construction, concluded emissions of NOx and PM10 are significant,[5] and proposed mitigation[6]. The proposed mitigation is inadequate. CURE-Fox-5

1. Construction Emissions Are Not Supported by Substantial Evidence

The construction emissions are summarized in Table 4.10-5. The DEIR/EIS summarizes the methods used to estimate construction emissions[7] and refers the reader to Appendix G1 for detailed assumptions and calculations.[8] However, Appendix G1 is not the starting point for all of the construction emission calculations.

For off-road construction equipment, Appendix G1 includes model inputs and outputs for most emission sources. However, Appendix G1 notes that some emissions were estimated outside of models, but fails to explain where or how.[9] This includes: CURE-Fox-6

- Operational emissions, DEIR/EIS, Appx. G1, pdf 35,78
- Worker and haul trips, DEIR/EIS, Appx. G1, pdf 36,79
- Grading, DEIR/EIS, Appx. G1, pdf 36, 79

[5] DEIR/EIS, Table 4.10-5, pp. 4.10-22 /24.

[6] DEIR/EIS, pp. 4.10-25/27.

[7] DEIR/EIS, p. 4.10-18, Section 4.10.4.2, Construction Emissions.

[8] DEIR/EIS, p. 4.10-22.

[9] DEIR/EIS, Appendix G1, pdf 36, 78,79 (worker and haul trips estimated outside of CalEEMod); 35, 78 (operational emissions are estimated outside of CalEEMod); 36, 78 (fugitive dust emissions estimated outside CalEEMod)

This lack of documentation deprives the public of the opportunity for independent review of the CPUC's conclusions regarding the significance of the Project's construction emissions. CURE-Fox-6 cont.

On-road operational and construction emissions were estimated using CARB's EMFAC2014 Burden Model.[10] This model generates emissions in (1) grams per mile for running exhaust, (2) grams per hour for running loss and diurnal/resting loss, (3) grams per idle-hour for idling exhaust, and (4) grams per trip for hot soak and start. These four sources of emissions cannot be simply summed to come up with a total emissions factor for on-road emissions as they are reported in different units. The starting point for the Appendix G on-road emissions is an emission factor in grams per mile.[11] However, the DEIR/EIS does not include the EMFAC input and output sheets or explain how it combined the EMFAC output, expressed in four different units, into grams per mile. CURE-Fox-7

While the use of models that have been approved by a regulatory agency is a reasonable starting point, the mere claim that such a model was used does not by itself establish substantial evidence to support the emission estimates and conclusions presented in DEIR/EIS Appendix G. Models are merely tools which can be used correctly or incorrectly depending on the assumptions made to develop project-specific input parameters and the accuracy of parameter inputs into the model. As such, the assumptions used to run EMFAC should be subject to public review. Here, they are not. CURE-Fox-8

The DEIR/EIS does not provide any support to demonstrate how ESA calculated the starting point for on-road construction emissions in Appendix G1 and other emissions calculated outside of models (grading, workers and haul trips, operational emissions). The DEIR/EIS should be recirculated with enough relevant information to verify the DEIR/EIS's estimates of construction emissions including: (1) identification of all Project-specific assumptions and input parameters; (2) a copy of the model run inputs and outputs; and (3) any other documentation prepared by ESA or other CPUC consultants, such as original Excel spreadsheet model inputs and outputs plus Appendix G1 spreadsheets used to make the final construction emission calculations, i.e., the record should include unlocked Excel spreadsheets that correspond to those in Appendix G1. These documents are routinely provided to support EIRs[12] and other CEQA-equivalent documents,[13] as required under CURE-Fox-9

[10] DEIR/EIS, Appendix G1, pdf 19, 23, 24-28, 31, 36.

[11] DEIR/EIS, Appendix G1, pdf 19.

[12] *See*, for example, City of Los Alamitos, General Plan Update, Draft Environmental Impact Report, August 2014, SCH No. 2013121055, Appendix C, Air Quality and GHG Modeling; Available at: http://cityoflosalamitos.org/?wpfb_dl=2323; County of Los Angeles, Los Angeles County General Plan Update, Draft Environmental Impact Report, SCH No. 2011081042, June 2014, Appendix G;

CEQA and California public records laws. They must be provided here to support the DEIR/EIS's conclusions regarding the significance of construction emissions. CURE-Fox-9 cont.

Thus, the DEIR/EIS's conclusions regarding construction impacts on air quality are not supported by substantial evidence. As it stands, the reviewer has no choice but to simply accept the DEIR/EIS's analysis without any opportunity to verify the CPUC's conclusions regarding the significance of construction CO, SO2, ROG, NOx, PM10, and PM2.5 emissions. This frustrates the public review requirements under CEQA. CURE-Fox-10

2. Construction Mitigation Is Not Adequate

The DEIR/EIS concluded that "[s]hort-term emissions associated with construction of the proposed project could contribute to an exceedance of a state and/or federal standard for ozone, NO2, and PM10 based on the estimated maximum daily mass emissions levels presented in Table 4.10-5, which would exceed the MBUAPCD significance threshold for PM10."[14] Elsewhere, the DEIR/EIS concluded that construction activities could conflict with implementation of the MBUAPCD's Air Quality Management Plan (Impact 4.10-2).[15]

The DEIR/EIS then concludes that the significant air quality impact with respect to ozone and NO2 standards "would be significant and unavoidable even with implementation of Mitigation Measures 4.10-1a and 4.10-1b."[16] An EIR may conclude that an impact is significant and unavoidable only if all available and feasible mitigation measures have been proposed, but are inadequate to reduce the impact to a less than significant level.[17] If supported by substantial evidence, the lead agency may make findings of overriding considerations and approve the project in spite of the significant and unavoidable impact(s). However, the lead agency cannot simply conclude that an impact is significant and unavoidable without requiring all feasible mitigation, as here. As discussed below, the proposed mitigation for ozone and NO2 impacts from construction is not all feasible mitigation.

CURE-Fox-11

[14] DEIR/EIS, p. 4.10-24, pdf 1048.

[15] DEIR/EIS, p. 4.10-26, Impact 4.10-2.

[16] Ibid.

[17] See Cal. Code Regs. Titl.14 ("CEQA Guidelines"), § 15126.2.

a. Mitigation Measure 4.10-1a: Equipment with High-Tiered Engine Standards

Mitigation Measure 4.10-1a proposes the use of equipment that meets asserted high-tiered engine standards.[18] This mitigation measure stipulates:

> **Mitigation Measure 4.10-1a: Equipment with High-Tiered Engine Standards.**
>
> For diesel-fueled off-road construction equipment of more than 50 horsepower, CalAm and/or its construction contractor shall make a good faith effort to use available construction equipment that meets the highest USEPA-certified tiered emission standards. For all pieces of equipment that would not meet at least Tier 3 emission standards, CalAm or its construction contractor shall provide to the CPUC documentation from two local heavy construction equipment rental companies that indicates that the companies do not have access to higher-tiered equipment for the given class of equipment. Such documentation shall be provided to the CPUC at least two weeks prior to the anticipated use of those pieces of equipment.

CURE-Fox-12

This measure is inadequate as mitigation. First, Tier 3 is not the highest tier (lowest emission) off-road engines available. Tier 4 engines are the lowest polluting engines and are widely available in new construction fleets, such as that offered by Garney Pacific,[19] one of the contractors for the pipeline.[20]

Second, a "good faith" effort is not adequate to satisfy CEQA. The Request for Proposal (RFP) for this Project should specify the use of Tier 4 engines or control(s) that yield the Tier 4 emission standards. If no contractor can comply (which is highly unlikely), this mitigation measure should be expanded to require consideration of lease or rental from private vendors within 1,000 miles of the Project site if Tier 4 is not available in any contractor's fleet. If a Tier 4 engine is not available from a contractor or via lease/rental, the lowest emitting engine should be retrofit with pollution controls to meet Tier 4 standards, e.g., SCR, particulate trap. The request to deviate from the use of Tier 4 engines should only be considered after all feasible actions have been taken to comply, accompanied by a report certified by a licensed California professional engineer, listing all steps taken to acquire Tier 4 engines supported by correspondence from all contacted suppliers.

CURE-Fox-13

[18] DEIR/EIS, p. 4.10-25, pdf 1051.

[19] Garney Construction, Construction Equipment Efficiency Plan, Monterey Pipeline Project, October 24, 2016, pdf 3 ("The Garney Construction project maintenance program starts with reduction of potential mechanical issues by utilizing new equipment (4 years or newer) for all heavy equipment utilized in our fleet. This ensures all equipment used is in compliance with emission (Tier 4) and noise regulations…").

[20] Garney Construction, Garney Pacific Lands Monterey Peninsula Water Supply Project, January 2016; Available at: http://www.garney.com/garney-pacific-lands-monterey-peninsula-water-supply-project-2/.

Third, the IS/MND for this Project and other similar EIRs have required Tier 4 engines, as noted in Comment I.A.2.a. CURE-Fox-14

b. Mitigation Measure 4.10-1b: Idling Restrictions

Mitigation Measure 4.10-1b establishes limits on idling time for on-road and off-road engines[21]:

> **Mitigation Measure 4.10-1b: Idling Restrictions.**
>
> On road vehicle idling time shall be minimized and shall not exceed a five minute maximum. Additionally, off-road engines shall not idle for longer than five minutes per Section 2449(d)(3) of Title 13, Article 4.10, Chapter 9 of the California Code of Regulations. Clear signage of this requirement shall be provided for construction workers at all access points to construction areas.

CURE-Fox-15

Limiting idle time to 5 minutes is required by 13 CCR 2449[d][3], 2485 for off-road vehicles.[22] Thus, this is not valid CEQA "mitigation". This mitigation measure should be modified to lower the maximum idling time to 2 minutes, which has been required for other similar projects[23] . Some states, Connecticut, Delaware, the District of Columbia, and New Jersey, and some cities, Santa Barbara, Minneapolis, Burlington and Chicago, for example, limit idling to 3 minutes for all on- and/or off-road vehicles.[24] In addition to lowering the idling time, the construction contractor should be required to maintain a written idling policy and distribute it to all employees and subcontractors. The on-site construction manager shall enforce this limit.[25]

c. Additional Feasible Mitigation for Construction Ozone and NO_2 Emissions

CURE-Fox-16

The Draft Initial Study and Mitigated Negative Declaration for the slant test well (IS/MND)[26] concluded air quality impacts would be "less than significant with

mitigation incorporation"[27] and imposed mitigation measures for NOx and ROG impacts.[28] However, most of these measures were not included in the DEIR/EIS. The omitted measures are all feasible, are listed below, and identified by "(IS/MND)". Additional mitigation is identified in the MBUAPCD's CEQA Guidelines.[29] The recently approved FEIR for the Chevron Modernization Program (Chevron) also includes mitigation measures for NOx and ROG emissions from construction equipment.[30] Finally, EPA has identified feasible mitigation for NOx and ROG emissions from construction emissions. Feasible mitigation measures from these and other sources for NOx and ROG not included in the DEIR/EIS are: CURE-Fox-16 cont.

- Maintain all construction equipment in proper tune according to manufacturer's specifications. The equipment must be check by an ASE-certified mechanic and determined to be running in proper condition before it is operated. (IS/MND; Chevron). CURE-Fox-17
- Diesel powered equipment shall be replaced by electric equipment whenever feasible to reduce NOx emissions (IS/MND, Chevron) CURE-Fox-18
- Diesel-powered equipment shall be replaced by gasoline-powered equipment whenever feasible (IS/MND, Chevron) CURE-Fox-19
- The number of construction equipment operating simultaneously shall be minimized through efficient management practices to ensure that the smallest practical number is operating at any one time (IS/MND) CURE-Fox-20
- The engine size of construction equipment shall be the minimum practical size (IS/MND) CURE-Fox-21
- Catalytic converters shall be installed on gasoline-powered equipment (IS/MND) CURE-Fox-22
- Signs shall be posted in designated queuing areas and job sites to remind drivers and operators of the idling limit (IS/MND, Chevron) CURE-Fox-23
- Diesel equipment idling shall not be permitted within 1,000 feet of sensitive receptors (IS/MND) CURE-Fox-24
- Engine size of construction equipment shall be the minimum practical size (IS/MND) CURE-Fox-25

[27] IS/MND, p. 38.

- The number of construction equipment operating simultaneously shall be minimized through efficient management practices to ensure that the smallest practical number is operating at any one time (IS/MND) CURE-Fox-26
- Construction worker trips shall be minimized by providing options for carpooling and by providing for lunch onsite (ISMND, Chevron) CURE-Fox-27
- Use electric fleet or alternative fueled vehicles where feasible including methanol, propane, and compressed natural gas (Chevron) CURE-Fox-28
- Use alternative diesel fuels, such as Aquazole fuel, Clean Fuels Technology (water emulsified diesel fuel), or O2 diesel ethanol-diesel fuel (O2 Diesel) in existing engines (SCAQMD, Monterey County General Plan EIR) [31,32] CURE-Fox-29
- Modify engines with ARB verified retrofits CURE-Fox-30
- Repower engines with Tier 4 Interim diesel technology CURE-Fox-31
- Convert part of the construction truck fleet to natural gas[33] CURE-Fox-32
- Use new or rebuilt equipment CURE-Fox-33
- Use diesel-electric and hybrid construction equipment[34] CURE-Fox-34
- Use low rolling resistance tires on long haul class 8 tractor-trailers[35] CURE-Fox-35

Korane, Hybrid Drives for Construction Equipment, Machine Design, July 7, 2009; Available at: http://machinedesign.com/sustainable-engineering/hybrid-drives-construction-equipment; Caterpillar's D7E Electric Drive Redefines Dozer Productivity; Available at: http://www.constructionequipment.com/caterpillars-d7e-electric-drive-redefines-dozer-productivity.

[35] EPA, Verified Technologies for SmartWay and Clean Diesel, Learn About Low Rolling Resistance (LRR) New and Retread Tire Technologies; Available at: https://www.epa.gov/verified-diesel-tech/learn-about-low-rolling-resistance-lrr-new-and-retread-tire-technologies; EPA, Verified Technologies for SmartWay and Clean Diesel, SmartWay Verified List for Low Rolling Resistance (LRR) New and Retread Tire Technologies; Available at: https://www.epa.gov/verified-diesel-

- Use idle reduction technology, defined as a device that is installed on the vehicle that automatically reduces main engine idling and/or is designed to provide services, e.g., heat, air conditioning, and/or electricity to the vehicle or equipment that would otherwise require the operation of the main drive engine while the vehicle or equipment is temporarily parked or is stationary[36] CURE-Fox-36
- Convert part of the construction truck fleet to natural gas[37] CURE-Fox-37
- Implement EPA's National Clean Diesel Program.[38,39,40] CURE-Fox-38

To assure the construction mitigation program is carried out, all off-road diesel-powered equipment should be tested to assure tailpipe emissions do not exceed 20% opacity for more than 3 minutes in any hour. Any equipment found to exceed 20% opacity must be repaired immediately. A visual inspection of all in-operation equipment must be made at least daily by the contractor and witnessed monthly or more frequently by the MBUAPCD, and a periodic summary of the visual survey results must be submitted by the contractor throughout the duration of the project to the MBUAPCD. The summary should include the quantity and type of vehicles inspected and dates. CURE-Fox-39

All feasible mitigation must be required when an impact is significant and unavoidable. Thus, the DEIR/EIS must be revised to include these additional mitigation measures and recirculated for public review. CURE-Fox-40

B. The DEIR/EIS Omits Indirect Operational Emissions

The DEIR/EIS estimated emissions from operation of the Project from three sources: on-road vehicle exhaust, emergency generator testing, and slant well maintenance.[41] However, the major source of Project emissions is indirect emissions from the generation of electricity. The DEIR/EIS did not include those emissions, arguing that "[i]t is generally not possible to determine the exact generator source(s) of electricity on the power grid that would supply the proposed project, or whether or not the electricity would even be generated within the Air Basin."[42] Further, the Monterey County General Plan EIR explicitly recognized that that ""Taking a conservative view, the indirect impacts of the water supply projects to be built would potentially make considerable contributions to air quality, biological, and electrical energy use."[43]

CURE-Fox-41

CURE-Fox-42

These are not valid reasons under CEQA to exclude the major source of emissions from this Project. EIRs routinely include indirect emissions from electricity generation.[44] In fact, the GHG section of this DEIR/EIS includes indirect GHG emissions from power generation.[45] Further, the MBUAPCD's CEQA guidelines state: "The following thresholds apply to all indirect and direct emissions, whether or not they are subject to District permit authority, unless noted otherwise."[46] The "following thresholds" are in Table 5-3, which indicates that the NOx and ROG significance thresholds of 137 lb/day are to be compared to "direct + indirect" emissions.[47] Thus, the DEIR/EIS must include the increase in emissions of criteria pollutants from the net increase in power production to support the Project.

CURE-Fox-43

Further, CEQA does not require that indirect emissions be limited to the Project's "Air Basin." Electricity from any generator in California could be used at the Project site. As the significance criteria are based on the maximum day, finding the "maximum" is all that is required.

[46] MBUAPCD 2008, p. 5-4.

[47] MBUAPCD 2008, Table 5-3. Table 5-3.

The DEIR/EIS indicates that PG&E would supply the power. The sources of PG&E's power are known. As any source within PG&Es system and elsewhere on the grid could be used via purchases by PG&E, unless the EIR includes a condition limiting power sources, emissions should be estimated for the plausible worst case daily maximum emissions, which is the basis of MBUAPCD's significance thresholds for NOx and ROG. As the DEIR/EIS does not provide substantial evidence that these emissions are de minimus, they must be estimated. Further, the DEIR/EIS does not include any of the information required to estimate these emissions. Thus, it fails as an informational document under CEQA and forces the public to generate its own estimates in order to properly evaluate the Project's impacts. CURE-Fox-45

As the DEIR/EIS contains none of the information required to estimate these emissions, I bounded the maximum plausible NOx emissions using two methods. CURE-Fox-46

First, I used AP-42 emission factors for natural gas fired turbines,[48] the most likely electricity source for the Project. The maximum daily emissions would occur at an uncontrolled gas turbine plant, i.e., during a startup/shutdown or uncontrolled operation. CURE-Fox-47

The NOx emission factor for an uncontrolled natural gas turbine plant is 2.56 lb/MWh.[49] The net increase in annual electrical power demand due to the Project is 51,698 MWh per year, relative to the baseline.[50] Thus, assuming a maximum day NOx emission factor of 2.56 lb/MWh, the Project would increase NOx emissions by up to 363 lb/day,[51] which exceeds the MBUAPCD's NOx significance threshold of 137 lb/day. Therefore, the NOx emissions from producing a net increase of 51,698 MWh per year of electricity to support the Project is large enough taken alone to exceed the MBUAPCD's NOx significance threshold. CURE-Fox-48

Therefore, the NOx emissions from producing a net increase of 51,698 MWh per year of electricity to support the Project is large enough taken alone to exceed the MBUAPCD's NOx significance threshold. This is a significant impact that was not disclosed in the DEIR/EIS and that must be mitigated. CURE-Fox-49

---

[48] U.S. EP, Compilation of Air Pollutant Emission Factors, (AP-42), Chapter 3.1: Stationary Gas Turbines, April 2000, Table 3.1-1; Available at: http://www.epa.gov/ttn/chief/ap42/ch03/final/c03s01.pdf.

[49] NOx emission factor from Table 3.1-1: (0.32 lb/10^6 Btu)(8000 Btu/KWh)(1000 KW/MW) **= 2.56 lb/MWh**.

[50] DEIR/EIS, p. 4.11-13.

[51] (2.56 lb/MWh)(51,698 MWh/yr)/365 day/yr = **363 lb/day NOx**.

Second, I identified all PG&E owned power plants in California.[52] I then determined the maximum daily emissions from each, using EPA's CAMD daily data for 2014. This analysis identified two fossil fuel fired PG&E owned power plants in California with the follow maximum daily emissions in 2014:

- Colusa Generating Station: 432 lb/day
- Gateway Generating Station: 1,152 lb/day

Thus, assuming 1,152 lb of NOx is emitted on the maximum day, operational NOx emissions would increase from 26.66 lb/day to 1,179 lb/day,[53] which exceeds the MBUAPCD's NOx significance threshold of 137 lb/day by a significant amount. Therefore, the NOx emissions from producing a net increase of 51,698 MWh per year of electricity is large enough taken alone to exceed the MBUAPCD's NOx significance threshold. This is a significant impact not disclosed in the DEIR/EIS that must be mitigated. CURE-Fox-50

This impact could be mitigated by purchasing local and contemporaneous emission reduction credits or by collaborating with a nearby NOx source to reduce their NOx emissions. Alternatively, the increase in electricity demand could be met by using 100% renewable sources of electricity. Comment IV.B. CURE-Fox-51

The DEIR/EIS should be revised to include indirect electricity generation emissions for all criteria pollutants and to mitigate the resulting significant NOx impacts. CURE-Fox-52

C. The DEIR/EIS Fails to Evaluate All Air Quality Impacts

The DEIR/EIS did not evaluate the significance of pollutants for which the Monterey Bay Unified Air Pollution Control District (MBUAPCD) had not set official CEQA significance thresholds. A lead agency has discretion to determine how to classify the significance of impacts. However, it does not have discretion to simply not evaluate the significance of impacts. Further, its judgment must be supported by scientific information and other factual data.[54] Here, the CPUC has simply failed to evaluate the significance of impacts from two pollutants: (1) NO_2 for impacts other than its contribution to ozone and (2) ROG for its impacts other than its contribution to ozone. CURE-Fox-53

[52] Power_Plants.xlsx; Available at: http://energyalmanac.ca.gov/powerplants/.

[53] Revised operational NOx emissions (DEIR/EIS, Table 4.10-7), to include electricity generation: 26.66 + 1,152 = **1,178.7 lb/day**.

[54] CEQA Guidelines §15064(b).

1. Nitrogen Oxides (NOx) Significance Criteria

Nitrogen oxides (NOx) is a family of seven highly reactive gases. The EPA only regulates nitrogen dioxide (NO_2) as a surrogate for this family, because it is the most prevalent in the atmosphere. NO_2 forms quickly from emissions from cars, trucks and buses; power plants; and off-road equipment. In addition to contributing to the formation of ground-level ozone, and fine particulate pollution, NO_2 is linked with a number of adverse effects on the respiratory system.[55] CURE-Fox-54

The DEIR/EIS only evaluated NOx as an ozone precursor, as the MBUAPCD's significance criteria for NOx (137 lb/day) is based only on this endpoint. However, NOx not only contributes to ground-level ozone, it can also causes adverse health effects, acid rain, form particulate matter, and contribute to global warming, water quality deterioration, and visibility impairment.

Thus, there are primary and secondary state and federal ambient air quality standards for nitrogen oxides established using NO_2 as a surrogate for all nitrogen oxides.[56] The primary standards (1-hour) are set to protect public health, including the health of sensitive populations. The secondary standards (annual) are set to protect public welfare, including protection against decreased visibility and damage to animals, crops, vegetation, and buildings.[57] The DEIR/EIS did not evaluate these primary and secondary impacts of NOx. CURE-Fox-55

First, NOx is harmful to public health. Children, people with lung diseases such as asthma, people who work or exercise outside, children, and the elderly are susceptible to adverse effects such as damage to lung tissue and reduction in lung function.[58] Thus, the Project's NOx emissions also should have been evaluated to determine if the existing primary NO_2 ambient air quality standards, set to protect public health, would be violated. As these standards are based on a 1-hour average, it is plausible that they would be exceeded during construction. CURE-Fox-56

Second, some of the emitted NOx (as well as SO_2) can be converted in the atmosphere to sulfate and nitrates, which contribute to acid rain and fine particulate matter (PM10, PM2.5). These fine particulates can be breathed in and lodged deep in the lungs, leading to a variety of health problems and even premature death. The NOx and SOx contribution to PM10 and PM2.5 should have CURE-Fox-57

[55] EPA, Nitrogen Dioxide, Available at: http://www.epa.gov/airquality/nitrogenoxides/.

[56] DEIR/EIS, Table 4.10-2.

[57] National Ambient Air Quality Standards (NAAQS), Available at: https://www.epa.gov/criteria-air-pollutants#self.

[58] U.S. EPA, Integrated Science Assessment for Oxides of Nitrogen – Health Criteria, EPA/600/R-08/071, July 2008, Available at: http://cfpub.epa.gov/ncea/cfm/recordisplay.cfm?deid=194645#Download.

been estimated and added to total PM10 and PM2.5 emissions, but was not. The DEIR/EIS failed to evaluate these impacts of NOx and (and SO2) thus fails as a public disclosure document. CURE-Fox-57 cont.

Third, NOx emissions contribute to visibility reduction and damages animals, crops, vegetation, and buildings.[59] As the Project is near prime farmland, the DEIR/EIS should have evaluated the potential impacts of construction emissions on these endpoints to determine if the secondary NO_2 ambient air quality standards, set to protect public welfare, were violated. The DEIR/EIS failed to evaluate these secondary NOx impacts and thus is deficient as a public disclosure document. CURE-Fox-58

Appendix G of the CEQA Guidelines indicates a project would have a significant impact if it also violates any air quality standard or exposes sensitive receptors to substantial pollutant concentrations. This determination can be made for NOx using dispersion modeling, which was not included in the DEIR/EIS, or CEQA significance thresholds from other air districts that are in attainment with ozone standards. CURE-Fox-59

There are both federal and state 1-hour and annual average ambient NO_2 air quality standards, set to protect public health and welfare.[60] NO_2 is a respiratory irritant and may affect those with existing respiratory illness, including asthma. Elevated concentrations increase the risk of acute and chronic respiratory disease. The annual average state NOx standard is 0.030 ppm.[61] The DEIR/EIS indicates that the maximum hourly average NOx concentration for the period 2011 to 2015 has been 0.04 ppm, but fails to report any annual average NOx concentration data.[62] As construction will last for more than one year and emissions from construction equipment are released at ground level, in the breathing zone of nearby sensitive receptors, the DEIR/EIS should have evaluated whether construction emissions violate the ambient NOx standards or expose sensitive receptors to substantial pollutant concentrations in the vicinity of construction activities. CURE-Fox-60

The absence of a MBUAPCD "CEQA significance threshold" for non-ozone precursor NOx impacts is not an impediment to evaluating this impact as the ambient air quality standards themselves are the CEQA significance thresholds. A CURE-Fox-61

[59] EPA, Review of the National Ambient Air Quality Standards for Nitrogen Dioxide: Assessment of Scientific and Technical Information, OAQPS Staff Paper, EPA-452/R-95-005, September 1995; Available at: http://www.epa.gov/ttn/naaqs/standards/nox/data/noxsp1995.pdf.

[60] DEIR/EIS, Table 4.10-2.

[61] DEIR/EIS, Table 4.10-2.

[62] DEIR/EIS, Table 4.10-1.

significance threshold is just a surrogate or short cut for avoiding the more time intensive modeling required to evaluate compliance with the ambient standard. When a CEQA significance threshold is missing, a lead agency must model emissions to determine if they cause or contribute to an exceedance of the ambient standards or look to other sources for significance criteria expressed as emission rates, e.g., other air districts.

CURE-Fox-61 cont.

CEQA significance thresholds established by other air districts that are in attainment with ozone standards could be used to evaluate NOx health and other impacts. Four air districts that are in attainment with ozone standards have established CEQA significance thresholds for NOx and ROG based on other considerations:

- Mendocino County AQMD construction: 110 lb/day[63] for NOx and ROG[64]
- Mendocino County AQMD operation: 180 lb/day for ROG and 42 lb/day for NOx[65]
- Colusa County APCD construction: 25 lb/day for NOx and ROG[66]
- Modoc County APCD construction & operation: 250 lb/day for NOx and ROG[67]
- Shasta County AQMD construction & operation: 25 – 137 lb/day for NOx and ROG[68]

CURE-Fox-62

As reported ROG emissions (34 lb/day) exceed the non-ozone significance thresholds of 25 lb/day for Colusa County APCD and Shasta County AQMD, non-ozone public health impacts for both ROG and NOx are significant. This is a new impact that was not disclosed in the DEIR/EIS.

2. Reactive Organic Gases (ROG) Significance Criteria

Reactive Organic Gases or ROG is a collection of volatile organic compounds (VOCs) that form ozone in the atmosphere in the presence of sunlight. The ROG

CURE-Fox-63

[63] BAAQMD, California Air District CEQA Significance Thresholds, Appendix A, Available at: http://www.baaqmd.gov/~/media/Files/Planning%20and%20Research/CEQA/Thresholds_Report_Revised_Appendices_082309.ashx?la=en.

[66] BAAQMD, Appendix A.

[67] BAAQMD, Appendix A.

[68] BAAQMD, Appendix A.

emissions from construction of the Project originate largely from diesel exhaust, which is a known Toxic Air Contaminant.[69] Ozone is an oxidant that attacks synthetic rubber, textiles, and other materials and causes extensive damage to plants by leaf discoloration and cell damage. It is also a severe eye, nose, and throat irritant and increases susceptibility to respiratory infections. Ozone is not emitted directly, but rather forms from photochemical reactions in the atmosphere involving VOCs and NOx.

However, the reactions can be slow and not all of the VOCs are converted into ozone under all conditions. The original VOCs emitted from the source can remain in the atmosphere for significant periods, where they result in health impacts of a different nature than ozone, depending upon the specific Toxic Air Pollutants (TAPs) present. The DEIR/EIS only evaluated ROG as an ozone precursor.

CURE-Fox-63 cont.

The VOCs present in ROG, before it is converted into ozone, include volatile organic compounds that are additionally hazardous to human health.[70] The DEIR/EIS's health risk assessment (HRA) only evaluated diesel particulate matter (DPM). It did not evaluate health impacts from toxic air pollutants subsumed in ROG that are not converted to ozone when they reach sensitive receptors, such those only 25 to 100 feet away from active construction sites. These include acutely and chronically toxic chemicals such as toluene, xylene, ethylbenzene, and 1,3 butadiene and carcinogens such as benzene, formaldehyde, acrolein, and acetaldehyde.

The conversion of ROG to ozone is a slow process, so nearby receptors would initially be exposed to unconverted VOCs. The significance thresholds discussed above for ROG by air districts that are in attainment with ozone standards can be used as a first step to evaluate non-ozone construction and operational ROG impacts of the Project. However, a health risk assessment should be conducted due

to the proximity of sensitive receptors. The health risk assessment in Appendix G1.4 only evaluated diesel particulate matter.

CURE-Fox-63 cont.

In sum, the DEIR/EIS did not evaluate the significance of emissions if a pollutant, such as NOx as respiratory irritant, does not have a MCUAPCD significance threshold because it failed to perform air dispersion modeling. In summary, NOx emissions have three separate impacts, of which only the first was considered in the DEIR/EIS.

CURE-Fox-64

First, NOx forms ozone in the atmosphere and thus contribute to violations of ozone ambient air quality standards. The MBUAPCD NOx significance threshold was developed specifically to address this impact.[71]

CURE-Fox-65

Second, NOx is a respiratory irritant. Separate, air quality standards to protect public health and welfare apply to NO_2 as itself, rather than just as an ozone precursor. The MBUAPCD's CEQA significance threshold for NOx is based on its impacts as an ozone precursor.[72] The MBUAPCD CEQA Guidelines do not include a significance threshold for this second set of impacts. These impacts are addressed by the primary NO_2 ambient air quality standards.

CURE-Fox-66

Third, NO_2 is a PM10/PM2.5 precursor, reduces visibility, and damages animals, crops, vegetation, and buildings. These impacts are addressed by the secondary NO_2 ambient air quality standards.

CURE-Fox-67

The DEIR/EIS is totally silent on these additional NOx impacts. Thus, it fails as a public disclosure document.

CURE-Fox-68

Other air districts that are in attainment with the state and federal ozone ambient air quality standards have established significance thresholds for NOx of 25 lb/day to 180 lb/day. The operational NOx emissions estimated in the DEIR/EIS of 26.66 lb/day[73] which excludes indirect emissions, exceed the 25 lb/day operational NOx significance threshold set by Shasta County AQMD. Thus they are *per se* significant without considering any other indiscretions. The DEIR/EIS failed to identify this significant impact, which must be mitigated.

CURE-Fox-69

When indirect NOx emissions from power production are added (1152 lb/day), as discussed above, total NOx emissions increase from 26.66 lb/day to 1,179 lb/day, which exceeds the non-ozone attainment NOx significance thresholds of attainment air districts (25 lb/day to 250 lb/day) by a huge amount for all air districts that have

CURE-Fox-70

[71] MBUAPCD 2006, p. 5-3.

[72] MBUAPCD 2006, p. 5-5 ("Projects which would emit 137 pounds per day or more of direct and indirect VOC emissions would have a significant impact on regional air quality by emitting substantial amounts of ozone precursors." NOx is indirect ozone.)

[73] DEIR/EIS, Table 4.10-7.

established NOx significance thresholds for operational emissions and are attainment for ozone. Thus, NOx emissions from power production, when evaluated for impacts other than ozone formation are significant under the NOx significance thresholds established by other air districts. The DEIR/EIS must disclose and analyze this significant impact.

CURE-Fox-70 cont.

II. HEALTH RISKS

The DEIR/EIS evaluated health risks of Project construction for diesel particulate matter (DPM) at two sites, the Carmel Valley Pump Station and ASR Injection/Extraction Wells.[74] This analysis concluded that cancer and chronic health risks are less than significant.[75] However, there are many problems with the DEIR/EIS's analysis, which when corrected, would result in a significant health impact. Further, the HRA analysis is unsupported, incomplete, and failed to include acute impacts.

CURE-Fox-71

A. All Sensitive Receptors Were Not Evaluated

The DEIR/EIS only evaluated the Carmel Valley Pump Station and the ASR Injection/Extraction well site. However, there are other facilities that are near sensitive receptors that were excluded from the HRA, including:

CURE-Fox-72

- Wells ASR-5 and ASR-6 would be constructed within 50 feet of existing residences.[76]

- "The ASR Conveyance Pipeline, ASR Recirculation Pipeline, and the ASR Pump-to-Waste Pipeline would be within 250 feet of Seaside Middle School, and within 50 to 100 feet of residences in the Fitch Park military housing area along Hatten Road and Ardennes Circle."[77]

CURE-Fox-73

B. The DEIR/EIS Did Not Follow OEHHA Guidelines, Substantially Underestimating Health Risk

The OEHHA's guidelines for preparation of health risk assessments, adopted in March 2015, explain that for short-term projects, such as construction of various components of the Project:

CURE-Fox-74

[74] DEIR/EIS, p. 4.10-27/29; Appendix G1.4.1.

[75] DEIR/EIS, Table 4.10-6; Appendix G1.4.1.

[76] DEIR/EIS, pp. 4.10-7 and 4.8-11.

[77] DEIR/EIS, p. 4.10-7.

"We recommend that exposure from projects longer than 2 months but less than 6 months be assumed to last 6 months (e.g., a 2-month project would be evaluated as if it lasted 6 months). Exposure from projects lasting more than 6 months should be evaluated for the duration of the project
….

Finally, the risk manager may want to consider a lower cancer risk threshold for risk management for very short-term projects…There is a valid scientific concern that the rate of exposure may influence the risk – in other words, a higher exposure to a carcinogen over a short period of time may be a greater risk than the same total exposure spread over a much longer time period. In addition, it is inappropriate from a public health perspective to allow a lifetime acceptable risk to accrue in a short period of time (e.g., a very high exposure to a carcinogen over a short period of time resulting in a 1 x 10^{-5} cancer risk). Thus, consideration should be given for very short term projects to using a lower cancer risk trigger for permitting decisions."[78]

CURE-Fox-74 cont.

The DEIR/EIS's analysis only evaluated risk for exposures of 0.25 years or 3 months after birth.[79] If the 3 months post-birth is increased to 6 months[80] per OEHHA guidance, the cancer risk increases from 5.2 in a million to 10 in a million, which is per se significant.

CURE-Fox-75

Further, the DEIR/EIS used the significance threshold for a lifetime exposure, which dilutes the risk when it is received over a very short period of time, as here. Babies exposed during the construction period would receive a lifetime dose of diesel exhaust in a 3 month period. This requires a lower significance threshold than the 10 in one million used in the DEIR/EIS for a 70 year exposure.

CURE-Fox-76

Historically, the significance threshold for cancer risk has been one in a million and still is for criteria set elsewhere, including Clean Water Act 304(a), Safe Drinking Water Act, and the National Toxics Rule.[81] The short-term cancer risks

[80] Excel Spreadsheet G1.4.1 Health Risk Assessment Calculations, tab "HRA Calcs", change cell E21 from 0.25 to 0.5. This increases the cancer risk from 5.2 per million to 10 per million.

[81] Cheryl Niemi, "Acceptable" Risk Levels for Carcinogens: Their History, Current Use, and How They Affect Surface Water Quality Criteria, Policy Forum #3, Human Health Criteria and Implementation Tools Rule-Makings, February 8, 2013; Available at: http://www.tmw-law.com/news-pdf/SWQSPolicyForumRiskLevel%2002-08-213.pdf.

estimated in the HRA are 5.2 to 6.4 in one million.[82] If the one in a million threshold were used to evaluate Project health impacts, these risk levels would be highly significant. Alternatively, if one assumes the risk is evenly spread out over a 70 year lifetime, the significant cancer risk threshold for a one-year-old would be 0.1 in one million. Under either scenario, cancer risk from diesel exhaust alone would be highly significant and unmitigated. This is a significant impact not disclosed in the DEIR/EIS. This impact could be and should be mitigated by requiring diesel particulate traps on all diesel fueled equipment.

CURE-Fox-77 cont.

C. All Hazardous Pollutants Were Not Included in the HRA

The HRA only evaluated diesel exhaust, which is emitted from construction equipment and on-road vehicles. As noted in Comment I.C, the VOCs present in ROG, before it is converted into ozone, include volatile organic compounds that are additionally hazardous to human health. The HRA only evaluated DPM and failed to evaluate the health impacts from toxic air pollutants subsumed in ROG that are not converted to ozone when they reach sensitive receptors. These include acutely and chronically toxic chemicals such as toluene, xylene, ethylbenzene, and 1,3 butadiene and carcinogens such as benzene, formaldehyde, acrolein, and acetaldehyde.

CURE-Fox-78

The conversion of ROG to ozone is a slow process, so nearby receptors would initially be exposed to unconverted VOCs. These should be included in the HRA, which as it standard, underestimates health impacts and further fails to evaluate acute health impacts.

III. VALLEY FEVER

Valley Fever, or *Coccidioidomycosis* (Cocci), is an infectious disease caused by inhaling the spores of *Coccidioides ssp. (*"Cocci spores"*)*[83], a soil-dwelling fungus. The fungus lives in the top 2 to 12 inches of soil. When soil containing this fungus is disturbed by activities such as digging, vehicles, construction activities, agricultural operations, dust storms, or during earthquakes, the fungal spores become air borne, exposing sensitive receptors. The Valley Fever fungal spores are too small to be seen by the naked eye, and there is no reliable way to test the soil for spores before working in a particular area.[84] The disease is endemic (native and

CURE-Fox-79

[82] DEIR/EIS, Table 4.10-6.

[83] Two species of *Coccidioides* are known to cause Valley Fever: *C. immitis*, which is typically found in California, and *C. posadasii*, which is typically found outside California. *See* Center for Disease Control, Coccidioidomycosis (Valley Fever), Information for Health Professionals; Available at: https://www.cdc.gov/fungal/diseases/coccidioidomycosis/health-professionals.html.

common, regularly found in a particular area) in the semiarid regions of the southwestern United States.[85] As there is no reliable test, presence is assessed based on the known occurrence of the disease in a particular area. Valley Fever is endemic to Monterey County where the Project will be constructed.[86]

Monterey County, including the Project site, is located within the established endemic range of Valley Fever, as shown in Figure 1 below, with one of the highest infection rates in California. The disease has become an increasing concern for Monterey County Health Department.[87] In 2013, there were 70 new cases of Valley Fever reported among Monterey County residents. The rate of new cases in 2013 was 15.7 cases per 100,000 individuals, well above the California statewide rate of 10.8 in 2012. Between 2009 and 2011, there were 145 hospital admissions in Monterey County, costing over $32 million. Forty one percent of these cases occurred in the north county area, which includes most of the project facilities. [88] There were 7 fatal cases in Monterey County between 2011 and 2013.[89] In recent years, reported Valley Fever cases in the southwestern United States have increased dramatically.[90]

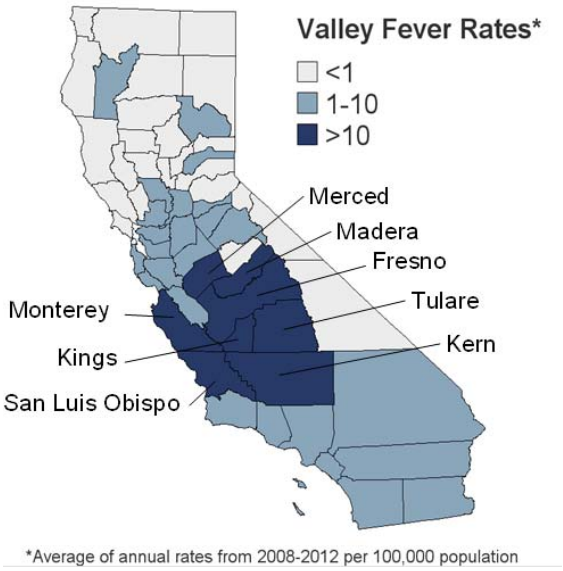

Figure 1. Endemic Areas for Valley Fever in California.[91]

Typical symptoms of Valley Fever include fatigue, fever, cough, headache, shortness of breath, rash, muscle aches, and joint pain. Symptoms of advanced Valley Fever include chronic pneumonia, meningitis, skin lesions, and bone or joint infections. The most common clinical presentation of Valley Fever is a self-limited acute or subacute community-acquired pneumonia that becomes evident 13 weeks after infection.[92] No vaccine or known cure exists for the disease.[93] Between 1990 and 2008, more than 3,000 people have died in the United States from Valley Fever with about half in California.[94]

The disease debilitates the population and thus prevents them from working.[95] The longest period of disability from occupational exposure in California is to construction workers, with 62% of the reported cases resulting in over 60 days of lost work.[96] Another study estimated the average hospital stay for each (non-construction work) case of Coccidioidomycosis at 35 days.[97]

CURE-Fox-80 cont.

In spite of this evidence, which I presented in my 2015 comments, incorporated here by reference, the DEIR/EIS dismisses the risk of Valley Fever to Project workers and nearby sensitive receptors by making two irrelevant arguments, discussed below.

A. The DEIR/EIS Fails To Identify Significant Health Impacts Due to Valley Fever

1. The DEIR/EIS Misrepresents Status Quo

First, the DEIR/EIS argues that cases of Valley Fever dropped substantially in 2014 (19 cases) compared to 2011-2013 (68-73 cases),[98] implying that Valley Fever is declining and thus not a concern. However, the Monterey County Health Department reported 73 confirmed cases in 2016, up more than 50% from 2015[99] and consistent with the 2011 to 2013 cases reported in the DEIR/EIS.[100] The decline in 2014 was an anomaly.[101] It is duplicitous for the CPUC to assert Valley Fever is declining based on an anomaly.

2. Valley Fever Impacts Are Significant

The DEIR/EIS argues that "much of the population of Monterey County has already been exposed to Valley Fever and would continue to be exposed because of the various earthmoving activities that have historically occurred and continue to occur as a result of agricultural and construction activities throughout the region. As a result of the endemic nature of the disease and the number of earthmoving activities in the County (e.g., grading and excavation for agriculture, as well as new residential, commercial, and industrial development and surface mining operations), there are new cases of Valley Fever documented in the County each year, however, many people who are exposed do not develop symptoms."[102] The DEIR/EIS then concludes, without conducting any analysis whatsoever, that[103]:

> Valley Fever-related impacts associated with the project would not be considered significant because ongoing ground-disturbing activities in the County currently represent a continual source of spores that contribute to the low number of Valley Fever cases reported each year. Construction activities associated with the project would result in similar localized ground disturbing activities to those that occur continually within the County and the project would not result in a substantial increase in spore release. Therefore, construction of the project would not represent an increased risk to public health. In addition, implementation of Mitigation Measure 4.10-1c (see above), which requires implementation of fugitive dust control measures, would ensure that fugitive dust that could contain coccidioides immitis spores would be controlled to the maximum extent feasible. Valley Fever-related impacts would be less than significant.

CURE-Fox-82

These assertions are inconsistent with CEQA, unsupported, and incorrect.

CEQA requires that impacts be evaluated relative to the baseline present at the time environmental review commenced. While some residents of Monterey County may have been exposed to Cocci spores as they live adjacent to agricultural fields or a construction site, this does not mean that an increase in the number spores due to Project construction would not result in an increase in Valley Fever cases. Even assuming, *arguendo*, that this line of argument is valid, the record contains no evidence that all residents downwind of Project construction and all construction workers who would build the Project have in fact been exposed to Cocci spores in sufficient amounts to assure immunity.

It is common, for example, to import construction workers when local skills are not available or cheaper wages can be gained by using out-of-state employees. The request for proposal for the slant wells, for example, requires that the Contractor "must make a good faith effort to employ qualified individuals who are, and have been for at least one year out of the three years prior to the opening of

[102] DEIR/EIS, p. 4.10-28.

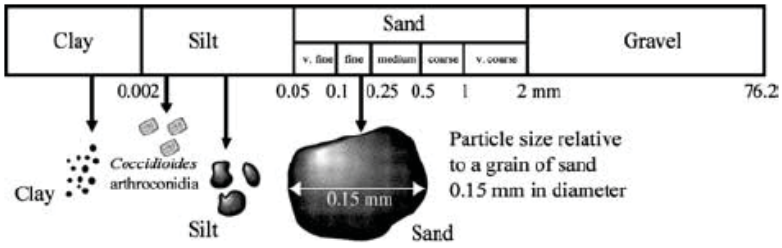
[103] DEIR/EIS, p. 4.10-28.

proposals, residents of Monterey County, San Benito County, or Santa Cruz County in sufficient numbers to achieve a goal of at least fifty percent of the Contractor's total construction work force, including any subcontractor work force."[104] The same condition is found in the RFP for the conveyance facilities.[105] Thus, it is duplicitous to suggest that all potentially exposed parties have already been exposed in Monterey County, which is a highly unlikely scenario.

Residents of the area also have been exposed to existing levels of PM10 and PM2.5, but the DEIR/EIS still evaluated the significance of an increase in PM10 and PM2.5 emissions relative to the baseline. The argument that County residents have been exposed to Cocci spores (a component of PM10, or PM2.5) (Figure 2) is simply a statement of the baseline or the status quo.

CURE-Fox-82 cont.

Figure 2. Size of cocci spores compared to soil particles (in mm)[106]



Valley Fever is contracted only by inhalation of Cocci spores, which are only inhaled when they become air borne, as during earth moving during construction of the Project, which increases PM10, PM2.5 and associated Cocci spores. If Cocci spores are present in the disturbed soil, which is highly likely given the Project location in an endemic area, they would increase in proportion to PM10 and PM2.5 emissions due to earth moving activities. Further, the fact that resident have been and are currently "exposed" to Cocci spores does not imply, nor can it guarantee, immunity to Valley Fever from increased exposure.

CURE-Fox-83

Digging, grading, trenching, and other earth disturbing activities will occur during construction of all Project's components over the 24 month construction period,[107] which will increase PM10, PM2.5 and associated Cocci spores, relative to

the CEQA baseline. These activities will disturb a significant amount of soil, including:

- slant wells (9 acres)[108];
- desalination plant (25 acres);[109]
- source water pipeline construction (16.4 acres);[110]
- desalinated water supply pipeline (35.4 acres);[111]
- Castroville pipeline (15 – 16 acres);[112]
- brine discharge pipeline/pipeline to CSIP Pond alignments (6.6 acres);[113]
- ASR pipelines (8.8 acres);[114]
- ASR 5/6 water retention depression (7.0 acres);[115]
- ASR wells (0.9 acres);[116]
- new transmission main (27.1 acres);[117]
- Ryan Ranch-Bishop Interconnection improvements (7.3 acres);[118]
- Terminal Reservoir (6-6.7 acres);[119] and
- Pump stations (>7 acres).[120]

In total, Project construction would disturb over 173 acres of endemic land, likely to contain Cocci spores. Additional intimate contact with soil would occur during spoils management and disposal and during periodic maintenance of the

[120] 2015 DEIR/EIS, p. 3-48.

slant wells, which would disturb roughly 6 acres every five years.[121] Thus, construction workers as well as maintenance workers during Project operation are at considerable risk of catching Valley Fever. This is a significant construction impact that was not identified in the DEIR/EIS. Further, many of the construction sites are very close to sensitive receptors, within 50 to 300 feet of residential areas, military housing, and schools, placing residents at risk.[122]

CURE-Fox-84 cont.

CURE-Fox-85

Further, the potentially exposed population is much larger than construction workers because the very small spores – 0.002-0.005 millimeters ("mm") – do not settle out as rapidly as other components of particulate matter and thus would be carried further, potentially into non-endemic areas, where they would expose large populations that may not have been previously exposed.[123,124] Valley Fever spores have been documented to travel as much as 500 miles[125] and, thus, dust raised during construction could potentially expose a large number of people hundreds of miles away, outside of endemic areas.

CURE-Fox-86

Further, there is no evidence that prior exposure to Cocci spores confers immunity, which is what the DEIR/EIS is arguing. *First*, this argument is fundamentally flawed because there is no "immunity" to Valley Fever. As explained by the Valley Fever Patient Advocacy Organization, "Once a person is infected with Valley Fever an immune resistance takes effect in the body, but this does not mean "immunity" in the sense that a person could never suffer from the disease again. Not only have reactivations occurred in many cases, but it has been proven that even "immune" hosts can suffer a severe case of Cocci if they inhale enough additional spores."[126] Thus, even if everyone in Monterey County has been exposed to Cocci spores, this does not mean that an increase in the number of Cocci spores due to Project construction would not result in new cases of Valley Fever, or that construction workers from a non-endemic area brought into the area to construct the Project would not catch Valley Fever.

[126] Valley Fever Survivor, Frequently Asked Question; Available at: http://www.valleyfeversurvivor.com/faq.html.

In fact, dust exposure, which occurs during construction, is one of the primary risk factors for contacting Valley Fever.[127] Specific occupations and outdoor activities associated with dust generation such as construction, farming, road work, military training, gardening, hiking, camping, bicycling, or fossil collecting increase the risk of exposure and infection compared to baseline exposure to individuals who do not engage in these activities.[128]

CURE-Fox-88

It is well known that the most at-risk populations are construction and agricultural workers,[129] the former being the very population that would be directly exposed by the Project. The Monterey County Health Department notes: "Workers who disturb the soil by digging, operating earth-moving equipment, driving vehicles, or working in dusty, wind-blown areas are more likely to breathe in the fungal spores and become infected."[130]

Similarly, a refereed journal article on occupational exposures notes that "[l]abor groups where occupation involves close contact with the soil are at greater risk, especially if the work involves dusty digging operations."[131] One study reported that at study sites, "generally 50% of the individuals who were exposed to the dust or were excavating dirt at the sites were infected."[132] The California Department of Public Health cites this as a typical example:

CURE-Fox-89

> "In October 2007, a construction crew excavated a trench for a new water pipe. Within three weeks, 10 of 12 crew members developed coccidioidomycosis (Valley Fever), an illness with pneumonia and flu-

[132] Fisher et al., 2007.

like symptoms. Seven of the 10 had rashes, and one had an infection that had spread beyond his lungs and affected his skin. Over the next few months, the 10 ill crew members missed at least 1660 hours of work and two workers were on disability for at least five months."[133]

Thus, the "potential" existing "background" exposure of the general population to Cocci spores is not a guarantee that Project construction workers, who are in intimate contact with soil in a Valley Fever endemic area, and many of whom may be from elsewhere or may have never worked in an endemic area, would not experience an increase in Valley Fever cases, relative to the baseline. The DEIR/EIS's assertions as to background exposures in Monterey Count is merely the statement of the baseline conditions. In fact, construction workers are in direct contact with soil and will inhale greater than baseline amounts of Cocci spores if construction occurs in an endemic area. Cocci spores are a component of PM10/PM2.5. Thus, it is indisputable that construction of the Project will increase not only PM10/PM2.5 but also Cocci spores.

CURE-Fox-89 cont.

[133] CDPH June 2013, p. 1.

B. The DEIR/EIS Fails to Mitigate Significant Valley Fever Health Risks

The DEIR/EIS asserts that Mitigation Measure 4.10-1c, a conventional construction fugitive dust mitigation measure[134], would contain *Coccidioides immitis* spores to the maximum extent feasible, resulting in a less than significant impact.[135] It is well known that conventional dust control measures that are included in the mitigation measures for the Project are not effective at controlling Valley Fever[136] as they largely focus on visible dust or larger dust particles, the PM10 fraction, not the fine particles where the Valley Fever spores are found. The DEIR/EIS does not contain any mitigation whatsoever for the very fine fraction of particulate matter, PM2.5, as the air quality analysis concluded this impact was not significant, without considering the fact that it harbors Cocci spores. CURE-Fox-90

While dust exposure is one of the primary risk factors for contacting Cocci spores and dust-control measures are an important defense against infection, it is important to note that PM10 and visible dust are only indicators that Cocci spores may be airborne in a given area. Freshly generated dust clouds usually contain a larger proportion of the more visible coarse particles. However, these larger particles settle more rapidly and the remaining fine respirable particles may be difficult to see and are not controlled by conventional dust control measures. CURE-Fox-91

Spores of *Coccidioides ssp.* have slow settling rates in air due to their small size (2 to 5 micrometers), low terminal velocity, and possibly also due to their buoyancy, barrel shape and commonly attached empty hyphae cell fragments.[137] Thus spores, whose size is well below the limits of human vision, may be present in air that appears relatively clear and dust free. Such ambient, airborne spores with their low settling rates can remain aloft for long periods and be carried hundreds of kilometers from their point of origin. Thus, implementation of conventional dust control measures will not provide sufficient protection for both on-site workers and the general public. CURE-Fox-92

Further, infections by *Coccidioides ssp.* frequently have a seasonal pattern with infection rates that generally spike in the first few weeks of hot dry weather that follow extended milder rainy periods. In California, infection rates are CURE-Fox-93

[135] DEIR/EIS, p. 4.10-28.

[136] *See, e.g.*, Cummings and others, 2010, p. 509; Schneider et al., 1997, p. 908 ("Primary prevention strategies (*e.g.*, dust-control measures) for coccidioidomycosis in endemic areas have limited effectiveness.").

[137] Frederick S. Fisher, Mark W. Bultman, and Demosthenes Pappagianis, Operational Guidelines (version 1.0) for Geological Fieldwork in Areas Endemic for Coccidioidomycosis (Valley Fever), U.S. Geological Survey Open-File Report 00-348, 2000; Available at: https://pubs.usgs.gov/of/2000/0348/pdf/of00-348.pdf.

generally higher during the hot summer months especially if weather patterns bring the usual winter rains between November and April.[138] The majority of cases of Valley Fever accordingly occur during the months of June through December, when 16 of the 24 months of construction would occur. Typically, the risk of catching Valley Fever begins to increase in June and continues an upward trend until it peaks during the months of August, September and October.[139] The majority of the construction will occur during these dry summer months.[140]

CURE-Fox-93 cont.

Drought periods can have an especially potent impact on Valley Fever if they follow periods of rain.[141] It is thought that during drought years the number of organisms competing with *Coccidioides ssp.* decreases and the fungus remains alive but dormant. When rain finally occurs, the arthroconidia germinate and multiply more than usual because of a decreased number of other competing organisms. When the soil dries out in the summer and fall, the spores can become airborne and potentially infectious.[142] The anticipated end of the current drought conditions in California coincides with the start of construction and may well have created ideal conditions for a uptick in Valley Fever cases.

CURE-Fox-94

C. Recommended Mitigation Measures to Reduce Risk of Valley Fever

In response to an outbreak of Valley Fever in construction workers in 2007 at a construction site for a solar facility within San Luis Obispo County, its Public Health Department in conjunction with the California Department of Public Health developed recommendations to limit exposure to Valley Fever based on scientific information from the published literature.[143] The recommended measures go far beyond the conventional dust control measures recommended in the DEIR/EIS to control PM10 emissions. They include the following measures that are not required in the DEIR/EIS to mitigate PM10 emissions from the Project:

[143] San Luis Obispo County Health Agency, Recommendations for Workers to Prevent Infection by Valley Fever in SLO County; Available at: http://www.slocounty.ca.gov/Assets/PH/Epidemiology/Cocci+Recomendations.pdf.

1. *Implement comprehensive Injury and Illness Prevention Program (required by Title 8, Section 3203) ensuring safeguards to prevent Valley Fever are included.*
2. *Work with a medical professional with expertise in cocci to develop a training program for all employees discussing the following issues: potential presence of C. immites in soils; the risks involved with inhaling spores; how to recognize common symptoms (which resemble common viral infections, and may include fatigue, cough, chest pain, fever, rash, headache, and body and joint ache); requesting prompt reporting of suspected symptoms to a supervisor and health care provider; discussing worker entitlement to receive prompt medical care if they suspect symptoms of work-related Valley Fever; and requesting the use of personal protection measures as outlined below.*
3. *Control exposure to dust:*
   - Consult with local Air Pollution Control District Compliance Assistance programs and with California Occupational Safety and Health Administration ("Cal/OSHA") compliance program regarding meeting the requirements of dust control plans and for specific methods of dust control.
   - Continuously wet the soil before and while digging or moving the earth. Landing zones for helicopters and areas where bulldozers, graders, or skid steers operate are examples where wetting the soil is necessary.
   - Wetting methods should use processes that do not raise dust or adversely affect the construction process.
   - Provide high-efficiency particulate ("HEP")-filtered, air-conditioned enclosed cabs on heavy equipment. Train workers on proper use of cabs, such as turning on air conditioning prior to using the equipment and keeping windows closed.
   - Provide communication methods, such as 2-way radios, for use in enclosed cabs.
   - When exposure to dust is unavoidable, use National Institute for Occupational Safety and Health ("NIOSH")-approved respirators rated as N95, N99, N100, P100, or HEPA. Respirators must be used within a Cal/OSHA compliant respiratory protection program that covers all respirator wearers and includes medical clearance to wear a respirator, fit testing, training, and procedures for cleaning and maintaining respirators.
   - Employees should be medically evaluated, fit-tested, and properly trained on the use of the respirators, and a full

CURE-Fox-95 cont.

respiratory protection program in accordance with the applicable Cal/OSHA Respiratory Protection Standard (8 CCR 5144) should be in place.[144]

- Prohibit eating and smoking at the worksite, and provide separate, clean eating areas with hand-washing facilities.
- Promptly secure graded areas using seeding, soil binders or paving and by laying building pads as soon after grading as possible.
- When digging a trench or fire line or performing other soil-disturbing tasks, position workers upwind when possible.
- Place overnight camps, especially sleeping quarters and dining halls, away from sources of dust such as roadways.
- Stop outdoor construction operations during unusually windy conditions or in dust storms.
- Minimize the amount of digging by hand. Instead, use heavy equipment with operator in an enclosed, air-conditioned, HEP-filtered cab.
- Consider limiting outdoor construction during the fall to essential jobs only, as the risk of cocci infection is higher during this season.

CURE-Fox-95 cont.

4. *Prevent transport of cocci outside endemic areas:*
   - Thoroughly clean equipment, vehicles, and other items before they are moved off-site to other work locations.
   - Provide workers with coveralls daily, lockers (or other system for keeping work and street clothing and shoes separate), daily changing and showering facilities.
   - Keep street clothes and work clothes separate by providing separate lockers or other storage areas.
   - Clothing should be changed after work every day, preferably at the work site.
   - Encourage workers to shower and wash their hair at the workplace or as soon as they get home if no on-site facilities are available.

[144] Short-term skin tests that produce results within 48 hours are now available. See Nick VinZant, New Skin Test for Valley Fever Produces Results within 48 Hours, April 15, 2015, Available at: http://www.abc15.com/news/region-west-valley/sun-city/new-skin-test-for-valley-fever-produces-results-within-48-hours.

- Train workers to recognize that cocci may be transported offsite on contaminated equipment, clothing, and shoes; alternatively, consider installing boot-washing.
- Train workers to recognize symptoms and ways to minimize exposure.
- Post warnings onsite and consider limiting access to visitors, especially those without adequate training and respiratory protection.

5. *Improve medical surveillance for employees*
   - Employees should have prompt access to medical care, including suspected work-related illnesses and injuries.
   - Work with a medical professional to develop a protocol to medically evaluate employees who have symptoms of Valley Fever.
   - Consider preferentially contracting with 1-2 clinics in the area and communicate with the health care providers in those clinics to ensure that providers are aware that Valley Fever has been reported in the area. This will increase the likelihood that ill workers will receive prompt, proper and consistent medical care.
   - Respirator clearance should include medical evaluation for all new employees, annual re-evaluation for changes in medical status, and annual training, and fit-testing.
   - Skin testing is not recommended for evaluation of Valley Fever.
   - If an employee is diagnosed with Valley Fever, a physician must determine if the employee should be taken off work, when they may return to work, and what type of work activities they may perform.

CURE-Fox-95 cont.

Two other studies have developed complementary recommendations to minimize the incidence of Valley Fever. The U.S. Geological Survey ("USGS") has developed recommendations to protect geological field workers in endemic areas.[145] An occupational study of Valley Fever in California workers also developed recommendations to protect those working and living in endemic areas.[146] These two sources identified the following measures, in addition to those identified by the San Luis Obispo County Public Health Department, to minimize the exposure to Valley Fever:

[145] Fisher et al. 2000.

[146] Schmelzer and Tabershaw, 1968, pp. 111 - 113.

- Evaluate soils to determine if each work location is within an endemic area.
- Implement a vigorous program of medical surveillance.
- Implement aggressive enforcement of respiratory use where exposures from manual digging are involved.
- Test all potential employees for previous infection to identify the immune population and assign immune workers to operations involving known heavy exposures.
- Hire resident labor whenever available, particularly for heavy dust exposure work.
- All workers in endemic areas should use dust masks to protect against inhalation of particles as small as 0.4 microns. Mustaches or beards may prevent a mask from making an airtight seal against the fact and thus should be discouraged.
- Establish a medical program, including skin tests on all new employees, retesting of susceptibles, prompt treatment of respiratory illness in susceptibles; periodic medical examination or interview to discover a history of low grade or subclinical infection, including repeated skin testing of susceptible.

CURE-Fox-95 cont.

In addition to these generic measures that apply to all construction projects that disturb soil, others are feasible that specifically address Project components. For example, construction will generate 25,110 cubic yards of excess spoils and construction debris. The majority of this earthmoving is from pipeline construction, contributing 96% of total excess debris[147] and thus is a potential major source of exposure to Cocci spores. Further, sensitive receptors are 100 to 250 feet away from many pipeline construction sites.[148] Most of the pipeline s will be installed using conventional open-trench technology, except where these methods are not feasible. Where not feasible, trenchless methods would be used.[149]

CURE-Fox-96

However, trenchless methods are feasible for most all pipelines. These methods are preferable as they do not generate as much fugitive dust. These include jack-and-bore, drill-and-burst, horizontal directional drilling, and/or microtunnelling.[150] These alternate methods should be used to minimize fugitive dust and the release of Cocci spores. The applicant should evaluate each Project component to determine whether modifications in construction methods can be

[147] DEIR/EIS, Table 3-5.

[148] DEIR/EIS, p. 4.10-7.

[149] DEIR/EIS, Section 3.3.4.2.

[150] DEIR/EIS, p. 3-52.

implemented to minimize the amount of soil that will be disturbed and released into the atmosphere. CURE-Fox-96 cont.

The DEIR/EIS's PM10 control measures do not include the above listed measures specifically developed by regulatory agencies to control Valley Fever. Some similar measures are required in the DEIR/EIS to mitigate PM10 impacts, but they do not go far enough to control Valley Fever. Some examples follow. CURE-Fox-97

Mitigation Measures 4.10-1c (#1, #7) require that all active construction areas and stockpiles be watered at least twice daily. Mitigation Measure 4.10-1c (#3) requires the application of water three times daily on unpaved access roads, parking area, and staging areas.[151] The CDPH, on the other hand, recommends for Valley Fever control, that "[w]hen soil will be disturbed by heavy equipment or vehicles, wet the soil before disturbing it and continuously wet it while digging to keep dust levels down."[152] The watering trucks themselves used in twice daily watering generate fugitive dust, which is not addressed by the DEIR/EIS's measure, but is addressed by CDPH by requiring the use of wetting methods that do not raise dust. CURE-Fox-98

Mitigation Measure 4.10-1a (#4, #5) requires daily sweeping, which generates fugitive dust that may contain spores.[153] CURE-Fox-99

Mitigation Measure 4.10-1a (#6) only requires hydroseeding or use of soil stabilizers in inactive construction areas (defined as previously graded areas that are inactive for 10 days or more) while CDPH's Valley Fever controls require "prompt" securing of graded areas.[154] CURE-Fox-100

Mitigation Measure 4.10-1a (#11) only requires wheel washers on trucks[155] while CDPH Valley Fever control requires "[t]horoughly clean equipment, vehicles, and other items before they are moved off-site to other work locations."[156] CURE-Fox-101

In addition, major onsite and offsite soil-disturbing construction activities should be timed to occur outside of any prolonged dry period, when Cocci spores are most abundant. After soil-disturbing activities conclude, all disturbed soils should be sufficiently stabilized to prevent air-borne dispersal of Cocci spores. CURE-Fox-102

[151] DEIR/EIS, p. 4.10-25.

[152] CDPH June 2013, p. 4.

[153] DEIR/EIS, p. 4.10-25.

[154] DEIR/EIS, p. 4.10-25.

[155] DEIR/EIS, p. 4.10-25.

[156] DEIR/EIS, p. 4.10-25.

In sum, the PM10 mitigation measures in the DEIR/EIS are not adequate to control Valley Fever or even PM10, as explained above. Projects that have implemented conventional PM10 dust control measures, such as those proposed here, have experienced several incidences of severe dust storms and reported cases of Valley Fever.

For example, construction of First Solar's Antelope Valley Solar Ranch One ("AVSR1") was officially halted in April 2013 due to the company's failure to bring the facility into compliance with ambient air quality standards, despite dust control measures similar to those proposed here. A dust storm in Antelope Valley on April 8, 2013 was so severe that it resulted in multiple car pileups in the sparsely populated region, as well as closure of the Antelope Valley Freeway. The company was issued four violations by the Antelope Valley Air Quality Management District. Dust from the project led to complaints of respiratory distress by local residents and a concern of Valley Fever. [157]

CURE-Fox-103

At two photovoltaic solar energy projects in San Luis Obispo County, Topaz Solar Farm and California Valley Solar Ranch, 28 construction workers contracted Valley Fever. One man was digging into the ground and inhaled dust and subsequently became ill. A blood test confirmed Valley Fever.[158]

CURE-Fox-104

All of the above health-protective measures recommended by the San Luis Obispo County Public Health Department and the California Department of Public Health are feasible for the Project and must be required in an enhanced dust control plan to reduce the risk to construction workers, on-site employees and the public of contacting Valley Fever. Many of these measures have been required by the County of Monterey in other EIRs.[159] Even if all of the above measures are adopted, a recirculated DEIR/EIS is required to analyze whether these measures are adequate to reduce this significant impact to a level below significance.

IV. GREENHOUSE GAS (GHG) EMISSIONS

The DEIR/EIS concluded that greenhouse gas (GHG) emissions from construction and operation of the Project are significant.[160] Thus, it imposed Mitigation Measure 4.11-1 for Project GHG emissions and Mitigation Measure 4.18-1 for construction GHG emissions.[161] The DEIR/EIS concludes that GHG emissions remain significant and unmitigated after compliance with these measures as "it is not possible to substantiate numerically that the mitigated GHG emissions would be reduced to a less-than- significant level."[162] CURE-Fox-106

The DEIR/EIS failed to substantiate that its GHG emissions cannot be reduced to an insignificant level and failed to include all feasible mitigation measures.

A. The DEIR/EIS Failed to Adequately Explain Why the Project's GHG Impacts Are Significant and Unavoidable

The DEIR/EIS jumps to the conclusion that GHG impacts are significant and unavoidable because "it is not possible to substantiate numerically that the mitigated GHG emissions would be reduced to a less-than- significant level."[163] The only reason the CPUC cannot substantiate mitigated emissions numerically is because it has improperly deferred identification of mitigation measures to a future plan, as discussed below.[164] Other applicants and lead agencies have succeeded in quantifying GHG emission reductions.[165] CURE-Fox-107

The DEIR/EIS must explain "why" the impact is significant and unavoidable. See *Keep Berkeley Jets Over the Bay Com. v. Board of Port Comrs.* (2001) which concluded: "simply labeling the impact "significant" without accompanying analysis" violates "the environmental assessment requirement of CEQA." Before the DEIR/EIS can make the "significant and unavoidable" finding, it must specifically identify the GHG mitigation measures and estimate the reduction in GHG achieved CURE-Fox-108

by each. Further, it must explain how the Project is or is not consistent with the State's energy and climate objectives.

CURE-Fox-108 cont.

B. The Proposed GHG Mitigation Measures Are Inadequate

The DEIR/EIS concluded that greenhouse gas (GHG) emissions from construction and operation of the Project (8,370 MT/yr)[166] are significant. Thus, it imposed Mitigation Measure 4.11-1 for Project GHG emissions and Mitigation Measure 4.18-1 for construction GHG emissions.[167] These mitigation measures are fundamentally flawed as they are unenforceable, ambiguous, and do not include all feasible mitigation that would allow impacts to reduced to a less than significant level.

CURE-Fox-109

1. Mitigation Measure 4.11-1: GHG Emission Reductions

This measure requires CalAm to do two things. First, it must prepare a "GHG Emissions Reduction Plan" and submit it to the CPUC for approval prior to start of construction. The Plan "shall include a commitment by CalAm to incorporate all available feasible energy recovery and conservation technologies…" Second, CalAm "shall make good faith efforts to ensure that at least 20 percent of the approved project's operational energy use requirements are achieved with "clean" renewable energy…"[168] This is not adequate mitigation under CEQA.

First, a "good faith effort" to use renewable energy to meet only 20% of the Project's operational energy demand is not adequate CEQA mitigation. The DEIR/EIS concluded the increase in GHG emissions was a significant and unavoidable impact, which requires all feasible mitigation under CEQA. The use of 100% renewable energy to meet the Project's demand of 51,698 MWh/yr[169] is feasible. The CPUC has procedures that would allow CalAm to pay to allow PG&E or other providers to build renewable generation to meet 100%of the Project's operational electricity demand as well as the increase in GHG emissions due to construction. The new renewable facilities would be dedicated to the Project, and any excess electricity could be sold, offsetting costs.

CURE-Fox-110

The GHG-free electricity generation required to offset the GHG emissions associated with the Project's electricity use and construction emissions would not have to be occur simultaneously with the emissions it would displace, since GHG emissions are a multi-year problem. Rather, the Applicant could procure

CURE-Fox-111

[166] DEIR/EIS, Table 4.11-5.

[167] DEIR/EIS, pp. 4.11-19/20.

[168] DEIR/EIS, p. 4.11-20.

[169] DEIR/EIS, p. 4.11-16.

incremental renewable generation sufficient to offset the annual GHG emissions that will result from its construction and operation, without regard to the intra-year timing of when that incremental generation would operate. The important point is that, in order to count as mitigation for the Project, the mitigation generation would have to be incremental generation that did not already exist and would not have been built but for its procurement by the Project.

The CPUC has previously addressed how to ensure that renewable generation that is dedicated to particular customers is indeed incremental. See D.15-01-051 creating a Green Tariff Shared Renewables (GTSR) program[170], a program which might be one way for the Project to procure the 100% renewables proposed here as mitigation (D.15-01-051 authorized up to 207 MW of unreserved new renewable capacity for PG&E customers (D.15-01-051, Table 1); 51,698 MWh/year corresponds to the output of approximately 25 MW of solar PV capacity).

CURE-Fox-111 cont.

Second, preparation of the Emissions Reduction Plan is deferred until after Project approval, pre-empting public review. The Plan must be prepared as part of the DEIR/EIS and circulated for public review. Otherwise, the public does not have an opportunity to evaluate the effectiveness of the GHG reduction measures.

CURE-Fox-112

Third, under CEQA, an EIR must not only discuss measures to avoid or minimize adverse impacts, it also must ensure that mitigation measures are fully enforceable through permit conditions, agreements, or other legally binding instruments.[171] Mitigation measures that are vague (e.g., "good faith effort") or so undefined [a future "plan"] that it is impossible to evaluate their effectiveness are inadequate.[172] A CEQA lead agency cannot make the required CEQA findings unless the record shows that all uncertainties regarding mitigation of impacts have been resolved. Further, an agency may not rely on mitigation measures of uncertain effectiveness or feasibility.[173] Thus, for example, "good faith efforts" to obtain "clean" renewable energy for project operation is not adequate. An enforceable condition requires that the CPUC obtain a commitment to use renewable energy, which is a feasible measure. The required findings cannot be made based on a Plan that will be prepared in the future, after the EIR has been certified, and "good faith efforts" to use "clean" renewable energy.

CURE-Fox-113

---

[170] CPUC, Green Tariff/Shared Renewables Program (GTSR); Available at: http://www.cpuc.ca.gov/General.aspx?id=12181.

[171] CEQA Guidelines §15126.4, subd. (a)(2).

[172] See *San Franciscans for Reasonable Growth v. City & County of San Francisco* (1984) 151 Cal.App.3d 61, 79.

[173] *Kings County Farm Bur. v. County of Hanford* (1990) 221 Cal.App.3d 692, 727-28 ("a groundwater purchase agreement was inadequate mitigation because there was no record evidence that replacement water was available).

Fourth, there is no assurance that all feasible measures will be identified unless the Plan is developed by a "qualified professional" as required in Mitigation Measure 4.18-1. The analyses and judgements required to draft this Plan fall under California's engineering licensing laws[174], specifically for Mechanical Engineers. This measure should be modified to require that a registered professional engineer (mechanical) in California confirm by stamp and signature that the Plan includes all feasible measures. CURE-Fox-114

Fifth, the Plan does not require any post-Project construction confirmation and on-going verification that the approved Plan has in fact has been implemented and is being complied with. Monitoring is a key component of successful mitigation under CEQA. This measure should therefore be modified to require that a registered professional engineer (mechanical) in California confirm by stamp and signature that the Plan has been implemented. Further, annual tracking/reporting on implementation of all measures should be required via a compliance checklist or similar documentation. CURE-Fox-115

Sixth, the Plan focuses only on Project operational facilities, i.e., "operational components" including the desalination plant, pipelines, and pumping system. It is silent as to construction GHG emissions. Further, there are other opportunities for CalAm to reduce GHG emissions. CURE-Fox-116

CalAm provides water and wastewater services to over 600,000 people at multiple locations in California. It operates other water facilities in the Monterey area, including facilities to secure water from the Carmel River and Seaside Groundwater Basin.[175] CalAm also operates water and wastewater facilities elsewhere including in Sacramento, San Diego, Larkfield, Los Angeles, and Ventura[176] and is actively acquiring additional water production and service facilities elsewhere in California[177]. Thus, CalAm has opportunities throughout its system to reduce GHG emissions, not only at the Project facilities. These opportunities include: CURE-Fox-117

- **Energy Audits and Retrofits at Existing CalAm Buildings:** Mitigation could include offsetting the Project's GHG emissions through a comprehensive audit of existing buildings owned by CalAm throughout California and processes to identify and implement energy saving measures, including improving the efficiency of existing equipment so that it uses less electricity or burns less fuel. As an example, in September 2007, the California Attorney General's office came to an agreement with ConocoPhillips, in which ConocoPhillips agreed to mitigate greenhouse gas emissions for a planned hydrogen facility by, among other measures, undertaking an energy efficiency audit and carbon emissions audit for all of its California facilities.[178] CURE-Fox-118

- **Community Energy Efficiency Building Retrofits:** Mitigation could include funding programs that provide for energy efficiency retrofits of existing buildings and housings in the local Project area, with a particular focus on rental and low-income housing. As one example, the Chula Vista Energy Upgrade Project included $210,000 worth of mitigation funds "for energy efficiency and related improvements to local homes and business, … intended to directly benefit the residents potentially most affected by the proposed project."[179] These upgrades could include installation of a heat-reflecting "cool roof" and heat-reducing window awnings, high-efficiency air conditioning systems with programmable thermostats, and energy-saving fluorescent lighting fixtures that feature daylight and occupancy sensors. CURE-Fox-119

- **Funding of Carbon Offset Programs:** Mitigation could include providing funds to the MBUAPCD, Audubon Society, California Wildlife ReLeaf, or other organizations to fund off-site carbon reduction or sequestration projects. AB 32 allows CARB to give credit for voluntary GHG reductions that are undertaken before the regulations require specific GHG reductions are adopted.[180] For example, the 2007 ConocoPhillips settlement included an agreement to mitigate and offset greenhouse gas emissions by providing: (1) $7 million to the BAAQMD to create a fund for carbon offsets, (2) $200,000 to the Audubon Society for restoration of wetlands in the San CURE-Fox-120

[180] Health & Safety Code, §38562, subd. (b)(2).

Pablo Bay for purposes of carbon sequestration, and (3) $2.8 million to California Wildlife ReLeaf for reforestation projects, estimated to sequester 1.5 million metric tons of CO_2 over the lifetime of the forest. As another example, Chevron agreed to a $30 million GHG reduction plan to offset the increase in GHG from its modernization project which included working with others to develop transportation and transit programs and a roof-top solar and energy retrofit program.[181] These programs also could include electric vehicle (EV) rebate; installation of EV charging stations; reserved parking for EV vehicles; clunker scraping programs with incentives for purchasing or leaving new or used EVs; and financing options for EVs for people with limited credit, among many other.

CURE-Fox-120 cont.

- **Water Conservation**: CalAm's Monterey system is among the best in California at conserving water. Its daily per-capita water use in the SWRCB's most recent statewide survey for October 2014 to April 2015 is 55.8 gallons per person, while its facilities in San Diego reported 65 gallons per person; in Sacramento 80.2 gallons per person; and in Los Angeles, 126.2 gallons per person.[182] The Monterey Division has implemented an aggressive water conservation program under a settlement agreement.[183] This program includes residential audits, leak detection, a house call pilot program, residential and commercial plumbing retrofits, large landscape audits and water budgets, a landscape grant program, and rain sensor and soil moisture sensor installation programs. CalAm should expand these measures to its other systems which use substantially more water. This would significantly reduce GHG emissions by reducing water demand, which requires significant amounts of electricity to supply. Reducing electrical demand throughout CalAm's system could significantly offset GHG emissions from the Project. CalAm should also agree to make these measures in its Monterey District permanent.

- **On-Site Solar:** A UC Berkeley study found that in order to meet the State of California's existing goal of 80% GHG reduction by 2050,[184] California must: (1) completely phase out fossil-fueled *electricity* and (2) electrify *transportation*. Thus, to comply with Executive Order S-3-05, the Project could install and operate a solar plant and battery storage facility on City property to supply 100% of its electricity needs.

CURE-Fox-122

2. Mitigation Measure 4.18-1: Construction Equipment Efficiency Plan

This measure requires CalAm to contract a "qualified professional" to prepare a "Construction Equipment Efficiency Plan" to identify specific measures that CalAm will implement as part of Project construction "to increase the efficient use of construction equipment to the maximum extent feasible."[185] This measure has the same deficiencies as Mitigation Measure 4.11-1, discussed above.

CURE-Fox-123

First, preparation of the Efficiency Plan is deferred until after the Project is approved, pre-empting public review. The Plan must be prepared as part of the DEIR/EIS and circulated for public review.

Second, the measure does not clarify what constitutes a "qualified professional". This measure should be modified to require that the qualified professional be a registered professional engineer (civil[186]) in California and the Efficiency Plan should be confirmed by stamp and signature that the Plan includes all feasible construction equipment efficiency measures.

CURE-Fox-124

Third, the Efficiency Plan[187] does not include all feasible mitigation measures. Many other such measures should have been identified in the DEIR/EIS as all feasible mitigation is required when the impact is not fully mitigated. These include the NOx and ROG mitigation measures identified above, plus measures recently required as GHG construction mitigation in the Chevron Modernization FEIR[188] (annotated here by "Chevron"):

CURE-Fox-125

[184] James H. Williams et al., The Technology Path to Deep Greenhouse Gas Emissions Cuts, Science, v. 335, pp. 53-59, January 6, 2012; Abstract available at http://www.sciencemag.org/content/335/6064/53.

[185] DEIR/EIS, p. 4.18-15.

[186] Business & Professions Code §§ 6700 – 6799. See especially, §6731 (Civil Engineering Defined) and 6735 (Preparation, Signing, and Sealing of Civil Engineering Documents).

[187] DEIR/EIS, p. 4.18-15.

[188] Chevron Refinery Modernization Project EIR, March 2014, Chapter 4.8, Greenhouse Gases; Available at: http://chevronmodernization.com/wp-content/uploads/2014/03/4.8_Greenhouse-Gases.pdf and Chapter 5, Mitigation Measure Monitoring and Reporting Program; Available at: https://s3.amazonaws.com/chevron/Final+EIR/5_MMRP.pdf.

- All construction equipment shall be maintained and properly tuned in accordance with manufacturer's specifications. All equipment shall be checked by a certified visible emissions evaluator (Chevron). CURE-Fox-126
- The idling time of diesel-powered construction equipment shall be limited to 2 minutes rather than the 5 minutes in Mitigation Measure 4.10-1c, as required in the Chevron FEIR. Clear signage shall be provided for construction workers at all access points as required in the Chevron FEIR (Chevron). CURE-Fox-127
- All contractors shall be required to use equipment that meets CARB's most recent certification standard for off-road heavy duty diesel engines (Chevron). CURE-Fox-128
- Reuse and recycle construction and demolition waste, including, but not limited to soil, vegetation, concrete, lumber, metal, and cardboard (Chevron). CURE-Fox-129
- Using alternative fueled, e.g., biodiesel, construction vehicles/equipment on at least 15% of the fleet (Chevron). CURE-Fox-130
- Consolidate truck deliveries. CURE-Fox-131
- Require a certified on-site inspector (licensed general contractor or similar) to confirm that the construction mitigation program is properly implemented. CURE-Fox-132
- Reduction in worker trips using carpooling or vans to transport construction workers from regional hubs. CURE-Fox-133

Fourth, no method to verify compliance is identified. To facilitate confirmation of compliance with the construction mitigation measures, and to verify the DEIR/EIS's estimated construction emissions, the FEIR should include a comprehensive inventory of all off-road equipment that will be used to construct the Project. The inventory should include the horsepower rating, engine production year, hours of use, and amount and type of fuel used. At least 48 hours prior to the use of heavy-duty off-road equipment at a new construction site, the project representative shall provide the inspector and MBUAPCD with the construction timeline, including start date and name and phone number of project manager and on-site foreman. CURE-Fox-134

Fifth, the Efficiency Plan does not require any monitoring during construction to assure that the measures are implemented. The Efficiency Plan should require an on-site construction mitigation manager to oversee and enforce implementation of all mitigation measures and to proactively ensure that construction activities do not result in noise, odor, dust, or other complaints. The monitor should be a licensed and qualified professional (QEP, CIH, PE) who is CURE-Fox-135

continuously present at the construction site(s) to confirm that the Efficiency Plan is implemented. Further, annual tracking/reporting on implementation of all measures should be required via a compliance checklist or similar documentation.

CURE-Fox-135 cont.

Therefore, the Efficiency Plan fails to adequately mitigate the air quality impacts resulting from Project construction. The DEIR/EIS must be revised in accordance with these comments and recirculated before the Project can be lawfully approved under CEQA.

CURE-Fox-136

V. VIBRATION IMPACTS ARE SIGNIFICANT AND UNMITIGATED

Construction activities that use impact tools (e.g., pile drivers, drill rigs, bulldozers, jackhammers, vibratory rollers) can produce significant groundborne vibration that can damage nearby buildings and annoy sensitive receptors.[189] The Project will employ impact equipment within close proximity to residential, commercial, and historic receptors that can be annoyed and/or damaged by vibration. The DEIR/EIS evaluated vibration impacts using a methodology from FTA 2006[190] and summarized the results in DEIR/EIS Table 4.12-10 as a fait accompli.[191] However, the DEIR/EIS fails to present supporting calculations or cite to any specific pages from FTA 2006 or disclose input values used in the calculations. I was unable to reproduce the DEIR/EIS's vibration analysis. Thus, the DEIR/EIS fails as an informational document under CEQA as to vibration.

CURE-Fox-137

This unsupported analysis concluded that vibration from pipeline installation using both compactors and pile drivers would result in significant building damage and annoyance from construction of the Castroville Pipeline and Source Water Pipeline, the new Desalinated Water Pipeline, and the new Transmission Main where trenchless construction methods are required.[192] The DEIR/EIS then imposes Mitigation Measures 4.15-1a and 4.12-3[193] to address construction-related vibration during pipeline installation and concludes that with mitigation, vibration impacts no longer would be significant.[194] These measures would restrict pile

CURE-Fox-138

[191] DEIR/EIS, Table 4.12-10, p. 4.12-43, pdf 1131.

[192] DEIR/EIS, Table 4.12-10, p. 4.12-43, pdf 1131 and p. 4.12-47, pdf 1136.

[193] DEIR/EIS, p. 4.12-48.

[194] DEIR/EIS, p. 4.12-62, pdf 1150.

driving to daytime hours, require vibration monitoring for the first 700 feet of pipeline construction and restrict the location of sheet piles, if necessary.[195]

However, the DEIR/EIS does not include any analysis to demonstrate that vibration impacts would be less than significant with the proposed mitigation. Further, the proposed mitigation is not adequate to reduce significant vibration impacts to a less than significant level, as asserted in the DEIR/EIS.[196] The DEIR/EIS proposes two mitigation measures to reduce significant vibration impacts to less than significant. These are both fundamentally flawed and not adequate to reduce vibration impacts to a less than significant level.

CURE-Fox-138 cont.

A. Avoidance Mitigation Measures

The DEIR/EIS proposes Mitigation Measure 4.15-1a: "Avoidance and Vibration Monitoring for Pipeline Installation in the Lapis Sand Mining Plant Historic District."[197] It then refers the reader to Impact 4.15-1 in the Cultural and Paleontological Resources section for a description of this mitigation measure. However, this section does not propose any mitigation for Impact 4.15-1 (cause a substantial adverse change in significance of a historical resource) and thus proposes no mitigation.[198] Therefore, the DEIR/EIS contains no description of Mitigation Measure 4.15-1a and thus no explanation of what is encompassed in "avoidance and vibration monitoring for pipeline installation in the Lapis Sand Mining Plant Historic District". In fact, this measure asserts, wrongly, that there are no historic resources within the direct or indirect APE of all project components. See Comment VI.

CURE-Fox-139

B. Vibration Reduction Mitigation Measures

The DEIR/EIS next proposes a series of vibration reduction measures in Mitigation Measure 4.12-3.[199] These have many of the problems previously discussed elsewhere for other impacts (Comment I.A.2) because they are not practically enforceable. Further, the City of Monterey's files include a "Vibration Control Plan for Monterey Pipeline Project,"[200] which identifies much more

CURE-Fox-140

[195] DEIR/EIS, p. 4.12-45,

[196] DEIR/EIS, 4.12-48.

[197] DEIR/EIS, p. 4.12-48.

[198] DEIR/EIS, p. 4.15-45.

[199] DEIR/EIS, pp. 4.12-48/49.

[200] Response Dynamics, Vibration Control Plan for Monterey Pipeline Project, As Per Technical Specifications, Division 1: General Requirements, 01062: Environmental Requirements, November 14, 2016 (Vibration Control Plan) (Exhibit 1).

aggressive mitigation for vibration impacts than identified in the DEIR/EIS. These include: CURE-Fox-140 cont.

- Use construction practices that do not generate vibration levels at the closest sensitive land use above 0.1 in/se PPV (continuous of frequent intermittent level CURE-Fox-141
- Avoid use of impact sheet piles unless needed in situations in which the soil cannot be stabilized by standard methods, such as by use of manual shoring jacks; CURE-Fox-142
- Sheet pile installation will be minimized and if needed, shall be conducted during daytime hours and access pits shall be located greater than 45 ft from standard structures and 80 feet from any listed historic resource CURE-Fox-143
- Wet-saw cutting shall be used before excavations, to minimize the need for jackhammer use CURE-Fox-144
- Whenever possible, the compaction requirement will be met by using a non-vibratory excavator-mounted compaction wheel, and a small smooth drum roller will be used for final compaction of asphalt base and asphalt concrete. If needed to meet compaction requirements, smaller vibratory rollers will be used to minimize vibration levels during repaving activities where needed to meet vibration standards CURE-Fox-145
- Contractor will provide no less than 30 days notification prior to beginning improvements at all listed historic resources. CURE-Fox-146

In addition, the City's vibration monitoring plan includes the following requirements omitted from the DEIR/EIS:

- Monitor vibration at adjacent historic resources during compaction efforts in close vicinity of any listed historic resource. If measured vibration exceeds the threshold for historic structures, construction will be stopped and alternate methods of compaction used. CURE-Fox-147
- If impact sheet pile installation is needed within 80 feet of any historical resource or within 80 feet of a historical district, vibration levels will be monitored to insure that the 0.12 in/sec PPV damage threshold is not exceeded. If vibration levels exceed the applicable threshold, alternate construction methods, such as vibratory pile drivers, will be used. CURE-Fox-148
- The vibration monitoring will be conducted using calibrated, industry standard, Instantel Series portable seismograph units with redundant CURE-Fox-149

internal batteries and the measures will be achieved for the project duration.

CURE-Fox-149 cont.

The City's Vibration Control Plan should replace the weak mitigation measures in the DEIR/EIS and the Plan itself should be included in full in an appendix to the DEIR/EIS.

CURE-Fox-150

VI. HISTORIC RESOURCES

The DEIR/EIS asserts in Impact 4.15-1 that construction will not cause an adverse impact to historical resources. This potential impact was narrowly evaluated only for historical resources listed in or eligible for listing in the California Register or historic properties listed in or eligible for listing in the National Register that are within the direct or indirect Area of Potential Impact of all project components.[201] However, CEQA Section 15064.5 defines "historical resources" much more broadly to include:

> (1) A resource listed in, or determined to be eligible by the State Historical Resources Commission, for listing in the California Register of Historical Resources (Pub. Res. Code §5024.1, Title 14 CCR, Section 4850 et seq.).
>
> (2) A resource included in a local register of historical resources, as defined in section 5020.1(k) of the Public Resources Code or identified as significant in an historical resource survey meeting the requirements section 5024.1(g) of the Public Resources Code, shall be presumed to be historically or culturally significant. Public agencies must treat any such resource as significant unless the preponderance of evidence demonstrates that it is not historically or culturally significant.
>
> (3) Any object, building, structure, site, area, place, record, or manuscript which a lead agency determines to be historically significant or significant in the architectural, engineering, scientific, economic, agricultural, educational, social, political, military, or cultural annals of California may be considered to be an historical resource, provided the lead agency's determination is supported by substantial evidence in light of the whole record. Generally, a resource shall be considered by the lead agency to be "historically significant" if the resource meets the criteria for listing on the California Register of Historical Resources (Pub. Res. Code, § 5024.1, Title 14 CCR, Section 4852) including the following:

CURE-Fox-151

[201] DEIR/EIS, p. 4.15-45.

(A) Is associated with events that have made a significant contribution to the broad patterns of California's history and cultural heritage;

(B) Is associated with the lives of persons important in our past;

(C) Embodies the distinctive characteristics of a type, period, region, or method of construction, or represents the work of an important creative individual, or possesses high artistic values; or

(D) Has yielded, or may be likely to yield, information important in prehistory or history.

CURE-Fox-151 cont.

The City of Monterey's Vibration Control Plan includes a list of historic architectural resources within the direct and indirect Area of Potential Impact (APE) of the Project. The list includes 24 historic structures that are close enough to be damaged from construction equipment induced vibration, based on the DEIR/EIS's analysis.[202] Thus, the Project would result in a significant adverse impact to historical resources. This is a new impact that was not disclosed or mitigated in the DEIR/EIS.

Subject: Comments on the CalAm Monterey Peninsula Water Supply Project Draft Environmental Impact Report/Environmental Impact Statement

Dear Ms. Sobczynski,

This letter contains my comments on the Draft Environmental Impact Report / Environmental Impact Statement (DEIR/S) for the Monterey Peninsula Water Supply Project (Project or proposed Project).

Professional Background

I am a conservation biologist and environmental consultant with 25 years of professional experience in wildlife ecology and natural resource management, and since 1994 have maintained U.S. Fish and Wildlife (USFWS) Recovery permits for listed species under the federal Endangered Species Act (ESA). In addition to these I hold several California state and federal certifications for surveys and monitoring of protected and special status species. I have extensive experience monitoring and studying many species across several taxa, including reptiles and amphibians, passerines and raptors, and marine and terrestrial mammals. I have served as a biological resources expert on over a hundred projects involving water projects, urban and rural residential developments, and industrial scale energy projects; on private, public, and military lands; in California, the southwest, and Latin America.

The scope of work I have conducted as an independent environmental contractor, supervisor, and full time employee has included assisting clients to evaluate and achieve environmental compliance, restoration, mitigation, and research as related to biological resources; as well as submitting written reports and comments for such work. This work often included analyzing and reviewing actions pursuant to the California Environmental Quality Act CEQA and the National Environmental Policy Act (NEPA), the Endangered Species Act (ESA), the Clean Water Act, the Migratory Bird Treaty Act (MBTA), and other regulations, along with surveying for, and preparing Biological Technical Reports and Assessments. I have been

contracted as an environmental consultant and biologist by the USFWS, the USDA Forest Service, Ultrasystems, ICF, Helix Environmental, URS, AECOM, AMEC, GeomorphIS, DUDEK, ESA, Brian Smith and Associates, Tetra Tech, Bridgenet Bioacoustics, among others. I am also a core member of the National Sierra Club's Wildlife and Endangered Species Advisory Committee and Marine Advisory Committee.

My conservation and natural history research on endangered vertebrate species in Latin America has received various awards, including the National Geographic Research and Exploration Award and the National Commission for Scientific and Technological Research Award. My research has been featured on National Geographic Television and Discovery Channel documentaries, and I have served as an on- and off-camera technical consultant for wildlife documentaries filmed by National Geographic Television, Discovery Channel, BBC, and Animal Planet.

I have a Master's degree in Ecology and my professional experience includes college instruction at the college level since 1991. I was an adjunct instructor in Biology and Zoology at Palomar Community College and San Diego State University between 1991 and 1995, where I authored a laboratory text for Biology majors. In 1999-2000 I taught semester-long field courses in Tropical Ecology in Ecuador and the Galapagos for Boston University. In 2008 I was a Visiting Full Time Professor in Environmental Science and Botany at Imperial Valley College (IVC), and since 2012 have been teaching Environmental Science at IVC as an Adjunct Professor. At present I am completing a MS degree program in Environmental Studies from Green Mountain College, focusing on developing a Program in Environmental Science field study.

I have gained particular knowledge of the biological resource issues associated with the Project through my work on numerous other projects in California, including several years of surveys on coastal projects for pre-, ongoing, and post-construction activities. My comments are based upon first-hand observations, review of the environmental documents prepared for the Project, review of scientific literature pertaining to biological resources known to occur in and near the Project area, consultation with other biological resource experts, and the knowledge and experience I have acquired throughout my 25 years of working in the field of natural resources research and management.

Finally, pursuant the species discussions below, it is important to note that I have extensive experience conducting focused and protocol-level surveys for sensitive wildlife in various marine and terrestrial California ecosystems, including species of cetaceans, pinnipeds, eagles and other raptors (i.e. burrowing owls, Swainson's hawks), lizards, butterflies, frogs, plovers and terns, many nesting bird species protected under the Migratory Bird Treaty Act., and rare plants.

I. PROJECT SCOPE

According to the DEIR/S the California-American Water Company's (CalAm or Applicant) proposed Project area extends about 18 miles from the from the town of Castroville in the north to the City of Carmel in the south (DEIR Figure ES-1)[1], from the northern site of the proposed desalination plant to the western end of the associated proposed pipeline, and east approximately eight miles to the community of Hidden Hills. In addition to the construction of the desalination plant located on the Salinas River in unincorporated Monterey County northeast of the City of Marina, with related facilities that include pretreatment, reverse osmosis, and post-treatment systems; backwash supply and filtered water equalization tanks; chemical feed and storage facilities; brine storage and conveyance facilities; and other associated non-process facilities[2]. The Project's vast scope also includes development of ten subsurface slant wells in the northern coastal area of the City of Marina and extending offshore into the submerged lands of the Monterey Bay National Marine Sanctuary (MBNMS), approximately 21 miles of pipelines with associated pump stations and water storage tanks. The project also includes improvements to the existing Seaside Groundwater Basin (SGB) aquifer storage and recovery system facilities (ASR); including two new additional injection/extraction wells and various related pipelines.

II. THE DEIR/S PROJECT FAILS TO ACKNOWLEDGE THE HIGH DEGREE OF IMPORTANCE OF THE PROJECT AREA TO REGIONAL CONSERVATION OF BIODIVERSITY

The area proposed for the Project is incredibly rich in biological terms, both in marine and terrestrial flora and fauna. The DEIR/S does mention how the MBNMS' biological marine communities host one of the highest levels of marine biodiversity in the world, including 27 federally listed threatened and endangered species. The report does not, emphasize the overall biological importance of the terrestrial habitats and species included in the Project footprint and buffer zone. Not only does Monterey County have some of the most diverse flora in California, the area has been identified as an important conservation "hot spot" due in part to its high endemism of species, and it has been described as one of the most essential coastal regions in the world in terms of conservation of biodiversity of plants and wildlife.[3,4,5] Biologists

recognize the importance of thorough and enlightened management conservation strategies in the region, especially where coastal development pressures are increasing, stating that for this area's rare habitats

> "Habitat conversion will clearly outpace expansion of formal protected-area networks, and conservationists must augment this traditional strategy with new approaches to sustain the Mediterranean biota."[6]

This statement emphasizes the importance of protections prescribed and implemented in areas exactly such as those proposed for development by this Project. Historical and recent data reflect the biological sensitivity of this area for both aquatic and terrestrial habitats and species. The U.S. Fish and Wildlife Service (2013)[7] reports no fewer than 35 listed threatened or endangered species that "occur within or may be affected by projects in the area". In terms of terrestrial species only, the California Natural Diversity Database (CNDDB) denotes within the Project area the occurrence of 17 Endangered Species Act (ESA) listed species, 10 California Endangered Species Act (CESA) listed species, and twenty-four Species of Special Concern. As such the DEIR/S should emphasize the importance, *and resultant fragility*, of the ecosystems, habitats, and sensitive species populations that are impacted by this project and incorporate this reality in impact analyses and mitigation measures discussions, especially in consideration of cumulative impacts.

CURE-Owens-1 cont.

III. THE PROJECT PROPOSAL FAILS TO COMPLY WITH LOCAL REGIONAL LAND USE PLAN(S)

This high degree of importance of the local biota to conservation is reflected in how many habitat management and conservation plans already exist in the region; including habitat and species protections within the City of Marina General Plan, the City of Marina Local Coastal Land Use Plan, the Marine Municipal Code, the Ford Od Dunes State Park General Plan and EIR, the Monterey City Code, the Seaside General Plan, the Seaside Municipal Code, Carmel Valley Maser Plan, Greater Monterey Peninsula Area Plan, Monterey County Code, Monterey County General Plan, North County Land Use Plan, For Ord Reuse Plan.[8]

CURE-Owens-2

In the DEIR/S' review (4.6.2.3) of these applicable regional and local land use plans, the authors identify where they believe the Project may be inconsistent with any given plan. They then state that, "Where the analysis concludes the proposed project would be potentially

[8] DEIR/S table 4.6-4

inconsistent with the applicable plan, policy, or regulation, the reader is referred to Section 4.6.5, Direct and Indirect Effects of the Proposed Project. In that subsection, the significance of the potential conflict is evaluated. Where the effect of the potential conflict would be significant, feasible mitigation is identified to resolve or minimize that conflict."[9]

Despite this claim, the DEIR/S does not adequately address each and every potential conflict ("inconsistency") with these plans in future discussions by way of its proposed mitigation measures, thus leaving insufficient information regarding how impacts will be minimized. Additionally, some Plans intend for most impacts not simply to be minimized but avoided altogether, with very specific standards set regarding mitigation, success criteria, if and when it must occur prior to issuance of a development permit.

For example: The City of Marina Local Coastal Land Use Plan (CMLCLUP) has very specific policies regarding potential impacts to sensitive species and habitats, and any mitigation coinciding with such. Specifically, it states,

> *"Much of the Marina Coastal Zone either is environmentally sensitive because of the presence of rare and endangered species or has the potential for supporting a rare and endangered species. In Marina, environmentally sensitive habitats include, but are not limited to area of undisturbed native dune vegetation [and other wetland habitats]…. The precise limits of such habitats shall be confirmed by professional on-site evaluation at the time development is proposed and before a Coastal Development permit is issued. In addition to indicating the location of primary habitat areas for rare and endangered plant and animal species (which are to be protected), the evaluation shall address protective measures, such as setbacks, restoration of habitat areas where natural dune landform remains, and limitations to uses in secondary and/or support areas which are necessary to the health of the identified primary habitat area.* ***Because of the variety of plants and animals involved, the secondary or support area will have to be individually identified and specifically protected on a site-by-site or case-by-case basis.*** *For this reason, it is important that the City establish a list of biologists qualified to prepare habitat evaluation reports within the City's Coastal Zone. Developers may then choose specialists from these lists.* ***In the case of wetlands, the biologists will have to determine the extent and landward boundary of the wetland. The biologist will then establish a 100 foot setback line from the boundary of the wetland.*** *This entire area, pond, wetland and setback, will be subject to Coastal Development Permit requirements as well as being in the Coastal Permit Appeal Zone.* ***In the case of dune habitat areas, the Environmental Analysis Report prepared for this plan identified a number of plant and animal species which are locally or generally rare, endangered, threatened, or are necessary for the survival of an endangered species. The habitats of these species, collectively referred to throughout this plan as "rare and endangered", warrant protection as environmentally sensitive…the list***

CURE-Owens-2 cont.

Minimum Habitat Mitigation/Restoration Plan Requirements

All direct and potential impacts to primary and secondary habitats shall be fully mitigated**. Appropriate acreage replacement/restoration ratios for any unavoidable direct impacts to habitat areas and buffer areas shall be applied to fully protect identified habitat**. Habitat restoration plans shall be prepared and approved prior to issuance of any grading or building permits.

Habitat Restoration Plan Requirement

All habitat restoration, enhancement and/or buffering plans shall be prepared by a qualified biologist and where appropriate, with the assistance of a qualified hydrologist. Plans shall be developed in consultation with the Department of Fish and Game and the U.S. Fish and Wildlife Service in cases where these agencies have jurisdiction. The plans and the work encompassed in the plans shall be authorized by a coastal development permit. The permittee shall undertake development in accordance with the approved final plans. Any proposed changes to the approved final plans shall be reported to the City. No changes to the approved final plans shall occur without a City-approved amendment. ***The elements of such plan shall at a minimum include**:*

a. A detailed site plan of the entire habitat and buffer area, with a topographic base map;

b. A baseline ecological assessment of the habitat and buffer area, including but not limited to, assessment of biological, physical and chemical criteria for the area;

c. ***The goals, objectives, performance standards and success criteria for the site, including specific coverage and health standards for any areas to be planted. At a minimum, explicit performance standards for vegetation, hydrology, sedimentation, water quality and wildlife and a clear schedule and procedure for determining whether they are met shall be provided. Any such performance standards shall include identification of minimum goals for each herbaceous species, by percentage of total planting and by percentage of total cover when defined success criteria are met; and specification of the number of years active maintenance and monitoring will continue once success criteria area met. All performance standards shall state in quantifiable terms the level and extent of the attributes necessary to reach the goals and objectives. Sustainability of the attributes shall be a part of every standard. Each performance standard shall identify:***

1. ***The attribute to be achieved;***
2. ***The condition or level that defines success; and***
3. ***The period over which success must be sustained.***

The performance standards must be specific to provide for the assessment of habitat performance over time through the measurement of habitat attributes and functions including, but not limited to, wetland vegetation, hydrology and wildlife abundance.

CURE-Owens-2 cont.

d. The final design, installation and management methods that will used to ensure the mitigation site achieves the defined goals, objectives and performance;

e. Provision for the full restoration of any impacts that are identified as temporary necessary to install the restoration or enhancement elements;

f. Provisions for submittal: Within 30 days of completion of initial (and subsequent phases, if any of) restoration work, of "as built" plans demonstrating that the restoration and enhancement has been established in accordance with the approved design and installation methods;

g. ***Provision for a detailed monitoring program to include, at a minimum, provision for assessing the initial biological and ecological status of the site. The assessment shall include an analysis of the attributes that will be monitored pursuant to the program, with a description of the methods for making that evaluation****;*

h. Provision to ensure that the site will be promptly remediated if the monitoring results indicate that the site does not meet the goals, objectives and performance standards identified in the approved mitigation program and provisions for such remediation. If the

final report indicated that the mitigation project has been unsuccessful, in part or in whole, based on the approved performance standards, the applicant shall submit a revised or supplemental mitigation program to compensate for those portions of the original program which did not meet the approved performance standards. Provisions for submission of annual reports of monitoring results to the City for the first five years after all restoration and maintenance activities have concluded (including but not limited to watering and weeding, unless weeding is part of an ongoing long-term maintenance plan) and periodic monitoring after that time, beginning that first year after submission of the "as-built" assessment. Each report shall also include a "Performance Evaluation" section where information and results from the monitoring program are used to evaluate the status of the project in relation to the performance standards. [Resolution No. 2001-118 (October 16, 2001); approved by CCC November 14, 2001]"[10] (bold emphasis only added)**.**

The DEIR/S notes that the Project is "potentially inconsistent" with the CMLCLUP by way of these project components: the installation of the subsurface slant wells, source water pipeline, new desalinated water pipeline, and new transmission main, and maintenance of the subsurface slant wells, since these developments would occur within special status species habitats, including wetlands and including those defined as primary and secondary habitat in the City of Marina LCLUP. The DEIR/S goes on to say these inconsistencies are addressed by way of mitigation measures that are "provided to reduce or avoid impacts on special-status species habitats. However, as described in Impact 4.6-4, construction of these facilities, and maintenance of the subsurface slant wells, would be inconsistent with the City of Marina LCLUP, a significant and unavoidable impact."[11]

CURE-Owens-2 cont.

The DEIR/S's mitigation measures provided may indeed reduce some of the impacts on special-status species and habitats, however they are not inclusive or detailed enough to demonstrate that all direct, indirect, and cumulative impacts can and will be reduced to below significant in a manner consistent with the City Plan. Additionally, the DEIR/S proposed mitigation measures fail to adequately comply with, or fulfill, the City of Marina's minimum habitat mitigation/restoration plan requirements as described above, requirements approved and certified by the City Council and the California Coastal Commission[12]. The detailed standards iterated above (items a – h) require mitigation protocols be prepared according to standards with vastly greater detail than the DEIR/S provides in its mitigation measures. The "minimal requirements" drafted by the City of Marina must be described in detail according to the City's (and possibly other) land use plans prior to any development permitting, not deferred

[10] City of Marina Local Coastal Program Volume II Implementation Plan, 2013. pp 5-7. Retrieved from: http://www.ci.marina.ca.us/DocumentCenter/View/4491

[11] DEIR/S p. 4.6-104

[12] City of Marine Local Coastal Program Volume II Implementation Plan, 2013. pp 5-7. Retrieved from: http://www.ci.marina.ca.us/DocumentCenter/View/4491

until a later date after permit approval as the DEIR/S seeks to do. The Applicant does not provide data necessary to develop such detailed mitigation protocols, including a lack of wetland delineation report[13], lack of reporting of protocol or focused surveys.

CURE-Owens-2 cont.

a. Sensitive Species Highlighted in the City of Marina's LCLUP Are Not Analyzed in the DEIR/S

The DEIR/S fails to analyze potential impacts to some species highlighted as of importance and required for minimum in the Coastal Land Use Plan's requirements for mitigation with their district, namely, the globose dune beetle (*Coelus globosus*), Salinas kangaroo rat (*Dipodomys heermanni goldmani*), seaside painted cup (*Castilleja latifolia ssp. Latifolia*), and Eastwood's Ericameria (*Ericameria fasciculate*). The Applicant's review should include analysis of the potential for impacts to these species. These species are present in the region covered by the City's Plan, therefore the burden is on the Applicant to explain why they are not necessary for consideration, including current ground-truthed evidence that potentially impacted habitat for these species does not exist within any of the Project's footprint. If such habitat does exist, the Applicant must present data and reports of recent focused surveys (not merely reconnaissance surveys or habitat assessments) that demonstrate that these species are not present, along with a record in the database that shows them to be consistently absent in focused surveys for many years.

CURE-Owens-3

Therefore the DEIR/S fails to provide essential data necessary to analyze the degree of significant biological impacts imposed by the Project, and thus how to adequately mitigate them. The Project's lack of compliance with the City of Marina's land conservation plan is not only of issue for state and federal statutory fulfillment, it represents a potential and serious precedent that could serve to diminish community efforts for conservation of biodiversity overall. Regardless of how much effort it may take for the Project Applicant to script specific plans that satisfy compliance, community plans like that of the City of Marina are agreements crafted, deliberated upon, and certified by many authorities and scientific experts throughout a long period of time, and thus have a weighty investment of deliberation whose purpose is to drive the actions and decisions for permitting of projects just like that of the one proposed in this DEIR/S. For this reason alone this project should be required to provide the necessary detail in its mitigation measures to meet the standards set by the City of Marina's land use plan detailed above, and all other land use and conservation plants respective to the Project sites.

The DEIR/S correctly states that the City of Marina has jurisdiction via their Local Coastal Program and must permit development proposed in the Coastal Zone, where the CCC retains jurisdiction over appeals[14]. Therefore permission from the City to move forward for coastal

[13] DEIR/S p. 4.6-35.
[14] DEIR/S 3-65

development is required, further reason for the Applicant to commit to fulfilling consistency with the City's Land Use Plan.

CURE-Owens-3 cont.

IV. THE DEIR/S FAILS TO ADEQUATELY SURVEY AND ANALYZE THE POTENTIAL IMPACT OF THE PROJECT ON TERRESTRIAL SENSITIVE SPECIES

a. Protocol and Focused Surveys Are Necessary To Establish Existing Conditions and Sufficient Mitigation Measures and Standards

Studies in the Monterey Bay area show not only abundance but presence of coastal species of various taxa can be highly variable from year to year based upon factors such as drought, El Niño conditions, and related prey-predator cycles.[15] And yet, instead of conducting project level, protocol or focused surveys for the majority of the many sensitive wildlife species potentially present onsite as should have occurred, the DEIR/S relies largely on databases and outdated reports (some over 10 years old) not only to predict presence/absence of species, but for the degree to which such a predicted species' status may be mitigated if and when Project impacts to the species are deemed significant based upon this prediction. Such predictions are not supported by actual, ground-truthed observations made by biologists who specialize in detecting the species for which protocol surveys have been required due to their protected status and resultant sensitivity to harassment.

CURE-Owens-4

For federally endangered and threatened species, protocol surveys are conducted by permitted biologists as they have the proven experience (as verified by USFWS, the permitting agency) to be able to detect the species and other essential characteristics important to individual and subpopulations assessments, including density, behavioral factors, breeding status, etc. Permitted biologists not only have the responsibility of formally reporting all such observations to USFWS, but also to insure harassment of species during surveys is minimized by default of their knowledge and training for the species in question.

The DEIR/S, however, does not recognize this important and widely accepted aspect of protected species surveys, and made little attempt to use focused surveys to determine the most current site-specific status threatened or endangered wildlife species on or near the site. It instead referred to habitat assessments to indicate, via anecdotal observations or assumptions from habitat onsite, to make protected species status determinations – and resultant creations of mitigation measures. This is a clear oversight in the DEIR/S, as species presence/ absence, and indications of 'likelihood to occur" are guidelines intended to assist consultants in determining where site-specific, protocol level surveys are warranted in order to determine essential details required for adequate mitigation analyses, such as current species

[15] Benson, S. R. 2002. *Ecosystem studies of marine mammals and seabirds in Monterey bay, California, 1996--1999* (Order No. 1408777). Available From ProQuest Dissertations & Theses Full Text; ProQuest Dissertations & Theses Global.

density, nesting or breeding status, species richness, and all of the other components that are part of a protocol survey and cannot be completely derived from any given database.

CURE-Owens-4 cont.

b. Databases and Reconnaissance Level Surveys (habitat assessments) Do Not Provide a Complete Assessment to Determine Baseline, Existing Conditions for the Project

Using databases is a standard part of gathering site-specific data, but it cannot replace focused or protocol surveys in its specificity or accuracy. For example, the CNDDB is relied upon heavily by the DEIR/S to make species impact determinations. However, the CNDDB is limited in its ability to predict species currently present at any given locale; instead it presents at best a conservative description of what may or may not be present on site. Many species sightings are not actually reported on the public CNDDB. For instance, according to the California Department of Fish and Wildlife CNDDB coordinator, for most birds the CNDDB keeps track of and maps only those occurrences that can be associated with "evidence of nesting". Observations of flyovers or foraging are generally not mapped into CNDDB as an 'Element Occurrence', the standard mapping unit, based on NatureServe natural heritage program methodology.[16] The CNDDB biologists state that the database represents summaries of species occurrences; not individual detections. "Given limited resources to map submissions, the CNDDB tries a best to map occurrences that relate to an important aspect of life history." (*pers. comm,* P. McIntyre, CDFW, June 6, 2015).

CURE-Owens-5

As importantly, CNDDB records are voluntarily reported and only exist for locations that have been surveyed to varying degrees. As a result, the lack of CNDDB records, or records from any other database, does not mean a species is absent. To reinforce this fact the California Department of Fish and Wildlife posts a disclaimer on its CNDDB website:

> *"We work very hard to keep the CNDDB and the Spotted Owl Database as current and up-to-date as possible given our capabilities and resources. However, we cannot and do not portray the CNDDB as an exhaustive and comprehensive inventory of all rare species and natural communities statewide. Field verification for the presence or absence of sensitive species will always be an important obligation of our customers."*[17]

Similarly, the California Native Plant Society's Inventory of Rare and Endangered Species states the following: "A reminder*:* Species not recorded for a given area may nonetheless be present, especially where favorable conditions occur."[18] The DEIR/S repeatedly mentions that they conducted "botanical" surveys. However, when focused surveys for sensitive species are conducted, they are termed rare plants species, yet this term is not used in the Report, and numbers (even estimates) of abundance, density, individual numbers of rare plants are not

[16] http://www.natureserve.org/conservation-tools/standards-methods. (Retrieved June 18, 2015)
[17] http://www.dfg.ca.gov/biogeodata/cnddb/cnddb_info.asp (Retrieved June 18, 2015)
[18] https://archive.is/northcoastcnps.org (Retrieved June 20, 2015)

provided or mapped in any documents with the DEIR/S. Once again the Report is lacking in specificity of on-the-ground data for protected species.

The DEIR/S does, however, recognize the difference between habitat assessments and focused, or protocol-level surveys where it states,

> *"Reconnaissance-level field surveys are conducted for the purpose of generally describing the vegetation communities present within a project area and assessing the potential for special-status species to occur within the project area plus a 50-foot buffer (i.e., the survey area). Focused surveys are conducted to determine the presence or absence of a certain species or habitat type. Protocol level surveys are a type of focused survey using specific survey protocol as defined by a regulatory agency".*[19]

The DEIR/S also acknowledges that reviewer comments to the previous DEIR for this Project (released in 2015) indicated that protocol surveys should have been included in the Draft EIR, and claims that such surveys have been completed and the "results are reflected in discussions of special status species and critical habitat in sections 4.6.1.4 and 4.6.1.10"[20]. Also, section 4.6.1.2 states that "The impact analysis described in this section [on terrestrial biological resources] is based on special-status species observations available to Environmental Science Associates (ESA) as of June 20, 2016." However, observations or data from ESA surveys are not made available anywhere in the DEIR/S or its Appendices. There is one citation for ESA 2016 that lists GIS shapefiles. All other ESA citations are dated between 2010 and 2014 but only cite reconnaissance level survey shapefiles, a memorandum about the test well sites surveys, and an email about a rare plant survey in 2010. Nowhere is there a thorough, written biological technical report made available that describes in detail the results of project-wide, or facility-wide focused or protocol level surveys of special status plant or animal species.

CURE-Owens-5 cont.

The DEIR/S refers to sections 4.6.1.4 and 4.6.1.10 for details on the purported additional surveys. 4.6.1.4 discusses vegetation communities and habitat mapping surveys as follows: "This mapping was conducted by AECOM between 2013 and 2015 in support of federal and state regulatory permit applications (AECOM, 2016). ESA verified this survey data in the field in 2016." Maps are provided that show habitat types throughout the Project, citing AECOM 2016, which it cited as "*GIS shapefiles from biological surveys conducted by URS within the Monterey Peninsula Water Supply Project ar*ea"[21]. It is unclear what exactly is meant by the statement that ESA "verified" the survey data in the field in 2016; in fact it is impossible to analyze since no biological technical report (BTR) was presented for this entire DEIR/S, there is no citation for this 2016 reference cited, and the citation of shapefiles from "AECOM 2016" was also not provided for review in any Appendix. This omission will be discussed further below.

[19] DEIR/S 4.6-5
[20] *Ibid* 4.6-1
[21] DEIR/S 4.6-262

Section 4.6.1.10 discusses sensitive terrestrial biological resources in the study area, and states that the potential for terrestrial biological resources to occur at each facility in the study area are based upon databases, "site-specific **reconnaissance level (habitat assessments) of the project area, and focused and protocol-level surveys of special-status species at select facility locations**"[22]. However, a search for "focused" level surveys reveals only vague inferences, again relying on the same cited shapefiles for botanical surveys (not even "rare plant surveys" specifically) for sections, not all, of the Project; i.e. "focused botanical surveys of the project area [were conducted] along General Jim Moore Boulevard (ESA, 2016; AECOM, 2016)";[23] and "coast horned lizard has been observed during focused surveys of the Terminal Reservoir site (AECOM, 2016)"[24].

Mention of protocol level surveys in the DEIR/S are in the same preliminary section where it states that such surveys were conducted by AECOM, cites the same shapefile citations noted above, but provides no further evidence or detailed discussion regarding the results of any Project-wide rare plant surveys or habitat-wide special status animal surveys, and despite stating that "new" habitats were assessed and measured including wetlands, the DEIR/S claims that no wetland delineation report is available.

CURE-Owens-5 cont.

Not having, or providing for review, a formal wetland delineation report is an oversight that prevents the reviewer to adequately assess analyses, or subsequent mitigation, of any and all wetlands for this Project. Its absence may also preclude issuance of a 404 permit since this Project will impact waters of the U.S. for which a permit it required, as the DEIR/S states "The proposed project has potential to result in fill of wetlands or other waters regulated under Section 404 of the CWA or activities in, over, or under navigable waters regulated under Section 10 of the Rivers and Harbors Act, which would be inconsistent with each of these regulations."[25]

Upon review of the entire discussion of terrestrial biological resources in the DEIR/S, it is apparent that every mention of focused, protocol, and most reconnaissance surveys for sensitive flora (not just habitat types) and fauna conducted for this Report hinge mostly upon data either not cited at all, vaguely alluded to by mentioning reports that covered only small sections of this Project footprint - some such report being 10 – 11 years old – and the citation of AECOM shapefiles, "AECOM 2016". In fact, "AECOM 2016" is cited at least 50 times throughout the document. Yet no report of data on individual species accounts are provided. For such a large, well-funded, and public Project that has had ample opportunity to contract biological specialists to conduct protocol level surveys for threatened, endangered, and Special Concern species, this is an overt oversight.

[22] *Ibid*. 4.6-70
[23] *Ibid* 4.6-82
[24] *Ibid* 4.6-85
[25] DEIR/S 4.6-3

c. The DEIR/S Lacks the Necessary Data to Assess Existing Conditions of the Project

The lack of focused and protocol surveys discussed above prevents the public reviewer of the DEIR/S from thoroughly assessing exactly what sensitive species are present throughout the Project site, and in what density or abundance. As noted, reconnaissance surveys, databases, and historic records are an important part of determining whether or not the habitat for special status species exists on site. However, they do not, and cannot, determine how many individuals of a species may be present, when, where, in what density, status of breeding and nesting, life stage (i.e. larvae or adult), and other important details that are necessary for developing an accurate impact assessment and, where necessary, developing appropriate standards and details for impact mitigation, including the type, size, and location of mitigation parcels designated to offset habitat and impacts that could result in 'take' for species listed under the federal and state Endangered Species Act.

A citation of a shapefile (a geospatial vector data format for GIS software, such as "AECOM 2016") does not provide this type of necessary information the same as a standard Biological Technical Report (BTR) can. A standard BTR provides thorough data on protocol surveys required for listed species, and includes details on how the surveys were conducted so that others can determine if they were done adequately to detect species as prescribed by the lead wildlife permitting agencies. Dates, times, weather conditions, duration, and other important information regarding behavior, breeding status, exact location, territory use, etc. are all types of information that are required for preparation of site-specific mitigation measures, protocols, plans, including selection of specific parcels for mitigation banking or habitat offset.

CURE-Owens-6

The necessity of this type of data is underscored by the DEIR/S own claim that "the definition of a substantial [impact analyses] as used in the significance criteria above has three principal factors: magnitude or intensity and duration of the impact; rarity and context of the affected resource; and susceptibility of the affected resource to disturbance"[26] and, "The evaluation of significance must also consider the interrelationship of these three factors. **For example, a relatively small-magnitude impact on a state- or federally listed species could be considered significant if the species is rare and highly susceptible to disturbance".**[27] This is true not only for determining significance of impact, but degree of significance in respect to what mitigation measures would be adequate. One cannot completely determine factors such as context and susceptibility of an entire population regarding impacts of the development of the Project if one does not know whether there may be one, ten, one hundred, or one thousand individuals of a special status species present. It is also impossible to determine, without such data, if any given mitigation measure can specifically reduce the Project impacts to below significant when the measure is based upon the assumption that the protected

[26] DEIR/S 4.6-121
[27] DEIR/S 4.6-121

species is present, as opposed to how many may be present, and under what conditions they are present as iterated above.

Focused and protocol surveys are key for conservation and mitigation analyses and subject to agency oversight; the California and federal Fish and Wildlife Agencies require them for development permits where the habitat of protected species is at risk by a given project. Therefore, focused and protocol survey data are essential not only for adequate CEQA review of the analysis of potential impacts, such surveys are required for section 7 and section 10 consultation under the ESA, and will be necessary for this Project as it has the potential to impact ESA listed species a and definitely their habitat. Focused and protocol surveys are conducted by biologists who have extensive and otherwise appropriate experience enabling them to observe and record all detectable individuals of the species in question, and are regulated by the agencies with certifications and permits. Reconnaissance surveys make observations at the habitat level, and any individual species observed are done so incidentally, not with a thorough procedure for which training and oversight (via project and annual reports) are required as is the case with biologists who hold ESA recovery permits (and certifications) for specific rare, threatened, and endangered species.

CURE-Owens-6 cont.

d. Incomplete Assessments of Special Status Species and Deferred Mitigation Contingent on Such Assessments and Surveys. This Results in an Incomplete Impact Analyses.

The DEIR/S states that for Mitigation Measure 4.6-1e: Avoidance and Minimization Measures for Special-status Plants that prior to construction "CalAm or its contractor shall conduct focused botanical survey(s) for special-status plants in all potentially suitable habitat during the appropriate blooming period for each species. Special-status plant species are widespread throughout the project area, and could occur at the following facility locations subsurface slant well site, MPWSP Desalination Plant site, ASR-5 and ASR-6 Wells sites, Terminal Reservoir site, and along the Source Water Pipeline, new Desalinated Water Pipeline and new Desalinated Water Pipeline Optional Alignment, the Castroville Pipeline and Castroville Pipeline Optional Alignments, new Transmission Main and new Transmission Main Optional Alignment, ASR Conveyance Pipeline, ASR Pump-to-Waste Pipeline, and ASR Recirculation Pipeline, Ryan Ranch-Bishop Interconnection Improvements, and Main System-Hidden Hills Interconnection Improvements, and at proposed staging areas. The results of these final surveys shall be combined with previous survey results to produce habitat maps showing habitat where the special status plants have been observed during either of the focused botanical surveys conducted for each facility site." Although future surveys as described are indeed helpful, what is missing are detailed accounts of the focused surveys already conducted.

CURE-Owens-7

Simply stating that surveys revealing potential presence of a sensitive species in a particular habitat provides only a partial picture of what is necessary to develop baseline mitigation plans. For instance, the DEIR/S mitigation measures briefly describe rare plant relocation and/or avoidance as the foundation of impact reduction. However, a mitigation protocol that is effective for one to a dozen individual plants on a given site may be very

different, and thus ineffective, for a site that hosts a special status species that has several hundred or more individuals on the same size site. Whereas on a site with very low occurrence and density of rare plants avoidance of these plants may be feasible, a site with high rare plant density and occurrence may well require additional mitigation measures, including specific restoration or other kinds of compensatory mitigation, not detailed by this DEIR/S' impact reduction analyses, including things like requiring significant alteration or movement of soils, roads, access to roads, impacts to ephemeral ponds and puddles, etc. Appropriate timing of such measures is specific to accurate impact analyses as well, since, for example, some species are blooming while others are still dormant or not yet merged, contained mostly in soils and undetectable at certain times by even the most attentive onsite botanist conducting last minute pre-construction surveys as is typical in many such projects. In summary, simply assuming presence of a special status species is clearly inadequate for mitigation planning that is species and site appropriate. Not having such accuracy in mitigation measures precludes the Applicant from correctly claiming that such measures will indeed reduce potential impacts to below significant.

CURE-Owens-7 cont.

Such information is necessary to draft appropriate mitigation measures **specific to species**, **and to each site, including parcels set aside for habitat loss compensation**. Such has not been provided in this DEIR/S, therefore it cannot be determined if proposed mitigation measures will effectively reduce potential impacts for rare plants to below significant, or if proposed measures are truly feasible, efficacious, and within the capabilities or expertise of the staff on hand to carry them out.

e. DEIR/S Biological Resource Maps are Inadequate for Determining Existing Conditions Regarding Special Status Species Calling Attention to Need for Focused and Protocol Surveys

The DEIR/S provides maps (figures 4.6-2a, 2b, 2c) that are of very limited utility regarding the existing status of sensitive species for the Project. The maps show circles and polygons to indicate presence of CNDDB listed plants and animals, however the "occurrences" do not indicate which animals or plant species correspond to which circle or polygon, therefore one can only determine from these maps that some unspecified species from the long list on the map legend was recorded for a given area on the Project. To enable thorough review of the existing site conditions, the Applicant should present maps of known locations within each Project site of each of these sensitive species, labeled appropriately (especially for those for which mitigation is deemed required), including representations of how many individuals occur in any given location. At this point it should be obvious that focused and protocol level surveys of species are necessary to create such maps that are current for this Project footprint.

CURE-Owens-8

V. THE DEIR/S FAILS TO ADEQUATELY ANALYZE AND MITIGATE IMPACTS ON SNOWY PLOVER

a. Western Snowy Plover Background and Relative Status for the Project Region

Historically, thousands of snowy plovers nested along the California coast, however by the late 1970s the snowy plover had disappeared from significant parts of its coastal California breeding range, and biologists estimate the breeding population along the coast has now dwindled to fewer than 1,500 birds. [28, 29, 30] The Pacific Coast population of the western snowy plover (*Charadrius nivosus nivosus*) was federally listed as Threatened in 1993,[31] and is a Bird Species of Special Concern in California. A Recovery Plan for the species was finally published in 2007, and a Final Rule for the revised designation of critical habitat was published in June 2012. [32]

CURE-Owens-9

b. Threats and Types of Impacts to the Snowy Plover

The primary threats to Pacific coast population of the western snowy plover are decreased habitat availability and anthropogenic disturbances to habitat.[33] Specific causes and effects vary geographically, but include fragmentation, degradation, and loss of habitat due to encroachment, habitat erosion, expansion of urban development and increased recreational beach use.[34] Increasingly, the impacts of climate change and resultant sea level rise are contributing to the cumulative impacts on populations. These adverse effects often are exacerbated by various anthropogenic influences that benefit or attract predators of the snowy plover.[35]

Recovery Plan for the Pacific Coast Population of the Western Snowy Plover *(Charadrius alexandrinus nivosus).* Sacramento, California. xiv + 751.

[34] United States Fish and Wildlife Service. 2007. Recovery Plan for the Pacific Coast Population of the Western Snowy Plover *(Charadrius alexandrinus nivosus).* Sacramento, California. xiv + 751.

[35] *Ibid*.

The Recovery Plan for the Pacific Coast Population of the Western Snowy Plover (Recovery Plan) specifically identifies habitat degradation caused by **human disturbance, urban development, introduced species** such as beachgrass, and expanding predator populations as resulting in significant decline in active nesting areas and in the size of the breeding and wintering populations, **while contributing to poorly analyzed, cumulative type of habitat loss for western snowy plovers**.[36] **In addition to causing direct loss of habitat, urban development causes a suite of other direct and indirect impacts that adversely affect plovers**. For example, increased development increases human use of the beach, thereby increasing disturbance to plovers.[37] In addition, the value of breeding and wintering habitat is diminished by increased levels of illumination at night (e.g., for parking, construction activities); increased sound and vibration levels; increased attraction of predators due to increased sources of garbage and other anthropogenic food attractants, and pollution drift.[38] Finally, activities such as beach raking and debris (e.g., driftwood) collection remove habitat features for both plovers and their prey, and precludes nests from being established.[39]

CURE-Owens-9 cont.

The Pacific coast population of the western snowy plover (SNPL) has continued to decline despite its listed status protections and development of the Recovery Plan. Point Blue Conservation Science (Point Blue), in collaboration with the USFWS and California Department of Parks and Recreation, has been monitoring the status of nesting snowy plovers along the coast of Monterey Bay and for the past 30 years, and in northern Santa Cruz County since 1988.[40] At the end of 2012 they issued a report of the snowy plover's nesting status in these areas, including an assessment of the species' response to management agencies efforts to enhance breeding success and population size.[41] According to the report the plovers experienced a 10% decrease from the previous year, with no plovers detected in Santa Cruz beaches for the third year, thus reinforcing the elevated importance of the nearby population in Monterey Bay area where the Project site is located. Specifically, the report stated, "The plovers experienced subpar breeding success in 2012. Their clutch-hatching rate was 51.0 % on Monterey Bay beaches. These rates were well below their respective averages from 1999-2011. The hatching rate on the beaches was 21% below the 64% average of the previous 13 years." They also reported that only 28-30% of the chicks that hatched on the beaches fledged; a rate about 32% below the average of 42.4% from 1999-2011. Fledging rates were below 10% at one survey site (Martin Property) that is in close proximity to the Project's proposed slant well site.

[41] Page G. W, Neuman K. K., Warriner J. C., Warriner J. S., Eyster C., Erbes, Dixon D., and Palkovic A., (December 2012). Nesting of the Snowy Plover in the Monterey, California in 2012. PRBO Conservation Science Publication # 1898.

The sensitivity of this species, and its slow progress in recovering even under ESA protections, demonstrate the need for detailed information regarding just how close nesting birds are to the Project prior to issuance of a permit that approves scripted mitigation measures. However due to the DEIR's:

(a) Complete lack of focused, protocol surveys for snowy plovers, or

(b) Lack of provisioning of data for public review regarding nest monitoring by other research agencies, including specific nesting grounds locations and numbers of breeding pairs over the past 5 plus years by other researchers, and

(c) Poor map detail and quality regarding adequate location details of Project components and proximity of current breeding pairs,

it is impossible to make such a determination, thus making it impossible for the public to thoroughly and accurately assess the impact of the Project's activities in this area to this segment of the plover population, and thus the regional population as a whole. This same argument can be made project-wide, since within the DEIR/S no such recent, detailed data regarding the specific subpopulation status of breeding pairs were provided for review, nor were protocol surveys conducted, or directly reported and mapped in detail for any segment of the Project, including Project development sites in close proximity to snowy plover critical habitat.

CURE-Owens-9 cont.

The Point Blue researchers concluded that the consequence of the low number of fledglings in 2012 will likely be a smaller breeding population in the Monterey Bay area in 2013, and their prediction was correct. The authors released a monitoring update for the 2013 breeding season, where once again breeding success was reported as declining compared to previous years: "Plovers experienced another year of subpar breeding success in the Monterey Bay area in 2013. Clutch hatching rate was 54% and chick fledging rate 31% below the prior 14-year average. As a result, the total of 116 fledges was 51% lower than the average of the prior 14 years. The consequence of the low number of fledglings produced in 2013 will likely be a smaller breeding population in the Monterey Bay area in 2014. One fledged young per male is necessary to sustain a population experiencing average mortality levels but only 0.6 chicks per male fledged in 2013."[42] Poor reproductive success has contributed to the decline and low population size of the western snowy plover, especially where it breeds on coastal beaches used by humans for recreation.[43] Due to increasingly low reproductive success, the Pacific coast population of the western snowy plover has become a management-dependent species.

[42] *Ibid*.

[43] Colwell MA, CB Millett, JJ Meyer, JN Hall, SJ Hurley, SE McAllister, AN Transou, RR LeValley. 2005. Snowy Plover reproductive success in beach and river habitats. Journal of Field Ornithology 76(4):373-382.

To sustain the breeding population requires provision of undisturbed nesting areas and wintering habitat, as well as protection from predators.[44]

The DEIR/S states that, "Western snowy plover are known to nest in the beach and sand dunes between Reservation Road and the Salinas River National Wildlife Refuge (Page et al., 2015). In 2015 there were 469 individual snowy plovers in the Monterey Bay breeding population. During surveys conducted for the MPWSP in 2012 (ESA, 2012) and 2013 (ESA, 2013), western snowy plovers were observed at the beach located north and south of the CEMEX sand mining facility, respectively. Multiple western snowy plover nests have been observed on the beach and foredunes within and at the proposed northernmost subsurface slant well cluster in the CEMEX active mining area (PRBO, 2012 in Zander Associates, 2013). Several western snowy plovers were observed among the sparse central dune scrub and iceplant mats of the CEMEX active mining facility during reconnaissance surveys in May 2016 (ESA, 2016). Western snowy plover has a high potential to nest along the beach and foredunes in the vicinity of the northernmost subsurface slant well cluster at the western terminus of the proposed Source Water Pipeline alignment. Additionally, western snowy plover may use the beach and dunes within all subsurface slant well and Source Water Pipeline work areas for wintering, roosting, and foraging. Western snowy plover has potential to nest in the backdunes in the proposed subsurface slant well area."[45]

CURE-Owens-10

This reviewer is unable to confirm any details about the current existing conditions (numbers and status of breeding and non-breeding, abundance, etc.) of SNPL on the project footprint and its buffer zones, since the surveys cited here are not focused or protocol level but instead are habitat assessments conducted near, but not on the site. The most detailed record of such available is from Point Blue's annual report from 2015[46], however it is important to note: (a) Point Blue's surveys did not cover all of the potential SNPL winter and breeding habitat potentially impacted by the Project, (b) Point Blue's report says that only *preliminary results* are printed in their report, and that the results are not to be cited in other reports or the scientific literature without the authors' permission. Also, the DEIR/S excuses the existence of a 2016 data on focused surveys of nesting or wintering SNPL by saying that, "ESA requested western snowy plover occurrence data from Point Blue Conservation Science, but Point Blue Conservation Science was unable to provide this data prior to publication of this EIR/EIS."[47] It is not, however, the responsibility of Point Blue to render services for this Project's timeline, and it appears nothing precluded the Applicant from hiring another biologist to conduct protocol

[44] Colwell M, NS Burrell, MA. Hardy, K Kayano, JJ Muir, WJ Pearson, SA Peterson, KA Sesser. 2010. surveys during breeding season to determine the number, and exact locations, of SNPL within and surrounding the Project footprint. Since Point Blue consistently publishes their annual reports in January for the previous year surveys, and since the Applicant has referenced these previous reports and is aware of this timeline, they could have predicted that a 2016 report from Point Blue would not be available for the DIER/S timeline and thus hired an independent permitted biologist to conduct the necessary surveys.

In regards to the slant well construction and its impacts to SNPL, the DEIR/S compares results of mitigation for a single test well with this proposed development of ten wells by saying "…the analysis and findings from the test slant well support the conclusion that impacts to plovers can be reduced through implementation of avoidance and minimization measures." Again the authors blur the lines of adequate mitigation and impact reduction by comparing site conditions and development impacts that are not equivalent, and fail to demonstrate that impacts can be reduced to below significant when the report does not describe what that the conditions are in respect to exact numbers of terns impacted, breeding, overwintering, etc. within and near the Project footprint.

CURE-Owens-10 cont.

c. The DEIR Fails to Adequately Mitigate Impacts to Snowy Plover Critical Habitat

The Project site not only supports snowy plovers, but as mentioned above is also located adjacent to federally designated critical habitat for the species. Critical habitat is defined as "a specific geographic area that is essential for the conservation of a threatened or endangered species and that may require special management and protection."[48] Within designated critical habitat, the USFWS protects areas that provide **primary constituent elements** (PCEs), which are the physical and biological features of a landscape that a species needs to survive and reproduce.[49] PCEs of critical habitat for the western snowy plover include:

1. Areas that are below heavily vegetated areas or developed areas and above the daily high tides;
2. Shoreline habitat areas for feeding, with no or very sparse vegetation, that are between the annual low tide or low-water flow and annual high tide or high-water flow, subject to inundation but not constantly under water, that support small invertebrates, such as crabs, worms, flies, beetles, spiders, sand hoppers, clams, and ostracods, that are essential food sources;
3. Surf- or water-deposited organic debris, such as seaweed (including kelp and eelgrass) or driftwood located on open substrates that supports and attracts small invertebrates described in PCE 2 for food, and provides cover or shelter from predators and weather, and assists in avoidance of detection (crypsis) for nests, chicks, and incubating adults; and
4. **Minimal disturbance from the presence of humans, pets, vehicles, or human-attracted**

CURE-Owens-11

[48] USFWS. 2002. Critical Habitat: What is it? Publication 703/358 2105. http://endangered.fws.gov. (Retrieved Jun 14, 2015).
[49] *Ibid*.

predators, which provide relatively undisturbed areas for individual and population growth and for normal behavior.[50] (Emphasis added).

Snowy plover critical habitat is within close proximity to the Project site, which currently provides these PCEs. It is essential to note that construction sites consistently create impacts that extend beyond the footprint boundaries in the form of temporary roads, parking areas, poorly contained construction vehicles, noise, erosion, dust and other pollutants that can markedly diminish the minimally disturbed quality of critical habitat as described above. It is therefore possible that the Project site could significantly reduce the quality of snowy plover critical habitat as defined by these PCEs.[51]

The Project proposes construction bordering critical habitat:

(a) At the proposed slant well site,

(b) At the west end of the proposed seawater intake system, and

(c) Along approximately **9 miles of coastal snowy plover critical habitat** from the northern slant well proposed site to Monterey State Beach, at times within less than 400 feet of the development footprint, with virtually no major visual, structural, or auditory barriers (from existing development or geographic topography) between the proposed construction footprint and critical habitat. The majority of this critical habitat has historically been occupied by nesting plovers, and was recorded as having active nesting during breeding season 2012 and 2013 by Point Blue researchers. Also, the site of the proposed seawater intake system pipeline where it runs west from the shoreline is historic nesting habitat for the snowy plover, according to Point Blue studies (*pers. comm.* Kriss Neuman June 23, 2015).[52,53]

CURE-Owens-11 cont.

d. The Importance of Avoiding Impacts to Non-breeding Season Snowy Plover Habitat is Underestimated

It is important to note that critical habitat provision #4 above does not distinguish between breeding and non-breeding season; in other words minimization of disturbance to critical habitat is important regardless of the time of year. Western snowy plovers are non-migratory residents along the Monterey coast, studies of banded birds demonstrate that many individuals occupy the same general habitat with little to no migration to other locales;

CURE-Owens-12

[50] Federal Register. 2012 Jun 19. Endangered and Threatened Wildlife and Plants; Revised Designation of Critical Habitat for the Pacific Coast Population of the Western Snowy Plover; Final Rule. Federal Register 77(118):36728-36869.

[53] Page G. W, Neuman K. K., Warriner J. C., Warriner J. S., Eyster C., Erbes, Dixon D., and Palkovic A., (December 2012). Nesting of the Snowy Plover in the Monterey, California in 2012. PRBO Conservation Science Publication # 1898.

researchers have discovered that banded plovers exhibited high site faithfulness, occupying small linear stretches of beach (752 +/- +/- 626 m).[54]

Successful management of highly sensitive, reduced populations such as those found along the Monterey coast require equal attention paid to avoiding significant impacts to occupied nesting habitat year-round, since the specific habitat, foraging, and predation factors continue to play a key role in population size and viability despite the time of year or breeding status of the individuals. In their Final Recovery Plan, the USFWS state that species' social factors play a role in attracting plovers to nest in any given area, and that the management of wintering flocks can be important relative to plover nesting sites.[55] In response to comments of their Final Recovery Plan, USFWS states that "Our designation of critical habitat recognizes the importance of both wintering and breeding areas."[56]

Western snowy plover research emphasizes the importance of careful management of habitat and nest sites during both breeding and non-breeding season, and how mitigation for impacts is not nearly as straightforward as avoiding major impacts during breeding season only, or relying on implementing avoidance measures for impact mitigation during breeding season only, such as fencing, nest exclosures, or 'educating' on-site workers about the presence of plovers.

CURE-Owens-12 cont.

Some snowy plover management scenarios have demonstrated that lethal predator removal and reducing human disturbance facilitate population recovery and may partially alleviate the reliance upon immigration of birds from other areas, a necessary function to maintain a viable subpopulation. However, in some cases the use of nest exclosures reduced population growth because they were found to compromise *adult* survival, thus highlighting the importance of maintaining viable source populations and re-evaluating the recovery objectives for plovers during both breeding and non-breeding seasons.[57]

It has been demonstrated that conservation of snowy plover populations in California, characterized by those located near and within the Project site, "requires managing habitat throughout the year, especially during winter when northern populations may be limited by

[54] Brindock, K. M., & Colwell, M. A. 2011. Habitat selection by western snowy plovers during the nonbreeding season. Journal of Wildlife Management, 75(4), 786-793. doi:http://dx.doi.org.jerome.stjohns.edu:81/10.1002/jwmg.106

[55] USFWS. 2007. Western snowy plover (*Charadrius alexandrinus nivosas*). Pacific coast population Recovery Plan, Portland, Oregon, USA.

[56] *Ibid.*

[57] Eberhart-Phillips, L., & Colwell, M. A. 2014. Conservation challenges of a sink: The viability of an isolated population of the snowy plover. *Bird Conservation International,* 24(3), 327-341. doi:http://dx.doi.org.jerome.stjohns.edu:81/10.1017/S0959270913000506

food and predation".[58] **Specific, often seemingly minor attributes of wintering sites can make a significant difference in survival and fecundity of individuals.** Northern coastal sites occupied by plovers had more brown algae (e.g., *Macrocystis, Nereocystis, Postelsia,* and *Fucus*) and associated invertebrates (e.g., amphipods and flies), were wider, and had less vegetation than unoccupied sites, suggesting that wintering plovers select habitats with more food and where they could more easily detect predators.[59] Maintaining habitat year-round with attributes that support abundant food and reduce predation risk (i.e., wide beaches, limited obstructive cover) is important to individual survival and maintaining the Pacific Coast population of snowy plovers. Specifically, researchers concluded that,

> *"Protecting occupied sites from human disturbance, which adversely alters nonbreeding habitat and directly causes mortality, may be essential for conserving the Pacific coast population of the snowy plover, and it may benefit other shorebirds."*[60]

For these highly sensitive nesting populations that occur near and on the Project site, within critical habitat, mitigation of the significant temporary, indirect, direct, and cumulative impacts of the Proposed Project requires more than is prescribed by the DEIR to reduce impacts below significant.

CURE-Owens-12 cont.

e. Mitigation Measure 4.6-1d: Protective Measures for Western Snowy Plover is Inadequate to Reduce Impacts Below Significant

The DEIR/S defers the mitigation impact analysis of the SNPL by stating that "for work that cannot be completed during the non-nesting season" SNPL surveys will be conducted as part of attempts to obtain approval by USFWS to develop SNPL habitat during breeding season. This infers that some construction must occur during breeding season. It goes on to say that "If nests are observed within 300 feet of construction activities, the qualified biologist shall notify and consult with USFWS to determine whether construction may proceed, based on detailed information on location of nest(s), proximity to construction, site lines and topography, and noise environment. Any additional avoidance or minimization measures shall be implemented prior to initiating construction activities."[61]

What if the Applicant does not receive permission to continue with construction activities due to presence of too close, or too many nesting SNPL immediately prior to development commencement, or during development? Or if such is the case and the developer is not given permission to continue, will the developer then pressure USFWS to allow such, claiming to delay construction for months is an undue hardship (for the company, or for the

CURE-Owens-13

[58] Brindock, K. M., & Colwell, M. A. 2011. Habitat selection by western snowy plovers during the nonbreeding season. Journal of Wildlife Management, 75(4), 786-793. doi:http://dx.doi.org.jerome.stjohns.edu:81/10.1002/jwmg.106

[59] *Ibid.*

[60] *Ibid.*

[61] DEIR/S 4.6-169

community's water needs), especially if it is for the duration of nesting and fledging as the mitigation measure explains could be the case? Such a tactic by developers is one I have commonly witnessed as a consulting biologist, increasingly so over the years, wherein the developer's mitigation measures are insufficient for various reasons including poor ground-truthing and poor knowledge of existing conditions for any given sensitive species. Despite this, permits are approved based upon vaguely described, deferred mitigation. And yet this deferred mitigation has less than rigorous oversight for many reasons, is lacking in details and insight, and sometimes the result is that construction must be temporarily halted to avoid take of a species. This incurs pushback from the developer claiming hardship, and such delays are often not upheld by USFWS due to this pressure.

In my years as an environmental consultant I have witnessed that it is far more common for the agency to give a "variance" of a permit and defer to the complaints of the developer when construction is at risk of being seriously delayed. These variances for the prescribed mitigation can and do lead to mitigation measures that are altered and diminished in effectiveness from their written prescriptions on paper, resulting in unmitigated, significant impacts, unanticipated (and sometimes unreported) take of species. This is an all-too common practice among developers and environmental consultants that I have personally witnessed as an independent biologist for construction sites with sensitive species of nesting birds and other rare animals present. Certain actions by the developer, including violations of regulations and mitigation measures, go unreported in part due to environmental consultants' ubiquitous use of extreme and rigid non-disclosure agreements (NDA), where biologists are required to sign strict NDAs to be employed and subsequently are at risk of losing their jobs, or worse, if they report any unpermitted harassment or take of protected species.

CURE-Owens-13 cont.

In short, these mitigation measures that seek to develop SNPL habitat during breeding season are unacceptable for reasons outlined above. To ensure adequate mitigation of indirect, direct, and cumulative impacts, the Applicant should commit to withholding all construction activities within SNPL habitat during SNPL breeding season, without exception.

The DEIR/S concludes impacts to SNPL would be significant throughout at least 9 acres of the Project footprint, yet they do not describe in detail the degree of such an impact since they do not provide any data on exactly how many of the birds have nested within and near the SNPL habitats within the Project footprint. The Report states, "Construction of the slant wells in the CEMEX active mining area could occur year-round"[62] where impacts could result in flight of breeding birds, nest abandonment, or nest failure, and "construction activities would be implemented in or around areas where plovers may occur during the winter. Construction during the snowy plover wintering season (October 1 through February 28) could directly or indirectly impact individual birds if present within or adjacent to the construction area. Human presence and construction noise and activities can cause roosting plovers to fly and disturb resting or foraging activities. This would be a significant impact."[63]

[62] *Ibid*. 4.6-129
[63] DEIR/S 4.6-130

The DEIR/S acknowledged impacts to wintering plovers would be significant, and states its primary mitigation measure to reduce ongoing construction during non-breeding season impacts as follows: "For work conducted during the non-nesting season, a qualified biologist will evaluate the nature and extent of wintering plover activity in the project area several days prior to construction and inform CalAm so they can make construction decisions that avoid or minimize disturbance to plovers. The biologist shall conduct periodic monitoring during construction to ensure that minimization measures are implemented to avoid or minimize disturbance to plovers."

This measure is not specific enough to ensure confidence in avoidance measures for temporary impacts that include harassment and possibly species take. Details must be provided as to exactly how the developers will avoid harassment, and to what degree of impact. For instance, to avoid one or two plovers may be easier than if many are found to be using the area to forage regularly on and near the site. If the latter is the case, what measures can be taken to avoid a moving target of foraging plovers, especially given the natural history details provided above regarding plover sensitivity to human disturbance, and importance of lack of disturbance of wintering habitat for breeding success?

The DEIR/S infers that direct, indirect, and cumulative impacts to SNPL by development of their habitat may be partly minimized by the simple fact that they have abundant habitat to the north and south of the site in which to relocate, forage, and breed; and that they would only be temporarily displaced by construction. They claim that harassed ("displaced") birds can simply move elsewhere due to there being abundant habitat nearby. This argument is biologically flawed and should be summarily dismissed. If impacts to species could be avoided simply by default of the existence of the presence of similar habitat nearby, much of the impacts of any given development on a given species could be ignored by default.

There is abundant evidence demonstrating how erroneous the DEIR's assumption here regarding how an animal (not just the SNPL) can simply just "go elsewhere" thanks to nearby habitat that it can use being present. It is an assumption that affects mitigation analyses and thus should not be ignored as minor. Nearby habitat of the same category may or may not be as adequate for an individual's needs as habitat already occupied. There is no way for the Applicant to determine to what degree 'nearby' habitat destinations for displaced birds may be occupied by conspecifics that may defend resources, or to what density predators may occur, or if, for instance, whether nearby habitat may or may not have adequate microsites or other resources for optimal foraging, thus potentially impacting foraging success and fecundity.[64] For instance, years of personal observations have revealed that Diegan coastal sage scrub, the habitat used by breeding California gnatcatchers (CAGN) (a federally threatened ESA species), can be quite different from one location to the next. Whether or not the CAGN chooses to use a

CURE-Owens-13 cont.

[64] Nol, E., MacCulloch, K., Pollock, L., & McKinnon, L. 2014. Foraging ecology and time budgets of non-breeding shorebirds in coastal Cuba. *Journal of Tropical Ecology, 30*(4), 347-357. doi:http://dx.doi.org.jerome.stjohns.edu:81/10.1017/S0266467414000182

particular causal sage scrub habitat for nesting depends invariably on characteristics including dominant shrub species, grade, slope, percentage of bare ground, and sometimes heterogeneity of the shrub habitat. Such choosiness for appropriate breeding, and nesting microhabitats is common for many species within all taxa. This factor is an important one when it comes to mitigation prescriptions for impacted habitats, including selection and analysis of efficacy of parcels for compensatory mitigation that are species-specific.

Additionally, research demonstrates that when birds and other vertebrates emigrate to a new location, risk of mortality increases due to factors such as increased visibility, decreased familiarity with a new area relative to competitors, predators, and resources.[65] Mortality for passerine juveniles during their first year, including during non-breeding season, is typically very high and based on many factors that can be compromised by anthropogenic influences. [66, 67, 68, 69] The Applicant provides no way of determining the degree to which direct and indirect impacts from harassment will reduce survival of first year juveniles, especially given the DEIR/S makes little attempt to discuss actual site population details such as number of breeding pairs, local breeding success in terms of chicks fledged in a given area each year, etc. Such oversights in isolation may appear minor, however when considered as part of a cumulative impact over time, especially in light of the difficulty of recovering threatened and endangered species that reside in areas increasingly urbanized and developed as California is, they become significant. As the USFWS Recovery Plan indicates, snowy plover population recovery requires undisturbed wintering as well as breeding habitat; this fact must be taken into consideration for impact analysis. (See below for additional supporting evidence regarding wintering habitat, cumulative impacts, and resultant inadequacy of snowy plover impact analysis.)

f. Plover Mortality Will Increase Due to Increase in Human Disturbance Despite Proposed Mitigation Measures

Disturbance by humans is a key factor in reducing or eliminating snowy plover nesting habitat.[70] Humans negatively impact plovers by causing: (1) destruction of nests and chicks; (2) increased disturbance leading to reduced incubation or brooding constancy; and (3) decreased foraging opportunities by adults and chicks.[71]

Direct mortality can occur when humans inadvertently step on chicks or them with mechanized vehicles.[72] Neither is mortality to birds due to nearby construction activities limited to chicks. As a professional environmental consultant specializing (in part) in wildlife monitoring for over 20 years, I have personally witnessed, as have other biologist construction monitors I have communicated with over time, that for various types of development - including pipeline installation – that despite a myriad of mitigation protocols and best management approved and imposed under standard multi-agency permitting processes, mortalities of ground nesting and foraging birds, along with reptiles and rodents, are an inevitable result of construction traffic on any given construction site that occurs in a species habitat (*pers. comm*, Patrick Hord, Jan 2014; Jane Higginson June 2015; Dr. Kelly Smith May 2015). These mortalities occur despite imposed speed reductions, fencing, signage, right-of-way-restrictions, imposed nest 'buffers', educational trainings for workers, pre-construction nest surveys, and other typical mitigation measures that purport to reduce impacts during both breeding and non-breeding season development. For instance, on one construction site for a large industrial complex, within the span of one month along one dirt road designated for construction traffic, over 30 flat-tailed horned lizards (a special status species) were inadvertently run over and killed due to their cryptic nature and attraction to the moisture provided by erosion control water trucks. The degree to which this phenomenon occurred was partly due to the construction site occurring near, but not within, occupied critical habitat for the species, and had little to do with breeding season or status of the individuals.

CURE-Owens-14

Although it can be argued whether or not such inevitable mortalities are significant based on the numbers of individuals injured or killed, it cannot be denied that when the mortalities occur among individuals of endangered or threatened species such as the Western snowy plover, it must be concluded that each breeding individual loss results to some degree in reduced viability of the population.

Recovery Plan for the Pacific Coast Population of the Western Snowy Plover *(Charadrius alexandrinus nivosus).* Sacramento, California. xiv + 751.

[72] *Ibid.*

As significantly, indirect mortality occurs because high levels of human activity hinder normal brooding, foraging, and sheltering activities. As mentioned above, snowy plover chicks are precocial. After hatching, the male bird cares for the chicks for approximately 28 days.[73] However, the chicks quickly must learn how to feed themselves, balance thermoregulatory needs, and avoid predators without assistance. Human activities can be especially detrimental to survivorship during this critical period in the species' life cycle. When a brooding adult is disturbed, it often leaves chicks exposed, and hence vulnerable to predation, inclement weather, and reduced foraging time.[74] Human activity may also cause brood movement, resulting in the separation of one or more chicks from the rest of the brood.[75] In addition, movement into adjacent territories can result in attacks on the young by other adult plovers, resulting in chick death and abandonment.[76]

Predation, by both native and nonnative species, has also been identified as a cause of mortality to plovers even in the presence of applied certain mitigation measures to reduce impacts of development projects, and is a major factor limiting western snowy plover reproductive success at many Pacific coast sites.[77]

CURE-Owens-14 cont.

While predominantly a natural phenomenon, predation is enhanced through the introduction of nonnative predators and unintentional human encouragement of larger populations of native predators (e.g., by providing supplemental food, water, and nest sites). Elevated predation pressures result from both temporary and permanent landscape-level alterations in coastal dune habitats that, in turn, now support increased predator populations within the immediate vicinity of nesting habitat for western snowy plovers.[78]

Because anthropogenic disturbance is the primary threat to the western snowy plover, numerous biologists have concluded that protecting occupied sites from human disturbance during both breeding and non-breeding season is essential to the conservation and recovery of the species.[79]

g. Case Studies Substantiating the Effects of Snowy Plover Disturbance

CURE-Owens-15

Numerous studies have demonstrated that human activities are affecting the

survivorship, numbers, and activity patterns of western snowy plovers. Escofet and Espejel concluded that human encroachment has caused nesting snowy plovers to completely disappear from many coastal breeding locations in California. Habitat that is opened to human disturbance, such as the Project construction proposed over a minimum of a six month period in occupied plover nesting habitat, even while temporary and possibly during non-breeding season may have permanent impacts on snowy plovers. Lafferty reported that snowy plovers immediately stopped breeding at the Reserve when it was opened to recreation, and ultimately permanently abandoned the site for wintering.[80] Page et al. observed western snowy plovers' response to human disturbance at two coastal beaches where normal beach use ranged from light to heavy.[81] When humans approached western snowy plovers, adults left their nests 78% of the time when people were within 50 meters and 34% of the time when people were over 100 meters away. Ruhlen et. al. examined the effects of human disturbance on snowy plover chick survival at Point Reyes National Seashore, California.[82] Chick loss on weekends and holidays was 72% greater than expected in 1999 and 69% greater than expected in 2000. This suggested that increased human recreation on Point Reyes beaches over weekends and holidays negatively affected snowy plover chick survival, even though humans were not observed to cause direct impacts to chicks. Rather, results suggest that the increased associated potential for anthropogenic disturbance (noise, predator attraction) was primarily responsible for chick mortality.

CURE-Owens-15 cont.

h. Summary about Impacts to Snowy Plover

First, Mitigation Measure 4.6-1d defers aspects of mitigation to consultation with USFWS. This prohibits the reviewer to analyze the efficacy of details of mitigation protocols (or success criteria for such), as they cannot be provided when they are as of yet to be determined. Deferment of mitigation measures and relevant details to some point in the future does not allow for adequate impact analysis as required under CEQA, and provides no guarantee such measures will even be undertaken.

CURE-Owens-16

Second, for construction during the breeding season, visual barriers are proposed to reduce impacts. In light of the complex causes and results of anthropogenic disturbances to breeding pairs and chicks, such barriers will not serve to significantly reduce the direct and indirect impacts of noise on breeding birds. Based upon the abundant evidence regarding the negative impact of human proximity to nesting birds, all construction during breeding season

should simply be avoided, as impacts will be inevitable and unavoidable despite construction of a barrier, or the presence of a biologist on-site to detect breeding birds. The Applicant should be reminded that detection, imperfect avoidance mechanisms, and reporting cannot and will not serve to restore the impacts that will inevitably occur to birds in the form of harassment, injury, and possibly mortality if construction occurs within their nesting area during breeding season.

The DEIR/S states that impacts will be minimized, under Measure 4.6-1d, by having an onsite biologist survey for nests and then consult with experts to determine any additional avoidance or minimization measures should be implemented prior to initiating construction activities. Once again mitigation is deferred to a future consult / plan, thus making it impossible for the public to review the efficacy proposed mitigation. This is important because although agency consultation for protected species take is required under the ESA, the agencies do not conduct oversight of all mitigation measure for such species, therefore confirming due diligence of mitigation detail is necessary prior to issuance of a development permit while oversight is still a reality.

CURE-Owens-16 cont.

Adequate details for analysis are not only preferable, but essential. For example, the snowy plover management plans for the proposed Monterey Bay Shores Resort – to be constructed in snowy plover occupied habitat in proximity to the Project's western Source Water pipeline - prescribed establishing exclosures around the nesting area "during fledging" (the interval between hatching and flight) as a method to reduce breeding season construction impacts.[83] However, this has little value as a take avoidance measure because snowy plovers have precocial chicks that leave the nest within hours after hatching.[84] Snowy plover chicks coming from nests on the project site or adjacent areas would be susceptible to direct (e.g., crushing) and indirect (heightened vigilance that precludes normal foraging activities) impacts from Project construction activities.[85]

Additionally, Muir and Colwell (2010) studied the response of incubating plovers to an observer approaching the nests. Incubating plovers ceased incubation and left nests when an observer approached to within a mean distance of 80 ± 33 meters,[86] thus further demonstrating the ease at which harassment to plovers can occur with the presence of humans in the general area. This is just one example of where a thorough analysis of mitigation protocols is essential for determining adequacy of mitigation measures; without such an accurate assessment of impact reduction is impossible. **Ultimately, the only reliable way to prevent such impacts is to prohibit construction activities during the entire snowy plover breeding season.**

[85] Muir JT, MA Cowell. 2010. Snowy Plovers Select Open Habitats for Courtship Scrapes and Nests. *Condor* 112(3):507-510.
[86] *Ibid.*

Third, the Applicant proposes to develop a Habitat Mitigation and Monitoring Plan (HMMP) to complete its obligation to reduce impacts to below significant for sensitive species including the snowy plover. Once again the description of adequate impact reduction is deferred, and as a result the reviewer is unable to determine the adequacy of the measures given that no site-specific or species-specific details or methodology have been provided for a plan that has yet to be created. This prohibits adequate review by the public to determine if impacts will satisfactorily be reduced to below significant as required. Not only does it prohibit thorough analysis, it provides no guarantee that the HMMP will actually be developed and function as promised to reduce impacts as proposed, nor are any standard success criteria for such presented. The DEIR/S states the HMMP will be given to the appropriate agencies for approval, but it does not discuss what, if any, actions will be taken if any of the "appropriate" agencies (such as USFWS, or CDFW, or a local jurisdiction) do not all approve the final HMMP, nor how such an impasse would affect impact mitigation as the DEIR/S asserts will occur be default of the mention of a Plan that has yet to be created.

Fourth, in respect to movement of SNPL and assuming that displacement can be easily mitigated partly because it is a temporary impact: it is important to note that the USFWS Recovery Plan specifically states,

CURE-Owens-16 cont.

> *"A portion of the Pacific coast population of western snowy plovers do not migrate up or down the coast and are year round residents. Additionally, the majority of western snowy plovers that do migrate are site-faithful, returning to the same breeding areas in subsequent breeding seasons (Warriner et al. 1986, Stenzel et al. 1994). Western snowy plovers occasionally nest in exactly the same location as the previous year (Warriner et al. 1986)."*[87]

The USFWS Snowy Plover Recovery Plan concludes that to bring the snowy plover population back to numbers above threatened status, it is essential to

> *"prevent disturbance of breeding* ***and wintering*** *western snowy plovers by people and domestic animals.* ***Disturbance by humans and domestic animals causes significant adverse impacts to breeding and wintering western snowy plovers****. Because human disturbance is a primary factor affecting western snowy plover reproductive success, land managers should give the highest priority to implementation of management techniques to prevent disturbance of breeding birds. Management plans (Actions 3.3.1, 3.3.2, and 3.4) should include appropriate human/domestic animal access restrictions to prevent disturbance of western snowy plovers* [emphasis added]".

i. Cumulative Impacts to Snowy Plovers are Not Adequately Analyzed

CURE-Owens-17

[87] USFWS. 1986. Snowy Plover Recovery Plan. p. 138

Several other projects have been proposed for the coastal zone in the vicinity of the Project site, and proximal to snowy plover critical habitat, including:[88]

1. The Collection at Monterey Bay Project (development of a 342-room coastal resort on a 26.46-acre site located west of State Route 1 in Sand City).
2. A new campground at Fort Ord Dunes State Park (development of 100 campsites, parking areas, an internal trail network with beach access, and various other infrastructures).
3. The Monterey Bay Shores Resort Project (development of a 40 acre parcel in Sand City, including approximately 680,000 cubic yards of grading)

The Fort Ord coastal HCP includes the creation of a new campground at Fort Ord beach and will greatly increase human use in plover habitat, causing significant impacts to wintering and breeding birds and habitat within the general region of this Proposed Project's pipeline development.

The Monterey Bay Shores Resort, an exceedingly large coastal hotel to be constructed at the southern boundary of Fort Ord, will preclude nesting and wintering of plovers within and adjacent to the Project footprint, thus causing permanent direct and long term impacts to nesting to the regional population. The California Coastal Commission, amazingly, did not require any sort of concurrence with USFWS when it issued its conditional development permit, and as a result impacts to snowy plovers (and other resident sensitive species) remain inadequately mitigated, thus contributing further to local impacts to plovers in close proximity to the Project proposal. The Collections is another hotel proposed slightly south of the Monterey Bay shores Resort, and is also in Sand City, with similar significant impacts to snowy plovers.

CURE-Owens-17 cont.

The DEIR/S acknowledges the potential for cumulative impacts as follows, "Specifically, the Monterey Shores Resort (No. 19), 90-Inch Bay Avenue Outfall Phase 1 (No. 43), Slant Test Well Project (No. 47), Moss Landing Community Plan (No. 37), and The Collection at Monterey Bay Resort (No. 56) would affect beach or dune areas that may support western snowy plover. Implementation of the Monterey Bay Shores Resort and Moss Landing Community Plan projects could occur at the same time as the proposed MPWSP construction and therefore could adversely affect western snowy plover and its habitat through heavy equipment use, dust generation, elevated noise levels, and increased human activity" but claims that the mitigation measures provide will reduce impacts to below significant. However, what is not addressed is that a comprehensive strategy for the conservation of western snowy plover breeding and wintering locations has not been incorporated into the Sand City General Plan, Local Coastal Program, or their implementing ordinances. The USFWS has expressed concern about the

[88] DEIR p. 5-4

aforementioned projects being addressed in a piecemeal fashion, **which does not allow an adequate assessment of their cumulative effects**.[89] **As a result, the USFWS and others have recommended the preparation of a habitat conservation plan (HCP) to adequately address cumulative effects**.[90] The City of Sand City, City of Marina, and the Monterey Bay Shores Resort developers each committed to preparing an HCP for the western snowy plover. None of these entities have fulfilled their commitment. To date, there exists no definitive habitat plan by any of these entities that addresses cumulative impacts to the plover, or proposes a strategy for conserving snowy plovers in the specific region. In light of these oversights the DERI/S has not provided a complete discussion of all projects and development plans that contribute to cumulative impacts of the species.

CURE-Owens-17 cont.

j. Compensatory Mitigation Details are Necessary for Complete Snowy Plover Impact Analysis.

Under Mitigation Measure 4.6-1n (discussed above) the DEIR/S does state that the HMMP would include a description of any compensation in the form of land purchase or restoration. Not only should a land purchase or restoration be considered with appropriate compensation ratios of habitat gained to habitat lost of a least 2:1, but ideally would collaborate with local SNPL conservationists. According to Point Blue snowy plover biologist Kriss Neuman (*pes. comm.* June 23, 2015),

> *"There is currently no dedicated funding to support the monitoring and conservation activities that are conducted to support this regional plover population and in particular at this site. The landowner [of the Cemex site] gladly allows Point Blue, California State Parks, and USFWS refuge staff to access habitat, and we jointly install protective fencing, manage habitat and predators, and monitor nesting. A dedicated conservation fund supporting these activities on the site and possibly in the region as well would help to ensure population stability in the region."*

CURE-Owens-18

Given that the Point Blue, in coordination with California State Parks, and the local USFWS Wildlife Refuge have been working to monitor and conserve snowy plovers for the past 30 years, it would appear that two of the most effective measures that could be taken to truly reduce the cumulative impacts to this sensitive species would be for the applicant to

(1) Contribute to a conservation fund, to be overseen by the appropriate oversight agency, that will be used for monitoring, habitat restoration, and other conservation actions that are key to the populations' viability over time, and

(2) Contribute to a region-wide Snowy plover Habitat Management Plan that incorporates

[89] United States Fish and Wildlife Service. 2007. Recovery Plan for the Pacific Coast Population of the Western Snowy Plover *(Charadrius alexandrinus nivosus).* Sacramento, California. xiv + 751.
[90] *Ibid*.

all of the relevant municipalities and agencies that are stakeholders for this regional plover population's habitat and conservation. Any such Plan should coordinate and consult with the Point Blue, California State Parks, and USFWS biologists who have been researching this region's snowy plovers for decades.

CURE-Owens-18 cont.

The hydrology of sand systems such as those found in dune habitats in complicated.[91] In a coastal setting such as this, the dune plants are typically neither xerophytic nor halophytic.[92] They typically germinate during a rain event and rapidly send down a fine root through wet sand until it reaches the water table. Fresh water "floats" on the salt. The ground water is drawn toward the surface, and if the dune gets built higher, complicated physics results in the water being drawn up so that the freshwater lens used by the plants stays a relatively stable distance from the surface of the dune, whether the dune is being built higher, or eroded lower.[93] In short, the effect and resultant impacts of imposing the construction of ten extraction wells through this intricate and sensitive hydrological system, and providing a strong pull toward the ocean, is not addressed but should be for adequate impact analysis.

CURE-Owens-19

VI. ADDITIONAL MITIGATION MEASURES PROPOSED FOR TERRESTRIAL BIOLOGICAL RESOURCES IMPACTS ARE INADEQUATE

In addition to those discussed above, there are other incidences where impacts proposed as significant are considered mitigated to below significance with the following measures, despite the fact that the specifics of these measures and their standard criteria for success are not adequately identified, and at times deferred to the future, preventing complete analysis of their efficacy.

CURE-Owens-20

a. Mitigation Measure 4.6-1a. Retain a Lead Biologist to Oversee Implementation of Protective Measures[94]

First, in the case of a potential sensitive species take or harassment, the lead biologist is said to have direct stop work authority, as is a typical prescription for construction sites, and most onsite mitigation protocols and potential actions rest on this unadulterated authority of the lead biologist. However in reality the lead biologist is often not actually onsite, and his/her responsibilities are handed to a subordinate who theoretically has power to stop work, but in reality does not due to the realities of who is asserting authority over construction, aggressive

[93] *Ibid.*

[94] DEIR/S 4.6-164

pressure from the developer to never stop work more than momentarily, and other pressures including the NDAs mentioned above that tie the hands of biologists who observe violations of permits but are at risk of losing jobs if they report them. This reality is the norm, not the exception (*pers. comm.* Patrick Hord, Sage Wildlife Biology; Kim Davis, Helix Environmental; Frank Dittmer, AECOM, 2016).

I have witnessed this scenario many times in my experience as an environmental consultant, where the onsite lead biologist is not in reality given full authority to cease any actions that threaten or are in the process of causing impact to sensitive species or their habitats, or any other related environmental violations of air or water. This remains a growing and serious problem on these construction sites, due largely to the delays inherent within the process, and the conflicts inherent when relying on construction or operational site supervisors to stop work on projects for which their primary responsibility, reinforced by their employer, is ensuring work proceeds with no interruption or delays. This scenario is ripe for conflict, and more often than not results in the impacts to species and habitats going unreported, under-reported, or the situation being settled in a manner that does not comply with the spirit or intent of the mitigation measure or protocol(s). The Applicant may claim that they have little control of conflicting parties onsite, but by default they do have authority of oversight to fix these problems given that as part of CEQA compliance they are tasked with creating mitigation measure that are actually effective, with criteria for measuring success that are relevant and enforceable.

CURE-Owens-20 cont.

Therefore the Applicant should provide some standard or assurance within the mitigation measures that insures that the lead biologist, onsite, has the un-revocable authority to stop work when needed, and is **working as an independent third party** (independent of the primary environmental consultant, and of the developer) assigned to such a duty with the responsibility of reporting violations or takes of species to the agencies. As importantly, any reports of mitigation monitoring, violations, daily or monthly activities, etc. related to biological resource protection shall be given to the agencies first, developer second. The developer should not be allowed to alter or suggest alterations to any reports prior to delivery to the regulatory agency(ies). As a consultant for a quarter of a century observing the on-the-ground interactions on construction sites, I can say with confidence that without such measures in place, the role of the lead biologist is often reduced to that of a paper tiger, one hired to appease the developer as employer, and not one hired to adequately comply with all mitigation measures and standards.

Second, according to this mitigation measure it appears that the lead biologist is expected to relocate any special status species that are 'at risk'. The DEIR/S does not specify what 'at risk' entails, yet such a definition for plants and animals of different taxa is extremely broad, nor any protocol for relocation methodology, nor even which species or taxa are being referred to in the first place. Confusingly, Mitigation Measure 4.6-1c(10) says that if special

status species are found on site during construction, construction activities shall cease (under whose authority it does not say) while everyone waits for the animal to move "on its own outside of the project area (if possible)". What makes this impossible, what are the parameters? If a sensitive species of reptile is sleeping under the parked truck of a construction worker - a common occurrence on some site - does s/he have to wait until the lizard moves before he can drive his vehicle? If a burrowing owl takes up residence overnight next to a pipeline trench, what then? If it is a plant species to be relocated, which is an almost inevitable reality, the DEIR/S does not identify to where the plant species shall be relocated, or with what methodology, despite the fact that areas of the Project site have been determined to be occupied by threatened and endangered plants species for which the risk of impacts on site could arise frequently, and despite the fact that different species can require vastly different relocation protocols. Consideration of where to relocate the animal to has been deferred and delegated to the field biologist, and thus goes undescribed. There is no consideration that it might not be possible to easily locate certain species, nor any discussion of what measures would be undertaken to reduce impacts if such is the case. This results in a failure to meet the assumption of these measures reducing impacts below significant.

CURE-Owens-20 cont.

b. Mitigation measure 4.6-1e Avoidance and Minimization Measures for Special-status Plants.[95]

First, the DEIR/S states that focused surveys will be conducted in the future prior to development. However, it also says that based upon the results of these surveys, sensitive plants will be flagged and avoided where possible, *or* salvaged, *or* a take permit may be solicited, and impacts may be mitigated as a result of a consult with USFWS and/or CDFW, the details for which are not provided to any degree[96]. At present, focused, protocol level, and rare plant surveys have not been conducted in the recent past, and therefore no data is available for review, beyond some predictions of presence and likelihood to occur. As iterated previously, the lack of data on existing conditions at the species-specific level makes it impossible for the reviewer to predict the efficacy of these mitigation measures that are mostly deferred to the future. It is inevitable that mitigation measures' efficacy can be quite different based upon how many individuals of a sensitive species are present.

CURE-Owens-21

Second, the DEIR/S also states that "compensation for temporary or permanent loss of special status plant occurrences, in the form of land purchase or restoration [on or off site], shall be provided to a level acceptable to the resource agencies with jurisdiction over those species." This is also deferment of mitigation prescriptions, it also provides no information for the reviewer to determine if and how impacts will be adequately reduced below significant, nor does it make any mention of what success criteria will be used to determine impacts have been adequately reduced, or for which species specifically. It additionally puts the entire burden of

[95] DEIR/S 4.6-171
[96] *Ibid*.

determining this Project's mitigation efficacy on one or a few individuals assigned to this project within a given lead agency. This negates the role of CEQA here, which exists in part to allow the public to provide input to impact mitigation including its applicability and efficacy, presuming the public has been provided with sufficient data to make such a review.

Experts on measuring effectiveness of mitigation measures, especially ones regarding compensatory tradeoffs as alluded to here, correctly state that, "Public choice theory suggests officials and traders have more incentive to facilitate barter than to ensure biodiversity protection. Thus, given the option of saying to developers "yes, with conditions" rather than "no," officials will prefer "yes, with conditions"— particularly when compliance with conditions cannot be credibly measured and officials can avoid accountability for outcomes. Legitimized bartering can thus create a policy situation "obscure enough to please all parties . . . and so ill-defined that failures will be difficult to detect."[97] This statement speaks profoundly to why so many compensatory conservation deals have failed to meet the goals of mitigation for projects over the years. If the CPUC and the Monterey Bay National Marine Sanctuary are truly concerned with their role in insuring adequate mitigation of all of the significant impacts described herein to plants and animal species, they will require detailed description and discussion of the adequacy of compensatory mitigation plans (such as funds for sensitive specie s research, HMPs, HCPs) and parcels prior to issuance of a development permit, and not leave all such prescriptions solely up to individuals of a lead agency.

CURE-Owens-21 cont.

c. Mitigation measure 4.6-1f Avoidance and Minimization Measures for Smith's Blue Butterfly.[98]

As with most if not all other special status species discussed in this document, the DEIR/s fails to conduct focused or protocol-level surveys for the Smith's Blue butterfly throughout any of the Project site. For reason already discussed above, such lack of data prevents the reviewer from adequately assessing existing status and resultant measures and standards necessary to mitigate potential impacts to this ESA listed species. The DEIR/S indicates that Slant Wells, Pipelines, Transition main, the CEMEX active mining area, CEMEX access road and the surrounding sand dunes, and staging areas all have Smith's Blue butterfly habitat (its host planta, coast and seacliff buckwheat, specifically). It states that construction within these areas has the potential to "temporarily impact" Smith's blue butterfly habitat, "which would be a significant impact. The impact is considered temporary because coast

CURE-Owens-22

[97] Walker, S.; Brower, A.; Stephens, R,T.; and Lee, W. 2009. Why Bartering Biodiversity Fails. *Conservation Letters* 2:149–157. Retrieved from: http://www.azoresbioportal.angra.uac.pt/files/publicacoes_Walker%20et%20al%202009.pdf

[98] DEIR/S 4.6-172

buckwheat is relatively easy to cultivate and reestablish in dune scrub habitat, and would be returned to pre-construction conditions".[99]

As its primary mitigation measure the Applicant states it will conduct a section 7 consultation implement all measures required by USFWS. This amounts to mitigation measures being deferred, unspecified, and thus impossible to assess for efficacy, regardless of a statement that purports compliance with the ESA contingent on future discussions.

Measure 4.6-1f states that 'floristic botanical surveys of all suitable habitat for coast buckwheat and seacliff buckwheat, both of which are host plants to Smith's blue butterfly, shall be conducted by a qualified biologist during project design and prior to project implementation. Maps depicting the results of these surveys shall be prepared to document the location of the host plants within or adjacent to the project area. Construction of project elements shall be planned to avoid mapped host plants for Smith's blue butterfly whenever feasible."[100] This is also deferral of mitigation planning and descriptions, and prevents thorough analysis of mitigation efficacy. Minimum required impact reduction actions can vary widely from standard avoidance procedures if just a few host species are present, to major changes necessary in development footprint and design and/or timing of construction if there are many host plants and even butterflies on site. The Applicant needs to provide not only complete habitat maps of the host plants, but also focused butterfly surveys, especially considering the sensitivity of this species and its slow road to recovery since its listing in 1976.

CURE-Owens-22 cont.

The unique natural history of the Smith's blue butterfly is important to be aware of, since it represents some of the difficulties in relying on mitigation measures whose details are generic or deferred to the future in order to address reduction in impacts to the species and its host plants. For example, individual adult males and females live approximately one week, therefore detecting them at the adult stage can be very difficult and depend on long term surveys efforts. Therefore presence of butterflies can be easily missed.[101] Young larvae feed on the pollen and developing flower parts, while older larvae feed on the seeds. Older larvae are tended by ants, which may provide some protection from parasites and predators. Upon maturing in about one month, the larvae pupate in the flowerheads or in the leaf litter and sand at the base of the buckwheat plant. Pupae that form in the flowerheads later drop to the ground. Some adults are quite sedentary, with home ranges no more than a few acres, however others may disperse farther and use home ranges between 20-30 acres.[102] This species prefers

[99] DEIR/S 4.6-129
[100] *Ibid*. 4.6-172
[101] Arnold, R.A. 1983b. Ecological studies of six endangered butterflies: Island biogeography, patch dynamics, and the design of habitat preserves. Univ. of Calif. Publications in Entomology 99: 1-161. Retrieved from: https://searchworks.stanford.edu/view/1049101
[102] USFWS. 2006. Smith's Blue Butterfly Five Year Review: Summary and Evaluation. Retrieved from: https://www.fws.gov/cno/es/Smith's%20blue%20butterfly%205-year%20review.FINAL.pdf

to feed on mature, robust individuals of the perennial buckwheats because they produce more flowers. Thus buckwheat stands that consist of younger or older, senescent individuals, which produce fewer flowers, may not be visited by the butterfly, and are of lesser value for this species' conservation.

These characteristics demonstrate that (a) detection of the species requires very specific training and a knowledge of the species natural history, and (b) host plants and habitats are not all alike in terms of viability and resultant importance for the species conservation. Thus treating any and all buckwheat habitats equally, especially in terms of both construction mitigation and parcel selection for compensatory mitigation, can result in failure to reduce potential impacts. Additionally, USFWS recommends that grading involving motor vehicles, heavy equipment, or ground disturbance will be scheduled outside the potential flight period of the Smiths blue butterfly (June-September)[103], and yet there is no mention of construction avoidance during this specific flight period in the mitigation measures. Also, since there are no surveys that provide estimates of the numbers of Smith's blue butterflies that might exist within or bordering the Project site, it is not possible to quantify the exact number of individual butterflies or host plants that could be taken, and thus impacted, by the removal of buckwheat in the area. Thus overall impacts and resultant detailed mitigation analyses for the Smith's blue butterfly by the Project cannot be thoroughly assessed.

CURE-Owens-22 cont.

d. Mitigation measure 4.6-1g Avoidance and Minimization Measures for Black Legless Lizard, Silvery Legless Lizard, and Coast Horned Lizard.[104]

Due to their cryptic nature and difficulty to detect without conducting focused surveys for such, reptiles are historically underestimated in all aspects of conservation, including surveys, monitoring, and impact analysis. I was co-researcher on the world's most extensive study in the wild of the world's largest snake species, the green anaconda (*Eunectes murinus*). This species had not been studied to any extent previously due primarily to the false belief that they were not in high abundance anywhere and thus difficult to observe for research. Even expert herpetologists recommended against commencing the study, convinced we would find very few of the snakes in the wild. However, once we began focused surveys in their known habitat, as just two researchers we caught and released over 800 green anacondas within a small region (a few square kilometers). We found the snakes primarily by tactile searching (walking the shallow wetlands until we stepped on them), due to the fact that visual searching of this cryptic predator would result in missing up to 90% of the individuals we encountered.[105] I mention this research to underscore the reality that even one of the largest reptile species in

the world can be very difficult to detect if one is not conducting focused surveys with a protocol designed for species-specific detection. Even during my research on the Orinoco crocodile – a species that can get upwards of 800 pounds – our biggest research challenge was visually locating them in known occupied habitats.[106]

This Project's underestimation of the impacts to reptiles – by way of zero attempts to survey them anywhere, or create species-specific mitigation protocols - falls within this sort of erroneous assumption that if individuals are not detected anecdotally, they are likely not abundant or not present, and/or can easily be detected in a very short period of time when construction monitoring requires such. Reptiles have a wide range of preferences for heat tolerance, some being purely nocturnal, while many will retreat into shallow burrows or rapidly shuffle from side to side to burrow into the sand in order to avoid extreme heat and cold, including sensitive lizard species including the black legless lizard, silvery legless lizard, and coast horned lizard. Environmental impacts assessments are notorious for underestimating, undervaluing, and under-mitigating reptile species, and this Project's Report is no different.

CURE-Owens-23 cont.

These lizard species forage and move within a broad range of habitats, beyond those identified in the DEIR/S as preferred habitats or optimal foraging habitats, and as a result the impact analyses estimating the "potential to occur" of these species based only such assertions of "preferred habitat" in the literature, and not focused field ground-truthing, fall short of accurate site assessments regarding species presence, density, and abundance.[107,108,109,110] For instance, I have observed flat-tailed horned lizards and fringe-toed lizards – both sensitive species that prefer small dunes and loose sandy soils– frequent very rocky and disturbed habitats. The fact that the Applicant also failed to conduct any focused migratory bird or raptor surveys only reinforces the importance of reptiles surveys, as these provide an important prey item for many species of birds.

Additionally, unexpected consequences of other practices on construction sites can negatively impact local species. On one such site I repeatedly observed workers spreading insecticide to kill all species of ants, in areas proximal to critical habitat occupied by protected flat-tailed horned lizards whose primary prey are various ant species. Avoidance of such actions

are one of the specific details that are important, but consistently omitted, by mitigation protocols for reptiles.

The lead biologist for this Project is presumed to prepare a relocation plan, and use relocation as a primary mitigation measure. The DEIR/S states that "only relocation sites that are not over-populated and have suitable habitat conditions (e.g., soils, moisture content, vegetation, aspect) shall be used", however provides inadequate details on how these conditions may be determined, which is important considering preferred habitats and prey items are different for each species of lizard. There is no information provided about the existence of such sites nearby, nor is there data, criteria, or standards established on likelihood of survival via relocation. The DEIR/S says the biologist shall survey for lizards by raking under bushes and walking "appropriately spaced transects" prior to construction. These mitigation descriptions and methods are inadequate, partly for the same reasons described above, since no ground-truthing has been conducted to assess or estimate whether or not these species are present and to what degree, result in the reviewer being unable to reasonably determine the efficacy of mitigation based upon generic protocols. Each species has different natural histories, and different characteristics in respect to detectability during any given time, temperature, and type of habitat. To assume the same protocol will work in detecting, not to mention relocating, these species will be adequate is unsupported. In my experience the taxa most susceptible to incidental mortality on construction sites are snakes and lizards, due to difficulty of detection by biologists and ease of hidden movements on the part of the animal. I have caught, documented, and released over 1,000 reptiles in the course of my natural history and consulting research, and to say these animals are highly susceptible to anthropogenic impacts would be an understatement. Such realities must be taken into consideration when reviewing mitigation measures, something the reviewing public cannot do in this case because no necessary details are provided.

CURE-Owens-23 cont.

e. Mitigation Measure 4.6-1i: Avoidance and Minimization Measures for Nesting Birds

This measure states that, "For all construction activities scheduled to occur during the nesting season (February 1 to September 15), the qualified biologist shall conduct a preconstruction avian nesting survey within 14 days of site clearing and/or ground disturbance. Copies of the survey results shall be submitted to the CPUC. If construction activities at any given facility site begins in the non-breeding season and proceeds continuously into the breeding season, no surveys are required. However, if there is a break of 14 days or more in construction activities during the breeding season, a new nesting bird survey shall be conducted before reinitiating construction."[111]

CURE-Owens-24

[111] DEIR/S 4.6-176

1. Pre-construction nesting survey reports must also be provided to the USFWS, since they have primary jurisdiction over enforcement and implementation of the Migratory Bird Treaty Act, and would be the agency providing a take permit if the developer seeks approval for any activities that risk violation of the MBTA.

2. There is no reason why ongoing construction activities that proceed into breeding season should not require nesting bird surveys; such surveys are required to insure nesting birds are not harassed by Project actions. As someone who has conducted hundreds of MBTA breeding bird surveys on and near construction sites, I can say with complete confidence that birds can, and often do, commence nesting within construction footprints, sites, and along construction access roads due to many species having high natal site fidelity, philopatry, and established territoriality, even despite human interference.[112,113,114]

CURE-Owens-24 cont.

Therefore any and all development activities can significantly impact a breeding bird regardless of when the actual construction began onsite, and nesting / breeding bird surveys should be conducted not only prior to any activities during breeding season, but throughout construction activities during breeding season. Sweeps for nesting birds should be made on a daily basis, and more thorough surveys conducted weekly. This includes surveys for ground-nesting birds as well as others.

f. Mitigation Measure 4.6-1n: Habitat Mitigation and Monitoring Plan

This Measure states that part of its criteria for reduction of significant impacts to special status species includes the **"**Description of any other compensatory mitigation in the form of land purchase, establishment of conservation easements or deed restrictions, contribution of funds in lieu of active restoration, or purchase of mitigation bank credits, or other means by which the mitigation site will be preserved in perpetuity."[115]

CURE-Owens-25

This Measure is inadequate for CEQA purposes of review and analysis since it is based upon deferral of mitigation, thus lacking in data, description, detail, and standard criteria to even begin to analyze its efficacy and success. Compensatory mitigation is highly variable in its targets (species and habitats) goals, efficacies, and prescriptions, and the reviewer is unable to make any determinations regarding the success when no further detail is provided on a habitat and species-specific basis. As such, this measure's contribution to impact reduction fails, and considering what a key part of most mitigation reductions compensatory tradeoffs must be, this

means the Applicant has failed to demonstrate impacts have been reduced below significant for every species and habitat for which this measure is used.

CURE-Owens-25 cont.

g. Field Case Study Supporting the Problem of Deferral of Mitigation Prescriptions to the Future

The following example demonstrates how:

(a) Mitigation measure deferred to the future can fail to reduce impacts including sensitive species mortality,
(b) Failure to recognize the importance of nearby critical habitat to a Project footprint can cause unanticipated sensitive species mortalities, and
(c) Failure to consider the natural history of lizard species or creating species-specific mitigation measures can result in species mortalities.

I and my biologist colleagues have witnessed an important phenomenon on project construction sites in arid regions, and during warmer spring and summer seasons in semi-arid temperate regions similar to that of this Project, where lizard species are present, and pre-construction surveys require minimal pre-construction surveys for reptiles along roads and within construction zones (similar to the mitigation measure for lizards discussed above for this DEIR/S regarding pre-construction survey to be conducted immediately before and during construction). Specifically, I have observed that lizards are directly and immediately attracted to roads on and around construction sites where trucks spraying water and other erosion control liquids are used to reduce airborne dust. We have observed that this practice serves to attract lizards of a variety of species, including coast horned lizards, to the higher moisture levels on the roads, resulting in marked increased lizard mortality and injury due to being hit by construction site traffic that use the roads subsequent to the water trucks passing. For instance, within the course of one month this phenomenon resulted in the mortality of over 20 flat-tailed horned lizards (*Phrynosoma mcallii*) (FTHL) (a state Species of Special Concern and previously petitioned for listing under the CESA and FESA) on one construction site in Southern California during the summer of 2014, and where an additional 110 FTHLs were relocated to avoid injury or mortality from vehicle impacts during several weeks of the construction phase.[116] During the construction of the Sunrise Powerlink gen-tie line just April to November, 103 flat-tailed horned lizards were relocated and 25 mortalities were recorded.[117]

CURE-Owens-26

[116] Wilton, Ben. Tenaska (*Pers. comm*., March 19, 2015)

[117] [FTHLICC] Flat-tailed Horned Lizard Interagency Coordinating Committee. (2011). What is key here is that this industrial project failed to anticipate significant impacts to lizards due primarily to the phenomenon described above, despite the site bordering habitat known to be occupied and critical to the species, despite recommendations by conservationists that mitigation measures as written in the EIR/S were inadequate, and as a result the developer had to completely stop work for at least two weeks. One independent contractor reported losing an alleged $146,000 a week due to the unexpected delay.[118] It is also important to note that because the FTHL mortalities were vastly beyond any predicted by the EIR/S and its mitigation measures for the project, the lead biologist was unable to compensate for the additional time requirements needed to relocate lizards, thus four more biologists had to be hired simply to monitor and relocate lizards. However, even despite this, the mortalities of lizards resulted in failed mitigation. Additionally relocations were haphazard and not assessed for success, and now the already at-risk population of this species has been reduced by this oversight that began with a lack of focused surveys, ignoring the importance of FTHL critical habitat proximal to the site, and providing vague mitigation measures mostly deferred to the future for development.

CURE-Owens-26 cont.

In order to adequately mitigate for such potential risks to the sensitive lizards species with high potential to occur on site, this phenomenon must be taken into consideration, and mitigation measures to reduce resultant impacts may include additional biologists, enhanced traffic restrictions, and a reptile relocation Plan and Monitoring Strategy during the construction phase.

VII. WILDLIFE CORRIDORS IMPACTS INAPPROPRIATELY DISMISSED AS NOT SIGNIFICANT

The DEIR/S asserts that there would be no significant impacts to species due to the lack of established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites because "the proposed project does not include the placement of structures within creeks, rivers, or other waterways and there are no established native resident or migratory wildlife corridors or wildlife nurseries within the project area[119]…The terrestrial wildlife habitat in the project area is fragmented by agricultural fields, residential developments, commercial / industrial developments, and roads and does not serve as wildlife movement corridors."[120]

CURE-Owens-27

There is abundant evidence in the literature regarding species that use wildlife corridors and nurseries in agricultural and industrial areas. The highest incidence of **burrowing owls** in

the state of California – almost 70% - occur and move throughout agricultural regions in Imperial county, and utilize the soft soils from agricultural disturbance in which to establish burrows and raise young.[121,122,123] As a biologist I have spent many months studying burrowing owls and other species, including American kestrels, cattle egrets, gray foxes, and various other passerines, that use corridors primarily within agricultural areas, bordering urbanized areas, to travel and get from one destination to the next for foraging and other territory requirements. For instance, research on peregrine falcons - a sensitive species known to have occurred recently within or near the Project area according to the CNDDB - have been observed to utilize non-forested and agricultural habitat as important post-fledgling corridors.[124] Red-tailed hawks and owls that live in highly urbanized areas travel between their urban nest sites and less urbanized areas to forage[125]. Snakes have been found to use agricultural habitats as important corridors, particularly in urbanized landscapes.[126] Movement corridors for various taxa often occur along (not just within) watercourses, coastal borders, or follow the cover of shrubs or trees; especially hedgerows or grassy areas between developed habitat, often found along roadsides to block residences from a view of the road. Such vegetation corridors bordering roads are characteristic of the footprint to be impacted by the pipeline development of the Project.

CURE-Owens-27 cont.

Corridors and nursery areas vary widely in characteristics and type of wildlife species that use them, and include movement to and from nesting areas to foraging areas, feeding areas to hilltopping areas, one part of range to another part of range, allowing genetic

exchange and viability.[127, 128] Considering that the Project includes at least 18 miles of more or less linear development along and near the coast, there is actually a high potential for construction, with its requisite erosion control fencing, other physical barriers, noise, and lighting to cause displacement and avoidance of wildlife along their habitual corridors, resulting in a significant impact including death due in part to the phenomenon that animals displaced in areas with many roads significantly increase their likelihood of being hit by traffic[129]. Therefore this development certainly could impact corridors by impeding movement of wildlife moving within in established territories.

Therefore the conclusion that the project does not significantly impact corridors is not supported. Existing corridors within and next to the project, including those incorporating agricultural, partly developed, and disturbed habitat, must be assessed with greater detail and supporting documentation, and mitigated with appropriate actions to allow movement and dispersal of native wildlife along this 18 + miles of Project development. Mitigation should include an analysis of the potential for increased mortality and harassment of native species due to various factors including time duration of development, acreage impacted, sensitive species potentially present, and ways to reduce the negative impact of movement barriers within corridors that cross and parallel the project footprint and buffer zones.

CURE-Owens-27 cont.

VIII. IMPACTS TO COASTAL DUNES NOT ADEQUATELY ANALYZED

Coastal dune habitat has been virtually extirpated from most parts of southern California. As such, in California it is one of our most impacted, most rare, and most fragile habitats. Yet because it is critical as a barrier to the sea, it is also one of our most important habitats.[130] Part of the project site is considered mostly primary habitat according to the City of Marina's Local Coastal Plan, with some secondary habitat (habitat adjacent to primary), and constitutes an environmentally sensitive habitat area" pursuant to the Coastal Act.[131] The habitat should thus by definition be protected against habitat losses; where only uses dependent on coastal resources shall be permitted in such areas.[132] The DEIR/S's proposed

actions appear to conflict with this description of this Environmentally Sensitive Habitat Area required management.

CURE-Owens-28 cont.

IX. CONCLUSION

Based on the issues described in this letter, it is my professional opinion that the Applicant has not met the obligations of CEQA, and that the Project would result in significant and unmitigated impacts to several sensitive biological resources.

Sincerely,

I. Introduction

California American Water Company (CalAm) has proposed a desalination plant for Marina City, California: the CalAm Monterey Peninsula Water Supply Project (Project or MPWSP). This Project will utilize subsurface slant wells as the water intake points. In 2014, the National Oceanic and Atmospheric Administration (NOAA) and the Monterey Bay National Marine Sanctuary (MBNMS) evaluated the impact of installing one test slant well in an Environmental Assessment (EA).[1] The test slant well was built in Monterey Bay at the CEMEX sand mining site to inform the geologic conditions for the full-scale project. If this Project is approved the test slant well will be converted to a permanent well and nine other wells will be built. The draft Environmental Impact Report/Environmental Impact Statement (DEIR/EIS) evaluates the impact of the full-scale Project, *i.e.,* the Proposed Project, as well as alternatives to the Proposed Project.[2] This letter evaluates the slant well intake technology.

The subsurface slant wells will draw from subsea aquifers. Due to the risk to marine life as a result of open-water intakes, several agencies have shown a preference for subsurface intake systems:

> *Several state and federal regulatory and permitting agencies (SWRCB, California Coastal Commission (CCC)) will not consider permitting an open-water intake unless a subsurface intake has been deemed infeasible or would result in greater environmental impacts. NOAA's MBNMS and National Marine Fisheries Service also established guidelines for discretionary approvals for new intake structures stating that subsurface intakes should be used where feasible and beneficial.*[3]

However, as I will set out below, I demonstrate that the DEIR/EIS fails to consider a number of conditions which may lead to an adverse environmental impact in the Monterey Bay National Marine Sanctuary.

I am qualified to evaluate the technical merits of the subsurface slant well, the potential physical and chemical impacts resulting from the slant well intake, and identify where the DEIR/EIS should disclose additional information. I have over thirty-five years of experience in the field of physical and natural sciences. I earned a doctorate degree in plasma chemistry diagnostics and laser spectroscopy, and a master's degree in spectroscopy and physical chemistry. I hold two US patents and one International and two more are pending. I have subject matter expertise in evaluating prior art patents and public domain proposals in spectroscopy and physical chemistry, and in utilizing high

performance computational methods for imaging and analytical chemistry applications.

My curriculum vitae is attached to this letter.

II. Background: Slant Well Technology

Dennis Edgar Williams, Ph.D., holds the patent for subsurface slant wells.[4] The patent was published on November 15, 2011, but has a priority date of January 7, 2010.[5] In 2015, Dr. Williams presented a paper entitled "Yield and Sustainability of Large Scale Slant Well Feedwater Supplies for Ocean Water Desalination Plants" for the International Desalination Association World Congress on Desalination and Water Reuse in San Diego.[6] In that paper Dr. Williams discussed the slant well technology. He begins:

> *Originating out of the necessity to explore subsea aquifers near Dana Point, CA, the first test slant well was constructed in 2006. . . . As of this writing, a 724 ft test slant well completed in March of 2015 near Monterey, California as part of the Monterey Peninsula Water Supply Project (MPWSP) is currently undergoing long-term test pumping.*[7]

Unlike open-ocean intakes, which draw water from above the sea floor, subsurface slant wells draw water from aquifers.

> *Slant wells receive recharge from vertical leakage through the sea floor (i.e., benthic zone) and horizontal flow from subsea and near shore aquifer system*s.[8]

The aquifer water is drawn through the seabed, through an artificial filter, and then finally through a mesh screen. The intake is made possible by a high power 300 hp submersible pump contained within the slant. Each slant well is capable of drawing in 3-4 million gallons of water per day of untreated ocean water, which equates to four-and-a-half Olympic swimming pools or a cube that is 74 feet long, 74 feet wide, and 74 feet high. The Project calls for a total of ten slant wells with eight operating at any given time.

Overtime, the slant well technology should draw primarily from "young" ocean water.

> *Geochemical tracers used to quantify water sources to the Doheny test*

slant well during an almost two year pumping test (2010-2012) were used to estimate slant well connectivity to the ocean and relevant amounts of water sources.

Test results support the increased capture of shallow, young marine ground water. Natural isotope data showed after one year of pumping, recharge to the slant well consisted of a mixture of brackish ground water (which showed a decreasing trend), ocean water (which showed an increasing trend), and old marine ground water which initially increased and then slightly decreased as it was being removed from the aquifer. This reflected the fresh/salt interface being induced to migrate toward the well. The geochemical data combined with a three-dimensional variable density flow and solute transport model predicted that the old marine ground water would be fully removed from the subsea aquifer within approximately one year at the full scale production rate of 30 mgd. Furthermore, upon reaching steady state conditions, (approximately one year), and after removal of the old marine ground water, the source of water to the feed water supply wells was predicted to consist of 95% "younger" ocean water (with very low levels of dissolved iron/manganese, ~ 2 µg/L), and 5% brackish ground water (~2 mg/L of dissolved iron/manganese), resulting in a blended concentration of approximately 0.10 mg/L.[9]

The anticipated hydrogeologic transition is illustrated in the Figure 1 below, which is from the Final Summary Report for the Doheny Ocean Desalination Project Phase 3 Investigation, prepared by the Municipal Water District of Orange County (MWDOC) in 2014.[10] This report for the Doheny wells indicated that the wells would draw 95% young ocean water once the project reached steady state operations. For the MPWSP, the slant wells "are projected to pull 93 percent seawater from the Monterey Bay and 7 percent groundwater from the surrounding area when the MPWSP is operating (GeoScience 2014b)."[11]

CURE-Sobczynski-1

III. Analysis

First, the DEIR/EIS underestimates the actual infiltration rate of water through the seafloor to the slant well. This estimation is based on the average bulk flow rate of the

[12] MWDOC – Final Summary, 2014, at pg. 19.

water over a 1,000,000 square foot area[13] and calculations done by Williams with respect to the Doheny slant wells.[14]

In reality, the flow rate will vary along the length of the slant well. The following factors will vary the flow rate: the utilization of the submersible pump in the slant well, filter medium and composition, the use of inflatable packers to limit flow to certain sections of the well, and the accumulation of suspended organic material (SOM), detritus and other biomass which would lower hydraulic conductivity of the medium around the slant well. Additionally, the DEIR/EIS does not consider the flow rate as it changes due to erosion, compaction, strong wave action, or violent storm events over the 40 year lifetime of the project.

When each factor is considered, the infiltration rate based on preliminary flow modeling of a 19-degree[15] axis angle slant well, will be 0.00052 ft/sec ($1.6x10^{-4}$ m/s) at its peak above the submersible pump and 0.000033 ft/sec ($1.0x10^{-5}$ m/s) at the well bore end. The infiltration rate for 14-degree axis angle yielded 0.0016 ft/sec ($5x10^{-4}$ m/s), see Figure 11. The DEIR/EIS is therefore deficient as it does not properly analyze the specific factors along each slant well which will create drastically higher infiltration rates at the slant well intake sites.

As a consequence of failing to accurately calculate the vertical infiltration rate, the DEIR/EIS also does not account for accumulation of biomatter in the seabed.[16] The DEIR/EIS states that biomatter will not accumulate because strong wave actions will prevent accumulation.[17] This statement is unsupported, as I will examine in further detail below.

I-19-20 (citing Williams, 2010.)

A. The DEIR/EIS underestimates the infiltration rate through the sea floor. In actuality, the infiltration rate at some sections of the well will be much higher.

The DEIR/EIS calculates the vertical infiltration rate by taking the entire 24.1 mgd amount of seawater and dividing approximately 1,000,000 square feet by that amount.[18] Using this method, the DEIR/EIS arrives at a vertical infiltration rate of 0.0000373 ft/sec or 0.011 mm/sec.[19] The DEIR/EIS compares this number to the infiltration rate, which Williams calculated in 2010[20] with site specific information for the Doheny wells. Williams used an entirely different methodology to calculate the infiltration rate, examining the hydraulic conductivity of seafloor sediments, effective porosity of seafloor sediments, hydraulic head difference between the ocean surface, and groundwater levels in the vicinity of feed water supply wellfield, and the average vertical distance from the seafloor to the middle of the intake well screen sections.[21] Williams arrived at an infiltration rate of 0.000051 ft/sec or 0.016 mm/sec, and 0.00000078 ft/sec at the outer limits of the ocean water source area.[22] The DEIR/EIS then proclaims because its number is "very similar" to the Williams' calculation, it will use a potential infiltration rate band of 0.011 to 0.016 mm/sec.[23]

CURE-Sobczynski-1 cont.

This methodology fails to take into consideration fundamental physical and chemical properties. As such, the DEIR/EIS is deficient at properly disclosing impacts.

1. Factors that Influence Infiltration Rate: Submersible Pump

The DEIR/EIS does not fully disclose the fluid mechanics along the screened segment of the slant well. We know from the patent that inventions incorporated into the well construction are important in terms of controlling the flow (*i.e.*, utilizing a submersible pump, inflatable/deflatable packers).[24] As is, the DEIR/EIS fails to recognize that the greatest draw of water will be above the submersible pump.

Based on the 2015 Williams White Paper[25], descriptions of the slant well in the patent[26], geometries from a 2006 test slant well drawing ("Well As Built, Test Slant Well

This design allows for a larger pump house casing near the land surface, with successively smaller casing and screen diameters as the well extends downward. The telescoping casings and screens facilitate extending the well to lineal lengths of 1,000 feet or greater beneath the floor of the saline water body, with angles below horizontal ranging from zero to ninety degrees.")

SL-1")[27], and the Request for Proposals (RFP) for the Project's slant wells[28], we have assumed that the submersible pump location is at the vertical depth of approximately 60-70 feet in the dune sand zone. This Project's RFP do not clearly identify the location of the submersible pump, but based on information from the documents above, the pump might possibly be as shallow as 48 feet for one of the proposed slant wells.[29] But, most submersible pump locations in the RFP appear to be at a depth of 65-76 feet, which is consistent with my assumption.[30] Similarly, it seems most pumps would be located 140-280 lineal feet.[31] Based on the RFP and the documents above, I assume that the pump is located at a depth of about 62 feet (19 meters) and a length of about 230 feet (70 meters). The DEIR/EIS should accurately disclose the location of the submersible pump because the submersible pump creates a pressure zone, which pulls seawater from above the seafloor via induced infiltration. This pressure zone should be adequately disclosed to the public in order to accurately evaluate the Project's impacts.

2. Factors that Influence Infiltration Rate: Location of Slant Wells With Respect to the Sediment Profile

The DEIR/EIS analysis of the infiltration rate is flawed because it does not account for the sediment composition of the Monterey Bay which will direct the flow of water to specific parts of the slant well as opposed to evenly distributing the infiltration rate force along the entirety of the well. Therefore, the DEIR/EIS's assumption that water will flow evenly through 1,000,000 square feet, is inaccurate.[34]

Section 4.2.1.1 of the DEIR/EIS presents a diagram for where the test slant well exists in the Monterey Bay geology.[35]

Figure 6. Project's slant well array.[38]

[38] DEIR/EIS, at pgs. 3-15, 3-17.

As one can see, the slant wells will traverse the older dune sand. This dune sand has "high permeability … suitable for the infiltration of water."[39] The proposed slant wells are at an even shallower angle (14 deg) than the test slant well (19 deg).[40] Therefore a greater percentage of the proposed slant wells will traverse the dune sand.

Utilizing the DEIR/EIS's maps and the models below, we have determined that most of the water will be drawn through this older dune sand, which is highly permeable and closest to the submersible pump, thus rendering only the upper third, approximately, of the well productive, unless the packers will be engaged.[41] Without additional details, which the DEIR/EIS does not provide, it is difficult to estimate the intake zone. Well's location figure 14 (see Appendix section in this report) is departing from conceptual presentations in figure 4, patent US 8,056,629 B2, William's 2015 white paper.

By averaging the expected infiltration rate,[42] the DEIR/EIS does not take into account the fact the infiltration rate will vary dramatically based on the sediment profile of the ocean floor and the location of the submersible pump, which will draw water along the shortest path of least resistance. The water flow will not be evenly distributed along the length of the slant well.

CURE-Sobczynski-1 cont.

3. Factors that Influence Infiltration Rate: Inflatable/Deflatable Packers

The DEIR/EIS fails to consider the distribution of infiltration rate due to the internal flow pattern controlled by inflatable/deflatable "packers." The patent describes this packer device as follows:

> *The slant well can be equipped with a submersible pumping system fitted with a dual-packer shroud assembly. Using the dual-packer shroud assembly, the slant well can selectively pump from upper or lower portions of the subsea aquifer, thereby varying feedwater salinity as required to help minimize variations in feedwater salinity due to hydrologic cycles. The dual-packer shroud assembly (DPSA) allows selective production from well screens both above and below the packers (maximum production), well screens above the upper packer only (lower salinity), well screens below the lower packer only salinity), or well screens between the packers (focused salinity).*[43]

Figures 17, 18, 19 of the slant well patent[44] show infiltration zones depending on the packer's activations. Whether the slant well deploys inflatable packers to block the well

[44] *Id.*

will impact how the water flows into the slant well. Figure 7 demonstrates the flow rate assuming both packers are deflated, so the entire length of the well is participating as the water feeding source. Even so, my results suggest preferential flow in close proximity of the submersible pump. Since details about inner flow are missing from DEIR/EIS, I cannot provide detailed evaluation of the infiltration zones.

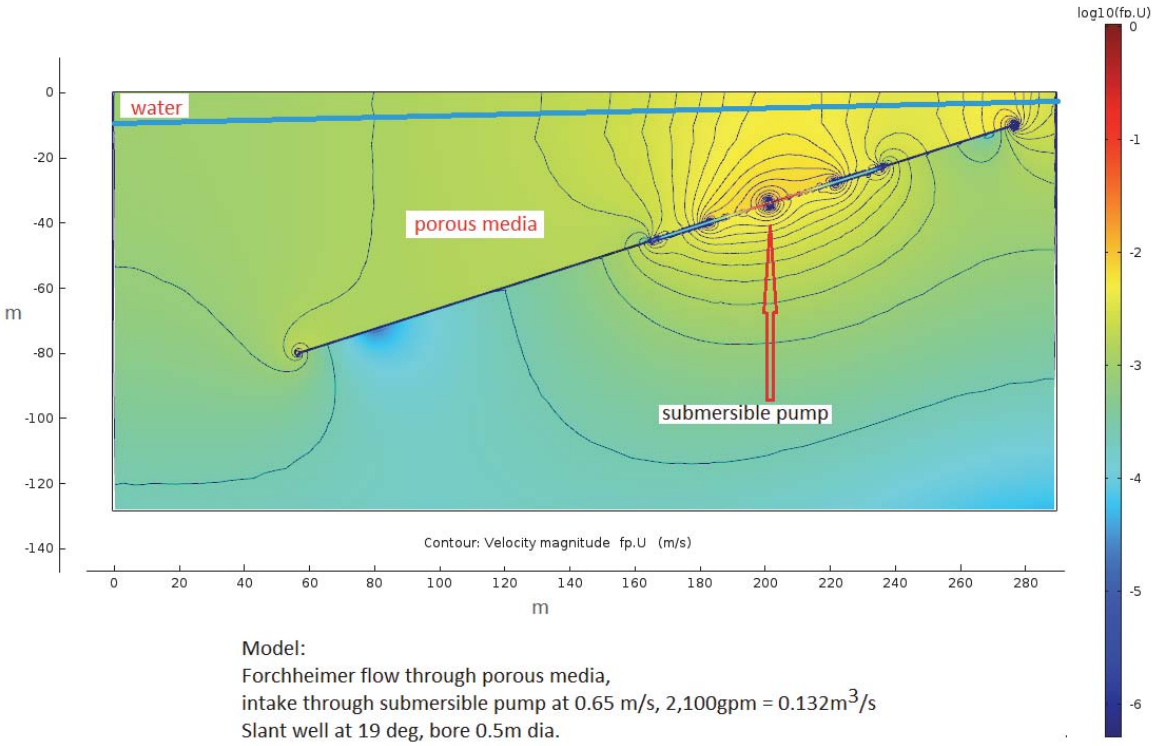

Figure 7. Illustrative model of intake zone velocity field for single slant well, per assumption that all packers are deflated, however it can be noticed that the strongest intake velocity field is above the submersible pump. It is not clear from the DEIR/EIS, how effective the control of the flow inside the bore is and which part of well is active. The invention disclosed in the patent clearly identifies the use of packers as an improvement in slant well technology.[45]

The test slant well appears to have had inflatable packers, but the DEIR/EIS is silent about this feature for the proposed slant wells.

> *This [operations] phase may also include a one-time repositioning of the packer device that is used to isolate one aquifer for testing and pumping. This special operation would involve removal of the submersible pump and pump column, removal of the initial packer, insertion of the second packer, and replacement of the pump. This modification would take 2 to 3 days to accomplish. Equipment and operations required for the repositioning of the device, including temporary laydown of the pump*

CURE-Sobczynski-1 cont.

[45] Slant Well Patent, 2011.

column, would be located within the original construction footprint shown in Figure 3a.[46]

By failing to disclose whether the proposed wells, like the test slant well, will have inflatable packers, and whether they would be deployed, the DEIR/EIS is factually insufficient. If the packers are used, the vertical infiltration rate would be far higher.

4. Factors that Influence Infiltration Rate: Clogging in the Seabed

The most glaring hindrance to water flow is clogging. This can occur at the intake screens and throughout the seabed. To maintain the intake screens, the DEIR/EIS states that the slant wells will need regular cleaning by using mechanical brushes, and possibly inert chemicals.[47] This requires taking the well out of service and brushing the screens. However the slant wells can only be cleaned from the inside, while the subsurface filter media and outer shell will still have substantial and permanent waste buildup.

Dr. Williams admits that clogging can be an issue for slant wells. In his patent, he claims:

CURE-Sobczynski-1 cont.

> *In the past, slant well technology has not been successfully applied to subsea construction of desalination feedwater supplies, as the well screen slots have become clogged during pumping. Once the well screen slot openings are clogged, it becomes difficult or impossible to continue to pump water. Accordingly, there is a need for a reliable slant well system that is able to supply water from near-shore or subsea aquifers to a desalination plant without becoming clogged with fine-grained materials (e.g., fine sands and silts) over time. There is also a need for a method of constructing such a system—especially at low angles below horizontal in order to minimize impacts to inland fresh water sources. <u>The present invention satisfies these needs and provides further related advantages, especially with regard to regulation of feedwater salinity.</u>* [48]

Despite his assurances, the invention did not prevent clogging at the Doheny wells at Dana Point.

> *During the two year pilot testing, the Doheny test slant well produced approximately 3 mgd with relatively stable drawdowns. When it was constructed in 2006, it was test pumped at approximately 2,100 gpm and displayed a well efficiency of 95%. During the extended pilot testing the well efficiency dropped from the original value of 95% in 2006 to 52% in 2012.*[49]

[46] EA, 2014, *available at* pg. 39.
[47] DEIR/EIS, at pg. 3-57.
[48] Slant Well Patent, 2011.
[49] Williams, 2015, at pg, 3.

Lessons learned from the Doheny wells indicated that the pump casing was too small, causing the loss of efficiency,[50] and that sand clogging can impair the well at the construction stage.[51]

> *Design and construction of the full scale slant wells will need to be approached similarly to conventional water well design and drilling, but since the wells will be relatively flat in slope, additional care must be taken in gravel placement and well development. The design and construction will be aided through the experience gained in design and construction of the Test Slant Well. A key to the long-term success of the wells will be to provide thorough development work to assure minimum levels of sand clogging to the gravel pack. Sand clogging can occur over time in a well when it is not properly designed, constructed and/or developed. Causes include too large of well screen slot spacing, too large of gravel size in the gravel pack, gaps in the gravel pack, and most commonly, insufficient development of the well. The well screen and gravel pack size can be properly sized assuming the well designer has good technical capability and experience. Improper well development can occur due to insufficient swabbing, bailing and/or air lifting and due to insufficient development pumping rate and time.*[52]

CURE-Sobczynski-1 cont.

Though Williams has claimed "improvements" that assure clogging will not be a problem for this Project, I challenge his assumptions in Section II, Calculating the Adjusted Infiltration Rate.[53]

Additionally, the DEIR/EIS does not consider the flow rate as it changes due to erosion, compaction, strong wave action, or violent storm events over the 40 year lifetime of the project. This is discussed in further detail in Section B and Section C, below.

B. Calculating the Adjusted Infiltration Rate

My analysis examines the effect of the flow dynamics and water intake pattern through the ocean floor driven by the required pumping rate. By reconstructing models and conducting computational hydro-dynamical flow analysis by the methods of Finite Element Analysis, I have estimated that the infiltration rate of the water through sea floor interface, presented in Figure 9, is a nonlinear function. This has not been adequately explained in the DEIR/EIS.

First, my analysis examines the well geometry in reference to the sea floor slope. Bathymetric charts of the project area and descriptions provided in patent[54], and the

[52] *Id.*
[53] Williams, 2015, at pg. 3.
[54] Slant Well Patent, 2011

2015 Williams White Paper[55] were used. Second, the analysis looks at the slant wells' pump outflow rate. Third, the analysis applies the hydraulic conductivities of the media, Darcy's and Forchheimer physics laws.[56] Finally, and fourth, computational fluid dynamics (CFD), based on Finite Element Analytical (FEA) method to determine zonal vertical infiltration rates. Note, the DEIR/EIS fails to mention the exact operational flow pattern and does not discuss the inflatable packers. Therefore my modeling did not consider flow control by inflatable packers, rather my modeling assumed only the full well length. If inflatable packers are used, the flow distribution will have to be recalculated.

The initial modeling was performed for a single well pumping with a rate of 2,100 mgd based on the 2015 Williams White Paper.[57] For my qualitative results, I can only compare with the drawings in the patent[58], and drawings published in the 2015 Williams, My qualitative results confirmed that the pumping profile is non linear. Though the proposed slant wells can have a pumping rate of up to 2,500 mgd,[59] the purpose of this initial modeling was to qualitatively demonstrate the pumping profile using CFD[60] methods. The flow profile, is non linear function, which in my expert opinion should apply to the test slant well and the proposed slant wells.

My decision to use the CFD method is to provide more detail about flow dynamics than the general draw down equations used by Williams.[61] Williams refers to this equation as "UDE" in his 2015 White Paper.[62]

1.7 Slant Wells Completed Beneath the Ocean

The drawdown solution in the vicinity of a slant well completed in subsea aquifers behaves exactly like a leaky artesian aquifer. The benthic zone (i.e., the zone of the sea floor and a few feet below), is generally a lower permeability zone than underlying subsea aquifers and behaves as a semi-pervious layer. This semi-pervious layer (i.e., leaky layer) has a vertical hydraulic conductivity of K' and a thickness of b' consistent with the leakance term of K'/b' as defined by Hantush [12]. Thus, the UDE concept of superposition may be applied to subsea leaky aquifers using the Hantush-Jacob leaky aquifer equation [13]. Figure 7 illustrates the concept of sea-floor leakage.

Figure 7. Induced infiltration to slant wells from vertical leakage through the sea floor

CURE-Sobczynski-1 cont.

Figure 8. 2015 Williams White Paper, figure explaining infiltration.[63]

Contrary to the DEIR/EIS, the flow velocities cannot be approximated by averaging total volume over the area of project field.[64] In fact, other literature has put the infiltration rate at a much higher rate than the DEIR/EIS's estimate of 0.011 mm/sec – 0.016 mm/sec. Inflow rates of 0.1- 2mm/sec are typical with rapid infiltration rates through the sand medium.[65]

However, for the purposes of being conservative in my calculations I did not use this much faster infiltration rate, and rather used the infiltration rate the DEIR/EIS provides. Thus, my calculations started with an infiltration rate based on the average bulk volume flow over 1,000,000 ft^2 flow provided by DEIR/EIS which I selected at 0.015mm/sec, which is within the range provided. I allowed the computational model to self adjust flow dynamics through the iterative steps, without any additional bias or intervention. The result is presented in Figure 9, which shows that at the peak (located at -60 meters or -196 feet) the infiltration velocity is 10x higher than the average infiltration published by EIR/EIS. For this modeling, the submersible pump was modeled at -70m along the x-axis and -18m along the y-axis.

Calculation of Vertical Infiltration Rate of Ocean Water Migrating Through the Seafloor

The vertical infiltration rate of ocean water migrating through the seafloor in the vicinity of the slant well intake system under full-scale project conditions (30 mgd) can be calculated using the following equation:

$$w = \frac{Kv}{\theta} \bullet \frac{\Delta h}{\Delta x}$$

Where:

- w = Vertical infiltration rate of ocean water migrating through the seafloor (ft/sec),
- Kv = Vertical hydraulic conductivity of seafloor sediments (0.000014 ft/sec),
- θ = Effective porosity of seafloor sediments (0.15),
- Δh = Hydraulic head difference between the ocean surface and ground water levels in the vicinity of feedwater supply wellfield (65 ft),
- Δx = Average vertical distance from the seafloor to the middle of the intake well screen[2] sections (120 ft)

Figure 10. GeoSciences Vertical Infiltration Rate Calculation of Ocean Water Migrating Through the Seafloor, 2010.[68]

CURE-Sobczynski-1 cont.

This vertical infiltration rate 0.016 mm/sec, which Dr. Williams calculated in his 2010 White Paper,[69] was then used to calculate the potential for seabed erosion by Dr. Scott A. Jenkins.[70] Jenkins's calculation for ventilation parameter and infiltration rate is below:

Analysis of Potential for Seabed Erosion: Figure 3 and equation (1) indicate that the percentage increase in wave induced bottom stress grows linearly with the ventilation parameter, $\tilde{V} = w_m / u_m$. To quantify the potential for seabed erosion we calculate this parameter in terms of the size of the reported infiltration rates w_m over the slant well field relative to the threshold velocity for transport, $u_m = u_{crit}$, of the native beach sediment. Figure 4 plots the grain size distribution of the native beach sand taken from the surf zone at Doheney Beach by Reed, et al. 1975. The median grain size is shown to be 0.22 mm (220 microns). Figure 5 gives the threshold velocity for transport (black curve) as a function of median grain size. Inspection of Figure 5 indicates that the threshold velocity for transport for 0.22 mm sized sand is $u_m = u_{crit} = 0.6$ ft/sec. Therefore the ventilation parameter directly over the well field when the wave oscillatory velocity is at the threshold of beach scour is:

$$\tilde{V} = w_m / u_m = \frac{5.1 \times 10^{-5}}{6 \times 10^{-1}} = 8.5 \times 10^{-5} \qquad (2)$$

With this value of ventilation parameter inserted into equation (1) or plotted in Figure 3, the infiltration rate over the well field will cause a net increase in wave induced bottom stress of $\langle \tau_v \rangle / \langle |\tau_0| \rangle = 1\%$.

Jenkins determined that the infiltration rate will increase in wave induced bottom stress

[68] Williams, 2010, at pg. 2.
[69] *Id.*
[70] Jenkins, 2010, at pg. 4.

of 1%.[71] However, if the Williams's infiltration rate is higher than 5.1 x 10^{-5} ft/s, which I demonstrate is possible in my modeling, then this implies a significantly higher stress than what Jenkins calculated. In fact, I calculated the ventilation parameter (to then determine bottom stress) using the same assumption as Jenkins, above, but I was using the infiltration rate from our model.[72] I found that the ventilation parameter yields 9x10^{-4}. This would imply a 10% stress value at the intake zone directly above the well, not 1%.

Since the DEIR/EIS is relying on Williams's and Jenkins's calculation[73] for the impact analysis for this Project, it is in my professional opinion that closer scrutiny and reexamination of the erosion — based on specifics of the actual site — is needed and such request is justified. I have shown that the value of infiltration can be 10x larger than what has been reported, and thus the bottom stress of 1%, calculated by Jenkins and later used by DEIR/EIS is underestimated.

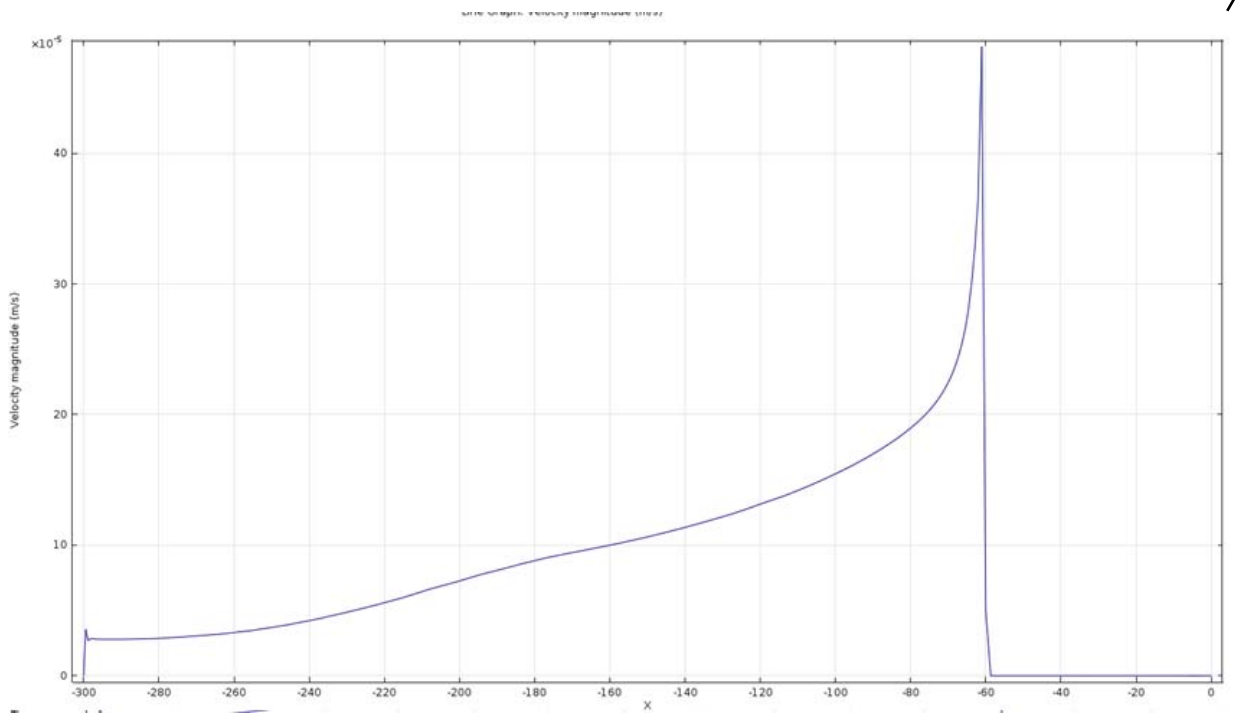

Figure 11. Infiltration rate, modeling of well drilled at 14 deg.

CURE-Sobczynski-1 cont.

The modeling of the well drilled at 14 degrees, resulted in a peak infiltration rate five times higher than my calculations for the 19-degree well. I found the 14-degree well could have an infiltration rate equaling 0.5mm/s. The reason behind such further infiltration increase is that the well will be, in this instance, closer to the sea floor. This result raises a concern that if the pump is operating during a storm then violent wave actions could pierce through the seafloor and be in close proximity to the slant well's screened intake. In such a case high turbidity water will enter the slant well (foregoing the usual natural filtration process)[74] and enter the desalination facilities.[75] This could damage the pre-treatment systems and the RO membrane. However an economical analysis of such catastrophic event is outside my expertise.

C. The DEIR/EIS fails to accurate evaluate the potential buildup of biomass.

CURE-Sobczynski-2

The DEIR/EIS fails to account for the buildup of biomass within the sedimentary strata. The buildup of biomass in the sedimentary strata over time will result in a lower infiltration rate, thus restricting the flux of dissolved oxygen, which can lead to anaerobic conditions for bacteria respiration. A possible result is the release of toxic hydrogen sulfide and other chemicals.

To accurately analyze this impact, the DEIR/EIS must provide existing dissolved

[74] DEIR/EIS, at pg. 1-6 ("The proposed slant wells would draw ocean water through the seafloor sediments, which would pre-filter the seawater for use at the desalination plant.")
[75] DEIR/EIS, at pg. ES-5.

oxygen levels (which it does in 4.3-8, but primarily in the context of salinity and temperature), and the Dissolved Organic Matter (DOM) or Suspended Organic Matter (SOM) levels. The DEIR/EIS proposes that the Dissolved Oxygen level is not less than 7.0 mg/L.[76] However, critically, the DEIR/EIS does not include the Dissolved Organic Matter (DOM), or Suspended Organic Matter (SOM) levels.

The DEIR/EIR does not adequately analyze the issue of biomatter accumulation. It focuses on entrainment and impingement issues of marine organisms in evaluating the marine impact.[77] It provides the following explanation for why entrainment and impingement, will not occur.[78] First, the DEIR/EIS argues the orbital currents at the sea floor are so aggressive that any small micro-organisms near the sea floor will be swept away and will not have the opportunity to settle on the sea floor before being pulled into the sedimentary layers.[79] Second, the DEIR/EIS states the infiltration rate is so low that those forces will be overwhelmed by the orbital currents and thus the slant well's suction will play no role in pulling micro-organisms into the sea floor.[80] These conclusions[81] are based on the work of Jenkins,[82] discussed above, which relied on the infiltration rate (5.1 X 10^{-5} ft/sec) that Williams's found in his 2010 White Paper.[83] Jenkins's conclusion is as follows:

CURE-Sobczynski-2 cont.

> **Conclusions:** Analytic calculations were made to determine the potential for seabed erosion and micro-organism impingement on the seabed due to infiltration rates and pressure gradients induced by the slant well field of the South Orange Coastal Ocean Desalination Project. The calculations were based on infiltration rates and seabed pressure gradients modeled by Geoscience. (2010). While the modeled infiltration rates were found to increase net bottom shear stress by no more than 1% at the onset of erosion, this value is considered statistically insignificant as it is nine times smaller than the error implicit in the net shear stress increases determined under controlled laboratory conditions. Even then, whatever sediment transport is attributable to this 1% increase in bottom stress is both limited to the immediate vicinity of the slant well intake and is insignificant in comparison to naturally occurring seasonal beach profile variation and storm induced erosion. Force balance calculations show that the ocean would have to become perfectly quiescent in order for nano- and netplankton and other neutrally buoyant, freely drifting micro-organisms to become impinged or trapped on the seabed by the vertical pressure gradient induced by the slant well field. Such a quiescent wave climate has never been measured or observed at this site.

In his analysis, Jenkins examines the effects of orbital velocities on organisms occupying the area just above the sea floor. Based on his equations and examination of vertical pressure gradients, Jenkins concludes that nanoplankton and net plankton of a spherical size between 5μm and 20-30μm have no chance of being impinged or trapped

[76] DEIR/EIS, at pg. 4.3-36.
[77] DEIR/EIS, at pg. 4.5-52-53.
[78] DEIR/EIS, at pg. 4.5-53 ("Even though impingement of plankton and larval fish is not expected to occur from the intake of ocean water into the slant wells, the operation of the slants wells could impinge fine organic matter against the sea floor, cause a build-up and change the normal distribution of sediment grain size.")
[79] *Id.* ("Consequently, normal wave generated water velocities at the sea floor locations of the slant wells is predicted to be 8 to 20 times greater than that required for fine-grained material to accumulate on the sea floor over the subsurface slant wells. As a result, there would be no potential for the impingement of fine organic matter on the sea floor or changes to soft substrate habitat.")
[80] *Id.*
[81] DEIR/EIS, at pgs. 4.5-52-53 (referring to SWRCB, 2015 and MWDOC, 2010, which includes Jenkins, 2010 and Williams, 2010 – see explanation of relationship among these references in fn. 14.).

[83] Williams, 2010.

on the seabed unless the ocean is completely still.[84]

This, however, is an oversimplification of the fluid mechanics operating on these creatures. I utilized hydro-mechanical theories to demonstrate that particles as large as 10μm can still be trapped in vortices on the sea floor even when the current is at 10m/s. The particles will be caught in a vortex. They may then be subject to the vertical forces of the infiltration rate and will be drawn into the sea floor.

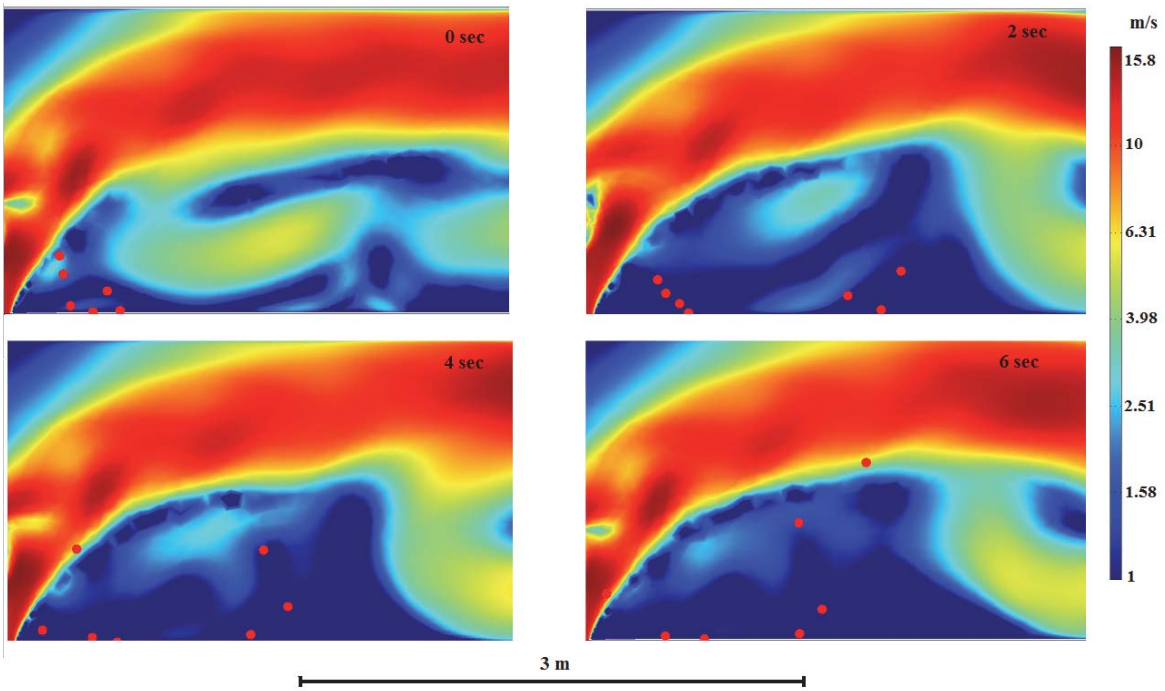

Figure 12. Numerically modeled snapshots of the particles (red dots) of size 10μm trapped by vortexes in highly turbulent current, the pseudo-color surface encodes velocity field ranging from 1 to 15.8 m/s, (3 to 47 ft/s)

CURE-Sobczynski-2 cont.

The DEIR/EIS relies on Jenkins's assertion that no biomatter could ever make it into the sea floor. This is inaccurate. First, the DEIR/EIS should provide existing levels of SOM and DOM from the sea floor to the intake. Second, the DEIR/EIS should reconsider the possibility that SOM and DOM can permeate the sea floor and build up in the sediment above the slant wells. Though the slant wells may be cleaned, the DEIR/EIS provides no proposal for cleaning the subsurface sediment.

This assumption that biomass need not be considered is undermined by the DEIR/EIS itself, which seeks to use the seabed as a "pre-filter"[85]:

[84] Jenkins, 2010, at pg. 8.

[85] Bar-Zeev, E., Belkin, N., Liberman, B., Berman, T., Berman-Frank, I. (2012). *Rapid sand filtration pretreatment for SWRO: Microbial maturation dynamics and filtration efficiency of organic matter.*

The Applicant proposes to use subsurface intakes (slant wells) to supply the desalination plant with source water. The well casings, or pipes, would extend seaward of MHW and would require a Special Use Permit to be present within MBNMS. The proposed slant wells would draw ocean water through the seafloor sediments, which would pre-filter the seawater for use at the desalination plant.[86]

Use of the sediment seafloor as a natural filter to remove bacteria, parasites, and other organic and inorganic impurities, besides sourcing the ocean water is the major driving force for the filtration, see illustration of source water in Figure 1. This is to ensure the water can be treated at the desalination plant without requiring extensive filtering.

Natural filtration in the subsea permeable deposits results in low turbidity and reduction or elimination of seawater reverse osmosis (SWRO) pretreatment.[87]

CURE-Sobczynski-2 cont.

Additionally, studies by Borodovskiy[88] and references contained within that study conclude that one cubic meter of surface sea water contains 0.5-1.5 grams of SOM. The estimated total mass of SOM above this Project's infiltration zone is 90 to 150kg/day. Based on our models, 50% of the SOM's flux will become concentrated within the 30 meter (98 foot) radius in the sand stratum above the highest water intake.

Distribution of the infiltered organic matter in sediment may vary, however once matter enters the filter medium it has no chance to escape, unless the deposit is scrubbed or dredged[89]. The rapid infiltration rate caused by the submersible pump only accelerates the process.

This result — i.e., the sand medium surrounding the intake zone has a high potential for plugging — is seen in other intake systems[90] with engineered filtering medium, such as infiltration gallery systems, not just slant wells.

Offshore Engineered Infiltration Gallery – An offshore engineered infiltration gallery is not expected to be able to reliably provide the required production capacity. The gallery would likely be plugged by fine sediment from winter storm discharge from the San Lorenzo River, which would reduce the production capacity and reliability. The engineered media would likely need to be dredged and replaced every few years, at great expense, and production would be stopped during those periods. Further, large storm events could also potentially reduce production capacity by eroding away the engineered media. Therefore, because an offshore infiltration gallery would have a high potential for plugging and erosion, and would not provide reliable production capacity, this alternative fails the screening level criterion, is not technically feasible and therefore is eliminated from further consideration.

In the case of strong storms, the layers covering the waste can be uncovered, see excerpt from section 7.1.1.1 below.[91] Based on USGS data to protect engineered media for an infiltration gallery, the gallery should be place 30 to 40 feet deep and 3,000 feet offshore. The slant well array is not being proposed to be built at distances of 3000 ft offshore. Therefore there is a risk that storm flows could "dig up" sediment that has accumulated. If toxic material has accumulated due to vertical infiltration, a storm will release the accumulated toxic material, which will spread and contaminate waters severely impacting the environment.[92]

CURE-Sobczynski-2 cont.

7.1.1.1 Wave Energy and Storm Flow Impacts on an Engineered Infiltration Gallery

Section 4 describes the impacts of wave and storm flows on the seafloor off the Santa Cruz coastline. Because wave energy could "dig up" an engineered infiltration gallery in the near-shore area, depending on where the waves are breaking and the orbital energy levels from the waves at the seafloor, an engineered infiltration gallery would need to be located farther offshore in deeper water. In the area near the Santa Cruz Municipal Wharf, Point Santa Cruz helps to protect this area from the predominant ocean wave energy. USGS data indicate that in the area of the offshore alluvial channel, approximately 3,000 ft offshore and approximately 30 to 40 ft depth, the typical wave energy does not cause significant erosion of the seafloor. Therefore, an engineered infiltration gallery would need to be placed at least 3,000 feet offshore (past the end of the wharf) to protect the engineered media from being scoured out by typical storm waves.

Based on this concern raised for infiltration galleries, it is in my opinion that the project has severe deficiencies in terms of planning for long term operations and storm events.

1. <u>Additional Factors that Lead to Bioaccumulation Impact: Colloidal Buildup</u>

CURE-Sobczynski-3

Compounding the issue of collected SOM is the problem of colloidal buildup of organic matter.[93] Colloidal buildup occurs when SOM attaches to clays contained within the sedimentary layers.[94] Once the SOM attaches to the clay, it can continue to grow

[91] *Id.* at pg. 7-2.
[92] *Id.*
[93] Moe, M. A., 1993.The Marine Aquarium Reference Systems and Invertebrates,. ISBN-0-939960-05-2
[94] Stevenson F.J., 1994. Humus Chemistry: Genesis, Composition, Reactions. New York: John Wiley & Sons.

and flourish[95], being supplied by oxygen pulled into the sedimentary layers by the slant well operations.

Thus, as the SOM follows hydrodynamic laws[96] it will bond to clays that are in the soil and directly above the submersible pump. As this detritus builds up above the pump, it will lead to reduced efficiency of the well resulting in clogging. The DEIR/EIS claims it will solve the issue of clogging through the application of mechanical brushes.[97] However, the DEIR/EIS does not account for how it will remove the organic detritus from the sediment above the slant wells. Without cleaning the sediment, the wells will continue to operate at low capacity.

CURE-Sobczynski-3 cont.

The DEIR/EIS is inconsistent with respect to the presence of clay, stating "in the specific area of the slant wells, the materials are dune sands with little to no fine-grained components (silt and clay) or soil components (organic materials) that would impede infiltration."[98] However, the test slant well's borehole lithologic log indicates that clay is present, see borehold lithologic log below.[99] The DEIR/EIS also states that "muds and clay slurry would be generated during the drilling and development of the subsurface slant wells." [100] Thus, the DEIR/EIS recognizes that clay will be present in the sedimentary layers around the well, but then provides no explanation as to how the project will address the buildup of organic matter that adheres to that clay.

2. **Additional Factors that Lead to Bioaccumulation Impact: Gas Discussion**

In addition to reduced slant well efficiency, the presence of accumulated bio-matter in the sediment presents the threat of the creation of toxic gas. As the bio-matter builds up on the colloidal deposits, it will serve as a nutrient for bacteria. This does not present a problem at first. As long as the slant wells are operational, then fresh, oxygenated sea water will be pulled through the sediment and supply the bacteria with oxygen. However, the DEIR/EIS admits the wells will periodically need maintenance and assumingly those wells would be taken offline.[101] At any given time, only eight wells will be operational, meaning the two on standby can be activated, while one of the eight deactivates.

When the wells go offline, the supply of oxygen will be cut off to the now thriving bacteria colonies. The bacteria will switch to anaerobic respiration. In anaerobic decay, the bacteria reduces organic matter to methane (CH_4), hydrogen sulfide (H_2S), ammonia (NH_3), amines (RNH_2), and methanethiol (CH_3SH).[102] Very few lifeforms can exist in this kind of a toxic environment.[103] CURE-Sobczynski-4

It is unclear how these gases will affect both the Monterey Bay environment as well as the quality of the water extracted by the desalination plant. While any slant well is offline, the hazardous gases will outgas through the sedimentary layers, entering back into the ocean water supply. However, once the slant wells are turned back on, the chemicals can potentially be taken in by the slant wells, leading to toxic corrosion of the slant well itself.

Regardless of the eventual effects, the DEIR/EIS should have considered the presence of these gases, estimated the quantity of the gases, determined how those gases would interact with the environment and the slant well equipment, and provided a mitigation plan. The DEIR/EIS does not account for even the presence of the gas. As such, it is once again deficient.

IV. Conclusion

The DEIR/EIS paints a rosy picture of the functioning of the slant wells in Monterey Bay. It underestimates the vertical infiltration rate and does not considering accumulation of any detritus, and permanent attachment of humic acids in the natural filter body. In reality, and without having been provided the necessary information, we can expect a negative impact on the environment from the slant wells. As it is, the DEIR/EIS fails to consider numerous environmental impacts generated as part of this project and is deficient as a public disclosure document. CURE-Sobczynski-5

V. Glossary [104]

- **Forchheimer** assumption requires that the water table will be flat, and groundwater be hydrostatic, i.e. equipotential lines are vertical to water table.

$$\frac{\partial P}{\partial z} = -\gamma = -\rho g$$

$$\frac{\partial h}{\partial z} = 0$$

where $\partial P/\partial z$ is the vertical pressure gradient, γ is the specific weight ρ is the density of water, g is the standard gravity and $\partial h/\partial z$ is the vertical hydraulic gradient.

- **Darcy's law**, at constant elevation is a proportional relationship between the instantaneous discharge rate through a porous medium, the viscosity the fluid and the pressure drop over a given distance.

$$Q = -\frac{\kappa A\,(p_\mathrm{b} - p_\mathrm{a})}{\mu L}\,.$$

Q (units of volume per time, e.g., m^3/s) is equal to the product of the intrinsic permeability of the medium, κ (m^2), the cross-sectional area to flow, A (units of area, e.g., m^2), and the total pressure drop $p_b - p_a$ (pascals), all divided by the viscosity, μ (Pa·s) and the length over which the pressure drop is taking place (L).

- **Computational fluid dynamics** (**CFD**) is a branch of fluid mechanics that

[104] Based in full or partially on articles published in Wikipedia. Forchheimer Assumption, Wikipedia, https://en.wikipedia.org/wiki/Dupuit%E2%80%93Forchheimer_assumption; Darcy's Law, Wikipedia, https://en.wikipedia.org/wiki/Darcy%27s_law; Computational Fluid Dynamics, Wikipedia, https://en.wikipedia.org/wiki/Computational_fluid_dynamics.

uses numerical analysis and data structures to solve and analyze problems that involve fluid flows. Computers are used to perform the calculations required to simulate the interaction of liquids and gases with surfaces defined by boundary conditions. With high-speed supercomputers, better solutions can be achieved. Ongoing research yields software that improves the accuracy and speed of complex simulation scenarios such as transonic or turbulent flows. Initial experimental validation of such software is performed using a wind tunnel with the final validation coming in full-scale testing, e.g. flight tests.

Figure 13. Scwd2,2011 – Seawater Desalination Intake Technical Feasibility Studies, picture shows sand morphology change due to infiltration.[105]

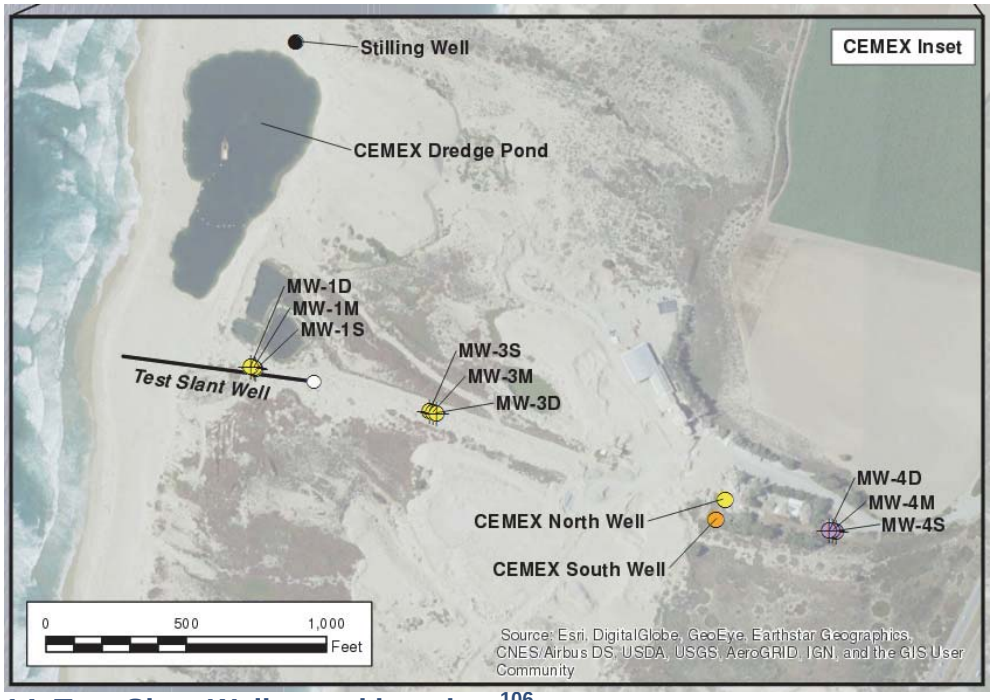

Figure 14. Test Slant Well actual location.[106]

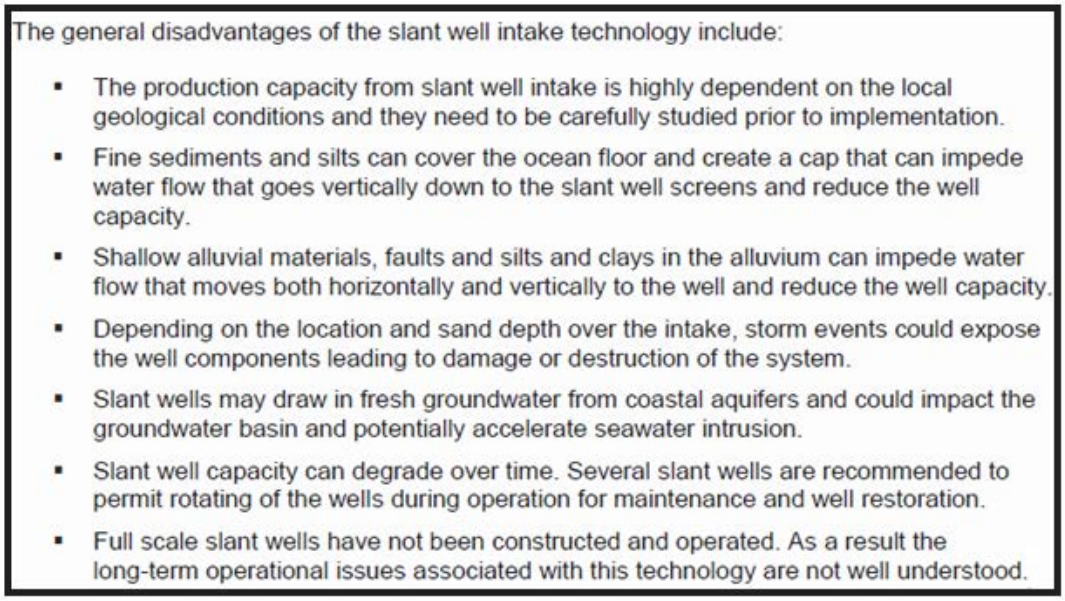
[105] Scwd2, 2011, at pg. 3-11.



The general disadvantages of the slant well intake technology include:

- The production capacity from slant well intake is highly dependent on the local geological conditions and they need to be carefully studied prior to implementation.
- Fine sediments and silts can cover the ocean floor and create a cap that can impede water flow that goes vertically down to the slant well screens and reduce the well capacity.
- Shallow alluvial materials, faults and silts and clays in the alluvium can impede water flow that moves both horizontally and vertically to the well and reduce the well capacity.
- Depending on the location and sand depth over the intake, storm events could expose the well components leading to damage or destruction of the system.
- Slant wells may draw in fresh groundwater from coastal aquifers and could impact the groundwater basin and potentially accelerate seawater intrusion.
- Slant well capacity can degrade over time. Several slant wells are recommended to permit rotating of the wells during operation for maintenance and well restoration.
- Full scale slant wells have not been constructed and operated. As a result the long-term operational issues associated with this technology are not well understood.

Re: Monterey Peninsula Water Supply Project Draft Environmental Impact Report/Environmental Impact Statement (Draft EIR/EIS)

Dear Ms. Borak and Ms. Grimmer:

On behalf of California-American Water Company (Cal-Am), the Applicant for the Monterey Peninsula Water Supply Project (Project), we appreciate the opportunity to provide written comments on the Draft EIR/EIS for the Project prepared jointly by the California Public Utilities Commission (CPUC) and Monterey Bay National Marine Sanctuary (MBNMS).

Cal-Am supports the analysis in the Draft EIR/EIS and believes the CPUC and MBNMS have performed an extremely thorough analysis of the Project and fully complied with their responsibilities under the California Environmental Quality Act (CEQA) and National Environmental Policy Act (NEPA), respectively, to assess the Project's potential adverse environmental impacts.

We understand that the CPUC, through its environmental consultants at Environmental Science Associates, and MBNMS will now begin the process of preparing the Final EIR/EIS for the Project, including responses to comments made on the Draft EIR/EIS, and any necessary corrections and additions to the Draft EIR/EIS. In reviewing the Draft EIR/EIS, Cal-Am identified various areas in the document that would benefit from some technical corrections, clarifications, and/or revisions. Accordingly, to assist the CPUC and MBNMS in preparing the Final EIR/EIS, we are attaching to this letter, as **Exhibit 1**, a matrix containing Cal-Am's suggested technical corrections, clarifications, and/or revisions to the Draft EIR/EIS.

CalAm-1

We believe that the comments and suggestions set forth in the attached matrix are technical corrections that fall within the scope of items to be addressed in the Final EIR/EIS. We have identified no issues that would warrant recirculation of the EIR/EIS per Public Resources Code section 21092.1 and CEQA Guidelines section 15088.5, and 40 Code of Federal Regulations section 1502.19. CalAm-1 cont.

In addition, as **Exhibit 2** to this letter we are providing you with a summary of Cal-Am's legal ability to develop water rights for the Project. This summary is intended to respond to several questions and comments that were raised by members of the public during public workshops on the Draft EIR/EIS in February 2017. As described in detail in this summary, Cal-Am can develop appropriative groundwater rights for the Project with respect to any water it may incidentally pump from the Salinas Valley Groundwater Basin as part of the Project. We hope that this summary helps clarify Cal-Am's position concerning groundwater rights. CalAm-2

Cal-Am fully supports the Project and looks forward to the CPUC's and MBNMS's continued review of the Project. Cal-Am would be happy to respond to any further questions you may have during the CEQA/NEPA process for the Project.

Very truly yours,

Duncan Joseph Moore
of LATHAM & WATKINS LLP

ES – Executive Summary						
1.	Dear Reviewer Letter	N/A	N/A	CalAm is not defined.	Please define CalAm as California American Water Company.	CalAm-3
2.	ES.2 Project Background	ES-2	First paragraph	The current language is in the Draft EIR/EIS is somewhat vague about exactly what kind of entity CalAm is, and what it provides to customers.	Please clarify that CalAm is a public water utility and that its Service District is the geographic area where it provides water to customers consisting of residential, commercial and industrial uses, among others.	CalAm-4
3.	ES.5.1 Description of Proposed Project	ES-5	First paragraph	Current description should explain what the Source Water Pipeline would do and to where it would convey water.	We suggest clarifying that Source Water Pipeline would convey water from the slant wells to the proposed desalination facility.	
4.	ES.5 The Proposed Project	ES-5	Second paragraph; sentence 2	Current description of the desalination plant should also discuss the proposed treated water storage tanks.	Consider adding text in **bold** to sentence 2 "… equalization tanks, **treated water tanks**, chemical feed . . ."	
5.	ES.5.1 Description of the Proposed Project	ES-6	Footnote 2	The City of Marina did not complete CEQA review of the test slant well project because its MND was not adopted, and instead its denial of the CDP was appealed to the Coastal Commission. The Coastal Commission then became the lead agency for CEQA review of the test well project.	Request that this be clarified in Footnote 2.	CalAm-5
6.	ES.6.5 Alternative 4	ES-10	First sentence	Typo – says Alternative 3 instead of Alternative 4.	Please correct typo.	CalAm-6
7.	ES Summary of Impacts and Mitigation Measures	ES-42	Table ES-2	There is an incorrect reference to the Presidio of Monterey Historic District, which would not be affected by the proposed project.	We request that the text be modified to read: "4.15-1a: Avoidance and Vibration Monitoring for Pipeline Installation in the ~~Presidio of Monterey Historic District, Downtown Monterey, and the~~ Lapis Sand Mining Plant Historic District."	CalAm-7
1. Introduction						
8.	1.4.2 The Monterey Peninsula Water Supply Project	1-9	Paragraph 7; Item 2	Current description of the desalination plant should also discuss the proposed treated water storage tanks.	Consider adding text in bold to sentence 2: "… equalization tanks, **treated water tanks**, chemical feed …"	CalAm-8
9.	1.4.4 Revisions Made in This EIR/EIS	1-11	Footnote 7	Similar to the comment in Executive Summary above, the City of Marina did not complete CEQA review of the test slant well project because its MND was not adopted, and instead its denial of the CDP was appealed to the Coastal	Request that this be clarified in Footnote 7.	CalAm-9

Comment #	Section Name	Page #	Paragraph or Table #	Issue	Suggested Resolution	
				Commission. The Coastal Commission then became the lead agency for CEQA review of the test well project.		CalAm-9 cont.
10.	References – Introduction and Background	1-18		NOAA 216-6A is cited but not placed in the List of References for that section.	Suggest adding citation to NOAA 216-6A.	CalAm-10
2. Water Demand, Supplies, and Rights						
11.	2.4.5 Groundwater Replenishment Project	2-20	Last paragraph of section	The Draft EIR/EIS references a September 15, 2016 CPUC decision allowing Cal-Am to enter a Water Purchase Agreement with the MRWPCA and MPWMD. The decision citation is not provided, although other CPUC decision citations are provided in this chapter. The correct citation is D.16-09-021.	We suggest that CPUC include the citation to this CPUC decision, which is D.16-09-021.	CalAm-11
12.	2.4.6.2 Malpaso Water Company LLC	2-21	Second paragraph of section	We note that the SWRCB recognizes that CalAm's interim use is offsetting Carmel River diversions.	We suggest a minor clarification to describe that excess water not used by Malpaso may be diverted for CalAm's use, and that such diversion offsets CalAm's Carmel River diversions. In other words, it is not an unauthorized diversion by CalAm, because it is under Malpaso's license.	CalAm-12
13.	2.5.3.3 Non-revenue Water Reduction	2-26	Footnote 29	Reference to Section 2.2.2 should be to 2.2.3.	Please revise Footnote 29 to correct reference.	CalAm-13
14.	2.6 Water Rights	2-31	First full paragraph	This paragraph discusses "[n]umerous court cases" but does not cite any cases.	Suggest adding citation to relevant court cases in References section.	CalAm-14
15.	2.6 Water Rights	2-31	Footnote 33	Footnote 33 repeats text in the previous paragraph.	Suggest deleting footnote.	CalAm-15
3. Project Description						
16.	3.1 – Introduction	3-2	First new paragraph	The proposed project would require 10 wells in total, and not nine wells	Suggest addition of a footnote to clarify that the existing test well would be converted to permanent 10th well if project is approved.	CalAm-16
17.	3.1 Introduction	3-2	Footnote 2	Similar to comments above, the City of Marina did not complete CEQA review because its MND for the test slant well project was not adopted, and instead its denial of the CDP was appealed to the Coastal Commission. The Coastal Commission then became the lead agency for CEQA review of the test well project.	Clarify in footnote.	CalAm-17
18.	3.2 Project Components	3-7	First paragraph; Bullet 2	Current description of the desalination plant should also discuss the proposed treated water storage tanks.	Consider adding text in bold to sentence 2: "… equalization tanks, **treated water tanks**, chemical feed …"	CalAm-18

Comment #	Section Name	Page #	Paragraph or Table #	Issue	Suggested Resolution	
19.	3.2 Project Components	3-8	Table 3-1; Row 6, Column 2, Bullet 1	The pretreatment building will be approximately 4,000 sf; not 6,000 sf.	Suggest changing "6,000-square foot" to "4,000-square foot."	CalAm-19
20.	3.2 Project Components	3-8	Table 3-1	Table 3-1 should be updated to clarify the nature of specific project components. Specific text revisions are recommended as noted in the following column.	The description of subsurface slant wells in Table 3-1 should be modified as follows: • Each well site would have one wellhead ~~**vault**~~ (Sites 1, 3, 4, and 5) or three wellhead**s** ~~**vaults**~~ (Sites 2 and 6), ~~**aboveground**~~ mechanical piping **vault** (meter, valves, gauges), one electrical control cabinet, and one pump-to-waste ~~**vault**~~ **basin**. • ~~Except for Site 1 (test slant well site), the aboveground facilities (at Sites 2 through 6) would be built on a concrete pad ranging between 5,250 and 6,025 square feet in area.~~	CalAm-20
21.	Section 3.2 Project Components	3-8	Table 3-1	Table 3-1 should be updated to show the need for two (2) surge vessels on site.	The DESCRIPTION SECTION of source water pipeline in Table 3-1 should be modified as follows: "~~**A**~~ **Two (2)** hydraulic surge ~~**facility comprising valves or hydro-pneumatic**~~ tanks would be located near the collector pipe/Source Water Pipeline connection point, south of the CEMEX access road and inland of the dunes." The PURPOSE SECTION of source water pipeline in Table 3-1 should be modified as follows: "The surge ~~**facility**~~ **tanks** would ~~**control the**~~ **protect the wells and pipeline infrastructure from** hydraulic **surge events (i.e., power loss) that could occu**r in the Source Water Pipeline."	CalAm-21
22.	3.2 Project Components	3-8 & 3-15	Table 3-1	Under the Subsurface Slant Wells portion of the table, the term "#8" is used without further explanation. This also occurs on page 3-15 under the Permanent Slant Wells discussion.	We believe this reference is to well 8 out of the 10 slant wells. We ask that this please be clarified, and suggest that a notation be added to a figure identifying which of the wells is being addressed here.	CalAm-22
23.	3.2 Project Components	3-10	Table 3-1	Brine Storage and Disposal – Brine Discharge Pipeline listed as 30 inch diameter. Correct diameter is 36 inch.	Please revise Brine Discharge Pipeline diameter to 36 inch.	CalAm-23
24.	3.2 Project Components	3-10	Table 3-1; Row 10, Column 2	The current design includes two (not four) large treated water pumps (each 4.8 mgd and 600 hp).	Request changing "- Four 4.8 mgd, 600 hp treated water pumps . . ." to "- Two 4.8 mgd, 600 hp treated water pumps . . ."	CalAm-24
25.	3.2.1 Seawater Intake System	3-13	Figure 3-3a	We believe some minor corrections to this Figure are necessary to show the current slant well layout.	See redlined figures provided. Please see Attachment A to this chart for corrections to this Figure.	CalAm-25
26.	3.2.1 Seawater Intake	3-13	Figure 3-3a	Sizing and specific project components require minor clarifications in this Figure.	We request the following additional minor clarifications to the Figure:	

Comment #	Section Name	Page #	Paragraph or Table #	Issue	Suggested Resolution	
	System				Pump-to-Waste ~~**Vault**~~ **Basin (Rip Rap) (12' x 8')** **Mechanical Piping** ~~**Wellhead**~~ Vault(s) **(14' x 8')** Electrical Control Cabinet **– Concrete Pad (12' x 4')** **Graded Area** ~~**Concrete Pad**~~ 5,250 – 6,025 sq ft **ADD:** "Surge Tank Location 1" (See Attachment A – marked-up Figure 3-3a) **ADD:** "Surge Tank Location 2" (See Attachment A – marked-up Figure 3-3a) **ADD:** "HDD Pipeline Route" (See Attachment A – marked-up Figure 3-3a) **ADD:** "Alternative (NO HDD) Pipeline Route" (See Attachment A – marked-up Figure 3-3a). In addition, revise line type to **dashed** for alternative route (Attachment A – marked-up Figure 3-3a) **ADD:** "HDD Pipeline Route" (See Attachment A – marked-up Figure 3-3a) **ADD:** "Typical Surge Tank Layout" (See Attachment B provided with this chart)	CalAm-25 cont.
27.	3.2.1.1 Subsurface Slant Wells	3-15	First paragraph	Reference to City of Marina in CEQA process for the test slant well.	Suggest removing reference to City of Marina in discussion of test well evaluation in accordance with CEQA, since the Coastal Commission was the lead agency.	CalAm-26
28.	3.2.1.1 Subsurface Slant Wells	3-17	Figure 3-3b	The lengths listed for onshore and offshore well lengths appear to require minor corrections. Please see table attached as Attachment C to this chart for values calculated by GEOSCIENCE (and refer to Attachment A – marked-up Figure 3-3a for well naming used for measurements/calculations). The updated well layout was used for the measurements. For comparison, lengths were calculated for current (2015) Mean High Water and the 2020 MHW used on Figure 3-3a.	The markups, from north to south, are: SW-1 Stand-by-1 SW-2 SW-3 SW-4 SW-5 SW-6 SW-7 Stand-by-2 Stand-by-3	CalAm-27
29.	3.2.1.1 Subsurface Slant Wells	3-18	First paragraph	Clarifications to certain project components are needed.	Sites 1 through 6 include the following ~~**aboveground**~~ facilities: **aboveground wellhead(s)**, ~~**one wellhead vault per slant well,**~~ **a below ground** mechanical piping **vault (12' x 6' x 6') for** ~~**(**~~meters, valves, gauges**, etc.)** ~~**)**~~ **per well**, an electrical **enclosure** ~~**control cabinet**~~, and a pump-to-waste **basin** ~~**vault**~~. Each wellhead would be ~~**enclosed in an**~~ **located** aboveground **for ease of maintenance**. ~~**12 foot long, 6 foot wide, and 8 inch**~~	CalAm-28

Comment #	Section Name	Page #	Paragraph or Table #	Issue	Suggested Resolution	
					~~**tall precast concrete vault.**~~ Each slant well would be equipped with **up to** a 2,500 gpm, 300 hp submersible well pump. The electrical controls for operation of the slant wells would housed in a single story, ~~**16**~~**17**-foot long, by ~~**7**~~**10**-foot wide**, 10 foot high** fiberglass ~~**electrical control cabinet**~~ enclosure located at each of the six well sites. Each site would also have a pump-to-waste ~~**vault**~~ **basin** for the percolation of turbid water produced during slant well startup and shutdown. The pump-to-waste ~~**vault**~~ **basin** would **be constructed of Rip Rap material, approximately 1-2 feet deep (12' x 8')** ~~**be a precast 12 foot long, 8 foot wide, and 1 foot tall concrete vault covered with a metal grate and underlain by clean gravel and permeable textile fabric**~~. The new permanent slant wells and associated ~~**aboveground**~~ infrastructure at Sites 2 through 6 would be constructed on a 5,250- to 6,025-square foot ~~**concrete**~~ **graded** pad located above the maximum high tide elevation on the inland side of the dunes ~~**(no concrete pad would be built at Site 1)**~~. A 750-foot long, 42-inch diameter buried ~~**NSF/ANSI 615**~~ certified pipe would collect the seawater pumped from Sites 2 to 6 and convey it to the proposed buried Source Water Pipeline located at the existing CEMEX access road.	CalAm-28 cont.
30.	3.2.1.2 Source Water Pipeline	3-18	Line 1	Source Water Pipeline incorrectly listed as NSF/ANSI 61	Remove NSF/ANSI 61	CalAm-29
31.	3.2.1.2 Source Water Pipeline	3-18	Line 8	"The alignment would continue north along Lapis Road for 0.5 miles."	Revise to "The alignment would continue north within the TAMC ROW, along Lapis Road for 0.5 miles."	CalAm-30
32.	3.2.2.1 Pretreatment System	3-21	First paragraph; Sentences 3 and 4	Sentence 3 describes pretreatment requirements and identifies "membrane filtration" but not multimedia gravity filtration.	Consider revising the text to read "The pretreatment requirements for seawater collected by the proposed slant wells has been determined through operation of the test slant well and pilot program, and would likely include pressure filters or multimedia gravity filters, a backwash supply storage tank, and backwash settling basins. If necessary, the pretreatment system could also include coagulation, flocculation, or membrane filtration."	CalAm-31
33.	3.2.2.5 Brine Storage and Disposal	3-27	First paragraph; line 8	Brine Discharge pipeline listed as 30-inch diameter. Correct diameter is 36 inch.	Please revise to 36-inch diameter.	CalAm-32
34.	3.2.3.2 Desalinated Water Pumps	3-28	First paragraph; Sentence 3	The current design includes two (not four) large treated water pumps (each 4.8 mgd and 600 hp).	Suggest changing "There would be four 4.8 mgd, 600 hp pumps …" to "There would be two 4.8 mgd, 600 hp pumps …"	CalAm-33
35.	3.2.3.3 New Desalinated Water Pipeline	3-29	First paragraph	Minor correction needed to the following language: "… approximately 800 feet to Lapis Road, and continue south along Lapis Road …"	Request revising this language to read "… approximately 800 feet to Lapis Road, and continue south within TAMC ROW along Lapis Road …"	CalAm-34
36.	3.2.3.7	3-35	Second	The draft EIR/EIS should also consider alternative placement of water pipe in the	We request expanding the discussion to include the potential alternative placement of	CalAm-35

Comment #	Section Name	Page #	Paragraph or Table #	Issue	Suggested Resolution	
	Castroville Pipeline		paragraph	county road ROW instead of within the TAMC.	pipeline within the County Road ROW along the same general route from Lapis Road and Del Monte, north on Monte Road, across county bridge, continue north in Monte Road ROW to Nashua Road and then continue back to TAMC route.	CalAm-35 cont.
37.	3.2.3.9 Interconnections with Highway 68 Satellite Systems	3-36	Last paragraph	The pipeline route does not include Blue Larkspur Lane, which is currently referenced.	Please revise as follows: "The pipeline would be installed within the rights-of-way of Ragsdale Drive, Lower Ragsdale Drive, and Wilson Drive~~, and Blue Larkspur Lane~~."	CalAm-36
38.	3.2.3.9 Interconnections with Highway 68 Satellite Systems Main System-Hidden Hills Interconnection Improvements	3-43	First paragraph	There are currently four pump stations in this area: Tierra Grande, Lower Tierra Grande, Middle Tierra Grande, and Upper Tierra Grande. The Tierra Grande and Lower Tierra Grande are new pump stations and appear to have been recently upgraded. The Lower Tierra Grande has two pumps with Pump 1 rated at 328 gpm at 195 ft TDH and Pump 2 rated at 370 gpm at 200 ft TDH. The Upper Tierra Grande Booster Station appears to have been recently upgraded to two 237 gpm pumps (not the 350 gpm mentioned in the Draft EIR/EIS). The Middle Tierra Grande Booster Station does require upgrades, as its pumps appear to be in the 165 gpm range.	Please consider revising as follows: "The existing interconnection between the main CalAm distribution system and the Hidden Hills system would be improved by installing approximately 1,200 feet of 6-inch-diameter pipeline along Tierra Grande Drive~~, with a connection to the existing Upper Tierra Grande Booster Station. The Upper Tierra Grande Booster Station has an existing capacity of 129 gpm. A new 350 gpm pump would be added to the booster station. In Addition, the existing pump capacity of the Middle Tierra Grande Booster Station, located on lower Casiano Drive, would be upgraded from 161 gpm to 400 gpm by adding a new 350 gpm pump (CalAm, 2013a)~~ **There are four pump stations in this area (from lowest to highest): Tierra Grande, Lower Tierra Grande, Middle Tierra Grande, and Upper Tierra Grande. The lowest station pumps into the next station and so on. The Middle Tierra Grande Booster Station pumps require an upgrade in capacity to approximately 400 gpm**."	CalAm-37
39.	3.2.4 Proposed ASR Facilities	3-43	General	The Draft EIR/EIS contains a very short discussion of the ASR system.	Suggest describing purpose and function of the existing ASR system so that the reader understands more clearly what the ASR system does.	CalAm-38
40.	3.2.4 Proposed ASR Facilities	3-44	Second paragraph	ASR 5 and 6 wells are incorrectly listed to have a combined injection capacity of 2.2 mgd (1,050 gpm).	Request that the text be revised to explain that the combined injection capacity is 4.3 mgd (3,000 gpm), which is the same as the extraction capacity.	CalAm-39
41.	3.3.2.1 Subsurface Slant Wells	3-48	Second full paragraph	Clarifications to certain project components are needed.	Please consider revising as follows: "The slant wells would be completed using telescoping casing ranging from 22 to 36 inches in diameter and super-duplex 12- to 20-inch diameter stainless steel well screens. A submersible pump would be lowered several hundred feet into each well. To develop the slant wells, each well would be pumped for 2 to 6 weeks during slant well completion and initial well testing. The groundwater pumped from the wells during well development would be discharged to the ocean within the waters of MBNMS via the test slant well discharge pipe and the existing MRWPCA ocean outfall. This well development process would produce a volume of water too great to percolate into the ground at the CEMEX mining area, as compared to the drill phase described above. Once built, **each** ~~**the**~~ well~~**heads**~~ would include **up to** 12-inch-diameter **mechanical** discharge piping (i.e., flow meter, isolation valve, check valve, pump control valve, air **release** valve, and pressure gauge). This discharge **mechanical** piping would **be located in a below ground vault (12' x 6'). The electrical controls would be located in a fiberglass enclosure** ~~**approximately 2 to 3 feet above the ground on an estimated**~~	CalAm-40

Comment #	Section Name	Page #	Paragraph or Table #	Issue	Suggested Resolution	
					~~**6,000 square foot concrete pad, with some of the mechanical and electrical gear covered by a pre-manufactured shelter to protect them from the elements**~~. The discharge piping would then transition underground via trenching and connect to the buried source water pipeline. The wellheads would be accessible and grade level once completed."	CalAm-40 cont.
42.	3.3.4 Pipeline Installation	3-50	Table 3-5	The table shows that construction of the desalination plant would result in 0 cy of excess spoils or construction debris, which is correct. However, we suggest a minor revision to the text associated with construction. In addition, there is an errant comment remaining in the document that needs to be removed. (see LB1 in last row).	It would be helpful in the construction description of the plant to note that cut and fill on the project site will not result in off-site transport of soils	CalAm-41
43.	3.4.1 Operation of the Seawater Intake System, etc.	3-58	Table 5-7	Table includes a typo and references 9.5 mgd for daily production. Daily production is 9.6 mgd as correctly noted in the remainder of the section..	Please correct typo in Table 5-7, as 9.6 mgd is the correct number.	CalAm-42
44.	3.4.5 Power Demand	3-60 to 3-61	First Paragraph	Clarification to power demand numbers is necessary due to the metrics used.	We request the following changes: • "Under existing conditions, the electrical power needed to operate the water supply system in CalAm's Monterey District Service Area is 11,466,000 ~~million~~ kilowatt hours per year (kWh/yr)." • "…the average annual power demand for the Monterey District Service Area would be 63,164,000 ~~million~~ kWh/yr." • "Therefore, the net increase in annual electrical power demand for water production would be approximately 51,698,000 ~~million~~ kWh/yr."	CalAm-43
45.	3.5 Permits, Approvals, and Regulatory Requirements	3-65	Table 3-8; Row 3	CDPH no longer regulates public water systems. The California Environmental Protection Agency, State Water Resources Control Board, Division of Drinking Water regulates public water systems.	Suggest replacing references to "CDPH" with "Division of Drinking Water."	CalAm-44
4. Environmental Setting, Impacts, and Mitigation Measures						
4.1 Overview						
46.	4.1 Overview	4.1-24	Table 4.1-2, Row 60	No location is listed for the Monterey Pipeline and Pump Station	Suggest including location for Monterey Pipeline and Pump Station	CalAm-45
47.	4.1 Overview	4.1-25	Figure 4-1	The Monterey Pipeline is not shown on map with cumulative projects	Suggest including Monterey Pipeline on map.	

Comment #	Section Name	Page #	Paragraph or Table #	Issue	Suggested Resolution	
4.2 Geology, Soils, and Seismicity						
48.	4.2.2.3 Applicable Land Use Plans, Policies, and Regulations	4.2-37 to 4.2-43	Table 4.2-6	Discussions of certain relevant policies disclose a "potential inconsistency" between the project and such policies. The Table is confusing because the project would be consistent with the applicable policies upon the implementation of mitigation (i.e., Impact 4.2-10's conclusion is that the project will be consistent with such policies upon implementation of Mitigation Measure 4.2-9).	Suggest revising Table 4.2-6 to note – for those policies where the project would be potentially inconsistent – that the project would be consistent with implementation of the applicable mitigation measure.	CalAm-46
49.	4.2.4.1 Geotechnical Investigations for Project Facilities	4.2-46	First paragraph	The Draft EIR/EIS indicates that it "used geotechnical information and data derived from project-specific geotechnical studies, including geotechnical investigations conducted for the proposed MPWSP Desalination Plant at Charles Benson Road (PCE, 2014; Zinn, 2014) and the conveyance pipelines (AECOM, 2015)." However, none of these studies are incorporated into the EIR/EIS as an appendix.	Consider including these studies as appendices or providing weblinks to the studies if they are available online.	CalAm-47
50.	4.2.5.2 Operational and Facility Siting Impacts	4.2-69	Impact 4.2-10 (Coastal Erosion/Sea Level Rise)	Although the Draft EIR/EIS correctly describes how the profiles for erosion/sea level rise/storm events established in the modeling for the 2014 study caused CalAm to resite the slant well clusters, the Draft EIR/EIS does not state that the Figures (Profiles 4a and 4b) from the 2014 study (which is attached as Appendix C2) are now no longer current.	Consider revising this in the Final EIR/EIS.	CalAm-48
4.3 Surface Water Hydrology and Water Quality						
51.	4.3.1.3 Surface Water Quality	4.3-9	Footnote 11	Typo - reference to Section 4.3.2.1 should be 4.3.2.2	Please correct typo in Final EIR/EIS.	CalAm-49
52.	4.3.2 Regulatory Framework	4.3-17	Figure 4.3-3	This figure shows areas subject to sea level rise in the Project Area. This figure should also be included and/or referenced in the discussion of sea level rise impacts in Section 4.2.	Please include reference to Figure 4.3-3 (or actual figure) in Section 4.2.	CalAm-50
53.	4.3.2.1 Federal Regulations	4.3-21	Fourth bullet	"EHF" is not defined.	Please define "EHF" in Final EIR/EIS.	CalAm-51
54.	4.3.2.2 State Regulations	4.3-34	First paragraph	Typo requiring minor correction.	Please correct in Final EIR/EIS as follows: "The Monitoring and Reporting Plan would require review and approval by the RWQCB and MBNMS prior to implementation of the MPWSP, and **be** revised if necessary, as part of the NPDES permit process."	CalAm-52
55.	4.3.5.2 Operational and Facility Siting Impacts	4.3-71	Impact 4.3-3	Sentence lacks units of measurement: "Seasonal average temperatures ranged between 11.5 and 14.5 and seasonal salinity levels ranged from 33.3 to 33.9 at the depth of the diffuser."	Please add measurement units.	CalAm-53

Comment #	Section Name	Page #	Paragraph or Table #	Issue	Suggested Resolution	
4.4 Groundwater Resources						
56.	4.4 Groundwater Resources	4.4-1	First paragraph, second sentence	Typo requiring minor correction.	Please revise sentence to read: "Specifically, this analysis focuses on how the proposed subsurface slant wells and aquifer storage and recovery (ASR) system improvements would change the groundwater aquifers adjacent to the coast **and** further inland beneath the Salinas Valley, and would change the groundwater levels, flow direction, and water quality within the Seaside Groundwater Basin."	CalAm-54
4.6. Terrestrial Biological Resources						
57.	4.6.2.2 State Regulations	4.6-99	Second paragraph	The Draft EIR/EIS states that FORA's Draft Habitat Conservation Plan for the former Fort Ord military base is expected to be complete in late 2016.	Determine whether an update to the schedule for the HCP can be provided in the Final EIR/EIS. [Note: This statement is also repeated on page 4.6-252.]	CalAm-55
58.	4.6.5.1 Construction Impacts	4.6-170	Mitigation Measure 4.6-1d	Mitigation Measure 4.6-1d requires that, for work conducting during the non-nesting season, a qualified biologist will evaluate the nature and extent of wintering plover activity in the project area "several days" prior to construction.	We request that a specific number of days or range of days prior to construction be provided for clarity.	CalAm-56
59.	4.6.5.1 Construction Impacts	4.6-179	Mitigation Measure 4.6-1l	Mitigation Measure 4.6-11 requires pre-construction surveys for special-status bats, but does not specifically state when the surveys should occur.	We request that a specific number or days or range of days prior to construction be provided for clarity.	CalAm-57
60.	4.6.5.1 Construction Impacts	4.6-231	Mitigation Measure 4.6-4	Mitigation Measure 4.6-4 requires Cal-Am to perform a comprehensive survey within the project footprint to identify, measure, and map trees subject to local tree removal ordinances, but does not specify when such surveys should be conducted.	We request that a specific number or days or range of days prior to construction be provided for clarity..	CalAm-58
4.8 Land Use, Land Use Planning, and Recreation						
61.	4.8.1 Setting	4.8-5	Figure 4.8-1	The Coastal Zone boundary does not clearly identify that Coastal Zone extends over the ocean.	Suggest revising figure to make clear that Coastal Act governs the area that is seaward of beach.	CalAm-59
62.	4.8.1 Setting	4.8-8	Figure 4.8-3	The Main System-Hidden Hills Interconnection is missing from figure due to the location of the legend.	Suggest providing an alternate figure in the Final EIR/EIS that includes Main System-Hidden Hills Interconnection.	CalAm-60
63.	4.8.1.3 to 4.8.1.12	4.8-9 to 4.8-13	General	Descriptions of pipeline segments do not expressly state that pipelines would be subterranean.	Suggest clarifying that pipelines would be constructed underground and note which pipelines are being constructed in public rights of way.	CalAm-61
64.	4.8.2.1 State Regulations	4.8-16	Fort Ord Reuse Plan	The Draft EIR/EIS is not clear what type of development is allowed within areas governed by Fort Ord Reuse Plan	Suggest clarifying any applicable use requirements/allowances for these properties.	CalAm-62
65.	4.8.2.1 State Regulations	4.8-17	Coastal Act	The discussion of Coastal Act does not make clear that the Coastal Commission has appeal authority over LCP determinations for major public works projects like the MPWSP.	Suggest addressing this fact in technical correction to the text in the Final EIR/EIS.	CalAm-63

Comment #	Section Name	Page #	Paragraph or Table #	Issue	Suggested Resolution
66.	4.8.2.3 Local Regulations	4.8-19	Monterey County Municipal Health & Saf. Code	The discussion of CPUC preemption mentions the CalAm Settlement Agreement.	Consider including the Settlement Agreement as an appendix to the Final EIR/EIS, given that it is being relied on in the analysis.
4.11. Greenhouse Gas Emissions					
67.	4.11.1.1 Climate Change	4.11-2	4.11.1.1	There is no framing of the role desalination can fill in response to a changing climate.	We suggest including a discussion of how desalination is addressed favorably in state policy documents regarding climate change. For example, see *Safeguarding California: Reducing Climate Risk – An update to the 2009 California Climate Adaptation Strategy*, California Natural Resources Agency, at 233-234 (July 2014) ("Droughts are also expected to increase in frequency, duration, and intensity; and drought affects all sectors - impacting public health, biodiversity, agriculture, and the economy. … To mitigate potential shortages during drought, a variety of measures may be utilized. State, regional and local agencies have increasingly been pursuing a strategy of making regions more self-reliant by developing new or underused water resources locally; improving water storage capacity may be another important strategy for preparing for drought risks. For instance, new or underused water resources may come from including: improved water conservation and water use efficiency, expanded water recycling, improved stormwater management, conjunctive use (coordinated management of local surface and groundwater), desalination, and groundwater remediation.")(emphasis added). The *Safeguarding California* Plan also identifies "Actions Needed to Prepare for Climate Risks to California Water Resources." One of those actions is "Diversify Local Supplies and Increase Water Use Efficiency," which provides: "Increasing regional self-reliance and diversification of local water supplies will enable Californians to better respond to changing economic and climactic conditions while ensuring a reliable water supply for the diversity of the state's water needs. California's water agencies utilize a variety of water management measures to improve local water supply reliability. These measures include agricultural and urban water use efficiency, local storage, conjunctive use, increasing stormwater capture and infiltration, recycled water, and ocean and brackish water desalination." *Id.* at 247 (emphasis added). One recommendation to achieve this action is "Develop a coordinated streamlined permitting process for desalination projects that provides strong environmental protection." *Id.* at 249. Another action is "Prepare California for hotter and dryer conditions and improve water storage capacity," which provides "[A] variety of measures may be utilized to mitigate potential shortages during drought, including minimizing reliance on imported water, improved water conservation and water use efficiency, expanded water recycling,

					improved stormwater management, desalination, groundwater remediation, conjunctive use, firming up existing water transfer agreements, and entering into spot transfer or short-term water transfer agreements." *Id.* (emphasis added).	CalAm-65 cont.
68.	4.11.2.2 State Regulations	4.11-8	Mandatory Reporting Requirements	The Draft EIR/EIS contains an imprecise discussion of the applicability of MRR.	We request adding the following sentence to the end of the paragraph: "In addition, many of the proposed project's sources of GHG emissions are not directly subject to CARB's reporting program."	CalAm-66
69.	4.11.2.2 State Regulations	4.11-9	Market-Based "Cap-and-Trade" Compliance Mechanism	The Draft EIR/EIS contains an imprecise discussion of the applicability of cap-and-trade program.	We request adding the following sentence to the end of the paragraph: "In addition, many of the proposed project's sources of GHG emissions are not directly subject to the cap-and-trade program."	CalAm-67
70.	4.11.4.3 Evaluation of GHG Emissions	4.11-14	First paragraph	The last sentence of the paragraph does not flow well from the prior sentence.	Suggest revising sentence to read: "While ~~this particular~~ the 10,000 metric tons CO2e per year significance threshold is not used, indirect emissions associated with electricity consumption are calculated and impacts are fully assessed in this chapter."	CalAm-68
71.	4.11.5 Operational Emissions	4.11-17	Bottom of page	The Draft EIR/EIS incorrectly states: "As of July 2016, state policymakers have not enacted this RPS program expansion into law."	We suggest replacing this sentence with the following: "Senate Bill 350 was signed by Governor Brown on October 7, 2015, codifying the 50% RPS."	CalAm-69
4.12. Noise and Vibration						
72.	4.12.6 Direct and Indirect Effects of the Proposed Project	4.12-34	Mitigation Measure 4.12-1d	The last sentence of Mitigation Measure 4.12-1d states that "Barrier blankets are available with a sound transmission class rating of 32, providing 16 to 40 dBA of sound transmission loss, depending on the frequency of the noise source (ENC, 2014)." It is not clear whether blankets meeting this rating are required.	Recommend clarifying whether blankets meeting this rating will be required.	CalAm-70
4.13. Public Services and Utilities						
73.	4.13.2.2 State Regulations	4.13-7	California Coastal Act	The first paragraph states that a preliminary assessment of MPWSP consistency with Coastal Act priorities concerning designing and limiting new or expanded public works facilities such that they are protective of costal resources "is provided here."	As written, it is unclear what "here" refers to. Consider adding a reference to particular section in which these priorities are discussed, or if discussed in the subsequent paragraphs of Section 4.13.2.2, consider changing "here" to "below." If "here" refers to the entire EIR, consider changing "here" to "in this EIR/EIS."	CalAm-71
74.	4.13.5.1 Construction Impacts	4.13-17	Consistency with Regulatory Requirements	Typo of "L-U6.1."	Revise to "LU-6.1."	CalAm-72
75.	4.13.5.1 Construction	4.13-18	Mitigation Measure 4.13-	Typo. MM 4.13-1c provides: "Construction managers shall hold regular tailgate meetings with construction staff on days when work near high-priority utilities will	Remove em-dash at the end of the sentence.	CalAm-73

Comment #	Section Name	Page #	Paragraph or Table #	Issue	Suggested Resolution	
	Impacts		1c	occur to review all safety measures regarding such excavations, including measures identified in the Mitigation Monitoring and Reporting Program and in construction specifications—."		CalAm-73 cont.
76.	4.13.5.1 Construction Impacts	4.13-18	Mitigation Measure 4.13-1e	MM 4.13-1e states that "CalAm or its contractor(s) shall notify local fire departments in advance of any time work that is to be performed in close proximity to a gas utility line, or any time damage to a gas utility line results in a leak or suspected leak, or whenever damage to any utility results in a threat to public safety."	We request that the phrase "close proximity" be made more specific so that it provides an objective standard/distance. In addition, please revise sentence as follows: "CalAm or its contractor(s) shall ~~**notify**~~ **meet with** local fire departments in advance of ~~**any time**~~ **commencing** work that is to be performed in close proximity to a gas utility line **to establish a protocol and procedures for notification of work occurring near gas utility lines and a list of emergency contacts, and to provide the local fire department with a copy of the Emergency Response Plan required by Mitigation Measure 4.13-1d**~~**, or any time damage to a gas utility line results in a leak or suspected leak, or whenever damage to any utility results in a threat to public safety**~~."	CalAm-74
4.14. Aesthetic Resources						
77.	4.14.3.2 State Regulations	4.14-22	California Coastal Act	The Draft EIR/EIS states that the operation of the project would be potentially inconsistent with Coastal Act policies re: scenic resource protection. Table 4.14-2, which contains a comparison of plans, policies, and goals against the project, does not include Coastal Act policies.	While Table 4.14-2 does include some LCP policies, if there is no desire to include actual policy sections of the Coastal Act, we suggest modifying the language on p. 4.7-22 to clarify that the policies in the table are LCP policies re: scenic resource protection that implement the Coastal Act.	CalAm-75
78.	4.14.6.1 Construction Impacts	4.14-29	Subsurface Slant Wells – Second Paragraph	The Draft EIR/EIS states, "Construction of the remaining subsurface slant wells in the CEMEX active mining area would take approximately 15 months to complete, and could take place anytime throughout the overall 24-month construction duration for the proposed project." However, this sentence does not take into account the durational limitations on slant well construction due to restrictions in the terrestrial bio mitigation measures.	Clarify that construction timing is subject to mitigation measures governing terrestrial bio impacts.	CalAm-76
4.18. Energy Conservation						
79.	4.18.2.2 State Regulations	4.18-6	State of California Integrated Energy Policy	The Draft EIR/EIS only discusses the 2013 Integrated Energy Policy Report (IEPR). The 2015 IEPR was adopted 2/10/2016 and the 2016 IEPR Update is scheduled to be considered for adoption at the CEC's 2/15/2017 meeting.	Update language to address 2015 IEPR and 2016 IEPR Update.	CalAm-77
4.19. Population and Housing						
80.	4.19.1.2 Employment	4.19-3	2nd on page	In the second sentence, the Draft EIR/EIS states that "the county" lost about 1,500 jobs, but does not specify which county.	The language should be clarified (appears to be Monterey County based on context).	CalAm-78
81.	4.19.5 Direct and Indirect Effects of Proposed	4.19-5	Header	Inconsistency noted: the header of section 4.19.5 includes "Indirect Effects," but section 4.19.3 states that indirect impacts are analyzed in the Growth Inducement chapter.	Address inconsistency.	CalAm-79

Comment #	Section Name	Page #	Paragraph or Table #	Issue	Suggested Resolution	
	Project					CalAm-79 cont.
4.20. Socioeconomics and Environmental Justice						
82.	4.20.2.3 Local Regulations	4.20-12	Settlement Agreement on MPWSP Desalination Plan Return Water	The first paragraph of section states that "[u]nder this agreement, CCSD will purchase water at a discounted cost pursuant to Item 4, Payment Provisions."	Consider defining CCSD. Also, is the title of subsection should read "Desalination Plant," not "Desalination Plan"	CalAm-80
5. Alternatives Screening and Analysis						
83.	5.3.5 Desalination Plan Site Options Screening Results	5.3-27	First paragraph	The Draft EIR/EIS assumes that a minimum of 10 acres is needed to accommodate desalination plant facilities, but does not explain why this minimum acreage is used.	Recommend providing additional information in comment letter to explain why an alternative site must be at least 10 acres.	CalAm-81
84.	5.4.2.4 Ability to Meet Project Objectives	5.4-11	Second paragraph	The sentence that reads "The GWR Project, when constructed, would provide 3,500 of potable supply for the CalAm service area" contains a typo.	This should read "The GWR Project, when constructed, would provide 3,500 **afy** of potable supply for the CalAm service area."	CalAm-82
85.	5.4 Description of Alternatives Evaluated in Detail	5.4-53	Table 5.4-9 Alternative 5A Facilities Subsurface Slant Wells	Number of well sites needs to be corrected.	We request the following clarifications to the text: • Seven slant wells located the CEMEX site, extending offshore beneath Monterey Bay (the conversion of an existing test slant well into a permanent well plus six new wells at ~~four~~ **five** new well sites) into MBNMS, with four to five wells operating under normal operating conditions but all wells could under certain operating conditions at any given time and two wells maintained on standby. • The slant wells would be grouped into ~~five~~ **six** wells: ~~four~~ **five** sites with one well each and one site with ~~three~~ **two** wells. Each well would have a wellhead ~~vault~~, and ~~aboveground~~ mechanical piping **vault** (meter, valves, and gauges); each well would have one electrical ~~control cabinet~~ enclosure, and one pump-to-waste ~~vault~~ **basin** (same as proposed project).	CalAm-83
86.	5.4 Description of Alternatives Evaluated in Detail	5.4-53	Table 5.4-9 Alternative 5A Facilities Source Water Pipeline	Minor clarifications required	We request the following clarifications to the text: • 2.7 mile longs versus 2.2 miles long in Table 3.1. Verify. • **ADD:** "Two (2) hydraulic surge tanks would be located near the collector pipe/Source Water Pipeline connection point, south of the CEMEX access road and inland of the dunes."	CalAm-84
87.	5.4.7.1	5.4-54	Table 5.4-9;	The current design does not include a "Clearwell Pump Station."	Consider the following changes:	CalAm-85

Comment #	Section Name	Page #	Paragraph or Table #	Issue	Suggested Resolution	
	Overview – Description of the Reduced Project		Row 6, Columns 1 and 2		Column 1: Change "Clearwells (Water Storage Tanks) and Clearwell Pump Station" to "Treated Water Storage Tanks" Column 2: Delete "6.4 mgd capacity, 120-horsepower pump"	CalAm-85 cont.
88.	5.4.7.1 Overview – Description of the Reduced Project	5.4-54	Table 5.4-9; Row 7, Columns 1 and 2	Descriptions of the treated water pumps for the 6.4 mgd plant need to be clarified.	Consider the following changes: Column 1: Change "Desalinated Water Pump Station" to "Desalinated Water Pumps" Column 2, Bullet 1: Change "6.4 mgd capacity, 800-horsepower pump . . ." to "Two 3.2 mgd capacity, 400-horsepower pumps and two 1.6 mgd capacity, 200-horsepower pumps" Column 2, Bullet 2: Change "1.4 mgd capacity, 20-horsepower pump …" to "Two 1.4 mgd capacity, 10-horsepower pumps …"	CalAm-86
89.	5.5.5.5 Direct and Indirect Effects of Project Alternative 2 – Open-Water Intake at Moss Landing	5.5-116 to 5.5-117	Mitigation Measure ALT 2-Marine-1: Marine Construction Measures	The Draft EIR/EIS includes mitigation measures that apply only to certain alternatives. For example, Mitigation Measure ALT 2-Marine-1: Marine Construction Measures, only applies to alternatives with open-water intakes.	Suggest clarifying that these measures do not apply to the proposed project or any ultimately-approved project that does not include an open-water intake.	CalAm-87
90.	5.5.5.5 Direct and Indirect Effects of Project Alternative 2 – Open-Water Intake at Moss Landing	5.5-119	Mitigation Measure ALT 2-Marine-2: Minimization of and Mitigation for Loss of Marine Life and Habitat	The Draft EIR/EIS includes mitigation measures that apply only to certain alternatives. For example, Mitigation Measure ALT 2-Marine-2: Minimization of and Mitigation for Loss of Marine Life and Habitat, only applies to alternatives with open-water intakes.	Suggest clarifying that these measures do not apply to the proposed project or any ultimately-approved project that does not include an open-water intake.	CalAm-88
91.	5.5.6.5 Direct and Indirect Effects of Project Alternative 2 – Open-Water Intake at Moss Landing	5.5-144	Last paragraph	There appears to be a missing word in the sentence: "Construction of the Alternative 2 intake would have the potential for indirect impacts on sensitive habitats, as none are located adjacent to sites where construction of the intake would occur."	May need to be revised to say: "Construction of the Alternative 2 intake would **not** have the potential for indirect impacts on sensitive habitats, as none are located adjacent to sites where construction of the intake would occur.	CalAm-89
92.	5.5.12.6 Direct and Indirect Effects of	5.5-250 to 5.5-251	Mitigation Measure ALT 3-NO:	The Draft EIR/EIS includes mitigation measures that apply only to certain alternatives. For example, Mitigation Measure ALT 3-NO: Operational Performance Noise Standard for Data Center Generators, only applies to	Suggest clarifying that this measure does not apply to the proposed project.	CalAm-90

Comment #	Section Name	Page #	Paragraph or Table #	Issue	Suggested Resolution	
	Alternative 3 - the Monterey Bay Regional Water Project		Operational Performance Noise Standard for Data Center Generators	Alternative 3.		CalAm-90 cont.
93.	5.5.12.7 Direct and Indirect Effects of Alternative 4 - the Peoples' Moss Landing Water Desalination Project	5.5-253 to 5.5-254	Mitigation Measure ALT 4-NO: Operational Performance Noise Standard for Desalination Facilities and Pump Station	The Draft EIR/EIS includes mitigation measures that apply only to certain alternatives. For example, Mitigation Measure ALT 4-NO: Operational Performance Noise Standard for Desalination Facilities and Pump Station, only applies to Alternative 4.	Suggest clarifying that this measure does not apply to the proposed project.	CalAm-91
94.	5.5.15.4 Direct and Indirect Effects of Alternative 1 – Slant Wells at Potrero Road	5.5-298	Mitigation Measure ALT 1-CULT (Conduct Subsurface Investigation)	The Draft EIR/EIS includes mitigation measures that apply only to certain alternatives. Applicant Proposed Measure 4.4-3: Groundwater Monitoring and Avoidance of Well Damage.

Prior to the start of MPWSP slant well construction, CalAm, working with MCWRA, shall develop a groundwater monitoring and reporting program (the "Program") to the satisfaction of MCWRA. All costs of Program development and implementation shall be borne by CalAm either directly or through funding of MCWRA's staff, consultants and Program activities. The Program shall augment the MCWRA's existing regional groundwater monitoring network to focus on the area that could be affected by the proposed slant wells. The geographic area of the Program shall be within the model domain of the North Marina Groundwater Model, also referred to as NMGWM^{2016} and include the Dune Sand Aquifer, the 180-Foot Aquifer, the 400-Foot Aquifer and the Deeper Aquifer (i.e., the 900-Foot Aquifer) of the Salinas Valley Groundwater Basin (the "Monitoring Area"). The purpose of the Program is to ensure that owners of existing public or private groundwater supply wells within the Monitoring Area on the date the MPWSP commences slant well pumping ("Active Supply Wells") suffer no harm as a result of MPWSP slant well pumping. The elements of the Program proposed under this measure are described below.

1. A network of monitoring wells has been completed on and near the CEMEX property as part of the CalAm test slant well project. These well clusters monitor water elevation and quality at various depth intervals within the Dune Sand Aquifer, the 180-Foot Aquifer, and the 400-Foot Aquifer and shall be included in the Program's monitoring network. These existing monitoring wells are subject to relocation, replacement, or substitution by new or other monitoring wells developed as part of the Program as determined by MCWRA.

2. In addition, using information from the Groundwater Extraction Management System (GEMS) maintained by MCWRA and from the State Water Resources Control Board's Division of Drinking Water, CalAm, in coordination with MCWRA, shall identify Active Supply Wells in the Monitoring Area and offer to owners of identified Active Supply Wells the opportunity to participate in the Program for groundwater elevation and water quality monitoring. The owners of Active Supply Wells in the Monitoring Area will receive at least 60 days' notice (via email, if available, and via certified mail) of the opportunity to participate in the Program, and may elect in writing to participate in the Program as to their Active Supply Wells ("Participating Active Supply Wells"). This opt-in process must occur sufficiently in advance of MPWSP slant well pumping so that information on pre-MPWSP conditions can be obtained for each Participating Active Supply Well. Prior to the start of MPWSP slant well pumping, an independent California-certified hydrogeologist retained and directed by MCWRA (the "Hydrogeologist") shall evaluate the conditions and characteristics (e.g., well depth, well screen interval, pump depth and condition, flow rates, and drawdown) of each Participating Active Supply Well to develop pre-pumping data for each well. Water elevation and quality monitoring pursuant to the Program shall begin

following initial groundwater well assessment, and shall continue at intervals specified in the Program (e.g., more frequently at the beginning of MPWSP slant well pumping and less often after stabilization of groundwater levels) until the well owner ceases pumping from the monitored well, or until the well owner agrees that monitoring is no longer required.

3. Prior to the start of MPWSP slant well pumping, CalAm and MCWRA shall review the current (as updated if needed) inventory of monitoring wells within the Monitoring Area, and identify locations within the Monitoring Area lacking monitoring coverage and that warrant monitoring in order to evaluate potential effects on Participating Active Supply Wells from MPWSP slant well pumping. Based upon that review, MCWRA may require that CalAm fund the installation of new monitoring wells in the Monitoring Area to be installed before MPWSP slant well pumping begins. The number of new monitoring well sites in the Monitoring Area and the location of those new monitoring well sites shall be determined by MCWRA. The area of groundwater monitoring under the Program may be extended outside of the Monitoring Area if warranted to evaluate potential MPWSP slant well pumping effects on Participating Active Supply Wells and recommended by the Hydrogeologist.

4. The groundwater data developed through the Program shall be collected by or provided to MCWRA at intervals identified in the Program, but in no event longer than 45 days from such data being obtained, to evaluate whether MPWSP slant well pumping is causing consistent and measurable drawdown of local groundwater levels that is distinguishable from seasonal or multi-year groundwater level fluctuations. In the event that MCWRA identifies a consistent and measurable drawdown in groundwater levels and determines that such drawdown is potentially attributable to MPWSP slant well pumping and independent of seasonal or multi-year groundwater level fluctuations or any regional trends, the Hydrogeologist shall then determine if the observed degree of drawdown would damage or otherwise adversely affect any existing Participating Active Supply Wells. Adverse effects from lowered groundwater levels in Participating Active Supply Wells may include water elevation acute and long-term declines that draw water below pump intakes, causing cavitation due to exposure of the well screen, reduced well yields and pumping rates, increased energy costs to power the well, or changes in groundwater quality indicating that MPWSP slant well pumping is drawing lower quality water toward the well. Active Supply Wells that are not Participating Active Supply Wells will be considered for a determination by the Hydrogeologist of potential damage or adverse effects reasonably attributable to MPWSP slant well pumping (as described above) if substantial, credible evidence is submitted by the owners of such Active Supply Wells concerning damage or adverse effects at such wells, and such effects are verified by CalAm and the Hydrogeologist.

5. If the Hydrogeologist determines that a Participating Active Supply Well or an Active Supply Well that Cal-Am and the Hydrogeologist have verified for damage or adverse effects pursuant to Section 4 above has been damaged or otherwise negatively affected by MPWSP slant well pumping, CalAm and the Hydrogeologist shall coordinate with the well owner to develop and implement a mutually agreed upon course of action. Such course of action may include but not be limited to repairing or deepening the existing well, restoring groundwater yield by improving well efficiency, facilitating an interim or long-term replacement of water supply, constructing a new well, or compensating the owner for increased pumping costs. Any interim or long-term replacement water supply shall be of the same or better quality (i.e., potable or non-potable) and predicted quantity as the existing supply of the Active Supply Well and shall be suitable for the purposes served by the existing Active Supply Well. Before CalAm undertakes any course of action to remedy the MPWSP slant well pumping effects on an Active Supply Well, the Hydrogeologist shall authorize such action and provide notice of such action to MCWRA.

Applicant Proposed Measure 4.4-3: Groundwater Monitoring and Avoidance of Well Damage.

Prior to the start of MPWSP slant well construction, ~~the project applicant~~CalAm, working with ~~the~~ MCWRA, shall ~~fund and~~ develop a groundwater monitoring and reporting program ~~that expands the current~~(the "Program") to the satisfaction of MCWRA. All costs of Program development and implementation shall be borne by CalAm either directly or through funding of MCWRA's staff, consultants and Program activities. The Program shall augment the MCWRA's existing regional groundwater monitoring network to ~~include~~focus on the area ~~near~~that could be affected by the proposed slant wells. ~~Once expanded, the program will monitor groundwater levels and water quality within the area where groundwater elevations are anticipated to decrease in~~ The geographic area of the Program shall be within the model domain of the North Marina Groundwater Model, also referred to as NMGWM^{2016} and include the Dune Sand Aquifer ~~and~~, the 180-~~FTE~~Foot Aquifer, the 400-Foot Aquifer and ~~within at least one mile outside of the predicted radius of influence. The area of groundwater monitoring shall be determined by MCWRA and the MPWSP HWG.~~the Deeper Aquifer (i.e., the 900-Foot Aquifer) of the Salinas Valley Groundwater Basin (the "Monitoring Area"). The purpose of the Program is to ensure that owners of existing public or private groundwater supply wells within the Monitoring Area on the date the MPWSP commences slant well pumping ("Active Supply Wells") suffer no harm as a result of MPWSP slant well pumping. The elements of the ~~groundwater monitoring program~~Program proposed under this measure are described below.

~~• Using a current survey of wells within the pumping influence of the slant wells, CalAm will offer to private and public well owners the opportunity to participate in a voluntary groundwater monitoring program to conduct groundwater elevation and quality monitoring. The voluntary groundwater monitoring program shall include retaining an independent hydrogeologist to evaluate the conditions and characteristics (e.g., well depth, well screen interval, pump depth and condition, and flow rate) of participating wells prior to the start of slant well pumping. Water elevation and quality monitoring shall begin following initial groundwater well assessment.~~

~~• Based on a review of the well network of voluntary well owners, CalAm will identify areas lacking adequate groundwater data and if deemed necessary, install new monitoring wells. These new wells would be in the 180-Foot Aquifer.~~

1. ~~• Seven clusters~~A network of monitoring wells ~~were recently~~has been completed on and near the CEMEX property as part of the CalAm test slant well project. These well clusters monitor water elevation and quality at various ~~depths~~depth intervals within the Dune Sand Aquifer, the 180-Foot Aquifer, and the 400-Foot Aquifer and shall be included in the Program's monitoring network. These existing monitoring wells are subject to relocation, replacement, or substitution by new or other monitoring wells developed as part of the Program as determined by MCWRA.

2. **In addition, using information from the Groundwater Extraction Management System (GEMS) maintained by MCWRA and from the State Water Resources Control Board's Division of Drinking Water, CalAm, in coordination with MCWRA, shall identify Active Supply Wells in the Monitoring Area and offer to owners of identified Active Supply Wells the opportunity to participate in the Program for groundwater elevation and water quality monitoring. The owners of Active Supply Wells in the Monitoring Area will receive at least 60 days' notice (via email, if available, and via certified mail) of the opportunity to participate in the Program, and may elect in writing to participate in the Program as to their Active Supply Wells ("Participating Active Supply Wells"). This opt-in process must occur sufficiently in advance of MPWSP slant well pumping so that information on pre-MPWSP conditions can be obtained for each Participating Active Supply Well. Prior to the start of MPWSP slant well pumping, an independent California-certified hydrogeologist retained and directed by MCWRA (the "Hydrogeologist") shall evaluate the conditions and characteristics (e.g., well depth, well screen interval, pump depth and condition, flow rates, and drawdown) of each Participating Active Supply Well to develop pre-pumping data for each well. Water elevation and quality monitoring pursuant to the Program shall begin following initial groundwater well assessment, and shall continue at intervals specified in the Program (e.g., more frequently at the beginning of MPWSP slant well pumping and less often after stabilization of groundwater levels) until the well owner ceases pumping from the monitored well, or until the well owner agrees that monitoring is no longer required.**

3. **Prior to the start of MPWSP slant well pumping, CalAm and MCWRA shall review the current (as updated if needed) inventory of monitoring wells within the Monitoring Area, and identify locations within the Monitoring Area lacking monitoring coverage and that warrant monitoring in order to evaluate potential effects on Participating Active Supply Wells from MPWSP slant well pumping. Based upon that review, MCWRA may require that CalAm fund the installation of new monitoring wells in the Monitoring Area to be installed before MPWSP slant well pumping begins. The number of new monitoring well sites in the Monitoring Area and the location of those new monitoring well sites shall be determined by MCWRA. The area of groundwater monitoring under the Program may be extended outside of the Monitoring Area if warranted to evaluate potential MPWSP slant well pumping effects on Participating Active Supply Wells and recommended by the Hydrogeologist.**

4. ~~• Using the~~**The** groundwater data developed through the ~~**voluntary well monitoring program and data gathered at the new monitoring wells, CalAm will**~~**Program shall be collected by or provided to MCWRA at intervals identified in the Program, but in no event longer than 45 days from such data being obtained, to** evaluate whether ~~**project**~~**MPWSP slant well** pumping is

causing ~~a~~**consistent and** measurable ~~**and consistent**~~ drawdown of local groundwater levels ~~**in nearby wells**~~ that is distinguishable from seasonal **or multi-year** groundwater level fluctuations. In the event that **MCWRA identifies** a consistent and measurable drawdown ~~**is identified, CalAm will**~~**in groundwater levels and determines that such drawdown is potentially attributable to MPWSP slant well pumping and independent of seasonal or multi-year groundwater level fluctuations or any regional trends, the Hydrogeologist shall then** determine if the observed degree of drawdown would damage or otherwise adversely affect ~~**active water supply wells**~~**any existing Participating Active Supply Wells**. RE: DEIR/DEIS MONTEREY PENINSULA WATER SUPPLY PROJECT

Gentleman:

The Carmel River Steelhead Association (CRSA) has been involved in water issues on the Monterey Peninsula, especially in regards the Carmel River, for forty years and makes the following comments on the Draft EIR/EIS for the Cal-Am Monterey Peninsula Water Supply Project.

CRSA has been in favor of this project since the beginning and is still in favor of the project. We do have one comment or item we would like added to the Final EIR/EIS when issued.

In reading the document we fail to see where it notes how Cal-Am will use its remaining legally permitted water; specifically when the pumping of that water will occur. We have been told on many occasions that Cal-Am will pump the majority of its legally permitted water during the wet season or when the river is running above 120 cubic feet per second. We have also been told that Cal-Am must pump some water during the dry season to keep their pumps and treatment facilities operational, but that necessary summer pumping would be at a minimum.

CRSA feels it is necessary to include language in the Final EIR/EIS that spells out the Cal-Am pumping regime once the Monterey Peninsula Water Supply Project is complete or the benefit to Carmel River Steelhead will not be as significant as required. If such a request is in the scope of this EIR/EIS then CRSA insists it be added to the document.

CRSA-1

Sincerely,

Brian LeNeve

RE: Draft Environmental Impact Statement for the Monterey Peninsula Water Supply Project

The Carmel River Watershed Conservancy wishes to express its support for the Monterey Peninsula Water Supply Project and in particular the proposed desalination plant with subsurface seawater intake system.

It is our strong belief that this Project is the most likely project that has been proposed that will increase the in-stream flows in the Carmel River and improve the chances of recovery of the South Central California Steelhead (a federally listed threatened species). Like any project, there are obstacles that must be overcome (such as permits to be issued) and mitigations that will be necessary, but the alternative proposed water supply project would also be required to test subsurface intake wells and that would greatly delay that project, possibly beyond the extension that has been granted by the SWRCB.

CRWC-1

Our Conservancy conducted the first watershed-wide assessment of the Carmel River Watershed in 2004-05 with a grant from the SWRCB, and developed the Watershed Assessment and Action Plan from that project. That Action Plan was revised in 2007 and 2015, and one of the highest-priority actions was "Support implementation of a water supply project that minimizes the export of water from the Carmel River basin during the dry season that causes a chronic reduction in flow and meets the goals of State Water Resources Control Board Order 95/10." In addition, the NOAA's National Marine Fisheries Service has issued a South-Central California Steelhead Recovery Plan (December 2013) that recommends as a "Critical Recovery Action" for the Carmel River to "Develop and implement alternative off channel water supply project to eliminate or decrease water extractions from the channel…" (page 7-12). The Carmel River has been over-drafted for decades to supply the water needs of the

Monterey Peninsula, and to eliminate such over-drafting an alternative water supply is absolutely essential.

The Water Supply Project's desalination plant is the only proposed project that is likely to provide such an alternative water supply source in sufficient quantity to preclude further over-drafting of the Carmel River and its acquifer and thereby restore high stream flows for much of the year that are critical to the recovery of our steelhead populations. Supplemented by the Aquifer Storage and Recovery (ASR) and the Pure Water Monterey Groundwater Replenishment (GWR) projects, this proposed desalination plan would enable California American Water to choose to take only its legal right of 3,376 acre feet of water annually from the Carmel River and its acquifer. While the River might still dry up in portions during the dry season and in drier water years, the amount of water flowing in the River will be substantially higher than it is now during those times. That is our goal if we are to accomplish our mission to restore the health and beauty of the Carmel River and watershed.

Re: CalAm Monterey Peninsula Water Supply Project Revised Draft EIR-EIS

Dear Ms. Borak and Ms. Grimmer:

I submit this letter on behalf of my client, CEMEX, for public comment on the Revised Draft Environmental Impact Report Environmental Impact Statement (DEIR/EIS) prepared for the Monterey Peninsula Water Supply Project (MPWSP or "Project"). The Project is proposed by California American Water Company ("CalAm"). The DEIR/EIS was prepared jointly by the California Public Utilities Commission (the "Commission"), as the lead agency under the California Environmental Quality Act (CEQA), and the National Oceanic and Atmospheric Administration (NOAA), Monterey Bay National Marine Sanctuary (MBNMS), as the lead agency under the National Environmental Policy Act (NEPA). The DEIR/EIS was released for public review and circulation in January 2017, and the public review period was subsequently extended until March 29, 2017. If, after public comment and review, the Commission approves the Project as proposed, CalAm will install ten subsurface slant wells on an existing CEMEX property with an active sand mine, known as the Lapis Site. The slant wells would provide water to a new desalination plant capable of producing 10,750 acre-feet per year of potable water.

The Commission previously issued a Draft EIR for the Project on April 30, 2015. CEMEX reviewed that Draft EIR and, on September 30, 2015, submitted a timely formal comment letter to the Commission. (Attachment A hereto.) CEMEX notes that, unfortunately, many of the concerns raised in that prior letter almost one and a half years ago still have not been addressed in the DEIR/EIS. As summarized in CEMEX's prior comment letter, CalAm proposes co-locating the slant wells and other Project-critical infrastructure on CEMEX's 400-acre Lapis Site, which CEMEX currently uses for active mining operations. The Lapis Site, which is located in the northern part of the City of Marina, has been actively and continuously mined since 1906 under a constitutionally-protected vested right to operate a sand production business. (See, e.g., Lapis Site Reclamation Plan approved by City of Marina in August 1989.) In addition, the Lapis

{00028949;6 }

Site is subject to an approved reclamation plan pursuant to the Surface Mining and Reclamation Act (SMARA). (See Cal. Pub. Res. Code §§ 2710 et seq.)

To the extent that any of CEMEX's prior comments from 2015 are not addressed in the DEIR/EIS, CEMEX reincorporates those comments with this letter. Furthermore, the failure of this letter to comment on any other DEIR/EIS inconsistencies with CEMEX's operation processes and rights and CEMEX's property rights should not be considered agreement by CEMEX with any such misstatements or construed as a waiver of any rights or remedies to which CEMEX may be entitled. In this context I submit the following comments for the Commission's consideration when preparing the Final EIR/EIS.

I. CEMEX's Global Comments on the DEIR/EIS Regarding Project Use of CEMEX Property

A. The 1996 Annexation Agreement speaks for itself, and the DEIR/EIS must analyze the impacts of a potential injection well on CEMEX property.

The DEIR/EIS states that an "issue to be resolved" and an "area of controversy" regarding CalAm's proposed use of subsurface slant wells to withdraw source water for the Project includes "whether CalAm has the legal right to extract groundwater from the Salinas Valley Groundwater Basin (SVGB)." (DEIR/EIS, p. ES-13.) This issue implicates the *Annexation Agreement and Groundwater Mitigation Framework for Marina Area Lands* (the "Annexation Agreement") executed in 1996 by the Marina Coast Water District (MCWD), the Monterey County Water Resources Agency (MCWRA), the owners of the Armstrong Ranch, RMC Lonestar ("RMC," CEMEX's predecessor in interest for the Lapis Site), and the City of Marina. The DEIR/EIS discusses the Annexation Agreement in section 2.6.4.

DEIR/EIS section 2.6.4 includes an additional discussion of whether CalAm has the legal right to extract groundwater from the SVGB. The DEIR/EIS concludes that implementation of the Project will be compatible with the Annexation Agreement, because CalAm "could conceivably construct and employ an injection well on CEMEX property." (DEIR/EIS, p. 2-42.) First, the Annexation Agreement speaks for itself, so CEMEX does not consider the DEIR/EIS's interpretations to be binding in any way regarding that Agreement. Second, the DEIR/EIS must analyze the impacts on CEMEX's property and active sand production operations of constructing an injection well on CEMEX property, since the DEIR/EIS acknowledges construction of the well is a reasonably foreseeable outcome of the Project.

CEMEX-1

B. CalAm's construction and Project operation ground disturbance will need to be addressed in a reclamation plan amendment.

Disturbance of land proposed by CalAm for construction and operation of the subsurface slant wells and the source water pipeline on the Lapis Site will need to be accounted for and addressed by a reclamation plan amendment in effect for CEMEX's operations pursuant to the

CEMEX-2

requirements of SMARA. (See Cal. Pub. Res Code § 2777.) DEIR/EIS section 4.17.1.2 states that "CEMEX, as the land owner, would need to amend the Reclamation Plan to include the construction and operation of the slant wells in the retired portion of CEMEX property and the source water pipeline underneath the CEMEX access road." (DEIR/EIS p. 4.17-3.) The DEIR/EIS does not address necessary coordination or cost of this undertaking. As CalAm is proposing this Project necessitating a reclamation plan amendment, CalAm must indemnify CEMEX for the monetary cost of any increase in CEMEX's reclamation obligations. As noted previously, CEMEX has an established vested right to mine the property, so the DEIR/EIS's reference to potential review by state and federal agencies does not reduce CalAm's obligations to either prepare or bear the cost of a reclamation plan amendment.

CEMEX-2 cont.

C. Project construction, operation, and mitigation must be consistent with the Mine Safety and Health Administration Requirements.

As previously noted by CEMEX, the DEIR/EIS does not address how CalAm will ensure compliance with the federal Mine Safety and Health Administration (MSHA) and the California Division of Occupational Safety and Health (also known as "Cal/OSHA"), Division of Mining and Tunneling, mine safety requirements. Section 4.7 should be revised to address this issue, and its current failure to do so is improper.

The proposed siting of the Project on an active mine site requires compliance during construction, operation, and decommissioning with MSHA and Cal/OSHA. The DEIR/EIS fails to address site-specific safety issues in any appreciable detail. For example, the DEIR must include a mitigation measure that commits CalAm to chocking tires of parked construction vehicles.

CEMEX-3

Considering the fundamental importance of safe operations on an active mine site and CEMEX's potential MSHA liability for CalAm's actions relating to the Project, the Commission must ensure through a condition of approval or other legal instrument that CalAm both indemnifies CEMEX for its actions and obtains its own Mine Identification Number from MSHA, so that CalAm will be the entity cited for any potential violations it commits, rather than CEMEX. This revision to the DEIR/EIS could be coordinated with the Health and Safety Plan required by DEIR/EIS mitigation measure 4.7-2a. (DEIR/EIS p. 4.7-29.) For these same reasons, CalAm must coordinate with CEMEX personnel to review the Traffic Control and Safety Assurance Plan, and the DEIR/EIS mitigation measure 4.9-1 should be updated to reflect this requirement.

CEMEX-4

D. CalAm's revisions to the Project, including well and pipeline locations and construction schedules, should be coordinated with CEMEX to ensure they do not interfere with operations and reclamation activities.

CEMEX-5

Due to revisions to the locations and configurations of the slant wells, CalAm must coordinate with CEMEX to review the revised Project design and ensure that no adverse impacts to

CEMEX's sand production operations and reclamation activities will occur. (DEIR/EIS p. 3-13, Figure 3-3a.) Additionally, the DEIR/EIS now describes the need for new aboveground and underground power lines at the Lapis site. (DEIR/EIS p. 3-44.) The location of these power lines should also be reviewed by and coordinated with CEMEX to ensure that the location will not interfere with its operations and reclamation activities. Finally, sections 3.3.2, 3.3.9, and 3.4 of the DEIR/EIS describe the construction activities and schedule associated with construction and maintenance of the slant wells. (DEIR/EIR pp. 3-47, 3-55, 3-57.) Construction activities and maintenance, as well as the location of temporary facilities, should also be coordinated with CEMEX to ensure locations and activities will not interfere with its operations and reclamation activities.

CEMEX-5 cont.

II. The DEIR/EIS Does Not Sufficiently Address Potentially Significant Geologic, Soils, and Seismicity impacts

The geology and soils analysis concludes that there will be no impact from subsidence associated with the subsurface slant wells on CEMEX's property. (DEIR/EIS p. 4.2-66.) This conclusion is based on the assumption that the slant wells will be drawing water from offshore coastal aquifers. However, the groundwater resources section acknowledges the slant wells could draw some portion of inland groundwater from the underlying aquifer. (DEIR/EIS p. 4.4-60.) Thus, potential impacts to CEMEX's property due to subsidence from the slant wells drawing some portion of groundwater must be analyzed.

CEMEX-6

In addition, the slant wells appear to be located in an area of moderate to high liquefaction susceptibility, but the potential impacts of liquefaction on the slant wells, including associated above-ground structures, are not addressed. (DEIR/EIS p. 4.2-60 to 4.2-61.) The potential for seismic influence to damage the slant wells, and any related impacts to CEMEX's on-going mining operations must be addressed.

CEMEX-7

Furthermore, the DEIR/EIS concludes that, based on the relocation of slant wells, the wells would remain buried and not exposed until sometime after 2060. (DEIR/EIR p. 4.2-70.) However, Mitigation Measure 4.2-9 requires that the wells be abandoned before the slant wells are exposed. (DEIR/EIS p. 4.2-71.) Thus, the DEIR/EIS must address necessary coordination with CEMEX on the abandonment procedure for the slant wells.

CEMEX-8

III. The DEIR/EIS Does Not Adequately Address Potentially Significant Hydrology Impacts to CEMEX's Property and Active Operations

A. Potential surface hydrology impacts to CEMEX's property must be analyzed.

CEMEX-9

The DEIR/EIS states that any flood flows diverted by the electrical control cabinets "would not affect other properties or structures." (DEIR/EIS p. 4.3-117.) However, the DEIR/EIS does not

address whether flows diverted by the electrical control cabinets and other surface infrastructure will have an impact within the CEMEX active mining area or otherwise interfere with CEMEX's operations. The DEIR/EIS should be revised to address this issue.

CEMEX-9 cont.

The DEIR/EIS also states that the slant wells would be designed to withstand inundation, so that there would be no significant risk of damage from flooding due to sea level rise. (DEIR/EIS p. 4.3-119.) Elsewhere, the DEIR/EIS concludes that impacts to the slant wells due to sea level rise will be insignificant because the wells will be decommissioned before sea level rise impacts occur. (DEIR/EIS p. 4.2-71 to 4.2-72.) Due to this inconsistency, the DEIR/EIS must consider the potential impacts to CEMEX's property of operating inundated slant wells in flood conditions.

CEMEX-10

B. The Groundwater Monitoring Program must be expanded to account for CEMEX's water supply well and drawdown impacts in the 400-foot aquifer.

The DEIR/EIS discussion for Impact 4.4-3 notes that aquifers underlying the slant wells, including the 400-foot aquifer, "are projected to exhibit a response to MPWSP slant well pumping." (DEIR/EIS, p. 4.4-59.) As demonstrated in Figure 4.4-16, CEMEX's production well will be subject to a one foot drawdown under both the 0% and 3% return water scenarios. To reach this estimate, the DEIR/EIS analysis for Impact 4.4-3 relies on modeling for the extent of pumping influence in the 180-FTE Aquifer. (DEIR/EIS p. 4.4-57, citing Appendix E2.)

As noted in CEMEX's comment letter on the prior draft EIR, the reliability of the groundwater drawdown model was assessed using well pumping data from the test slant well. (Appendix E2.) Based on this model, the DEIR/EIS concludes that groundwater drawdown impacts, including impacts to CEMEX's well, will be less than significant. (DEIR/EIS p. 4.4-68.) Despite this conclusion, the DEIR/EIS includes an applicant proposed mitigation measure to expand an existing regional groundwater monitoring program to include the Dune Sand Aquifer and the 180-FTE Aquifer.

CEMEX-11

Specifically, Mitigation Measure 4.4-3 proposes an expansion of the current regional groundwater monitoring network to include monitoring of groundwater levels "in the Dune Sand Aquifer and the 180-FTE Aquifer." (DEIR/EIS, p. 4.4-74.) While the measure references well monitors in the 400-foot aquifer, it is not clear that the measure applies to the 400-foot aquifer. Since the Project could result in drawdown under 0% and 3% water return scenarios, Mitigation Measure 4.4-3 must be revised to include monitoring of the 400-foot aquifer to ensure that the Project does not adversely impact CEMEX's existing water production well. In addition, the Mitigation Measure only requires mitigation if CalAm determines drawdown is resulting in adverse impacts. This measure fails to identify a performance standard for measuring when an adverse effect might trigger mitigation. Since this determination is left to CalAm's discretion, the mitigation measure is unenforceable and illusory.

Furthermore, as noted in CEMEX's prior comment letter on the 2015 draft EIR, Mitigation Measure 4.4-3 must not only be developed prior to Project construction, the requisite agency must also *approve* the submitted plans prior to Project construction. Agency approval of an applicant-developed mitigation program is necessary to ensure mitigation is not impermissibly deferred. CEMEX-12

C. The DEIR/EIS should be revised to sufficiently analyze and address Project drawdown impacts on the Lapis site.

i. The DEIR/EIS geologic description of CEMEX's dredge pond is not accurate.

The DEIR/EIS analysis of Impact 4.4-3 also considers whether the Project will have an impact on CEMEX's existing dredge pond or on the current sand mining operations. The DEIR/EIS states that the water level for CEMEX's dredge pond is assumed to be 10 to 20 feet deep. (DEIR/EIS, pp. 4.4-70 to 4.4-71.) CEMEX-13

The DEIR/EIS assumptions regarding the dredge pond and related settling ponds for analysis of Impact 4.4-3 is not accurate. As noted in CEMEX's prior comment letter, the depth of the dredge pond is allowed to 30 feet, not 10 to 20 feet as assumed in the DEIR/EIS. In addition, CEMEX's property consists of either "Qd" (seafloor deltaic deposits) or "Qd" (dunes) , as shown on Figure 4.4-3. Therefore, the DEIR/EIS should be revised to reflect appropriate assumptions for CEMEX's site, including the allowable 30 foot depth of the dredge pond and appropriate hydrogeologic layers underlying the site.

ii. The DEIR/EIS fails to analyze impacts that drawdown could have on vegetation.

The DEIR/EIS analysis lacks an evaluation of the impacts that drawdown would have on existing vegetation at the Lapis site. The DEIR/EIS must be revised to ensure that CalAm is responsible for adverse impacts that drawdown may have on vegetation on CEMEX's property. At minimum, Mitigation Measure 4.4-3 should be extended to monitor drawdown impacts on vegetation and provide remediation for adverse impacts to the extent that monitoring determines that any impacts are caused by drawdown. CEMEX-14

iii. The DEIR/EIS modeling of impacts to CEMEX's dredge pond is insufficient.

The DEIR/EIS concludes drawdown impacts to CEMEX's dredge pond will be less than significant, despite the potential for pumping at the slant wells to cause a drawdown response. The DEIR/EIS reasons that tidal influences and recharge will offset any drawdown impacts. CEMEX-15

(DEIR/EIS pp. 4.4-71 to 4.4-72.) CalAm supports this conclusion by extrapolating results from pumping the test slant well.

In September 2014, CalAm simulated test slant well pumping for eight months at 2,500 gpm and determined that a drawdown of 1 foot at the dredge pond was attributable to pumping at the test well. Based on the measured results and localized model, the DEIR/EIS concludes that "there is a possibility that additional drawdown would occur" during the Project's operation of 10 slant wells. (DEIR/EIS, p. 4.4-71.) The DEIR/EIS reaches this conclusion based on the localized CEMEX model, which is intended to simulate "the response of the Dune Sand Aquifer in its second, third, and fourth vertical layers." (*Ibid.*) Thus, the DEIR/EIS still appears to assume that the depth of CEMEX's dredge pond corresponds to the second and third layers. (*Ibid.*) However, during Hydrogeology Working Group sessions, suggestions were made that the dredge pond is more appropriately assigned to the first layer (Ocean Floor), which suggestion is reflected in Table 3.1 of Appendix E-2. (DEIR/EIS, Appendix E-2, p. 15.) However, it does not appear that the updated 2016 model was incorporated in the analysis of drawdown impacts to CEMEX's dredge pond, or that the first layer is modeled at all. (DEIR/EIS pp. 4.4-71 to 4.4-72.)

The modeling cited in the DEIR/EIS focuses on the aquifer response, rather than providing any localized models of the dredge pond response. As a result, the DEIR/EIS fails to identify or analyze estimated drawdown at the dredge pond during operation of all 10 slant wells. Rather, the DEIR/EIS concludes that tidal fluctuations in the dredge pond water levels of up to eight feet per year, along with recharge, would mask any drawdown impacts associated with operating the Project. (DEIR/EIS pp. 4.4-71 to 4.4-72.) This conclusion does not appear to be consistent with the DEIR/EIS or physical conditions on CEMEX's site. For example, aquifer drawdown in the area of the slant wells could reach 10 to 20 feet or more, as shown in Figure 4.4-13, but no similar estimates are provided for drawdown at the dredge pond. In addition, tidal fluctuations in the dredge pond are not eight feet, which actually represents the maximum amplitude of the open ocean tide.

CEMEX-15 cont.

The DEIR/EIS asserts that data collection from a water-level transducer indicated that "the water level in the dredge pond was not being influenced by the pumping of the test slant well." (DEIR/EIS p. 4.4-71.) This statement is inconsistent with the prior statement in the DEIR/EIS that test slant well pumping resulted in a one-foot drawdown in the dredge pond. (*Ibid.*) Discrepancies such as these call into question the DEIR/EIS's current analysis and reliance on aquifer modeling of drawdown impacts to estimate potential impacts to CEMEX's dredge pond.

The DEIR/EIS cumulative impacts analysis also concludes that the Project will not result in significant adverse cumulative impacts. However, the DEIR/EIS notes that groundwater pumping from this Project and a potential MCWD desalination plant could cause "some degree of well interference and increased drawdown." (DEIR/EIS p. 4.4-90.) Localized impacts to CEMEX's well and dredge pond are not modeled or analyzed. Thus, it's unclear how the

DEIR/EIS reaches the conclusion that cumulative drawdown impacts to CEMEX's dredge pond or ongoing mining operations will be less than significant without mitigation.

Ultimately, the DEIR/EIS does not sufficiently connect the dots between its analysis of drawdown impacts on CEMEX's dredge pond and the DEIR/EIS conclusion that any such impacts will be less than significant. CEMEX recommends that the groundwater monitoring program required by Mitigation Measure 4.4-3 also be extended to CEMEX's dredge pond to ensure that Project operations do not actually result in significant impacts to CEMEX's operations. Specifically, Mitigation Measure 4.4-3 should be revised to also include ongoing monitoring of the water level transducer in the dredge pond. In addition, at specified levels of dredge pond drawdown, the CalAm wells should have to be shut down until the water level recovers in the dredge pond.

CEMEX-15 cont.

IV. The DEIR Should Be Revised to Ensure That Mitigation for Biological Resource Impacts Will Not Interfere With CEMEX's Operations and Obligations

A. Mitigation measures for biological resource impacts should be revised in coordination with CEMEX.

The DEIR/EIS discussion for Impact 4.6-1 concludes that impacts due to construction of the subsurface slant wells and the source water pipeline will result in significant impacts for certain species and habitats. (DEIR/EIS pp. 4.6-124 to 4.6-132; pp. 4.6-134 to 4.6-138; pp. 4.6-186 to 4.6-188; pp. 4.6-189 to 4.6-190.) The DEIR/EIS concludes that these impacts can be reduced to less than significant upon implementation of certain mitigation measures. (*Id.* at p. 4.6-131; p. 4.6-136; p. 4.6-204.) These same mitigation measures are applied to ensure other impacts, such as periodic maintenance of the slant wells, will not result in significant impacts to terrestrial biological resources. (See DEIR/EIS pp. 4.6-235; 4.6-244 to 4.6-255.)

CEMEX-16

As a general matter, DEIR/EIS discussion of these Mitigation Measures does not address whether implementation of the Mitigation Measures are consistent with or otherwise will not interfere with CEMEX's pre-existing operations on the Lapis Site. Therefore, CalAm should revise these Mitigation Measures in coordination with CEMEX. At a minimum, the terrestrial biological Mitigation Measures applicable to construction, operation, or maintenance of the subsurface slant wells and the source water pipeline should be revised to account for CEMEX's pre-existing operations on the Lapis Site as follows:

- Avoidance and minimization measures required under Mitigation Measure 4.6-1c (general avoidance and minimization measures) should not affect CEMEX's operations and reclamation activities;
- Seasonal construction limitations under Mitigation Measure 4.6-1d should not interfere with, and should be distinguished from, existing operations;

- The habitat mitigation and monitoring plan under Mitigation Measures 4.6-1d (Protective Measures for Snowy Plover), 4.6-1e (Avoidance and Minimization Measures for Special-Status Plants), 4.6-1f (Avoidance and Minimization Measures for Smith's Blue Butterfly, 4.6-1h (Avoidance and Minimization Measures for Western Burrowing Owl) and 4.6-1n should be reviewed and developed for consistency with CEMEX's already-existing reclamation plan;
- Habitat restoration efforts under Mitigation Measure 4.6-1f that are proposed to occur onsite at the Lapis Site, if any, must be coordinated with CEMEX and limited to areas disturbed by CalAm operations within the Lapis Site; and
- Any relocation efforts under Mitigation Measure 4.6-1g that are proposed to occur onsite at the Lapis Site, if any, must be coordinated with CEMEX as CalAm does not own the Lapis Site and has limited rights with respect to its activities on the Lapis Site and its ability to encumber, access, or otherwise use the surface property at the site.

In addition, all biological mitigation measures need to be consistent with CEMEX's usage of existing operational areas and access roads. For example Mitigation Measures 4.6-1d, 4.6-1e, and 4.6-1f all call for restoration of habitat impacted during construction. These Mitigation Measures should be revised in coordination with CEMEX to ensure that any rehabilitation or restoration efforts do not improperly affect the portions of the Lapis Site that CEMEX uses for its active operations (*e.g.*, no rehabilitation of the mining access road). In addition, any rehabilitation must be consistent with existing reclamation requirements for the site under SMARA. Failure to coordinate with CEMEX's existing sand production activities and obligations could render the mitigation measure ineffective or illusory (e.g., a mitigation on surface property impacted by on-going mining operations would not actually result in any effective mitigation).

CEMEX-16 cont.

Similarly, the Project Description section of the DEIR states that for site clearing and preparation generally, "[u]pon completion of construction activities, the construction contractor would … contour the construction work areas and staging areas to their original profile, and hydroseed or repave the areas, as appropriate." (DEIR/EIS, p. 3-46.) CalAm has not consulted with CEMEX regarding the timing, location, or scope of any proposed reclamation or re-contouring of the Lapis Site. The DEIR/EIS should be revised to require that, after full construction buildout on the Lapis Site, CalAm must reclaim the Project area to an appropriate end use consistent with CEMEX's existing use or otherwise coordinate with CEMEX regarding its role and share of responsibility/obligations under a reclamation plan amendment.

B. CEMEX disagrees with the DEIR's characterization of jurisdictional water features on the Lapis Site.

The DEIR/EIS states that "surface waters within the study area [are regarded] as potentially jurisdictional." (DEIR/EIS p. 4.6-2.) This includes the dredge pond and related facilities located on CEMEX's property. (DEIR/EIS pp. 4.6-210 to 4.6-211; see also DEIR/EIS p. 4.6-248.)

CEMEX-17

CEMEX disagrees with any implication in the DEIR/EIS that these areas within CEMEX's property are wetlands and with the DEIR/EIS's overall characterization of waters on the Lapis Site as jurisdictional. The subject features are all industrial process ponds. In addition, the DEIR/EIS statements regarding the water features on the Lapis Site are unwarranted because none of the described water features are within the Project's construction/ground disturbance footprint. (*See* DEIR Figure 4.6-1a, p. 4.6-11.)

In any case, the DEIR/EIS concludes that impacts to all described features would either be less than significant or reduced to less than significant following implementation of mitigation measures. (*See generally* DEIR/EIS Impact 4.6-3, pp. 4.6-209 to 4.6-212.) As noted above, implementation of any such mitigation measures must be coordinated with CEMEX's active operations and the existing reclamation plan requirements for the site.

CEMEX-17 cont.

V. CEMEX Disagrees With the DEIR's Characterization of Structures on the Lapis Site as Potentially Significant Cultural Resources

The DEIR/EIS states that the CEMEX facility was determined to be a Historic District eligible for listing in the National Register and California Register under Criteria A/1 (association with an important event) and Criteria C/3 (architectural merit). (DEIR/EIS p. 4.15-21.) The DEIR/EIS further states that the direct and indirect area of potential effects ("APE") for the source water pipeline encompasses the Lapis Sand Mining Plant Historic District (the "Mining District"). (See DEIR/EIS, p. 4.15-23.) Though survey efforts did not identify any archaeological resources in the portion of the source water pipeline direct APE located within the CEMEX facility, the DEIR/EIS states that the area surrounding the pipeline alignment is generally considered to have a high potential for buried cultural resources associated with prehistoric populations and Native Americans. (DEIR, p. 4.15-29.)

CEMEX-18

CEMEX disagrees with the DEIR/EIS analysis and conclusion that the CEMEX facility is eligible for listing in the National and California Registers. CEMEX does not believe that the site is properly considered a historic district, especially because the facility is currently in operation and has been a working facility since its inception.

In the end, the DEIR/EIS concludes that "[n]o historical resources listed in or eligible for listing in the California Register or historic properties listed in or eligible for listing in the National Register are within the direct or indirect APE of all project components." (DEIR/EIS p. 4.15-45.) CEMEX agrees with this conclusion and requests that the earlier analysis suggesting that the facility is eligible for listing be updated for consistency with the DEIR/EIS conclusion for impact 4.15-1.

VI. The DEIR/EIS Analysis of Potential Impacts to Mineral Resources in Section 4.17 is Inaccurate and Not Supported by Substantial Evidence

DEIR/EIS section 4.17 acknowledges that Project construction could delay movement of vehicles at the site and otherwise cause minor disruptions to CEMEX's operations. (DEIR/EIS, pp. 4.17-8 to 4.17-9.) However, the DEIR/EIS concludes that these construction-related impacts and any temporary loss of mineral resources would be less than significant. (*Ibid.*) The DEIR/EIS reaches this conclusion without providing any substantial evidence. In fact, the Project would interfere with a valuable operation that produces sand for numerous needs in our society. The current DEIR/EIS's failure to understand that impact is inaccurate and legally incorrect.

CEMEX-19

We request that the DEIR/EIS be revised to address all of these issues. Thank you for your consideration of these comments on behalf of CEMEX.

Sincerely yours,

MITCHELL CHADWICK LLP

Patrick G. Mitchell

Re: Draft Environmental Impact Report/Environmental Impact Statement
Monterey Peninsula Water Supply Project

Dear Ms. Borak and Ms. Grimmer:

Citizens for Just Water is a citizens group on the Monterey Peninsula and an identified party by the CPUC in this matter. Just Water provides the following written comments regarding the Draft Environmental Impact Report/Environmental Impact Statement (hereinafter DEIR/EIS) issued in January 2017 for the above-referenced California American Water Company (CalAM) project. Just Water respectfully requests these comments be made part of the administrative record for all state and federal proceedings relating to this project.

CALAM HAS NO WATER RIGHTS IN THE SALINAS VALLEY GROUNDWATER BASIN AND HAS NO VIABLE LEGAL CLAIM TO ACQUIRE RIGHTS

CalAM erroneously represents that the MPSWP is "designed to take supply water from the ocean via underground slant wells that draw water from the earth underneath the ocean" (DEIR/EIS p. 2–30). The proponent's statement that the source water is from "the submerged lands of the Monterey Bay National Marine Sanctuary" is a *flagrant misrepresentation* (DEIR/EIS p. 3–15), but necessary to the assertion that it is pumping seawater, and that no water right is needed for seawater extraction (See 2–37). CJW-1

The brackish water of the SVGB is the intended water source for the project—not the ocean. This is even more obvious as "the slant well clusters were moved farther inland" to address the issue of coastal erosion (DEIR/EIS p. ES–16).

The DEIR/EIS makes clear the Project will extract and export groundwater from the Salinas Valley Groundwater Basin and specifically the 180' aquifer—not the ocean. In fact, all

subsurface slant well pumping by the MPWSP will be from the 180' aquifer of the SVGB. CalAM has no overlying rights, no prescriptive rights, and no appropriative rights to groundwater in the SVGB (see DEIR/EIS 2-30 to 2-31). The Project seeks certification of its DEIR/EIS on *an unsupported assertion* that there "is a sufficient degree of likelihood" that CalAM will have the necessary water rights (see DEIR/EIS 2-30). The absurdity of Project approvals under these circumstances is obvious.

CJW-1 cont.

The SVGB is already critically overdrafted. **There is no surplus water.** Thus, CalAM will not be able to perfect water rights in the basin.

The overdraft has contributed to the eastward (inland) intrusion of seawater in both the 180' and the 400' aquifers for at least 70 years. Since the planning for the Project commenced, there has been new intervening legislation on groundwater management. In September 2014, the State of California passed the Sustainable Groundwater Management Act (SGMA) and the Department of Water Resources designated the 180'/400' subbasin of the Salinas Valley Groundwater Basin as **among 21 basins that are "critically overdrafted" in California**. **SGMA directs restoration of these basins as a top priority**.

According to this first-ever regulatory legislation enacted by the state as to groundwater, local governments are to manage groundwater supplies, including the adoption of a "groundwater management plan." The management plan is to maintain and maximize long-term reliability of groundwater resources, prevent significant depletion of groundwater over the long term, and prevent degradation of groundwater quality. The 180'/400' "critically overdrafted" subbasin of SVGB is assigned by SGMA for immediate improvement. It is also the proposed site for this Project, *owing to the asserted degradation of its water quality.* **The DEIR/EIS fails to address this conflict of interests.**

CJW-2

In the DEIR/EIS, the proponent relies on its conclusion that water in the aquifer at the CEMEX site is useless to those with rights to it. The SGMA directive to restore the SVGB sits in direct contradiction to CalAM's *proclaimed ability* to acquire water rights due to the brackish condition of the aquifer. In this instance, the quality of the water is not determinative of rights to the aquifer water.

The DEIR states (page 4–37),

> The proposed project would not adversely affect groundwater management in the Basin, because it would be extracting groundwater that is not presently being used as a potable or an

> irrigation supply. Rather, when considering seawater intrusion and water surface elevations in the 400-Foot Aquifer, the proposed project may have a positive contribution to the sustainable management of groundwater.

This is untrue. SVGB users continue to pump from the 180' and the 400' aquifers. The aquifer water has beneficial uses to those with water rights, including MCWD. With the development and implementation of the required groundwater sustainability plan, that pumping will continue and foreseeably increase.

Secondly, the assertion that the Project may have a positive contribution to the sustainable management of groundwater is *unsubstantiated* in the DEIR/EIS and is included simply as a gratuitous statement. A self-serving, unsupported claim needs to be deleted from the document.

CJW-2 cont.

The DEIR/EIS is silent as to a basis in the law for the acquisition of water rights in the Basin. Rather, the allegation of an ability to acquire legal rights to water in the near future is premised upon proponent's self-serving assertions in a convoluted narrative in the DEIR/EIS. The DEIR/EIS does little more than dismiss the project opponents' concerns about CalAM's lack of rights to source water in the SVGB. Although the writers of the DEIR/EIS attempt to obfuscate this legal issue, **CalAM has failed consistently to make a credible legal argument for the acquisition of any rights to pump from the SVGB.** CalAM has had years to try, and had it the ability to do so under California law, it would have. The extraordinary expenditure of ratepayer funds on this Project without water rights is egregious. The CPUC should not allow CalAM to continue expending additional funds on a Project without water rights. There are alternatives available for CalAM to develop its Project with legally acquired source water.

The CPUC is not the arbiter of whether CalAM possesses water rights for the project, and nothing in the DEIR/EIS should be construed as the CPUC's opinion regarding such rights (see Chapter 2.6). The Project should <u>not</u> move forward. **All approvals, including certification of the DEIR/EIS should be stopped immediately.** The project is not feasible without water rights (see Chapter 2.6).

CJW-3

THE EXPORT OF WATER TO THE CAL AM SERVICE AREA IS PROHIBITED BY CALIFORNIA LAW.

As clearly shown in Appendix E-2, all Project wells are, in fact, in the 180' layer of the aquifer. The slant design does not achieve the objective of ocean intake.

CJW-4

Monterey County Water Resources Agency Act provides:

> The Legislature finds and determines that the agency is developing a project which will establish a substantial balance between extraction and recharge within the Salinas River Groundwater Basin. For the purpose of preserving that balance, **no groundwater from that basin may be exported for any use outside the basin, except that use of water from the basin on any part of Fort Ord shall not be deemed such an export.** If any export of water from the basin is attempted, the agency may obtain from the superior court, and the court shall grant, injunctive relief prohibiting that exportation of groundwater. [Emphasis added.]

Basin groundwater may not be exported for use outside the Basin for any purpose. This prohibition is certainly applicable both to the selling and the arrogation of Basin water.

In support of its arrogation of Basin water, CalAM asks the CPUC to accept a distinction between "brackish/ unusable" water (pumped from their slant wells) versus potable, fresh water. In the section 2.6.2 (Pg. 127), CalAM accurately states **brackish water is "a combination of ocean water and water that originated from the inland aquifers of the Basin".** Whether drawing water from the aquifer inland from the mean high tide or seaward of mean high tide, the source water is from the same aquifer at the Project's CEMEX location. However, CalAM continues to focus exclusively on the "unusable" aspect of brackish water and not on the association of brackish water with fresh water aquifers. This distinction between brackish water as completely different from fresh water is intentionally promoted to support the *false claim* that "fresh water is not withdrawn by the project". **Contrary to CalAM's position, water quality is not determinative of the right to export. The prohibition against exportation of water under the Agency Act is applicable to any and all water extracted from the Basin.**

CJW-4 cont.

CalAM has *neither* the right to pump water from the SVGB, nor the right to export Basin water to sell in its service area to customers. Conversely, MCWD has no right to take water from the Carmel River or the Seaside Basin, which CalAM does. MCWD may not take source water protected for other public and private water agencies defined by law regardless of need. Reciprocity of enforcement of these legislative protections is critical throughout the State of California. It is not within the authority of the CPUC to make exceptions, or ignore the law. Changes to state legislation is the only means to remove the prohibition for the export of SVGB water.

The Project proposes to return to the SVGB a small fraction of the water extracted and exported. [DEIR/DEIS 2-22 to 2-23] **The Project proponent erroneously assumes it is required to**

return *only* that percentage of water it characterizes as "fresh water" to the Basin. CalAM's plan to return the "fresh water" to Castroville Seawater Intrusion Project Distribution Systems [DEIR/EIS 1-12] does not ameliorate the Agency Act prohibition to exporting water. The majority of the water will be exported to the CalAM customers on the Monterey Peninsula, matched by an approximate equal amount exported to the bay. The amount the project intends to return is a very small percentage of the amount taken. The Project's scheme of amelioration is creative, but woefully inadequate to protect those harmed by an unlawful taking. The lack of concern for the harm to MCWD ratepayers is spotlighted by the Project's failure to consider delivery (return) of the fresh water to the local purveyor from which it was taken – MCWD. This fact is yet another example of the overall failing of the DEIR/EIS to identify the harm this Project will wreak if sited at the CEMEX property.

If there is scientific evidence that water extracted from Marina and returned to Castroville will "benefit" the water source of MCWD it is not set forth in the DEIR/EIS.

CJW-4 cont.

In Section 4.4.2.3 the proponent makes the following statement relative to the Agency Act:

> The Agency Act further authorizes the MCWRA to commission groundwater studies to determine whether any portion underlying its territory is threatened with the loss of useable groundwater supply and to adopt an ordinance prohibiting further extraction of groundwater from an area and depth defined by the MCWRA.

The proposed CEMEX location is within the jurisdiction of the MCWRA and the Agency Act. Not only does the Agency Act apply, but the MCWRA is empowered to prohibit further extraction of groundwater at the CEMEX location. CalAM's self-proclaimed exclusion of its geographical location from the Act is without merit. The CPUC is *without authority* to make a ruling as to whether the 180'/400' subbasin of the SVGB at the CEMEX property is beyond the scope of the Agency Act and the authority of the MCWRA.

SVGB Users Have Been Assessed Millions of Dollars, Over Decades, for the Protection and Recharge of SVGB Aquifers

CJW-5

Monterey County Water Resources Agency levies assessments on water consumers within Zones 2 and 2A to fund its efforts to manage the quality and quantity of water within these zones. Millions of dollars have been assessed and invested in projects intended to ensure the SVGB provides a long-term, sustainable water supply for Basin users. CalAM has contributed nothing to the protection of this groundwater resource. The foreseeable impact of the Project is adverse to the investment made to date and counterproductive to continuing efforts supported by public tax

dollars. The Project's end users (CalAM ratepayers) are not required to pay their fair share of these taxes. Ratepayers within Zones 2 and 2A will bear the tax obligation for them. **This is harm.**

CJW-5 cont.

CalAM Fails to Establish No Harm to Legal Users of SVGB

As clearly shown in Appendix E–2, all Project wells are, in fact, in the 180' layer of the aquifer, regardless of slant design. The CalAM MPWSP mischaracterization of brackish water as "unusable" water attempts to obfuscate that the slant wells are accessing the 180' aquifer, a current source of regional water and a prospective source for additional users with the buildout of former Fort Ord properties. MCWD has previously demonstrated its ability to restore brackish water to potable with its own small desalinization plant (located within a ½ mile of the Project's current test well).

With rights to the water and as a Groundwater Sustainability Agency under the Sustainable Groundwater Act, MCWD is obligated to manage and improve water quality in the 180' aquifer. As the 180' and 400' aquifers will be the source of an additional 5200 AFY to meet production requirements, any increase in salinity and any reduction in available water in the Basin will be harmful. **The taking of water by CalAM's project is harmful.**

CJW-6

Concerns regarding an inadequate water supply for everyone with rights in the SVGB are not new; nor were these concern precipitated by the siting of the Project at the CEMEX property. But the Project's location at CEMEX and the planned pumping of source water from SVGB have elevated fears of an inadequate supply to a top priority.

It is well accepted by every agency, entity, and user that the SVGB is in overdraft—simply stated, the demands on the Basin exceed its yield of potable water. Experts from many scientific disciplines have reviewed the same materials and given opinions as to the ability of the Basin to provide water for the our increasing needs over time. The Army knew it had water problems on Fort Ord at least a decade before base closure. At page 86 of a study done by the Army Corps of Engineers in 1986, entitled "Long-range Water Supply Development for Fort Ord, California," seawater intrusion is identified as the adverse outcome of increased pumping near the coast, and is credited with fouling wells on the fort. Seawater contamination resulted in the Army's drilling of a new well field further inland. The ineffectiveness of this corrective measure as a long-term solution is noted in the report. "The installation realizes that this is an interim measure and the Army needs to eliminate the reliance on local groundwater for other than backup supplies." **The recognition of a regional problem is made clear with the inclusion of this observation in the 1986 Army report, "Marina's water problems are very similar."**

The Army abandoned the installation without a new water project. Now in 2017, MCWD stands in the shoes of the Army as the water purveyor for 28,000 acres of land. In place and instead of 13,500 soldiers and fewer than 4000 civilian workers on the base, the Fort Ord Reuse Plan assumes growth to a population of 37,000 and the creation of 18,000 jobs. Thirty years later, there is no new water project for those dependent upon the SVGB aquifers.

In 1993, the U.S. Army and Monterey County Water Resources Agency executed an agreement setting forth how MCWD will take over water services for the 28,000 acres of land. Therein the right to pump 6600 AFY is "transferred" and a pumping limit for the former fort property is established. 6600 AFY was the highest volume ever pumped by the Army (in 1984)—not a historical average. The agreement specifically states that the pumping of 6600 AFY is permissible until a new water supply project becomes available. The Basin's ability to provide the source of 6600 AFY was unsupported and dubious in 1993.

Clearly, the demands of *another water purveyor* in the Basin is inadvisable at present. ***There is no more water.***

CJW-6 cont.

The reports issued over the last thirty years, including those whose data is represented in the "Historic Seawater Intrusion Map[s]" for the 180' and 400' aquifers produced by the Monterey County Water Resource Agency, affirm more pumping from the Basin is irresponsible, as the threatened harm is irreversible. The DEIR/EIS do not provide sufficient scientific proof that an alternative result will occur with a significant increase in pumping. Those dependent upon the Basin for survival and livelihood need the CPUC to demand that CalAM meet the legal requirement of proving "no harm." The degree of review in the DEIR/EIS fails miserably to establish that proof.

Any increased salinity in the Basin constitutes harm, as the cost of purification increases and MCWD necessarily passes that added expense to its ratepayers. Any lowering of the water level in the aquifer is harm, as the cost of extraction will increase and MCWD will necessarily pass the added expense to its ratepayers. Any need for wells to be sited in more remote locations to avoid conflict with the Project will necessitate higher costs for pipes and pumping—again, harm.

The ability of MCWD to rely on the SVGB to continue to provide water to its *existing 30,000 ratepayers and deliver water to its reasonably foreseeable customer increase* (to whom delivery commitments have been made)—*at reasonable rates*—is questionable in 2017. The limitations of the SVGB are presently undefined; there is simply a lack of information. This lack of information precludes any finding that the Project will cause no harm.

Representations and Omissions in the DEIR/EIS Are Misleading.

The footnote on page 1–11 of the DEIR/EIS states, "In November 2014 the City of Marina and the California Coastal Commission completed their CEQA review." This statement infers that both the California Coastal Commission and the City of Marina approved some aspect of the test-well project. This representation ignores City of Marina's rejection of the permit for the test slant well. The DEIR gives the impression that this is a non-controversial project. **This is not true.** CJW-7

The April 2012 CalAM Application A.12-04-019 (CalAM, 2012) seeking CPUC approval to build, own, and operate a desalination facility for water supply (the MPWSP) incorporates many of the same elements previously analyzed in the Coastal Water Project EIR. What the DEIR/EIS fails to identify, however, are the significant differences between the Coast Water Project EIR and the MPWSP, all of which are critical to any proof of "no harm" to current users of the SVGB. Namely, this Project is an invasion of a neighboring water jurisdiction without invitation, without water rights, without compliance with state law and county ordinance, and without regional benefits within the invaded jurisdiction. CJW-8

CalAM Fails to Utilize and Rely on Accepted Standards of Good Scientific Inquiry

CalAM has short-shrifted standard research protocol.

- **CalAM Failed to Establish Meaningful Baseline Information as Required Before Installing the Test Slant well**

The DEIR states that "the EIR/EIS takes as its baseline the existing condition on or about October 5, 2012" (Section 4.1.3). Protocol and common sense indicate that sampling one day's data as a baseline for a complex system with fluctuations as to season, tide, rainfall, etc., will not yield a meaningful baseline for analysis. Without such a baseline, projections cannot be made with confidence. The Hydrogeologic Working Group does not present or explain its baseline. Without this information, there is no basis to evaluate impacts. The omission of this analysis is reason to reject certification. CJW-9

- **Failure to Exploit Electrical-Resistivity Tomography Imaging**

CalAM unreasonably rejects use of electrical-resistivity tomography (ERT) for mapping seawater intrusion and the fragile hydrogeology of the SVGB. ERT is readily available, data rich, non-intrusive, and low cost. ERT data can be expected to significantly reduce the degree of uncertainty. Readily attainable imaging is especially critical in the high-risk context of water. CalAM's failure to use ERT amounts to gross negligence in today's technological environment. CJW-10

The proponents of the project knew of the availability of this technology and the value it would add to the preparation of the DEIR/EIS for the Project in 2014. A degree of certainty as to the predicted outcomes is necessary for any CEQA review and for the determination that no harm will result if the Project is approved. The *degree of uncertainty in predicted outcomes* would be greatly reduced with use of ERT mapping of seawater intrusion and the fragile hydrogeology of the SVGB at the CEMEX property and surrounding area. The DEIR/EIS is silent as to any degree of uncertainty in its predicted outcomes.

The DEIR/EIS warns the siting of the intake wells is critical to preventing increased seawater intrusion and further harm to the aquifer. The following cautionary statement is found in Subsurface Intakes, Appendices I1-3.

> In general, source water derived from subsurface intakes requires significantly less filtration when compared to raw seawater (SGD, 1992). **However, if not appropriately sited, subsurface intakes can adversely affect coastal aquifers and increase the risk of saltwater intrusion in freshwater aquifers** (CCC, 2004). [Emphasis added.]

CJW-10 cont.

Better knowledge of the hydrogeology of the SVGB for placement of Project intakes in the aquifer is a significant benefit ERT mapping would reveal.

A Stanford University research team under the leadership of Professor Rosemary Knight was denied access to the location of the Project when it collected imaging of the Monterey Bay coastline. Inclusion of the CEMEX property within the scope of the Stanford research was free, and was readily understood to produce beneficial understanding of the aquifer where the Project is intended. Use of the imaging at CEMEX in 2015 would also have added to the knowledge and understanding of the SVGB aquifers, the interrelations between its shallow and deeper layers, and the impacts of the test slant well.

CalAM's failure to take advantage of available and affordable scientific study likely to produce relevant data is inexcusable. It is a fair inference that denial of access at CEMEX in 2015 for collection of relevant data was antagonistic to the standards for rigorous study of impacts when preparing environmental impact reviews.

Should the proponent assert it was solely the decision of CEMEX to deny access to the site of the Project, **CalAM has had the ability to utilize ERT technology independent of the Stanford study and opted not to.** The DEIR/EIS does nothing more than acknowledge the availability of the technology and the work of Rosemary Knight. The Project proponent elected to summarily dismiss ERT, which has been proven to be a tool that would provide a greater degree of certainty

as to the effects of the project on the Basin. CPUC should not endorse this selective review. If selective inquiry and review is allowed by the CPUC, environmental impact reports become a meaningless exercise. The DEIR/EIS is incomplete without requiring ERT mapping. CJW-10 cont.

- **There Are No Successful, Operating Slant Wells for Subsurface Ocean Desalination Anywhere in the World**

The DEIR/EIS offers no historical data or refers to any successful operation of sub surface ocean intake slant well for use in desalination. The one test slant well at the CEMEX site is the only feasible source for data relevant to this Project, and this well has had multiple disruptions in its operation. The proponent provides no other data regarding the viability and long term performance of slant wells delivering desalinated water to customers—because none exist.

Use of slant well technology for subsurface ocean desalination has been resoundingly unsuccessful or infeasible. A review of slant well projects in an article *Yield and Sustainability of Large Scale Slant Well Feedwater Supplies for Ocean Water Desalination Plants* (2015) by Dennis Edgar Williams identified communities considering slant well projects in the State of California. As of 2016 the following communities mentioned in the article rejected use of slant well technology for production of water to meet municipal demands.

- Cambria opted for a brackish-water-reclamation plant in 2014.
- Oxnard is developing a treatment facility for brackish groundwater without use of slant-wells.
- Huntington Beach rejected the Poseidon slant well in 2014 after tests showed unacceptable amounts of groundwater uptake and increased salt water intrusion.
- Dana Point had test wells and began the EIR process in June 2016. No slant well providing water to the community to date.
- Camp Pendleton is still in feasibility studies.
- Long Beach has not adopted or completed any slant well project.
- Oceanside is developing a desalinater without slant well technology.
- The Santa Cruz Water District 2 Task Force dropped consideration of slant wells in 2013.

CJW-11

The DEIR/EIS's silence as to examples of existing use of slant well technology for subsurface ocean intake in similar circumstances cannot be ignored by the CPUC when weighing and considering the Project alternatives. Other communities concluded slant wells are costly, experimental and not equal to less costly, proven technologies to meet municipal water demands.

Without historical use in other communities and data from successful projects, the DEIR/EIS offers little proof that placement of slant wells into the 180' layer of the aquifer will not increase seawater intrusion. Nor is the proponent able to support the continued investment of vast amounts of money into unproven slant well intakes. Approval for this project cannot be based

on the modeling of its one test well at CEMEX. This test well has provided insufficient data for (a) a predictable outcomes to be extrapolated; and (b) information necessary for siting of the multiple intakes proposed by the Project *so as to avoid the harm of increased seawater intrusion.* The lack of data creates an unacceptable degree of uncertainty and leaves the SVGB users with an unacceptably high risk of harm.

CJW-11 cont.

The CPUC should exclude an unproven technology in an environment where risk to existing water sources, dependent populations, and the operations of existing water purveyors is high.

CalAM has Alternatives

Just Water supports CalAM in its endeavor to secure a new water supply. This must not be achieved at the expense of other water purveyors and citizens who will be adversely affected. CalAM has alternative technologies available and alternative source-water locations, which are less likely to harm the SVGB or any other protected water source. Pursuit of an alternative less likely to impair MCWD's ability to supply affordable, sustainable, long-term water to Marina and Fort Ord populations is mandatory.

CJW-12

With the lack of success of slant well technology, a different location and a different extraction are much more likely to succeed in the delivery of water to those needing it on the Monterey Peninsula.

For the reasons set forth above, Just Water respectfully requests you deny certification of the DEIR/EIS and reject any other pending approvals of the Project.

Very truly yours,

Just Water

Comments on draft EIR/EIS for Monterey Peninsula Water Supply Project

Dear ESA:

The Coalition of Peninsula Businesses submits these comments on the draft Environmental Impact Report/draft Environmental Impact Statement (EIR/EIS) prepared for the Monterey Peninsula Water Project on behalf of the Monterey Peninsula organizations and entities listed above and their thousands of members, associates, and employees.

Generally speaking, the EIR/EIS seems well-prepared and comprehensive. We find some parts a little troubling and those are listed below.

Chapter 2 - Water Demand, Supplies, and Water Rights

Operating the desal modules at full capacity was earlier estimated to require operation at 98% of capacity all day every day of the year. That strikes us as an unrealistic method of operation that far exceeds the optimum operation of 80% of capacity and further dictates that a more relaxed schedule be planned. CPB-1

The water supply schedules reflect a slight excess of proposed supply over the ten-year average of experienced demand, but the ten-year period includes years of increasing demand for water conservation to the point where average water per capita consumption is among the lowest, possibly the lowest, in California. It is necessary to plan a water supply for a more relaxed water conservation ethic in the future after the Peninsula's water supply is no longer constrained by extreme conservation measures or legal decisions. CPB-2

The demand schedules do not seem realistically to reflect the need to return fresh water to the Salinas Valley Groundwater Basin to avoid legally prohibited exportation of water from that basin and to avoid harm to basin water users. CPB-3

The demand schedules also do not seem to reflect non-revenue water. Cal Am has rarely met its goal of reduced non-revenue (unaccounted for water or system losses of water). CPB-4

Chapter 6 – Other Considerations at Section 6.3 et seq and Appendix J2

The Monterey Peninsula Water Supply Project does not anticipate developing enough water to supply various local jurisdictions within the Cal Am service area for their General Plan Build-out needs; this seems extremely shortsighted.

The marginal costs of planning and building enough capacity now are small in comparison to the eventual cost of adding that capacity later.

The increase in environmental damage would also be marginal if sufficient capacity were planned now. CPB-5

The Cal Am service area would be far better served if the General Plan Build-out needs are addressed now so that the area avoids another expensive (multi-million dollars) and time consuming process (a decade or more) later.

An added benefit of adding the increased capacity now is that the desal modules could be operated for the immediate future on a much more relaxed schedule than the required and unrealistic 98% of capacity currently anticipated according to the testimony of Cal Am's Director of Engineering Richard Svindland.

Section 6.3 et seq. of Chapter 6 and Appendix J2 do a reasonable good job of analyzing the impacts of future development planned for in the General Plans of the various local CPB-6

jurisdictions within the Cal Am service area. With a little minor tweaking this EIR/EIS combined with the local jurisdiction certified General Plans (and their equivalents) could be sufficient to provide a reasonable basis for a small expansion of the Monterey Peninsula Water Supply Project to eventually provide enough water for all the Monterey Peninsula area's foreseeable future needs.

CPB-6 cont.

Appendix E-1 – Lawrence Berkeley National Laboratories Peer Review

The vetting of the work of the Hydrologic Working Group (HWG) by Lawrence Berkeley National Laboratories (LBNL) was encouraging in the sense that the results of the work paralleled closely the original findings of the (HWG) but one finding in the peer review report was troubling. LBNL found what could be a serious shortcoming in the hydrostratigraphy modeling – the absence of the Salinas Valley-Fort Ord Aquitard (SV-FOA) – and states the absence "could potentially change the impact assessments." It is incredibly important that the absence of the SV-FOA be explained in more detail and the resulting impact assessments changes, if any, be detailed.

CPB-7

Chapter 5.6 – Environmentally Superior Alternative/Preferred Alternative

We note that early on this section states that "… no alternative stands out from the others as eliminating all significant and unavoidable, long-term environmental effects." The combination of a smaller desal with the purchase by Cal Am of GWR water is given the nod as superior/preferred but this judgment ignores some key facts.

The now-approved water purchase agreement whereby Cal Am is committed to buying GWR water contains several provisions that allow for less than expected GWR water production for limited periods of time (essentially two or three year periods of production of significantly less than the 3,500 acre feet per year of "normal" production relied on to determine the size of the smaller desal interspersed with the anticipated "normal" production).

How is the Monterey Peninsula to deal with less water production than needed for up to several years at a time – go into emergency rationing again and again? That seems a poor way to plan for the Monterey Peninsula's water supply and contradictory to the goal of the California Public Utilities Commission to ensure adequate water service to Cal Am customers.

CPB-8

Brine discharge issues

We are not expert in analyzing brine disposal issues, so we leave those areas to the Monterey Peninsula Regional Water Authority and others to comment on.

Coalition of Peninsula Businesses comments are intended to be helpful

We offer these comments to be helpful and help strengthen the EIR/EIS. We are very much in favor of the project and want it to be constructed as quickly as possible.

Very truly yours,

John Narigi, Chair
General Manger, Monterey Plaza Hotel and Spa

Bob McKenzie
Consultant to the Coalition of Peninsula Businesses

To whom it may concern:

DeepWater Desal LLC (DWD) is currently developing the Monterey Bay Regional Water Project (MBRWP) in Moss Landing, California. MBRWP would consist of a drinking water desalination plant co-located with a seawater-cooled data center. The objective of the MBRWP is to provide a reliable water supply to the entire region, which is affected by seawater intrusion and surface water shortages. The MBRWP is currently undergoing a very thorough environmental review of the project that includes information that was not yet available to Environmental Science Associates (ESA) at the time of their preparation of the DEIR/DEIS. The MBRWP sponsors believe it is premature to make determinations of significance on a project without having all the information on that project. DWD-1

While DWD understands the logic in comparing the impacts of the Cal Am proposed project to a version of the MBRWP scaled down to supply only the Monterey Peninsula, DWD is not proposing a scaled down desalination facility. A scaled down desalination facility would not meet the objective of being a regional water source. The region has water challenges that extend beyond the peninsula, and DWD feels strongly that water customers who are outside of CalAm's more affluent Monterey Peninsula franchise, many of whom reside in disadvantaged communities, deserve to have their needs treated with equal importance. DWD-2

Finally, it is DWD's belief that the scenario in the Draft Environmental Impact Report/Draft Environmental Impact Statement (DEIR/DEIS) of "either/or" is not correct. It is highly likely, as the DEIR/DEIS points out in several places that both projects will be constructed. This means that the construction of the CalAm Desalination project would not result in the avoidance of the impacts related to the DWD project. While understanding the DEIR/DEIS process has a very specific set of requirements for how projects are compared, we feel it necessary to point out that there are no additional environmental impacts that would arise from CalAm entering into a water purchase agreement with the MBRWP. It would result in the avoidance of the impacts related to construction of the CalAm project, except the construction of a single pipeline, while still providing potable water to the remainder of the region not served by the CalAm desalination project DWD-3

With those caveats, DWD submits the following comments on the DEIR/DEIS for the CalAm Monterey Peninsula Water Supply Project.

7532 Sandholdt Rd., Suite 6, Moss Landing, CA 95039 Phone: 831-632-0616

General Project Description/Scaled Alternative Description

Comments 1 – 6 are strictly technical in nature and related to the DEIR/DEIS description of the MBRWP. As stated above, while we are providing information about a scaled down version of our desalination project, there is no proposal to build such a plant since it would not be a regional facility. DWD-4

1. Table 5.3-1 (p. 5.3-11):

Table 5.3-1 on p. 5.3-11 of the DEIR/DEIS referring to Intake 9 states:

> "*From the screened intakes, raw seawater would flow by gravity through the intake pipeline to an onshore wet well and pump station.*"

The proposed MBRWP does not include a wet well at the pump station on Dolan Road. Water is pumped, rather than gravity flow, due to the significant depth that would be required at the pump station for a wet well.

Strike "flow by gravity through the intake pipeline to an onshore wet well and pump station" and replace with "would be pumped to an onshore pump station." DWD-5

2. Section 5.3.3.9 p. 5.3-17 (para. 2):

Paragraph 2 on p. 5.3-1 of the DEIR/DEIS referring to Intake 9 states:

> "*Seawater would be conveyed from the intake structure to an onshore pump station via a 42-inch diameter subsurface intake pipeline.*"

The DEIR/DEIS states on page 5.3-16, paragraph 4, that for analysis of the MBRWP as an alternate project, the size would be scaled down to 9.6 MGD water production. A 9.6 MGD plant would require a 36" diameter intake pipeline.

Change pipeline size to 36" diameter.

3. Table 5.3-2 (p. 5.3-20):

Table 5.3-2 on p. 5.3-20 of the DEIR/DEIS referring to Outfall Option 7 states: DWD-6

> "*Brine would discharge from the desalination facility to the offshore discharge diffuser structure via one proposed subsurface 36-inch-diameter discharge pipeline.*"

"Operation of the outfall would include a multi-jet linear diffuser that would be located on the seafloor, and that would consist of five separate standing pipe risers emerging from a single 36-inch pipe manifold."

The DEIR/DEIS states on page 5.3-16, paragraph 4, that for analysis of the MBRWP as an alternate project, the size would be scaled down to 9.6 MGD water production. A 9.6 MGD plant would require a 24" diameter discharge pipeline. A 9.6 MGD plant would require a single 24" pipeline manifold and three standing pipe risers.

Change pipeline size to 24" diameter. **Change** pipeline manifold size to 24". **Change** number of standing pipe risers to three.

DWD-6 cont.

4. Section 5.3.4.7
p. 5.3-26 (para. 5):

Paragraph 5 on p. 5.3-26 of the DEIR/DEIS referring to Outfall Option 7 states:

"The multi-jet diffuser structure would be located on the seafloor and would consist of standing pipe risers emerging from a single 36-inch pipe manifold that would be connected to the end of the discharge pipeline."

The DEIR/DEIS stated that for analysis of the MBRWP as an alternate project, the size would be scaled down to 9.6 MGD water production. A 9.6 MGD plant would require a 24" diameter discharge pipeline.

Change pipeline size to 24" diameter.

5. Section 5.4.5.1
p. 5.4-21 (para. 2):

Paragraph 2 on p. 5.4-21 of the DEIR/DEIS referring to Whole Project Alternative 3 states:

"Also, the intake design would be similar to the intake facility design in Alternative 2, but the Alternative 3 structures would be larger (two intake pipes for Alternative 3 versus one intake pipe for Alternative 2) to accommodate a larger project."

DWD-7

The dual pipelines for the MBRWP are for 100% redundancy to allow for maintenance or in case of failure. Either one of the two pipelines will handle the entire flow needed for the larger project.

Change "to accommodate a larger project" to read "to provide redundant intake and discharge ability."

6. Section 5.4.5.1
p. 5.4-31 (para. 5):

DWD-8

Paragraph 5 on p. 5.4-31 of the DEIR/DEIS referring to Whole Project Alternative 3 states:

> "*Three data center buildings are planned and a fourth building would be a modular data center that could be constructed in the future.*"

The modular data center is a landing pad for portable, self-contained server modules. The landing pad consists of a concrete pad and utility connections for the server modules. The landing pad will be completed with initial construction.

Change sentence to read "Three data center buildings and a concrete landing pad for modular data center equipment are planned."

DWD-8 cont.

Geology, Soils, and Seismicity

7. Table 5.3-4 (p. 5.3-31):

Table 5.3-4 on p. 5.3-31 of the DEIR/DEIS referring to Intake Option 9, referring to impacts related to exposure of people or structures to seismically induced ground-shaking, liquefaction and lateral spreading, and exposure of structures to coastal erosion and bluff retreat caused by sea level rise, states:

> "***Decreased.*** *No coastal erosion or bluff retreat impact. All other impacts would be similar to those of the proposed project.*"

It is our understanding that the slant wells identified for the proposed project are located in an identified liquefaction zone. Because sands or other saturated granular layers are required for liquefaction, and they are also required for the passage of seawater through the ground into a slant well, the potential for damage to the proposed project intake from liquefaction is high. This could result in permanent damage to slant wells and could constitute a public health emergency if an alternate source of water is not available.

DWD-9

The Liquefaction Map cited in the document is Ninyo & Moore, 2005. The more recent 2015 Stanford University Liquefaction Susceptibility Zones map for Monterey County (Attachment 1) shows that the DWD pipelines pass through two small areas of liquefaction susceptibility. One area is at the HDD launch site, and the other is the Moss Landing sand spit.

Studies conducted after the 1989 Loma Prieta earthquake involving boreholes on the Moss Landing sand spit show that there is liquefaction potential in the upper 30' of soils. At the sand spit, the pipeline is nearly 200 feet below grade. It is also approximately 160 feet directly below the power plant discharge pipelines which were not damaged during the Loma Prieta earthquake because they were well below the liquefaction zone. The intake pump station at Dolan Road is located on the Moss Landing Power Plant facility in an area

with a lower water table and medium-dense to dense sands. During the Loma Prieta earthquake, there was no evidence of liquefaction on the plant site (Mejia, 1998). The pump station structure extends to 30' below ground, well below any possible liquefaction zone.

Following the Loma Prieta earthquake, side scan sonograms also documented liquefaction that took place offshore. Evidence of liquefaction was seen at depths of 9-12 meters, much shallower than the proposed intake (Greene, 1991)

Based on data collected following the Loma Prieta earthquake, damage to the intake as a result of liquefaction is geologically unlikely. This is a lesser impact than the possible impact of liquefaction on the proposed slant well intakes. Failure of the intake would result in a threat to health and human safety.

DWD-9 cont.

Change "No coastal erosion or bluff retreat impact" to read "No coastal erosion or bluff retreat impact and reduced impact related to liquefaction."

Mejia, Lelio H. "Liquefaction at Moss Landing." *The Loma Prieta, California, Earthquake of October 17, 1989—Liquefaction* 1551-B (1998)

Greene, H. Gary, et al. "Offshore and onshore liquefaction at Moss Landing spit, central California—Result of the October 17, 1989, Loma Prieta earthquake." *Geology* 19.9 (1991)

8. Table 5.3-6 (p. 5.3-44):

Table 5.3-6 on p. 5.3-44 of the DEIR/DEIS referring to Desalination Plant Site Option 3 states:

> *"**Increased** --In addition to the impacts identified for the proposed project, this desalination site option could expose people or structures to a significant risk of loss, injury, or death from flooding due to sea level rise and coastal flooding. Other surface water hydrology and water quality impacts would be similar to the proposed project."*

DWD-10

The MBRWP plant site is outside of both the tsunami inundation area and the 100-year flood zone. The Pacific Institute California Flood Risk: Sea Level Rise Moss Landing Quadrangle (Attachment 2) places the plant site outside of the 100-year floodplain even with the inclusion of a 55" sea level rise as well.

Strike "In addition to the impacts identified for the proposed project, this desalination site option could expose people or structures to a significant risk of loss, injury, or death from flooding due to sea level rise and coastal flooding", **add** "The plant site is not located in a 100-year flood zone, even considering sea level rise." and **change** impact to "Similar".

Terrestrial Biological/Land Use

9. Table 5.3-4 (p. 5.3-36):

Table 5.3-4 on p. 5.3-36 of the DEIR/DEIS referring to Intake Option 9 states:

> *"**Increased.** Intake location would conflict with agricultural zoning and the potential to otherwise result in the conversion of farmland to nonagricultural use. New mitigation measure(s) would be required."*

DWD-11

Monterey County Land Use Plan North County (1982) designates all property to be disturbed for the intake as Industrial - Coast Dependent – Heavy (Attachment 3). The developed areas of the intake consist only of the pump station site. Even if this site were not zoned Industrial - Coast Dependent – Heavy, the location is an existing rail line on power plant property, and the location could not be used for agriculture due to past contamination (soil and water) and compaction issues. No construction activities are proposed for any lands zoned Agricultural. No mitigation would be required.

Strike sentence and **change** impact to "Similar."

Marine Biological Resources

10. Table 5.3-4 (p. 5.3-32):

Table 5.3-4 on p. 5.3-32 of the DEIR/DEIS referring to construction activities of Intake Option 9 states:

> *"**Increased**. Impacts would be increased, except for the impact on the movement of fish or wildlife species during construction. New mitigation measures would be required to reduce the impacts resulting from entrainment and impingement to less than significant."*

DWD-12

The DEIR/DEIS incorrectly identifies entrainment and impingement in impacts related to the construction of the MBRWP seawater intake. Entrainment and Impingement are operational impacts but are not construction related impacts.

Strike the words "resulting from entrainment and impingement."

11. Table 5.3-4 (p. 5.3-32):

DWD-13

Table 5.3-4 on p. 5.3-32 of the DEIR/DEIS referring to operational impacts of Intake Option 9 states:

"Operational impacts associated with impingement and entrainment would be greater and could be substantial if feasible mitigation were not available."

See response to Item 13 below.

Strike "and could be substantial if feasible mitigation were not available," **add "**and would require mitigation to reduce impacts to less than significant."

DWD-13 cont.

12. Section 5.5.5.6 p. 5.5-122 (para. 5):

Paragraph 5 on p. 5.5-122 of the DEIR/DEIS referring to Whole Project Alternative 3 states:

"*Additionally, Alternative 3 would draw up to 55 mgd of source water (compared to 24.1 mgd for the proposed project and Alternatives 1 and 2) through a screened open-water intake. A preliminary assessment determined that northern anchovy, Pacific sardines, white croaker, sanddab, rockfish, smelt, sculpin, Dungeness crab, cancer crabs, and unidentified larval fish would all be entrained (Tenera Environmental, 2014).*"

The Tenera report (Tenera, 2014, p ES-12) identifies the marine impact due to entrainment and impingement as less than significant due to ". . . a combination of low flows of the proposed intake relative to a large source water volume, the abundances and life history characteristics of fish species susceptible to entrainment, and the siting characteristics of the intake in deeper water and at the head of Monterey Submarine Canyon ". The report details the source water studies completed by DWD that led to this determination. Samples were collected at two different depths, day and night, between June 2012 and June 2013. Samples were taken to the laboratory, where all fish and target invertebrate larvae were removed, counted, and identified. Length was determined for a representative number of larval fish during each survey using an image capture and analysis system. The length data and estimates of larval growth rates were used to determine the age of the larval fish captured. Individuals longer than 30 mm (1.18 in) were considered non-entrainable because of their size. This is because they would be too large to physically pass through the proposed 1mm wedgewire screen on the intake or they have reached the stage in development that would allow them to swim away from the intake.

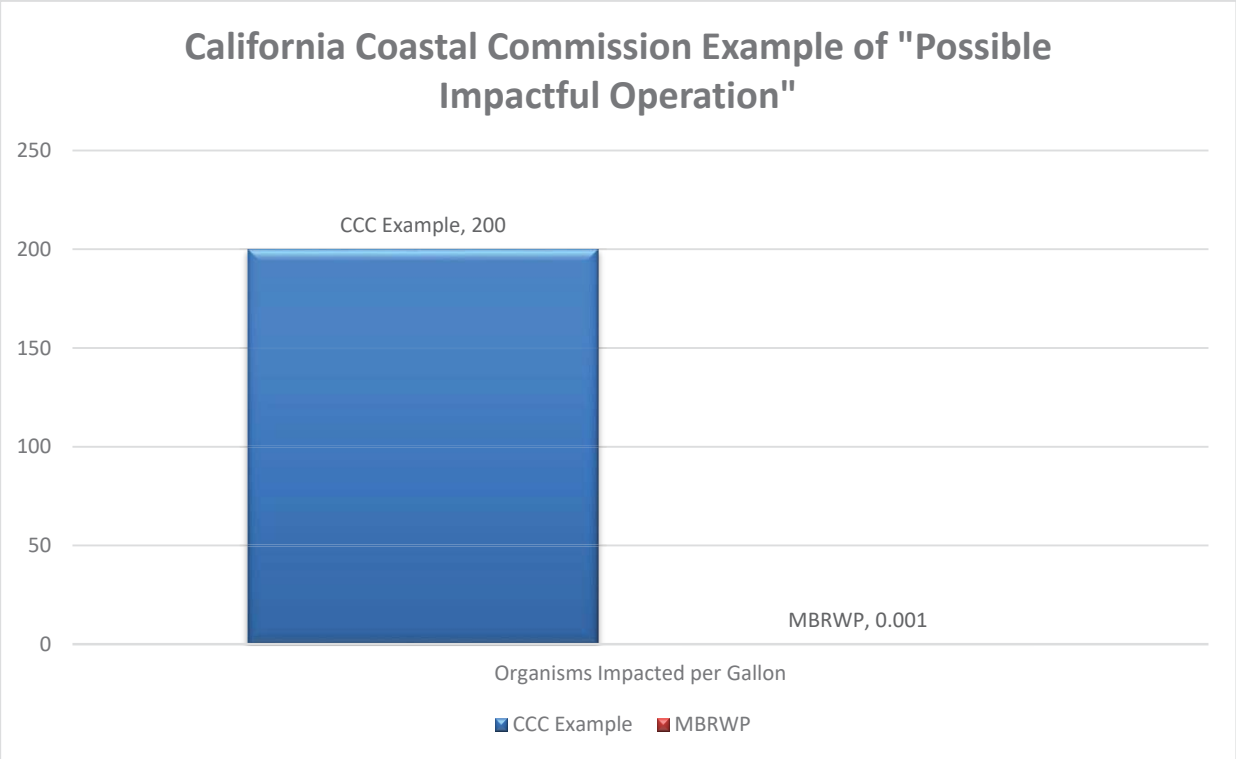
DWD-14

The best method, according to California State environmental agencies and scientists working in the field (see Steinbeck et al. ; Desal amendment, etc.), for assessing the intake impact due to entrainment is to calculate an estimate of proportional mortality. This estimate represents the number of deaths within a fish or invertebrate population due to effects of the intake relative to the estimated number in the source water population that is at risk of entrainment. The estimates of larval losses in the Tenera (2014) report ranged

from 0.009 – 0.109% for the various fishes analyzed based on an intake volume of 63 MGD. An addendum to the report (Tenera, 2016) was prepared using the final intake volume of 49 MGD and included adjustments to account for the depth of the intake and the use of a 1.0 mm wedgewire screen at the intake. The proportional mortality estimates for the six main species identified in the addendum ranged from 0.007 – 0.077%. In other words, between seven-thousandths, and seventy-seven hundredths of one percent of the larval populations identified within the source water would be at risk due to the intake, dependent on species. The high estimate was for CIQ goby and the low estimate for KGB rockfish. The estimates in the addendum were lower because the average concentration of total fish larvae through the entire water column at the intake site was estimated at 0.002088 larvae per gallon, while the estimate of number of larvae in deep water at the intake location was 0.001026, approximately half the number of larvae per gallon in the entire water column. This concentration is also less than a third of the estimated average concentration inside Moss Landing Harbor (0.003615 larvae per gallon). Based on this information, the intake for the MBRWP is proposed to be located at a depth that minimizes impacts.

DWD-14 cont.

While there is no direct quantitative threshold for significance, Chapter 5 of the Seawater Desalination and the California Coastal Act report (CCC, 2004) states "a desalination facility producing 50 million gallons per day of drinking water would pull in at least 100 million gallons per day of seawater and discharge at least 50 million gallons per day of highly saline brine. Since each gallon of seawater can contain hundreds of organisms, this amount of water could have significant adverse effects on marine life and water quality at the local or regional level." It is unclear what the estimate of hundreds of organisms cited in the CCC report represents, but since zooplankton and diatoms have such large numbers and reproduce rapidly, they typically would not be included in the number of organisms that would be impacted. Therefore, the assumption can be made that this number only includes fish and target invertebrate larvae, which are the focus of all scientific impact assessments done to date in California. For comparison to hundreds of organisms per gallon which “may be significant,” the MBRWP intake assessment shows that only a single fish larva will be entrained per approximately 1,000 gallons of intake water. Clearly not significant compared to the CCC example.



DWD-14 cont.

Fisheries Management Plans

Intake assessments in California and throughout the United States have historically been focused on fishes because of the potential for impacts to fish populations if large losses occurred to a severely depleted or listed population. One of the reasons that the proportional mortality estimates discussed above provide the best basis for determining the significance of the effects of the intake is because the results provide the same type of information used in fishery management. Groundfish fisheries in Washington, Oregon, and California are managed under the Pacific Coast Groundfish Fishery Management Plan (FMP) (PSFC 2016). This approach to fisheries management was approved by the U.S. Secretary of Commerce and implemented in 1982. The plan was implemented to better manage fish populations that overlapped state boundaries. Before the FMP, there was a lack of uniform of regulations across states. The plan covers all the Federal waters between the borders with Canada and Mexico and separates the coast into five management areas. Monterey Bay is part of the Monterey management area which extends from just south of Point Sur north to approximately Cape Mendocino. The FMP covers 85 species including all species of rockfish, and species such as cabezon, kelp greenling, and lingcod that are usually associated with shallow habitats.

The FMP, which is updated on a regular basis, is used as the guidance document in setting fishing limits. The current plan was issued in March 2016 with the most recent amendment (Magnuson-Stevens Act Provisions; Fisheries off West Coast States; Pacific Coast Groundfish Fishery; 2017–2018 Biennial Specifications and Management Measures; Amendment 27) published in February 2017. This amendment established allowable fishing limits for 2017–2018. The catch limits established by the regular plan amendments are designed to prevent overfishing while achieving the optimum yield from each fish species.

The goal of the FMP is to provide planning information for the seafood industry, protect recreational fishing, and maintain the health of fish populations. It develops allocation and harvest targets for each species that support a maximum sustainable yield (F_{MSY}) while allowing for self-sustaining fish populations. The plan is based on a conservative approach that assumes a high degree of uncertainty in the accuracy of the estimates used in the models.

Blue Rockfish

For impact comparison purposes, we will look at blue rockfish. This is an important fishery species with a management plan, which is largely restricted to nearshore areas along the central coast which are most likely to be subject to entrainment. While there is also information on pacific sanddab and northern anchovy, these species have distributions out into deeper water and over large areas of the coast. Because of the much larger geographic distribution of these species compared with blue rockfish, any project impacts on these species would be less than the impacts on blue rockfish. The Addendum identified a proportional mortality for blue rockfish due to MBRWP intake of 0.014%, meaning that the increased mortality of blue rockfish larvae due to effects of the intake is 14-hundredths of one percent of the local source population.

DWD-14 cont.

The maximum sustainable yield of 50% for rockfish that was identified in the 2016 FMP, was also used in a stock assessment for blue rockfish (Key et al. 2008). It identified the threshold biomass impact for overfishing as follows:

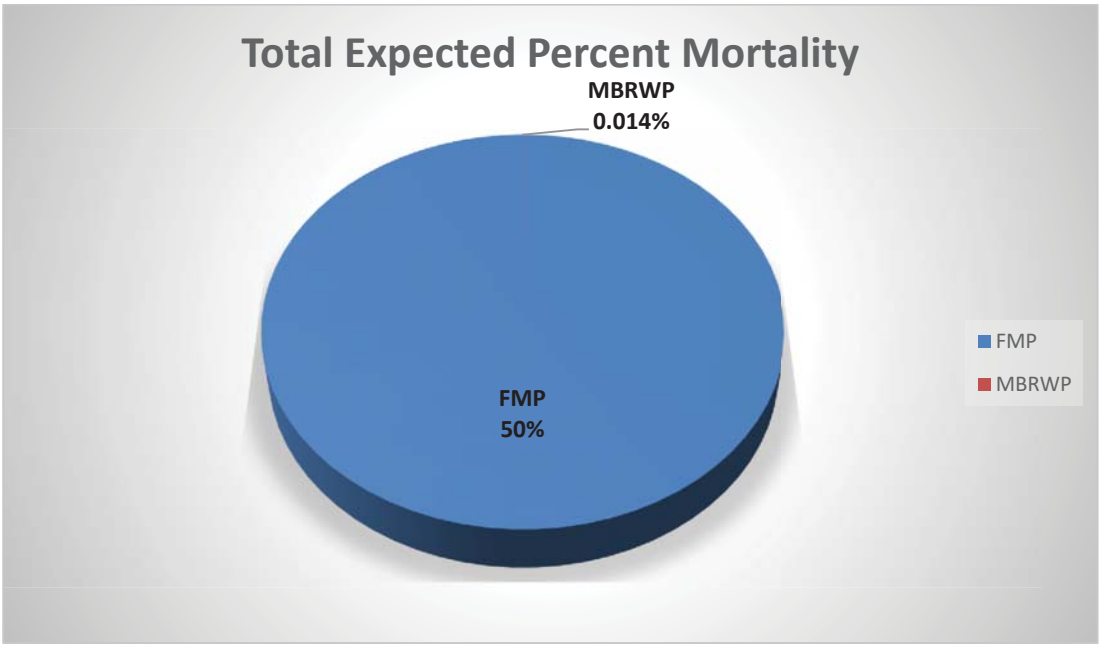
"This assessment uses the default target rate of F50% (equivalent to F_{MSY} of 50%) used for rockfishes on the West coast of the US. Under Pacific Fishery Management Council (PFMC) Groundfish management policy, if the current spawning biomass of the stock falls at or below 25% of the unexploited biomass, the stock is considered overfished. Under the state's guidelines, the stock is considered overfished at or below 30% of the unexploited biomass. Unfished spawning biomass was estimated to be 2077 million larvae in the base model, with the target stock size at 831 million larvae. The base model estimated that the stock could support a maximum sustainable yield (MSY) of 275 metric tons."

The implementation of management controls on several fisheries in California based on information in stock assessments has helped the recovery of many populations. For example, the blue rockfish sport catch from Monterey Bay area ports has increased over the five years from 2011 to 2015 by 300% (RecFin data accessed February 7, 2017).

The FMP recognizes that recommended levels of fishing will result in a reduction in both the spawning biomass and the average lifetime egg production of the females in the population. Using this same logic, the proportional mortality estimate used in the intake assessment for the MBRWP can be compared to acceptable fishing mortality within a population. A proportional loss due to intake entrainment will also translate directly to an equivalent loss in the adult population.

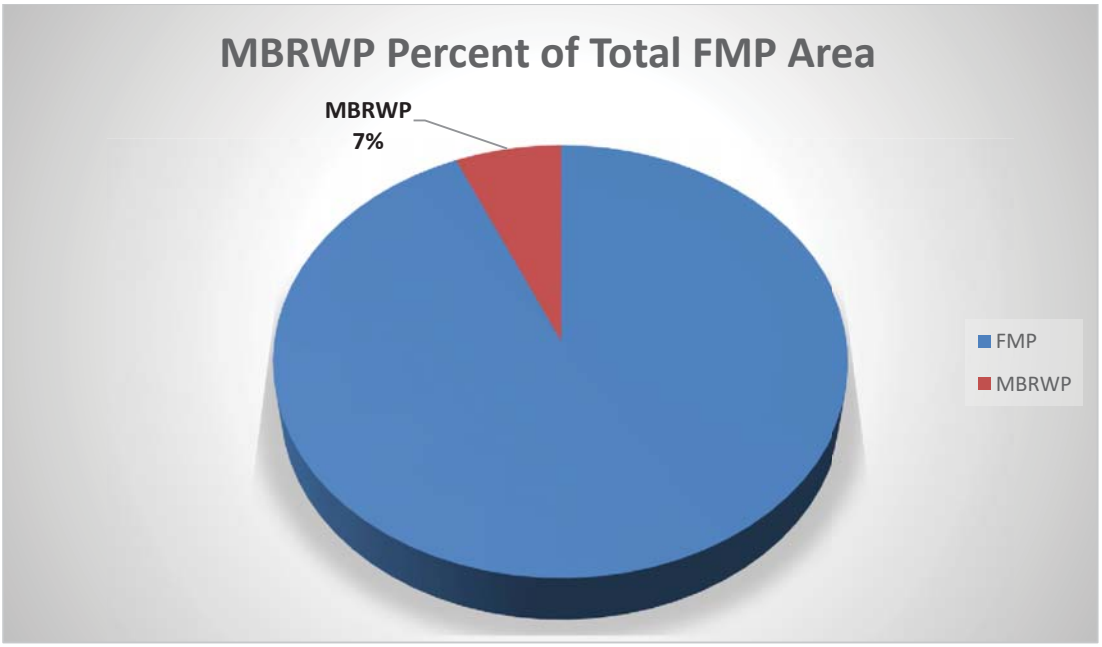
The fishing mortality of 50% used in the blue rockfish stock assessment model is over 3500 times higher than the estimated loss to blue rockfish due to entrainment of 0.014%. As noted in the blue rockfish stock assessment (Key et al. 2008), fisheries managers are concerned when the stock falls below levels representing 25–30% of the estimated unfished biomass. As you can see from the pie chart below, .014% is such a small portion of the allowable FMP impact that it is difficult to see. An additional source of local population mortality of 0.014% due to entrainment is not significant. It would have no material effect on the population when fishery managers are evaluating population effects with a fishing mortality rate of 50%.

DWD-14 cont.



It is also important to recognize that the estimated proportional mortality from the MBRWP intake on a species such as blue rockfish would occur in a limited area of approximately 8 to

12 mi (13 to 19 km) of shoreline inside Monterey Bay. Although this represents 20 to 25% of the shoreline of Monterey Bay, the actual rocky reef or kelp bed adult habitat for blue rockfish along this area of Monterey Bay is much smaller. As shown in the back-projections from the intake and map of hard substrate in Monterey Bay (Attachment 4), the areas with natural hard rocky substrate in Monterey Bay are limited to the north and south edges of the Bay and not the area potentially subject to entrainment. We have concluded that most rockfish larvae collected during sampling were probably spawned along the breakwater and other rocky locations associated with the Moss Landing Harbor. Including this additional Moss Landing Harbor habitat, the total shoreline area of Monterey Bay that could potentially be subject to entrainment due to the MBRWP intake represents approximately 7% of the coastline from Point Conception to the Oregon border used in the blue rockfish assessment.



The previously discussed entrainment loss impacts compared to the acceptable FMP impacts are reduced even further due to the small area impacted. **Entrainment losses represent an additional source of mortality to the population of less than a thousandth of a percent (0.14% entrainment over only 7% of total planning habitat). This number is much too small to show graphically in comparison to the levels of fishing mortality used in the blue rockfish FMP, and therefore not a material impact.**

In addition to comparing the expected mortality rate due to entrainment with rates of fishing mortality, the estimated mortality can also be compared with the range of variation in the population. Since fishing mortality affects adult and juvenile populations, a more valid

DWD-14 cont.

comparison of the effects of entrainment is the variation in the numbers of fish larvae that successfully develop into juvenile fish. This transition is also referred to as "recruitment." The blue rockfish assessment (Key et al., 2008) includes estimates of recruitment from 1998–2007, the life stage potentially subject to increased larval mortality due to entrainment. The estimates ranged from low of 735,000 in 2006 to a high of 7,792,000 in 1998. With a 95% confidence interval, the estimates range from approximately 50% of the annual estimate of recruitment, to greater than 100%. Given this range of variation in the annual estimate of recruitment, a 0.014% increase in larval mortality due to entrainment would not have any effect on the larger population subject to the FMP. The same type of information presented here could also be compiled for the other fishes included in the assessment to support the conclusion that the entrainment losses due to the DWD intake would be less than significant.

The finding of a "substantial" or "significant" effect under CEQA should have some basis. Applying scientific principles to the determination of a "substantial" or "significant" effect would require that an effect is compared to some baseline number and assessed regarding an identified threshold for impact. When fisheries managers set a threshold for overfishing for blue rockfish, it is to maintain a sustainable population. That identified threshold is the allowable fishing catch limit. In the absence of any established threshold for entrainment losses, fishing limits provide a guide for determining the magnitude of actual effects on fish populations. An increase of 0.014% in mortality of blue rockfish larvae due to entrainment, along 8 to 12 mi (13 to 19 km) of shoreline inside Monterey Bay, is more than 3500 times lower than the allowable levels of fishing mortality over the hundreds of miles of coastline from Point Conception north to the Oregon border. This level of loss could never be detectable given the variation in the annuals levels of recruitment to the population. The independent comparisons with allowable fishing mortality and the variation in recruitment, as well as the other information presented in the intake assessment, support the conclusion that the effects of the intake would be less than significant.

DWD-14 cont.

Add "These impacts are less than significant due to the small proportion of the larval populations subject to entrainment mortality, either on the local population or the larger population subject to the Fisheries Management Plan."

California Coastal Commission. "Seawater Desalination and the California Coastal Act." (2004).

Key, M., A. D. MacCall, J. Field, D. Aseltine-Neilson, and K. Lynn. 2007. The 2007 Assessment of Blue Rockfish (Sebastes mystinus) in California. Available at: http://www.pcouncil.org/wp-content/uploads/KeySAFE_BlueRF_Jan08.pdf

Pacific Fishery Management Council. 2016. Pacific Coast Groundfish Fishery Management Plan for the California, Oregon, and Washington Groundfish Fishery. Portland, OR. March 2016. Available at: http://www.pcouncil.org/wp-content/uploads/2016/03/GF_FMP_FINAL_Mar2016_Mar282016.pdf

DWD-14 cont.

13. Section 5.5.5.6 p. 5.5-122 (para. 6):

Paragraph 6 on p. 5.5-122 of the DEIR/DEIS referring to Whole Project Alternative 3 states:

> "*The potential ETM/APF for this alternative was estimated at greater than 40 acres (Luster, 2016), and similar to Alternative 2, would require mitigation.* ***Mitigation Measure ALT 2-Marine-2*** *would be required to minimize and mitigate for impacts on marine biological resources, but similar to Alternative 2, residual impacts may remain due to the uncertainty of the efficacy of the mitigation."*

NOAA implementation of NEPA requires the analysis of "the direct, indirect, and cumulative environmental impacts of the proposed action and the alternatives in clear terms and with sufficient information to ensure the professional and scientific integrity of the discussion and analysis" (NOAA, 2017). CEQA requires an agency to evaluate the factual and scientific data to determine whether an impact may be significant. Impacts, in either case, can be determined to be significant (requiring mitigation) or insignificant. The Ocean Plan Amendment, in contrast, treats all marine life impacts as requiring offsetting mitigation through the ETM/APF approach at a 95% confidence level ***regardless of significance***. Therefore, there is neither a legal or practical justification for basing a significance determination on the extent of ETM/APF calculations resulting from Ocean Plan Amendment required mitigation. Where scientific information on the actual impacts of impingement and entrainment are available, as in this case, they are required to be used to determine significance under CEQA/NEPA.

DWD-15

Also, the ETM/APF estimate was based on preliminary information, before finalization of the Tenera Intake Assessment and Addendum which includes the reduction of impact related to the wedgewire screen and is calculated based on the final proposed plant flow. This document was made available to ESA for review. This document is the basis for the required ETM/APF calculation. The California Coastal Commission is currently peer reviewing this document to assure there is adequate information to calculate the ETM/APF. An opinion based on preliminary documentation in the absence of a completed ETM/APF calculation does not meet the legal standard of "the direct, indirect, and cumulative environmental impacts of the proposed action and the alternatives in clear terms and with sufficient information to ensure the professional and scientific integrity of the discussion and analysis" (Policy and Procedures for Compliance with the National Environmental Policy Act and Related Authorities, (NOAA, 2017).

National Oceanic and Atmospheric Administration. "Policy and Procedures for Compliance with the National Environmental Policy Act and Related Authorities." (2017)

Strike entire paragraph and **change** finding to less than significant based on results and conclusions in Tenera Intake Assessment.

DWD-15 cont.

14. Section 5.5.5.6
p. 5.5-124 (para. 2):

Paragraph 2 on p. 5.5-124 of the DEIR/DEIS referring to Whole Project Alternative 3 states:

> "*In addition to physical impacts, Alternative 3 may be inconsistent with MBNMS Desalination Guidelines (NOAA, 2010), with regard to its open water intake and lack of a combined discharge. Guidelines state:*
>
> • *All desalination plants should be designed and sited to avoid and minimize impingement and entrainment to the extent feasible. Project proponents should investigate the feasibility of using subsurface intakes as an alternative to traditional intake methods.*
> • *Project proponents should investigate the feasibility of diluting brine effluent by blending it with other existing discharges."*

DWD-16

The DWD project was determined by the proponent, partially using CalAm scientific evidence of bore hole analysis, to not be feasible for meeting project objectives using a subsurface intake. Initial subsurface feasibility material was available to ESA for review. In addition, locations available to DWD for subsurface intake have either been identified in this DEIR/DEIS prepared by ESA as infeasible due either to hydrogeological conditions or failure of the option to provide enough water for even the smaller CalAm plant due to pulling in 12% groundwater from the critically over drafted, and soon to be regulated, Salinas Basin. The proponent is coordinating with the State Water Resources Control Board to finalize a subsurface feasibility study for review. DWD also spent a year doing marine testing to determine the least impactful site for the intake. These activities show compliance with the Ocean Plan. See comments addressing Discharge feasibility in Item 16.

Strike entire section, **add** "MBRWP is expected to be in compliance with regard to its open water intake and lack of combined discharge due to current, ongoing regulatory activities, and **reevaluate** without assuming inconsistence with MBNMS Desalination Guidelines (NOAA, 2010) in Whole Project Analysis.

Brine Discharge

15. Section 5.5.3.6
p. 5.5-49 (para. 4):

DWD-17

Paragraph 4 on p. 5.5-49 of the DEIR/DEIS referring to Whole Project Alternative 3 states:

> "*Model analysis (Jenkins, 2016) identified discharges from Alternative 3 would occasionally (1 day out of 3.4 years) exceed the significance threshold of 2 ppt above natural background salinity at the BMZ boundary by a small margin (i.e., by 0.15 ppt).*"

The model analysis provided to ESA identified that under a very particular set of circumstances, there is a 0.08% chance of exceeding 2ppt at the BMZ by 0.15. Circumstances required for this situation include the data center using no water for cooling, a Davidson current, and the desalination plant undergoing start-up activities. Jenkins goes on to say "This amount is within the sampling error of standard monitoring equipment. Possible over limit cases are not statistically significant, therefore under all practical, measurable, long-term ocean conditions, DWD meets the dilution standards of the Ocean Plan Amendment" (Jenkins, 2016, pp 129-131).

The discharge louvers have been modified slightly in a recently revised report. The current diffuser design has more jets at a lower velocity which minimize the size of the BMZ while simultaneously minimizing turbulent shear impacts and sediment resuspension. There are no longer any modeled exceedance outcomes. This report will be provided for your review under separate cover.

DWD-17 cont.

Jenkins, Scott. "Brine dilution analysis for DeepWater Desal, LLC." (2016).

Delete sentence: "Model analysis (Jenkins, 2016) identified that under very specific operational circumstances, there is a 0.08% (1 day out of 3.4 years) probability that discharges from Alternative 3 would exceed the significance threshold of 2 ppt above natural background salinity at the BMZ boundary by a small margin (i.e., by 0.15 ppt).

Add sentence: "Option 3 meets all measurable dilution standards of the Ocean Plan Amendment".

16. Section 5.5.3.6
p. 5.5-52 (para. 3):

Paragraph 3 on p. 5.5-52 of the DEIR/DEIS referring to Whole Project Alternative 3 states:

> "*In addition to physical impacts, Alternative 3 may be inconsistent with MBNMS Desalination Guidelines (NOAA, 2010), with regard to its lack of a combined discharge compared to the proposed project, which would use an existing outfall. One of the guidelines states: "project proponents should investigate the feasibility of diluting brine effluent by blending it with other existing discharges.""*

DWD-18

The MBRWP EIR/EIS is evaluating a combined discharge using the power plant cooling water. This was identified in the Project Narrative provided to ESA. This option is only feasible if the Moss Landing Power Plant will agree to allow it, which they have not done to

date. If MLPP agrees, MBRWP will use this discharge method. Therefore, MBRWP is following the requirement to investigate the feasibility of diluting brine effluent by blending. The Ocean Plan Amendment states that "Multiport diffusers are the next best method for disposing of brine when the brine cannot be diluted by wastewater and when there are no live organisms in the discharge (California Ocean Plan, 2015, p. 41)." If the Moss Landing Power Plant isn't agreeable to accepting brine for blending, a multiport diffuser will be used (the proposed project since the MLPP has not agreed to accept the brine). Therefore, the DWD project is not inconsistent with the Ocean Plan Amendment.

DWD-18 cont.

Strike entire paragraph, **add** "MBRWP is expected to be in compliance with MBNMS Desalination Guidelines (NOAA, 2010) based on current, ongoing regulatory activity."

17. Section 5.5.3.6
p. 5.5-49 (para. 5):

Paragraph 5 on p. 5.5-49 of the DEIR/DEIS referring to Whole Project Alternative 3 states:

> "*As described in detail in Section 4.3.2.2 for the proposed project, the Ocean Plan includes monitoring and reporting requirements for the operation of new desalination facilities (Section III.M.4, "Monitoring and Reporting Program"; SWRCB, 2016b). A monitoring and reporting plan has not been defined and proposed as part of Alternative 3; as such and similar to the proposed project, Alternative 3 would not be consistent with the Plans, Policies, and Regulations described in Section 4.3, Surface Water Hydrology and Water Quality. This would be a significant impact and would result in an increased level of impact compared to the proposed project, which could be reduced to less than significant with the implementation of* ***MM 4.3-4****. Therefore, Alternative 3 would result in the* ***same impact conclusion*** *for salinity compared to the propose project, less than significant with mitigation. "*

DWD-19

DWD agrees with this statement, but it conflicts with the statement quoted in Item 18. **Correct** contradictory statement on page 5.5-53, paragraph 4 (see Item 18).

18. Section 5.5.3.6
p. 5.5-53 (para. 4):

Paragraph 4 on p. 5.5-53 of the DEIR/DEIS referring to Whole Project Alternative 3 states:

> "*As discussed above, Alternative 3 discharges would exceed the 2 ppt salinity significance threshold by 0.15 ppt and could exceed Ocean Plan water quality objectives for PCBs. Because proponents of the DeepWater Desalination Project have not demonstrated methods of compliance with the Ocean Plan objectives that are protective of beneficial uses, and feasible mitigation strategies have not yet been identified, Alternative 3 in combination with other cumulative projects would result in significant and unavoidable cumulative impacts on ocean water quality and Alternative 3 would*

have a cumulatively considerable contribution to such effects (significant and unavoidable).”

Paragraph 3 on page 4.3-124 of the DEIR/DEIS states that “it is conservatively determined that under the assessed discharge scenarios, operational discharges from implementation of the MPWSP could exceed Ocean Plan water quality objectives for certain constituents. This would result in a significant impact, and because the Ocean Plan water quality objectives are based on the effects of cumulative impacts on ocean water quality, an exceedance of water quality objectives also would represent a cumulatively considerable contribution to a potential significant cumulative impact. The proposed project contribution would be minimized to a less-than-significant level by implementation of **Mitigation Measure 4.3-4 (Operational Discharge Monitoring, Analysis, Reporting, and Compliance)** and **Mitigation Measure 4.3-5 (Implement Protocols to Avoid Exceeding Water Quality Objectives).”** This statement recognizes that even though the proposed CalAm project discharges could exceed water quality objectives, mitigation measures would reduce impacts to less than significant.

Paragraph 2 of pas 4.3-91 says “The analysis and reporting conducted as part of the Plan shall determine the need for corrective actions to be implemented in the form of the design features and operational measures prescribed in **Mitigation Measure 4.3-5** to reduce identified impacts to less-than-significant levels.” The plan referenced is the Water Quality Monitoring Plan identified in Mitigation Measure 4.3-4. The DEIR/DEIS recognizes that this plan is required to receive an NPDES permit, (para. 4, p. 4.3-124). Therefore, MBRWP, if permitted, will have a plan for water quality monitoring in place that has been reviewed and approved by the RWQCB and MBNMS.

DWD-19 cont.

The DEIR/DEIS recognizes the use of granular activated charcoal as a method of removal for PCB’s (para. 5, p. 4.3-105). It also recognized that actions required for Mitigation Measure 4.3-5, such as the use of granular activated charcoal to remove PCB’s, must be informed by the results of Mitigation Measure 4.3-4, the monitoring plan.

Paragraph 3 of page 5.5-3 of the DEIR/DEIS states “Where applicable, mitigation measures that are applied to the proposed project in Chapter 4 are applied to potentially significant impacts of the alternatives.” Mitigation Measure 4.3-4 is clearly applicable to MBRWP and Mitigation Measure 4.3-5 can’t be determined until 4.3-4 is in place, it would be inconsistent with the rest of the document to not provide credit for Mitigation Measures 4.3-4 and 4.3-5,

Strike “Because proponents of the DeepWater Desalination Project have not demonstrated methods of compliance with the Ocean Plan objectives that are protective of beneficial uses, and feasible mitigation strategies have not yet been identified, Alternative 3 in combination with other cumulative projects would result in significant and unavoidable cumulative impacts on ocean water quality and Alternative 3 would have a cumulatively considerable contribution to such effects (significant and unavoidable).” **Add** “The implementation of **Mitigation Measure 4.3-4 (Operational Discharge Monitoring, Analysis, Reporting, and Compliance)** and **Mitigation Measure 4.3-5 (Implement Protocols to Avoid Exceeding**

Water Quality Objectives) would ensure that brine constituents from Alternative 3, such as PCBs, are discharged at concentrations below Ocean Plan requirements. Thus, Alternative 3 in combination with other cumulative projects would not have a cumulatively considerable contribution to a potential significant cumulative impact related to such effects."

DWD-19 cont.

Whole Project Comparison

19. Section 5.4.5.4
p. 5.4-38 (para. 5):

Paragraph 5 on p. 5.4-38 of the DEIR/DEIS referring to Whole Project Alternative 3 states:

> "*An additional 6.5 miles of product water pipeline would be required to connect the alternative to the proposed project's pipelines in Marina;"*

The proposed pipeline routing between Castroville and the connection to the CalAm project in Marina has been revised to match the proposed Castroville Pipeline (CalAm project). This pipeline will connect to the Salinas Pipeline which is included in the 25 miles of additional pipeline for the project. Since the Castroville pipeline is included in the CalAm DEIR/DEIS to deliver return water to Castroville, the impacts of the pipeline between Castroville and the point of connection in Marina have already been considered in the proposed project. No additional "new" pipeline is needed to connect the peninsula to the MBRWP transmission line in Castroville.

DWD-20

Strike this portion of the sentence.

20. Section 5.5.2.6
p. 5.5-17 (para. 3):

Paragraph 3 on p. 5.5-17 of the DEIR/DEIS referring to Whole Project Alternative 3 states:

> "*The alternative would also include 6.5 miles of desalinated water pipeline to connect with the CalAm system and up to an additional 25 miles of pipelines to convey the desalinated water to other areas (total of 31.5 miles of additional pipeline).*"

No additional pipeline is required between Castroville and the point of connection in Marina (see item 19).

Strike "6.5 miles of desalinated water pipeline to connect with the CalAm system and".

21. Section 5.5.2.6
p. 5.5-17 (para. 3):

Paragraph 3 on p. 5.5-17 of the DEIR/DEIS referring to Whole Project Alternative 3 states:

"*The alternative would also include 6.5 miles of desalinated water pipeline to connect with the CalAm system and up to an additional 25 miles of pipelines to convey the desalinated water to other areas (total of 31.5 miles of additional pipeline).*"

DWD-20 cont.

No additional pipeline is required between Castroville and the point of connection in Marina (see item 19).

22. Section 5.5.5.6 p. 5.5-122 (para. 2):

Paragraph 2 on p. 5.5-122 of the DEIR/DEIS referring to Whole Project Alternative 3 states:

"*Similar to Alternative 2, mitigation would be required to reduce the short and long-term impacts of construction on marine biological resources in MBNMS. Although implementation of* ***Mitigation Measure ALT 2-Marine-1*** *or similar measures would reduce this impact, it would not be reduced to a less-than-significant level for the same reasons described for Alternative 2. Therefore, compared to the proposed project, the construction of Alternative 3 could result in a substantially increased impact on marine biological resources including candidate, sensitive, or special-status species identified in local or regional plans, policies, regulations or conservation plans during construction and would result in an* ***increased impact conclusion*** *compared to the proposed project; significant and unavoidable even with implementation of* ***Mitigation Measure ALT 2-Marine 1****.*"

DWD-21

The reasons referenced for Alternative two in this paragraph state "residual impacts may remain significant due to the sensitivity of the resources. Therefore, the construction of Alternative 2 could result in an increased impact on marine biological resources including candidate, sensitive, or special-status species identified in local or regional plans, policies, regulations or conservation plans during construction". Potential effects from Alternative 3 construction include temporarily suspended sediment, underwater noise, and burial or displacement of organisms in the construction areas. Tenera in the MBRWP Marine Resources Assessment (2016) states "The degree of effect depends on the relative area of disturbance compared to the overall habitat and community, either locally or regionally, and the types of species." They found that "effects are also considered temporary and localized and would not result in substantial effects on marine resources."

NOAA has provided the following Interim Sound Threshold Guidance:

For continuous and intermittent sound sources, the Level A (injury) and Level B (behavioral disruption) thresholds for marine mammals are 180-, and 120-dB re 1 µPa root mean square (RMS), respectively (NOAA Interim Sound Guidance). NOAA Fisheries and USFWS have used 150 dBRMS as the threshold for behavioral effects on ESA-listed fish species, such as salmon for most biological opinions evaluating pile driving (Technical Guidance for Assessment and

Mitigation of the Hydroacoustic Effects of Pile Driving on Fish. California Department of Transportation November 2015). This was based on information that sound pressure levels above 150 dBRMS can cause temporary behavioral changes that could affect the ability of fish to avoid predators. NOAA Fisheries staff indicated at the June 2008 FHWG meeting that they do not expect exceedance of the 150 dBRMS behavior threshold to trigger any mitigation requirement (Fisheries Hydroacoustic Working Group 2008). Underwater noise levels from HDD installation will not be of concern until the ocean floor is breached. Noise levels related to this are typically less than those for vibratory installation of piles (120 dB re 1 micropascal) and for a much shorter duration. Therefore the sound associated with HDD drilling is expected to be below Level B thresholds.

DWD-21 cont.

Suspended sediments would also be a temporary effect "because of the localized nature of the disturbance (area of the HDD drill head where it emerges) compared to the very large areas of undisturbed habitat in the project region, and because recolonization and recovery would likely occur within a year or less. Also, mobile individuals such as fishes, marine mammals, and sea turtles would be able to leave disturbed areas during construction and return to these areas after construction is completed." (Tenera 2016).

Based on this information, construction impacts should have been found to be LSM.

Change "significant and unavoidable" to "less than significant with mitigation."

23. Section 5.5.18.6
p. 5.5-330 (para. 3):

Paragraph 3 on p. 5.5-330 of the DEIR/DEIS referring to Whole Project Alternative 3 states:

> "*Operations and maintenance of the data center and cooling system would require 150 megawatts (MW) of electrical power) resulting in a substantial increase compared to the proposed project, which requires less than 6 MW. This energy demand would be 25 times the net energy demand of the proposed project, and represents approximately half of the County's electricity usage in 2014 (PG&E, 2015). This additional energy load could substantially constrain local and/or regional energy supplies if not adequately addressed by PG&E."*

DWD-22

The MBRWP is proposing to connect directly into PG&E's Coburn tower transmission line and be transferred through a new dedicated distribution line to a dedicated substation. DWD has met with PG&E to discuss the best way to connect to their system and will follow up with a formal Interconnect Study that will identify any impacts. The loads for Monterey County are a small portion of the capacity in the Moss Landing transmission infrastructure, which was designed to handle the production of the Moss Landing Power Plant, and the MBRWP load will be half again as small. PG&E has indicated there are currently no power constraint issues in the Moss Landing transmission system. As the offtaker DWD will be required to pay for any upgrades to the PG&E system as a result of system transmission

constraints due to the project. MBRWP will also purchase power from the wholesale market, rather than directly from PG&E. So there will be no effect to PG&E supplied power available to the region.

Change "This additional energy load could substantially constrain local and/or regional energy supplies if not adequately addressed by PG&E." to "Any constraint on local and/or regional power transmission will be identified by PG&E and mitigated by MBRWP" before interconnection.

DWD-22 cont.

DeepWater Desal, LLC appreciates the opportunity to comment on the DEIR. To reiterate, the objective of the MBRWP is to provide a regional water supply, not just a supply for the Monterey Peninsula. For this reason, while MBRWP may be a suitable alternative to the CalAm project, the CalAm project would not meet the project objective of MBRWP. We do not believe it is accurate to present the projects as an either/or scenario. It is highly likely, as the DEIR/DEIS points out in several places that both projects will be constructed. This means that the construction of the CalAm Desalination project would not result in the avoidance of the impacts related to the DWD project.

DWD-23

We understand that the DEIR/DEIS process has a very specific set of requirements for how projects are compared, but feel it necessary to point out that CalAm entering into a water purchase agreement with the MBRWP would not result in any environmental impacts over and above the CalAm proposed project. Also, while DWD understands the logic in comparing the impacts of the Cal Am proposed project to a scaled down version of the MBRWP, a scaled down desalination facility would not meet the objective of being a regional water source. In reality, the projects are complimentary and address the many water challenges of the greater region.

DWD-24

If you have any questions regarding these comments, please contact me at (831) 632-0616 or by email at kim@dwdesal.com.

Karen Grimmer, NEPA Lead
Monterey Bay National Marine Sanctuary
99 Pacific Avenue, Bldg 445a
Monterey, CA 93940

Dear Ms. Borak and Ms. Grimmer:

I submit these comments on behalf of Ecological Rights Foundation, the Center for Biological Diversity, and Our Children's Earth Foundation, regarding the Draft Environmental Impact Report/ Environmental Impact Statement ("EIR/EIS") for the Monterey Peninsula Water Supply Project (Project), and proposed desalination plant ("Facility"). As described in detail below, the EIR/EIS is fundamentally inadequate, and meaningful public review and comment are precluded given its flawed analyses. Once the EIR/EIS is fixed, under CEQA and NEPA it must be recirculated for public review and comment. ERF-1

The EIR/EIS Insufficiently Describes Baseline Environmental Conditions

CEQA requires an accurate description of the existing "baseline" environmental conditions in order to understand a project's potential impacts. CEQA Guidelines § 15125(a). The EIR must describe the physical environmental conditions in the vicinity of the project, as they exist at the time the notice of preparation is published. CEQA Guidelines § 15125(a). Similarly, under NEPA, agencies must identify baseline environmental values in adequate detail. 40 C.F.R. §1501.2(b). To determine whether a project may cause significant impacts, an Environmental Assessment must consider the context and the intensity of impacts. Id. at 1508.27. As "significance" varies with a project's setting, "context" includes the affected region, the affected interests, and the locality. *Id*. "Intensity" refers to impact severity and requires consideration of an area's unique characteristics." *Id*., 1508.27(b)(3). ERF-2

The EIR/EIS does not satisfy these basic requirements in its descriptions of marine and terrestrial environments. For example, the EIR/EIS reports that the largest source of contaminants is agricultural runoff into the Pajaro and Salinas Rivers. Seasonal data collected by the Central Coast Long-term Environmental Assessment Network (CCLEAN) between 2001 and 2013 indicate numerous instances where water quality objectives and human health alert levels in Monterey Bay were exceeded due to the presence of contaminants (CCLEAN, 2011 and 2014). Nearshore waters of Monterey Bay have failed to meet the Ocean Plan water quality objective for the protection of human health (i.e., concentrations are higher than numeric water quality objectives) for PCBs, Dieldrin, chlordanes, and DDTs. PCBs in the northern portion of Monterey Bay have increased significantly since 2006 and annual average concentrations across all samples have increased exponentially (CCLEAN, 2014). Yet, despite the Project's proximity to the Salinas River, and despite the acknowledgment that Monterey Bay water quality and contaminant concentrations are relevant, since the seawater extracted from the

bay through the subsurface intakes would be used as source water for the MPWSP Desalination Plant, the EIR/EIS does not discuss the concentrations of these contaminants of concern in the water or sediments near the proposed slant wells or outfall.

The EIR/EIS states that the Ocean Plan and NPDES permit monitoring requirements will require the facility operator to establish baseline biological conditions at the discharge location as well as at a reference location outside the influence of the discharge prior to commencement of construction. "To achieve this requirement, the owner or operator is required to conduct biological surveys (e.g., Before-After Control-Impact studies) that evaluate the differences between biological communities at a reference site and at the discharge location before and after the discharge commences. The pertinent regional water board uses the data and results from the surveys and any other applicable data for evaluating and renewing the requirements set forth in a facility's NPDES permit (in the case of the proposed project, the MRWPCA's outfall)." EIR/EIS 4.3-33. The same baseline environmental information is necessary to the evaluation of potential environmental impacts under CEQA and NEPA.

Local, site-specific baseline data on chemical concentrations in water and sand/sediment is particularly needed in this instance, due to the Project's co-location with the MRWPCA Regional Wastewater Treatment Plant. In winter months, secondary treated wastewater from the Treatment Plant is discharged to Monterey Bay through a diffuser positioned 11,260 feet offshore at a depth of approximately 100 feet. The Wastewater Treatment Plant is a source of numerous pollutants, and thus the water quality and sediment quality in the local environment may be significantly different, with likely higher concentrations of chemical and biological contaminants, than the water and sediment quality of Monterey Bay generally. The EIR/EIS acknowledges that the amendment process for the Wastewater Treatment Plant's NPDES Permit "would require an extensive water quality assessment, which would involve MRWPCA (as the discharger defined in the current NPDES Permit) and/or CalAm (as a contributor of a new discharge) to perform testing and monitoring of the water quality of the discharges, including the testing of the source water drawn from the subsurface water intake wells and piped to the MPWSP Desalination Plant and assessing the resulting water quality of the discharges from the MPWSP Desalination Plant." A similar water and sediment quality assessment is necessary at this stage, to establish the environmental baseline, and to adequately evaluate the Project's potential impacts.

ERF-2 cont.

The EIR/EIS unjustifiably relies on what it describes as a "long-term monitoring study of the ocean outfall," for the assertion that there have been "no effects from the outfall discharge on benthic communities, or biological accumulation of contaminants in tissue" and that "[n]o effects were observed on the physical and chemical properties of the sediments and water column except adjacent to the outfall." In fact, the cited report, "Analysis of MRWPCA Marine Outfall Benthic Monitoring Program" was prepared for Monterey Regional Water Pollution Control Authority by ABA Consultants in 1999, identifies scores of reasons why the existing monitoring data is flawed and insufficient to establish a baseline of environmental data for assessing marine impacts. The ABA report makes the following conclusions:

- The sampling methodology and design has changed over the time frame of sampling, between 1977 and 1994. This limits the comparisons that can be done within the data set and severely restricts the utility of the data. It cannot be emphasized strongly enough that a consistent sampling design is necessary for long term studies to be useful.

ERF-3

- Chemical analysis of sediments followed a standardized list of metals that was derived from studies at other sites and was inapplicable for the local area. It is not clear whether these trace metals have elevated concentrations in the effluent reaching Monterey Bay. Properly conducted chemical analysis require clean techniques, well-trained researchers, and are expensive, so it is important that we be sure that the analyses conducted are pertinent. The chemicals currently analyzed are simply a generic "laundry list" compiled from requirements in other areas that may not be of concern in this location. Carefully selecting appropriate indicators that may include chemicals not on the EPA list and may not include some standard tests as relevant for the area is an important way to customize a sampling strategy.

- Bioaccumulation studies were discontinued after 1991 and only conducted for metals.

- Arsenic concentrations increased over time at all sediment sampling stations.

- The species used for the bioaccumulation work, *Citharichthys stigmaeus* and *Crangon nigromarnlata,* were usually the most abundant species captured in trawls near the outfall. Unfortunately, these are highly mobile species whose chemical body burden may not reflect the local conditions accurately. Since these species are known to undergo substantial seasonal migrations, the concept of adjacent "impacted" and "control" stations was inappropriate.

- There has been an increase in the abundance of crustaceans and a decrease in the numbers of echinoderms. The general pattern suggested is an increase in mobile epifauna *(Hemilamprops californica, Zeugophilomedes oblonga)* and opportunistic species (magelonids) and a decrease in sessile species *(Dendraster excentriws, Tellina modesta),* predators *(Nephtys cornuta)* and sensitive species *(Rlzepoxynius abronius)* (Figure 14). Together, the results suggest increasing disturbance in the benthic community within 2 m of the outfall;

- Because of the change in station locations in 1994, comparisons with previous years' data must be made with caution. The value of the data set for detecting changes and long-term patterns is greatly reduced by the location change; only when no station differences are found can data sets be compared between years, and there is no way to look for potential effects of the outfall. Less than half of the groupings (11 of 25) can be compared over the entire time frame of data collection; 10 more partial comparisons can be made. The station location change has greatly compromised the utility of the data, both for outfall monitoring, and for comprehensive long-term ecological research.

- The stations would be particularly useful if the scope of the chemical analyses was enlarged to include pesticide screening; pesticides are of far more concern in Monterey Bay then the metals analysed for around the outfall.

ERF-3 cont.

The Federal Register Notice for this Project was issued on August 26, 2015. The EIR/EIS uses a 2012 baseline and does not provide adequate support for the assertion that "environmental conditions in the study area have been relatively static such that 2012 conditions remain representative of meaningful baseline conditions." By relying on a 2012 baseline, rather than a 2015 baseline, the EIR/EIS may not

ERF-4

neglect recent changes in relevant environmental factors, such as habitat use or loss, and recent increases in Monterey Bay shoreline erosion. ERF-4 cont.

The EIR/EIS Is Vague and Inconsistent as to the Purpose and Need for the Project.

Under CEQA an EIR must include a statement of objectives sought by the proposed project. The statement of objectives should include the underlying purpose of the project. CEQA Guideline 15124 (b). Under NEPA the agency must provide consistent information about important aspects of the Project that are crucial for an informed consideration of project impacts.

The EIR/EIS is vague and inconsistent as to the purpose of the Project. After review of the EIR/EIS, the reader does not know if the purpose is (1) to replace existing water supplies or (2) replace existing supplies and expand water supplies, or (3) authorize otherwise prohibited activities.

The EIR/EIS at pdf 3 states "The purpose of the MPWSP is to replace existing water supplies for CalAm's Monterey District service area."

The EIR/EIS at section "ES.3.1 Cal Am Project Objectives" doesn't state the purpose of the Project, but does state 9 primary and 3 secondary objectives.

The EIR/EIS at section "ES.3.2 MBNMS Purpose and Need" states the "purpose of these proposed [federal] actions are to authorize otherwise prohibited activities to occur within MBNMS, to ensure that the State and Federal permits and the proposed project comply with MBNMS regulations, and to ensure that MBNMS resources are protected by requiring terms and conditions that may be necessary. The need for MBNMS action is to respond to CalAm's request in accordance with NMSA regulations and to protect sanctuary resources." ERF-5

EIR/EIS section 1.3 states that "The MPWSP is needed to replace existing water supplies" that have been constrained by legal decisions affecting the Carmel River and Seaside Groundwater Basin water resources.

Yet, EIR/EIS section 2.3 states that "Based on State Water Board Orders 95-10 and 2009-0060 and the Seaside Groundwater Basin adjudication, CalAm must develop a replacement water supply to meet existing demand in its Monterey District service area. **In addition, CalAm proposes** to provide sufficient supply to meet demand associated with the development of existing legal lots of record, Pebble Beach water entitlements in the Del Monte Forest area, and tourism demand under improved economic conditions within its service area."

These are not hypothetical concerns. As a factual matter if the Project purpose is to replace existing water supplies approximately 12,351 acre feet per year (afy) will be required, however if the purpose includes expanding water supply an additional 2,005 afy is required.

As a legal matter, CEQA Guideline 15124 (b) explain that a clearly written statement of objectives, that includes the project purpose, aids in development of a reasonable range of alternatives, as well as any statement of overriding considerations.

The EIR/EIS Fails to Adequately Analyze the Project's Potential Adverse Impacts on Monterey Bay Marine Life

Impingement of Organisms

Desalination intake technologies can pose major mortality threats to marine organisms if they impinge species on the seafloor or entrain species. Impingement occurs when organisms are trapped against the seafloor or the screens of intake pipes due to the constant force of water being drawn in. Entrainment occurs when very small organisms are sucked through the screens, into the pipes, and are killed within the facility during the desalination process. It is acknowledged that CalAm's proposed slant well intake design is meant to have a lessened effect on marine life by not intruding into the ocean and reducing impingement and entrainment. The EIR/EIS claims that the project will completely "eliminate" the risk of impingement or entrainment of marine life, (though sources indicate a slant well system has never been used in a full-scale desalination plant).[1] In a seeming contradiction, the 2015 DEIR concluded that "impacts from the operation of the slant wells could involve impingement of organisms against the seafloor."[2] Eliminating impingement may be true of larger marine life that typically fall prey to open water intake systems, but this technology may introduce its own negative impacts on epifaunal and infaunal organisms that live on and within the seafloor sediment, respectively. Plankton, eggs, and fish larvae are common inhabitants of this zone and may be threatened by a slant well intake pipe.[3] Subsurface slant well intake systems utilize the sandy seafloor as a preliminary filter, but also draw in organisms that inhabit this zone.[4] Squid are a valuable commodity in Monterey Bay.[5] The species *Dorytheuthis opalescens*, a native to the North American coast, for example, is protected from commercial fishing outside of fisheries because squid "demand…now exceeds supply."[6] Because squid lay their eggs in the sediment of the seafloor, they may be more greatly impacted by a subsurface intake system if they are harmed by impingement and are trapped on the seafloor. As noted in the DEIR, "a relatively small magnitude effect…could be considered significant if the species is rare and highly susceptible to disturbance."[7]

ERF-6

Brine Discharge and Hypoxia

The Project will produce up to 14 million gallons per day of high-salinity brine during the desalination process. EIR/EIS 4.3-64. The Project plans to discharge that brine through the Monterey Regional Water Pollution Control Agency's existing outfall and into Monterey Bay. Id. 4.3-64. The discharge will occur within the federally protected Monterey Bay National Marine Sanctuary, which contains "habitats that support extensive marine life," including "numerous special-status" marine species. Id. 4.5-2, 4.5-8.

Brine byproduct may not be easily dispersed in the ocean. According to Carol Reeb (a marine scientist at Stanford Hopkins Marine Lab), the density of concentrated brine causes it to sink and form an oxygen-starved layer, "like Saran Wrap,"[8] that suffocates marine life; brine discharge is "the most immediate threat to marine/estuarine life."[9] This dense byproduct accumulates on the seafloor, restricting oxygen exchange and creating hypoxic (oxygen deficient) environments. "Hypoxia is lethal to squid eggs, halibut, Dungeness crab and anything else that lives on the sandy seafloor."[10] The discharge can also contain "caustic chemicals"[11] at dangerously concentrated levels which can harm benthic organisms in ways that are not yet entirely understood. Squid, for example, lay their fragile eggs in the sandy seafloor of this benthic zone for protection, and detecting the impacts that brine has on them and other organisms "may take many years to observe."[12] These smaller benthic organisms, which may provide food sources to countless other marine species,[13] are potentially the most at-risk species and have not received adequate attention in the Cal Am DEIR. The EIR/EIS addresses the possibility of brine sinking to the seafloor. After hearing public concerns about an effect known as "Coanda attachment" which could result in substantially reduced dilution, or a dense saline plume that forms a connection to and travels along the sea floor. In response to this concern, modeled the anticipated discharge to see if this effect was likely to occur. Roberts (2016). It is unclear, however, whether the model considered the impact of the slant wells vertical infiltration rate in the area of sea floor through which seawater would be taken into the wells – approximately 1,000,000 square feet.

ERF-7 cont.

The EIR/EIS analysis of potential brine discharge impacts were based on predicted salinity at the edge of the Zone of Initial Dilution (ZID), 100 meters from the point of discharge. EIR/EIS at 4.5.4. The EIR/EIS cites the Ocean Plan limits on salinity of receiving water from desalination plant discharges - a daily maximum of 2 parts per thousand (ppt) above natural background salinity as measured no further than 100 meters (328 ft) horizontally from each discharge point (known as the brine mixing zone [BMZ]). For the MPWSP, the BMZ represents an area of approximately 27 acres based on the existing outfall diffuser structure. EIR/EIS Figure 4.3-7. This approach is insufficient as it ignores potential impacts that may occur within the BMZ, including impacts on special-status species including the California gray whale, the Southern sea otter, and bottom dwelling and foraging fish, which may live in or pass through the BMZ, as well as impacts benthic organisms and the reef-like marine community that has developed on the discharge outfall itself.

ERF-8

The EIR/EIS acknowledges, elevated salinity and its impact on marine ecology, both within and outside of the ZID, is one of the "major concerns associated with coastal desalination projects." A report commissioned by the State Water Resources Control Board to evaluate the impacts and management of brine discharges, (cited in the EIR/EIS) found "benthic infaunal communities and sea grasses are the most sensitive to the acute effects of concentrate discharge." Management of Brine Discharges to Coastal Waters: Recommendations of a Science Advisory Panel, Southern California Coastal Water Research Project ("SCCWRP Report") at 9. Yet "very few studies" have examined the sublethal impacts of long-term brine exposure on marine life and data on impacts to California biota

"are extremely limited." SCCWRP Report at 9, 11. Given this uncertainty, the SCCWRP Report recommends that salinity levels at the ZID boundary be limited to an increase of either 2 parts-per-thousand ("ppt") or 5% above pre-project ambient salinity levels, whichever is less. The EIR/EIS acknowledges that a 5% increase would be the equivalent of a 1.7 ppt salinity increase above ambient conditions, but instead basis its impact analysis on the 2 ppt threshold of significance, which represents more than a 17% increase over the 1.7 ppt threshold recommended by the SCCWRP Report. While the 2 ppt threshold aligns with the regulatory standard adopted in the recent Ocean Plan Amendment, the EIR lacks substantial evidence to justify why the 2 ppt threshold is more appropriate for the Project than a 5% increase above ambient salinity (1.7 ppt) threshold recommended by the SCCWRP Report. CEQA and NEPA analyses require such an explanation.

ERF-9 cont.

The public has also raised concerns that the Project's brine analysis is susceptible to modeling error because the existing outfall and its diffusers were not designed for brine discharge. There is limited scientific literature studying mixing scenarios for a horizontal discharge of undiluted brine like the discharge that the Project proposes, as most existing studies have been conducted for inclined jets which increase the initial mixing of the plume. Fewer studies are available to characterize the mixing of negatively buoyant plumes from horizontally-oriented discharge ports. Additionally, most of the studies looking at desalination impacts on marine environments lack quantitative data, adding uncertain and demanding caution when making environmental decisions about introducing this technology at such a large scale.[14] Due to the importance and sensitivity of the Monterey Bay marine environment, the cost of developing the Facility, and the fact that it will produce and discharge such significant amounts of brine each day, the Project must be held to rigorous standards for its potential impacts.

ERF-10

Another common critique of brine byproduct disposal is that the salt can be harnessed and used for other purposes. For example, salt extraction technology may triple the revenue of desal facilities, while eliminating brine byproduct altogether.[15] Alternatives to brine disposal are not sufficiently evaluated in the EIR/EIS.

ERF-11

Toxic Substances

As reported in the Monterey Peninsula Water Supply Project Hydrogeologic Investigation Technical Memorandum, results of water quality sampling in isolated aquifer zones at the Cemex facility, collected via exploratory boreholes between February and March 2014, found elevated levels of hydrocarbons throughout the aquifer zones, including 1,2-Dichlorobenzene-d4; 1,3-Dimethyl-2-nitrobenzene; 1-Br-2-Nitrobenzene; Tetrachloro-meta-xylene (TCMX). The sampling also discovered elevated levels of pesticides, including aminomethylphosphonic acid (AMPA) and 2,4-dichlorophenoxyacetic acid (DCPAA). AMPA, the primary degradation product of glyphosate in plants, soil and water. AMPA's chemical structure is very similar to that of glyphosate, recently determined by the International Agency for Research on Cancer to be a probable human carcinogen. The State of California has determined it will include glyphosate on its list of known carcinogens. Elevated levels of AMPA were found throughout the aquifer layers at every screen interval sampled.
